Overview

Amazon Bedrock is a fully managed service that provides secure, enterprise-grade access to high-performing foundation models from leading AI companies, enabling you to build and scale generative AI applications.

Quickstart

Read the Quickstart to write your first API call using Amazon Bedrock in under five minutes. For new applications, we recommend the `bedrock-runtime` endpoint.

Messages API

```
from anthropic import Anthropic
from aws_bedrock_token_generator import provide_token

token = provide_token(region="us-east-1")

client = Anthropic(
    base_url="https://bedrock-runtime.us-east-1.amazonaws.com/anthropic",
    api_key=token,
)

response = client.messages.create(
    model="global.anthropic.claude-opus-4-7",
    max_tokens=1024,
    messages=[{"role": "user", "content": "Can you explain the features of Amazon
 Bedrock?"}]
)
print(response)
```

Responses API

```
from openai import OpenAI

client = OpenAI()

response = client.responses.create(
    model="global.openai.gpt-5.6-sol",
    input="Can you explain the features of Amazon Bedrock?"
    )
```

```
print(response)
```

Chat Completions API

```
from openai import OpenAI

client = OpenAI()

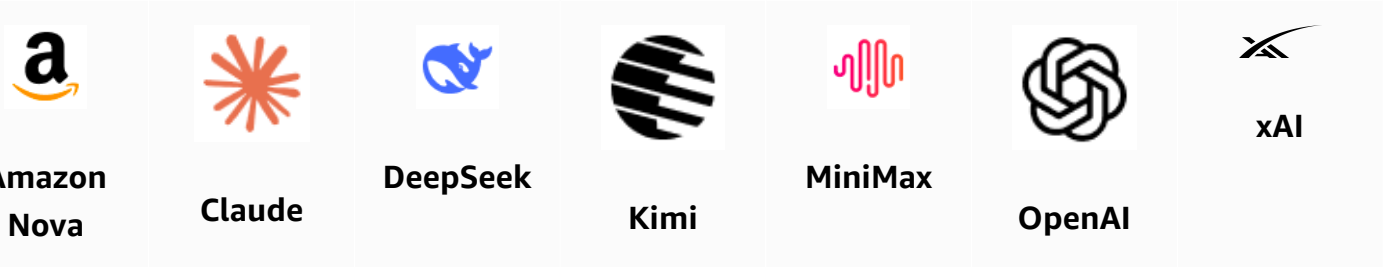
response = client.chat.completions.create(
    model="global.openai.gpt-5.6-sol",
    messages=[{"role": "user", "content": "Can you explain the features of Amazon
 Bedrock?"}]
    )
print(response)
```

Converse API

```
import boto3

client = boto3.client('bedrock-runtime', region_name='us-east-1')
response = client.converse(
    modelId='anthropic.claude-opus-4-7',
    messages=[
        {
            'role': 'user',
            'content': [{'text': 'Can you explain the features of Amazon Bedrock?'}]
        }
    ]
)
print(response)
```

Invoke API



```
import json
import boto3

client = boto3.client('bedrock-runtime', region_name='us-east-1')
response = client.invoke_model(
    modelId='anthropic.claude-opus-4-7',
    body=json.dumps({
            'anthropic_version': 'bedrock-2023-05-31',
            'messages': [{ 'role': 'user', 'content': 'Can you explain the features
 of Amazon Bedrock?'}],
```

```
            'max_tokens': 1024
    })
)
print(json.loads(response['body'].read()))
```

Supported models

Amazon Bedrock supports 100+ foundation models from industry-leading providers, including Amazon, Anthropic, DeepSeek, Moonshot AI, MiniMax, OpenAI, and xAI.

What's new?

- OpenAI GPT-6 Astra is now generally available on Amazon Bedrock: GPT-6 Astra is OpenAI's newest and most capable model. It can reason through hard choices in business tasks. It can write and design polished content. It can also use computers and web browsers. The model has a 1,050,000-token context window shared between input and output, with up to 128,000 output tokens. See the GPT-6 Astra model card for details.
- Grok 4.6 from xAI now available in Amazon Bedrock: xAI's latest flagship model, built for long-running agents, coding, and knowledge work, with a 500K context window and configurable reasoning efforts (low, medium, high, xhigh). Available in all AWS Regions where Amazon Bedrock is offered. See the Grok 4.6 model card for details.
- Amazon Bedrock expands API support and adds cross-Region inference for OpenAI models: OpenAI GPT-5.6 Sol, Terra, and Luna are now available on the `bedrock-runtime` endpoint through the Responses, Converse, and Chat Completions APIs, and now support Global and Geo cross-Region inference for higher throughput and lower per-token cost (including new US Geo CRIS). See Cross-Region inference for details.
- Daybreak Red and Daybreak Blue from OpenAI now available in Amazon Bedrock (limited availability): Specialized cybersecurity models from OpenAI's Daybreak initiative, available to eligible customers. Daybreak Red (GPT-5.6 Cyber) is purpose-trained for vulnerability research,

exploit reproduction, and mitigation development. Daybreak Blue (GPT-5.6 Sol) has safeguards calibrated for defensive cybersecurity work. See the Daybreak Red: GPT-5.6 Cyber and Daybreak Blue: GPT-5.6 Sol model cards for details.

- Web Search now available in Amazon Bedrock: A built-in server-side tool that grounds OpenAI GPT models on Amazon Bedrock in current web knowledge through a single tool-use parameter in the Responses API, with no third-party search vendor to onboard. Search uses an AWS-hosted web index, and Fetch can optionally retrieve from the external web under explicit IAM control. Available in US East (N. Virginia), US East (Ohio), and US West (Oregon). See Web Search for details.
- OpenAI GPT-5.6 Sol, Terra, and Luna now available in Amazon Bedrock: A family of models from OpenAI that ranges from advanced reasoning to fast, cost-effective inference, now generally available through the Responses API on Amazon Bedrock. See the GPT-5.6 Sol, GPT-5.6 Terra, and GPT-5.6 Luna model cards for details.

Start building

	Explore the APIs and Endpoints supported by Amazon Bedrock.
	Build using the the section called “Making inference requests” operations provided by Amazon Bedrock.
	*Model customization*

Quickstart

Get started with Amazon Bedrock in minutes. For new applications, we recommend the `bedrock-runtime` endpoint. The following steps walk you through running your first inference request using the Anthropic-native Messages API, the OpenAI-compatible Responses API and Chat Completions API, and the Converse and Invoke APIs. For a complete list of APIs, see *Build*. After you complete these steps, you can send inference requests to any supported foundation model.

To run your first inference request

1. Sign up for an AWS account.

   If you already have an AWS account, skip this step.

2. Generate a short-term API key to authenticate your requests to Amazon Bedrock by opening the **Amazon Bedrock** service in the AWS Management Console.

   For the complete procedure, see the API keys section.

   For production applications, use IAM roles or temporary credentials.

3. Install the relevant SDK for the APIs you plan to use. Python must already be installed.

   > **Note**
   >
   > API key authentication through the `AWS_BEARER_TOKEN_BEDROCK` environment variable requires `boto3` version 1.39.0 or later. Earlier versions ignore the variable and fail with `Unable to locate credentials`. If you already have `boto3` installed, run `pip install --upgrade boto3` to make sure you are on a supported version.

   Messages API

   ```
   pip install anthropic aws-bedrock-token-generator
   ```

   Responses/Chat Completions API

   ```
   pip install boto3 openai
   ```

Invoke/Converse API

```
pip install boto3
```

4. Set the following environment variables in the terminal session where you run your code to use the API key for authentication.

   Messages API

   ```
   # macOS/Linux
   export AWS_BEARER_TOKEN_BEDROCK="<provide your Bedrock API key>"
   export ANTHROPIC_BASE_URL="https://bedrock-runtime.<your-region>.amazonaws.com/
   anthropic"

   # Windows (PowerShell)
   $env:AWS_BEARER_TOKEN_BEDROCK="<provide your Bedrock API key>"
   $env:ANTHROPIC_BASE_URL="https://bedrock-runtime.<your-region>.amazonaws.com/
   anthropic"
   ```

   Responses/Chat Completions API

   ```
   # macOS/Linux
   export OPENAI_API_KEY="<provide your Bedrock API key>"
   export OPENAI_BASE_URL="https://bedrock-runtime.<your-region>.amazonaws.com/
   openai/v1"

   # Windows (PowerShell)
   $env:OPENAI_API_KEY="<provide your Bedrock API key>"
   $env:OPENAI_BASE_URL="https://bedrock-runtime.<your-region>.amazonaws.com/
   openai/v1"
   ```

   Invoke/Converse API

   ```
   # macOS/Linux
   export AWS_BEARER_TOKEN_BEDROCK="<provide your Bedrock API key>"

   # Windows (PowerShell)
   $env:AWS_BEARER_TOKEN_BEDROCK="<provide your Bedrock API key>"
   ```

5. Choose a model and run your first inference request.

a. Choose a model. Amazon Bedrock supports 100+ foundation models.

> **Note**
>
> The OpenAI-compatible examples use a global system inference profile. If you have data residency requirements, choose a supported geographic inference profile from the model card instead.

b. Use the following Python code to run your first inference request.

Messages API

```
from anthropic import Anthropic
from aws_bedrock_token_generator import provide_token

token = provide_token(region="us-east-1")

client = Anthropic(api_key=token)

response = client.messages.create(
    model="global.anthropic.claude-opus-5",
    max_tokens=1024,
    messages=[{"role": "user", "content": "Can you explain the features of
 Amazon Bedrock?"}]
)
print(response)
```

Responses API

```
from openai import OpenAI

client = OpenAI()

response = client.responses.create(
    model="global.openai.gpt-5.6-sol",
    input="Can you explain the features of Amazon Bedrock?"
    )
print(response)
```

Chat Completions API

```
from openai import OpenAI

client = OpenAI()

response = client.chat.completions.create(
    model="global.openai.gpt-5.6-sol",
    messages=[{"role": "user", "content": "Can you explain the features of
 Amazon Bedrock?"}]
    )
print(response)
```

Converse API

```
import boto3

client = boto3.client('bedrock-runtime', region_name='us-east-1')
response = client.converse(
    modelId='global.anthropic.claude-opus-5',
    messages=[
        {
            'role': 'user',
            'content': [{'text': 'Can you explain the features of Amazon
 Bedrock?'}]
        }
    ]
)
print(response)
```

Invoke API

```
import json
import boto3

client = boto3.client('bedrock-runtime', region_name='us-east-1')
response = client.invoke_model(
    modelId='global.anthropic.claude-opus-5',
    body=json.dumps({
            'anthropic_version': 'bedrock-2023-05-31',
            'messages': [{ 'role': 'user', 'content': 'Can you explain the
 features of Amazon Bedrock?'}],
```

```
            'max_tokens': 1024
    })
)
print(json.loads(response['body'].read()))
```

c. Save the file as `bedrock-first-request.py`.

d. Run the code with the following command:

```
python3 bedrock-first-request.py
```

You should see the output of your inference request.

To learn more about using other APIs and endpoints, see *Build* and the section called "Inference endpoints".

Next steps

Now that you have run your first request, explore the following resources to build more with Amazon Bedrock:

- the section called "Agents: Automate tasks" – Create agents that can orchestrate multi-step tasks.
- the section called "Knowledge Bases" – Connect foundation models to your data sources.
- *Model customization* – Fine-tune models for your use case.
- the section called "Evaluate models" – Evaluate model performance for your workloads.

Models at a glance

With access to hundreds of top foundation models (FMs) to power your applications and the ability to swap them in and out without rewriting code, Amazon Bedrock gives you the flexibility to build and innovate as your needs evolve.

AI21 Labs

The following AI21 Labs models are available in Amazon Bedrock:

Model	Description
the section called “Jamba 1.5 Large”	Jamba 1.5 Large is AI21 Labs' hybrid SSM-Transformer model with 398B total parameters and a 256K context window, optimized for complex reasoning tasks across long documents.
the section called “Jamba 1.5 Mini”	Jamba 1.5 Mini is AI21 Labs' lightweight hybrid SSM-Transformer model with 52B total parameters and a 256K context window, optimized for low-latency enterprise tasks.

Jamba 1.5 Large

AI21 Labs — Jamba 1.5 Large

Model Details

Jamba 1.5 Large is AI21 Labs' hybrid SSM-Transformer model with 398B total parameters and a 256K context window, optimized for complex reasoning tasks across long documents. For more information about model development and performance, see the model/service card.

Model launch date: Aug 22, 2024

EOL no sooner than: Aug 22, 2025

Legacy period: at least 6 months

Model lifecycle policy: Model lifecycle (For Models Launched Prior to Sept 7 2026)

Model EOL date: November 26, 2026

End User License Agreements and Terms of Use: View

Model lifecycle: Legacy

Context window: 256K tokens

Max output tokens: 4K

Knowledge cutoff: Mar 2024

Marketplace product ID: `prod-evcp4w4lurj26`

Input Modalities	Output Modalities

⊗ Video	⊗ Video

Endpoints and APIs supported

The following tables show which endpoints and APIs are supported for Jamba 1.5 Large. For more information, see the section called “APIs” and the section called “Inference endpoints”.

Endpoint support

Endpoint	Supported
`bedrock-runtime`	✓
`bedrock-mantle`	✗

APIs supported on `bedrock-runtime` endpoint

Messages	Responses	Chat Completions	Converse	Invoke
✗	✗	✗	✓	✓

APIs supported on `bedrock-mantle` endpoint

Messages	Responses	Chat Completions	Converse	Invoke
✗	✗	✗	✗	✗

> **Tip**
>
> Whenever possible, we recommend using the `bedrock-runtime` endpoint for new applications. See the section called “Inference endpoints” for details.

Capabilities and Features

Bedrock Features

Features supported using `bedrock-runtime` endpoint

Supported	Not Supported
Response streaming Guardrails Client-side tool calling	Structured outputs Watermarking

Pricing

This model is a third-party model offered and billed through AWS Marketplace. Charges appear on your AWS bill and in AWS Cost Explorer under the model provider (not under Amazon Bedrock). For pricing, see the Amazon Bedrock Pricing page.

Programmatic Access

Use the following model IDs and endpoint URLs to access this model programmatically. For more information about the available APIs and endpoints, see APIs supported and Endpoints supported.

Endpoint	Model ID	In-Region endpoint URL	Geo inference ID	Global inference ID
`bedrock-runtime`	`ai21.jamba-1-5-large-v1:0`	`https://bedrock-runtime.{region}.amazonaws.com`	Not supported	Not supported

For example, if region is us-east-1 (N. Virginia), then the bedrock-runtime endpoint URL will be "https://bedrock-runtime.us-east-1.amazonaws.com" and for bedrock-mantle will be "https://bedrock-mantle.us-east-1.api.aws/v1".

Service Tiers

Amazon Bedrock offers multiple service tiers to match your workload requirements. **Standard** provides pay-per-token access with no commitment (set `"service_tier": "default"` or omit the field). **Priority** delivers the fastest response times for a price premium (set `"service_tier": "priority"`). **Flex** provides lower-cost access for flexible, non-time-sensitive workloads (set

`"service_tier": "flex"`). **Reserved** provides dedicated throughput with a term commitment for predictable workloads; it is set at the account level rather than per request (contact your AWS account team to enable). For more information, see service tiers.

Standard	Priority	Flex	Reserved
✓	✗	✗	✗

Regional Availability

Regional availability at a glance

Amazon Bedrock offers three inference options: **In-Region** keeps requests within a single Region for strict compliance, **Geo Cross-Region** routes across Regions within a geography (such as US, EU, and APAC) while respecting data residency, and **Global Cross-Region** routes anywhere worldwide when there are no residency constraints. Refer to the the section called "Regional availability by models" page for more details.

Availability differs by endpoint.

Availability using the `bedrock-runtime` endpoint

Region	In-Region	Geo	Global
`us-east-1` (N. Virginia)	✓	✗	✗

Quotas and Limits

Your AWS account has default quotas to maintain the performance of the service and to ensure appropriate usage of Amazon Bedrock. The default quotas assigned to an account might be updated depending on regional factors, payment history, fraudulent usage, and/or approval of a quota increase request. For more information, see the section called "Quotas" documentation and see the limits for the model.

Sample Code

Step 1 - AWS Account: If you have an AWS account already, skip this step. If you are new to AWS, sign up for an AWS account.

Step 2 - API key: Go to the Amazon Bedrock console and generate a long-term API key.

Step 3 - Get the SDK: To use this getting started guide, you must have Python already installed. Then install the relevant software depending on the APIs you are using.

```
pip install boto3
```

Step 4 - Set environment variables: Configure your environment to use the API key for authentication.

```
AWS_BEARER_TOKEN_BEDROCK="<provide your Bedrock API key>"
```

Step 5 - Run your first inference request: Save the file as `bedrock-first-request.py`

Invoke API

```
import json
import boto3

client = boto3.client('bedrock-runtime', region_name='us-east-1')
response = client.invoke_model(
    modelId='ai21.jamba-1-5-large-v1:0',
    body=json.dumps({
            'messages': [{ 'role': 'user', 'content': 'Can you explain the features
 of Amazon Bedrock?'}],
            'max_tokens': 1024
    })
)
print(json.loads(response['body'].read()))
```

Converse API

```
import boto3

client = boto3.client('bedrock-runtime', region_name='us-east-1')
response = client.converse(
    modelId='ai21.jamba-1-5-large-v1:0',
    messages=[
        {
            'role': 'user',
            'content': [{'text': 'Can you explain the features of Amazon Bedrock?'}]
        }
```

```
    ]
)
print(response)
```

Jamba 1.5 Mini

AI21 Labs — Jamba 1.5 Mini

Model Details

Jamba 1.5 Mini is AI21 Labs' lightweight hybrid SSM-Transformer model with 52B total parameters and a 256K context window, optimized for low-latency enterprise tasks. For more information about model development and performance, see the model/service card.

Model launch date: Aug 22, 2024
EOL no sooner than: Aug 22, 2025
Legacy period: at least 6 months
Model lifecycle policy: Model lifecycle (For Models Launched Prior to Sept 7 2026)
Model EOL date: November 26, 2026
End User License Agreements and Terms of Use: View
Model lifecycle: Legacy
Context window: 256K tokens
Max output tokens: 4K
Knowledge cutoff: Mar 2024
Marketplace product ID: `prod-ggrzjm65qmjhm`

Input Modalities	Output Modalities
⊗ Audio	⊗ Embedding
⊗ Image	⊗ Image
⊗ Speech	⊗ Speech
✓ Text	✓ Text

Input Modalities	Output Modalities
⊗ Video	⊗ Video

Endpoints and APIs supported

The following tables show which endpoints and APIs are supported for Jamba 1.5 Mini. For more information, see the section called “APIs” and the section called “Inference endpoints”.

Endpoint support

Endpoint	Supported
`bedrock-runtime`	✓
`bedrock-mantle`	⊗

APIs supported on `bedrock-runtime` endpoint

Messages	Responses	Chat Completions	Converse	Invoke
⊗	⊗	⊗	✓	✓

APIs supported on `bedrock-mantle` endpoint

Messages	Responses	Chat Completions	Converse	Invoke
⊗	⊗	⊗	⊗	⊗

Tip

Whenever possible, we recommend using the `bedrock-runtime` endpoint for new applications. See the section called “Inference endpoints” for details.

Pricing

This model is a third-party model offered and billed through AWS Marketplace. Charges appear on your AWS bill and in AWS Cost Explorer under the model provider (not under Amazon Bedrock). For pricing, see the Amazon Bedrock Pricing page.

Programmatic Access

Use the following model IDs and endpoint URLs to access this model programmatically. For more information about the available APIs and endpoints, see APIs supported and Endpoints supported.

Endpoint	Model ID	In-Region endpoint URL	Geo inference ID	Global inference ID
`bedrock-runtime`	`ai21.jamba-1-5-mini-v1:0`	`https://bedrock-runtime.{region}.amazonaws.com`	Not supported	Not supported

For example, if region is us-east-1 (N. Virginia), then the bedrock-runtime endpoint URL will be "https://bedrock-runtime.us-east-1.amazonaws.com" and for bedrock-mantle will be "https://bedrock-mantle.us-east-1.api.aws/v1".

Service Tiers

Amazon Bedrock offers multiple service tiers to match your workload requirements. **Standard** provides pay-per-token access with no commitment (set `"service_tier": "default"` or omit the field). **Priority** delivers the fastest response times for a price premium (set `"service_tier": "priority"`). **Flex** provides lower-cost access for flexible, non-time-sensitive workloads (set `"service_tier": "flex"`). **Reserved** provides dedicated throughput with a term commitment for predictable workloads; it is set at the account level rather than per request (contact your AWS account team to enable). For more information, see service tiers.

Standard	Priority	Flex	Reserved
✓	✗	✗	✗

Regional Availability

Regional availability at a glance

Amazon Bedrock offers three inference options: **In-Region** keeps requests within a single Region for strict compliance, **Geo Cross-Region** routes across Regions within a geography (such as US, EU, and APAC) while respecting data residency, and **Global Cross-Region** routes anywhere worldwide when there are no residency constraints. Refer to the the section called “Regional availability by models” page for more details.

Availability differs by endpoint.

Availability using the `bedrock-runtime` endpoint

Region	In-Region	Geo	Global
`us-east-1` (N. Virginia)	✓	✗	✗

Quotas and Limits

Your AWS account has default quotas to maintain the performance of the service and to ensure appropriate usage of Amazon Bedrock. The default quotas assigned to an account might be updated depending on regional factors, payment history, fraudulent usage, and/or approval of a quota increase request. For more information, see the section called “Quotas” documentation and see the limits for the model.

Sample Code

Step 1 - AWS Account: If you have an AWS account already, skip this step. If you are new to AWS, sign up for an AWS account.

Step 2 - API key: Go to the Amazon Bedrock console and generate a long-term API key.

Step 3 - Get the SDK: To use this getting started guide, you must have Python already installed. Then install the relevant software depending on the APIs you are using.

```
pip install boto3
```

Step 4 - Set environment variables: Configure your environment to use the API key for authentication.

```
AWS_BEARER_TOKEN_BEDROCK="<provide your Bedrock API key>"
```

Step 5 - Run your first inference request: Save the file as `bedrock-first-request.py`

Invoke API

```
import json
import boto3

client = boto3.client('bedrock-runtime', region_name='us-east-1')
response = client.invoke_model(
    modelId='ai21.jamba-1-5-mini-v1:0',
    body=json.dumps({
            'messages': [{ 'role': 'user', 'content': 'Can you explain the features
 of Amazon Bedrock?'}],
            'max_tokens': 1024
    })
)
print(json.loads(response['body'].read()))
```

Converse API

```
import boto3

client = boto3.client('bedrock-runtime', region_name='us-east-1')
response = client.converse(
    modelId='ai21.jamba-1-5-mini-v1:0',
    messages=[
        {
            'role': 'user',
            'content': [{'text': 'Can you explain the features of Amazon Bedrock?'}]
        }
    ]
)
print(response)
```

Amazon

The following Amazon models are available in Amazon Bedrock:

Model	Description
the section called “Nova 2 Lite”	Nova 2 Lite is Amazon's cost-efficient multimodal model for simple automation, document processing, and customer support across text, images, and video.
the section called “Nova 2 Sonic”	Nova 2 Sonic is Amazon's speech-to-speech foundation model for building natural, real-time voice conversation applications.
the section called “Nova 2.5 Sonic”	Nova 2.5 Sonic is Amazon's latest speech-to-speech foundation model with improved reasoning, instruction following, and tool calling for real-time, agentic voice applications.
the section called “Nova Lite”	Nova Lite is Amazon's low-cost multimodal model that processes text, images, and video inputs for tasks like document analysis and visual Q&A.
the section called “Nova Micro”	Nova Micro is Amazon's fastest text-only model, optimized for speed and low cost in tasks like summarization, translation, and classification.
the section called “Nova Pro”	Nova Pro is Amazon's balanced multimodal model offering strong accuracy, speed, and cost for a wide range of tasks across text, images, and video.
the section called “Amazon Nova Multimodal Embeddings”	Amazon Nova Multimodal Embeddings is Amazon's embedding model that converts text, images, and video into vector representations for search and retrieval use cases.
the section called “Nova Canvas”	Nova Canvas was Amazon's image generation model. It added an invisible watermark and content credentials to the images that it generated.
the section called “Nova Reel”	Nova Reel is Amazon's video generation model that creates short videos from text and image prompts with camera motion controls.
the section called “Titan Text Embeddings V2”	Titan Text Embeddings V2 is Amazon's second-generation text embeddings model with configurable output dimensions and improved accuracy for retrieval tasks.

Model	Description
the section called “Titan Multimodal Embeddings G1”	Titan Multimodal Embeddings G1 is Amazon's model that generates embeddings from text and images for multimodal search and recommendation use cases.
the section called “Titan Embeddings G1 - Text”	Titan Text Embeddings G1 is Amazon's text embeddings model that converts text into numerical vector representations for search, personalization, and clustering.
the section called “Titan Embeddings G1 - Text v2”	Titan Text Embeddings V2:2 is an updated version of Amazon's text embeddings model with configurable output dimensions and improved accuracy for retrieval tasks.

Nova 2 Lite

Amazon — Nova 2 Lite

Model Details

Nova 2 Lite is Amazon's cost-efficient multimodal model for simple automation, document processing, and customer support across text, images, and video. For more information about model development and performance, see the model/service card.

Model launch date: Dec 02, 2025
EOL no sooner than: Dec 02, 2026
Legacy period: at least 6 months
Model lifecycle policy: Model lifecycle (For Models Launched Prior to Sept 7 2026)
Model EOL date: N/A
End User License Agreements and Terms of Use: View
Model lifecycle: Active
Context window: 1M tokens
Max output tokens: 64K
Reasoning: Supported, off by default (enable with `reasoningConfig`; effort configurable: low, medium, high)
Knowledge cutoff: Oct 2025

Input Modalities	Output Modalities	APIs supported	Endpoints supported
⊗ Audio	⊗ Embedding	⊗ Responses	✓ bedrock-runtime
✓ Image	⊗ Image	⊗ Chat Completions	⊗ bedrock-mantle
⊗ Speech	⊗ Speech	✓ Invoke	
✓ Text	✓ Text	✓ Converse	
✓ Video	⊗ Video		

Tip

Whenever possible, we recommend using the `bedrock-runtime` endpoint for new applications. See the section called "Inference endpoints" for details.

Capabilities and Features

Bedrock Features

Features supported using `bedrock-runtime` endpoint

Supported	Not Supported
✓ Response streaming	⊗ Intelligent prompt routing
✓ Abuse detection	⊗ Count tokens
✓ Guardrails	⊗ Knowledge base
✓ Prompt optimization	⊗ Structured outputs
✓ Client-side tool calling	⊗ Model evaluation
	⊗ Prompt management
	⊗ Flows
	⊗ Agents

Supported	Not Supported
	⊗ Watermarking

Implicit and Explicit Prompt Caching using `bedrock-runtime` endpoint

For more information, see Prompt caching for faster model inference.

Explicit Prompt Caching supported	Min tokens per cache checkpoint	Max cache checkpoints per request	Supported TTL	Fields that accept prompt cache checkpoints
Yes	1K*	4	5 minutes	`system` and `messages`

** Amazon Nova models support a maximum of 20K tokens for prompt caching. Prompt caching is primarily for text prompts.*

Pricing

For pricing information, see the Amazon Bedrock Pricing page.

Programmatic Access

Use the following model IDs and endpoint URLs to access this model programmatically. For more information about the available APIs and endpoints, see APIs supported and Endpoints supported.

Endpoint	Model ID	In-Region endpoint URL	Geo inference ID	Global inference ID
`bedrock-runtime`	`amazon.nova-2-lite-v1:0`	`https://bedrock-runtime.{region}.amazonaws.com`	`us.amazon.nova-2-lite-v1:0` `eu.amazon.nova-2-lite-v1:0`	`global.amazon.nova-2-lite-v1:0`

Endpoint	Model ID	In-Region endpoint URL	Geo inference ID	Global inference ID
			`jp.amazon.nova-2-lite-v1:0`	

For example, if region is us-east-1 (N. Virginia), then the bedrock-runtime endpoint URL will be "https://bedrock-runtime.us-east-1.amazonaws.com" and for bedrock-mantle will be "https://bedrock-mantle.us-east-1.api.aws/v1".

Service Tiers

Amazon Bedrock offers multiple service tiers to match your workload requirements. **Standard** provides pay-per-token access with no commitment (set `"service_tier": "default"` or omit the field). **Priority** delivers the fastest response times for a price premium (set `"service_tier": "priority"`). **Flex** provides lower-cost access for flexible, non-time-sensitive workloads (set `"service_tier": "flex"`). **Reserved** provides dedicated throughput with a term commitment for predictable workloads; it is set at the account level rather than per request (contact your AWS account team to enable). For more information, see service tiers.

Quotas and Limits

Your AWS account has default quotas to maintain the performance of the service and to ensure appropriate usage of Amazon Bedrock. The default quotas assigned to an account might be updated depending on regional factors, payment history, fraudulent usage, and/or approval of a quota increase request. For more information, see the section called “Quotas” documentation and see the limits for the model.

Sample Code

Step 1 - AWS Account: If you have an AWS account already, skip this step. If you are new to AWS, sign up for an AWS account.

Step 2 - API key: Go to the Amazon Bedrock console and generate a long-term API key.

Step 3 - Get the SDK: To use this getting started guide, you must have Python already installed. Then install the relevant software depending on the APIs you are using.

```
pip install boto3
```

Step 4 - Set environment variables: Configure your environment to use the API key for authentication.

```
AWS_BEARER_TOKEN_BEDROCK="<provide your Bedrock API key>"
```

Step 5 - Run your first inference request: Save the file as `bedrock-first-request.py`

Invoke API

```
import json
import boto3

client = boto3.client('bedrock-runtime', region_name='us-east-1')
response = client.invoke_model(
    modelId='amazon.nova-2-lite-v1:0',
    body=json.dumps({
            'messages': [{
                'role': 'user',
                'content': [{'text': 'Can you explain the features of Amazon
 Bedrock?'}]
            }],
            'inferenceConfig': {
                'maxTokens': 1024
            }
    })
)
print(json.loads(response['body'].read()))
```

Converse API

```
import boto3

client = boto3.client('bedrock-runtime', region_name='us-east-1')
response = client.converse(
    modelId='amazon.nova-2-lite-v1:0',
    messages=[
        {
            'role': 'user',
            'content': [{'text': 'Can you explain the features of Amazon Bedrock?'}]
        }
    ]
)
print(response)
```

Nova 2 Sonic

Amazon — Nova 2 Sonic

Model Details

Nova 2 Sonic is Amazon's speech-to-speech foundation model for building natural, real-time voice conversation applications. For more information about model development and performance, see the model/service card.

Model launch date: Dec 2, 2025

EOL no sooner than: Dec 2, 2026

Legacy period: at least 6 months

Model lifecycle policy: Model lifecycle (For Models Launched Prior to Sept 7 2026)

Model EOL date: N/A

End User License Agreements and Terms of Use: View

Model lifecycle: Active

`us-west-2` (Oregon)	✓	✗	✗
`eu-north-1` (Stockholm)	✓	✗	✗
`ap-northeast-1` (Tokyo)	✓	✗	✗

Quotas and Limits

The default quota for Nova 2 Sonic is 20 concurrent `InvokeModelWithBidirectionalStream` sessions per AWS account in each supported Region. This quota is not adjustable.

Your AWS account has default quotas to maintain the performance of the service and to ensure appropriate usage of Amazon Bedrock. The default quotas assigned to an account might be updated depending on regional factors, payment history, fraudulent usage, and/or approval of a quota increase request. For more information, see the section called "Quotas" documentation and see the limits for the model.

Sample Code

Step 1 - AWS Account: If you have an AWS account already, skip this step. If you are new to AWS, sign up for an AWS account.

Step 2 - API key: Go to the Amazon Bedrock console and generate a long-term API key.

Step 3 - Get the SDK:

```
pip install boto3
```

Step 4 - Set environment variables:

```
AWS_BEARER_TOKEN_BEDROCK="<provide your Bedrock API key>"
```

Step 5 - Run your first inference request: This model uses `InvokeModelWithBidirectionalStream`. See API reference for details.

Nova 2.5 Sonic

Amazon — Nova 2.5 Sonic

Model Details

Nova 2.5 Sonic is Amazon's latest speech-to-speech foundation model for building natural, real-time voice conversation applications. It delivers improved reasoning, instruction following, and tool calling accuracy over Nova 2 Sonic, along with lower latency and more concise responses. These improvements make it well suited for agentic voice applications. For more information about model development and performance, see the model/service card.

Model launch date: Oct 5, 2026
EOL no sooner than: Oct 5, 2027
Legacy period: at least 6 months
Model lifecycle policy: Model lifecycle
Model EOL date: N/A
End User License Agreements and Terms of Use: View

Model lifecycle: Active
Context window: 256K tokens

Capabilities and Features

Bedrock Features

Features supported using `bedrock-runtime` endpoint

Supported	Not Supported
⊙ Response streaming ⊙ Tool use (function calling) ⊙ Asynchronous tool calling	⊗ Intelligent prompt routing ⊗ Abuse detection ⊗ Guardrails

Supported	Not Supported
Watermarking	Prompt optimization Count tokens Knowledge base Model evaluation Prompt management Flows Agents

Model Capabilities

- **Speech-to-speech** — Real-time bidirectional speech understanding and generation in a single model.
- **Enhanced reasoning** — Stronger multi-step reasoning during live conversations.
- **Improved instruction following** — More reliable adherence to system prompts, persona instructions, and multi-step directives.
- **Tool use (function calling)** — Higher-accuracy tool calling for agentic workflows: look up an order, check eligibility, and take action in one session.
- **Asynchronous tool calling** — Keeps the conversation going while tools run in the background.
- **Cross-modal input** — Mix text and voice in the same session.
- **Polyglot voices** — Voices that speak naturally across multiple languages.
- **Natural turn-taking** — Graceful handling of user interruptions with configurable turn detection.
- **Code-switching** — Switches between languages mid-conversation.
- **Streaming text transcripts** — Real-time text transcription of the voice conversation.
- **Lower latency** — Reduced response times for more natural conversations.

Pricing

For pricing information, see the Amazon Bedrock Pricing page.

Programmatic Access

Use the following model IDs and endpoint URLs to access this model programmatically. For more information about the available APIs and endpoints, see APIs supported and Endpoints supported.

Endpoint	Model ID	In-Region endpoint URL	Geo inference ID	Global inference ID
bedrock-runtime	amazon.nova-2-5-sonic	https://bedrock-runtime.{region}.amazonaws.com	Not supported	Not supported

For example, if region is us-east-1 (N. Virginia), then the bedrock-runtime endpoint URL will be "https://bedrock-runtime.us-east-1.amazonaws.com" and for bedrock-mantle will be "https://bedrock-mantle.us-east-1.api.aws/v1".

Service Tiers

Amazon Bedrock offers multiple service tiers to match your workload requirements. **Standard** provides pay-per-token access with no commitment (set `"service_tier": "default"` or omit the field). **Priority** delivers the fastest response times for a price premium (set `"service_tier": "priority"`). **Flex** provides lower-cost access for flexible, non-time-sensitive workloads (set `"service_tier": "flex"`). **Reserved** provides dedicated throughput with a term commitment for predictable workloads; it is set at the account level rather than per request (contact your AWS account team to enable). For more information, see service tiers.

Standard	Priority	Flex	Reserved
✓	✗	✗	✗

Regional Availability

Regional availability at a glance

Amazon Bedrock offers three inference options: **In-Region** keeps requests within a single Region for strict compliance, **Geo Cross-Region** routes across Regions within a geography (such as US, EU, and APAC) while respecting data residency, and **Global Cross-Region** routes anywhere worldwide when there are no residency constraints. Refer to the the section called “Regional availability by models” page for more details.

Region	In-Region	Geo	Global
us-east-1 (N. Virginia)	✓	✗	✗
us-west-2 (Oregon)	✓	✗	✗
eu-north-1 (Stockholm)	✓	✗	✗
ap-northeast-1 (Tokyo)	✓	✗	✗

Quotas and Limits

The default quota for Nova 2.5 Sonic is 20 concurrent `InvokeModelWithBidirectionalStream` sessions per AWS account in each supported Region. Contact your AWS account team to request a higher limit.

Your AWS account has default quotas to maintain the performance of the service and to ensure appropriate usage of Amazon Bedrock. The default quotas assigned to an account might be updated depending on regional factors, payment history, fraudulent usage, and/or approval of a quota increase request. For more information, see the section called "Quotas" documentation and see the limits for the model.

Sample Code

Step 1 - AWS Account: If you have an AWS account already, skip this step. If you are new to AWS, sign up for an AWS account.

Step 2 - API key: Go to the Amazon Bedrock console and generate a long-term API key.

Step 3 - Get the SDK:

```
pip install boto3
```

Step 4 - Set environment variables:

```
AWS_BEARER_TOKEN_BEDROCK="<provide your Bedrock API key>"
```

Step 5 - Run your first inference request: This model uses `InvokeModelWithBidirectionalStream`. See API reference for details.

Nova Lite

Amazon — Nova Lite

Model Details

Nova Lite is Amazon's low-cost multimodal model that processes text, images, and video inputs for tasks like document analysis and visual Q&A. For more information about model development and performance, see the model/service card.

Model launch date: Dec 05, 2024
EOL no sooner than: Dec 05, 2025
Legacy period: at least 6 months
Model lifecycle policy: Model lifecycle (For Models Launched Prior to Sept 7 2026)
Model EOL date: No sooner than 12/4/2025
End User License Agreements and Terms of Use: View
Model lifecycle: Active
Context window: 300K tokens
Max output tokens: 10K
Knowledge cutoff: Oct 2024

Input Modalities	Output Modalities	APIs supported	Endpoints supported
⊗ Audio	⊗ Embedding	⊗ `Responses`	⊙ `bedrock-runtime`
⊙ Image	⊗ Image	⊗ `Chat Completions`	⊗ `bedrock-mantle`
⊗ Speech	⊗ Speech	⊙ `Invoke`	
⊙ Text	⊙ Text	⊙ `Converse`	
⊙ Video	⊗ Video		

> **Tip**
>
> Whenever possible, we recommend using the `bedrock-runtime` endpoint for new applications. See the section called "Inference endpoints" for details.

Capabilities and Features

Bedrock Features

Features supported using `bedrock-runtime` endpoint

Supported	Not Supported
Response streaming Guardrails Client-side tool calling	Structured outputs Watermarking

Implicit and Explicit Prompt Caching using `bedrock-runtime` endpoint

For more information, see Prompt caching for faster model inference.

Explicit Prompt Caching supported	Min tokens per cache checkpoint	Max cache checkpoints per request	Supported TTL	Fields that accept prompt cache checkpoints
Yes	1K*	4	5 minutes	`system` and `messages`

** Amazon Nova models support a maximum of 20K tokens for prompt caching. Prompt caching is primarily for text prompts.*

Pricing

For pricing information, see the Amazon Bedrock Pricing page.

Programmatic Access

Use the following model IDs and endpoint URLs to access this model programmatically. For more information about the available APIs and endpoints, see APIs supported and Endpoints supported.

Endpoint	Model ID	In-Region endpoint URL	Geo inference ID	Global inference ID
bedrock-runtime	amazon.nova-lite-v1:0	https://bedrock-runtime.{region}.amazonaws.com	us.amazon.nova-lite-v1:0 ca.amazon.nova-lite-v1:0 eu.amazon.nova-lite-v1:0 apac.amazon.nova-lite-v1:0	Not supported

For example, if region is us-east-1 (N. Virginia), then the bedrock-runtime endpoint URL will be "https://bedrock-runtime.us-east-1.amazonaws.com" and for bedrock-mantle will be "https://bedrock-mantle.us-east-1.api.aws/v1".

Service Tiers

Amazon Bedrock offers multiple service tiers to match your workload requirements. **Standard** provides pay-per-token access with no commitment (set `"service_tier": "default"` or omit the field). **Priority** delivers the fastest response times for a price premium (set `"service_tier": "priority"`). **Flex** provides lower-cost access for flexible, non-time-sensitive workloads (set `"service_tier": "flex"`). **Reserved** provides dedicated throughput with a term commitment for predictable workloads; it is set at the account level rather than per request (contact your AWS account team to enable). For more information, see service tiers.

Quotas and Limits

Your AWS account has default quotas to maintain the performance of the service and to ensure appropriate usage of Amazon Bedrock. The default quotas assigned to an account might be updated depending on regional factors, payment history, fraudulent usage, and/or approval of a quota increase request. For more information, see the section called “Quotas” documentation and see the limits for the model.

Sample Code

Step 1 - AWS Account: If you have an AWS account already, skip this step. If you are new to AWS, sign up for an AWS account.

Step 2 - API key: Go to the Amazon Bedrock console and generate a long-term API key.

Step 3 - Get the SDK: To use this getting started guide, you must have Python already installed. Then install the relevant software depending on the APIs you are using.

```
pip install boto3
```

Step 4 - Set environment variables: Configure your environment to use the API key for authentication.

```
AWS_BEARER_TOKEN_BEDROCK="<provide your Bedrock API key>"
```

Step 5 - Run your first inference request: Save the file as `bedrock-first-request.py`

Invoke API

```
import json
import boto3

client = boto3.client('bedrock-runtime', region_name='us-east-1')
response = client.invoke_model(
    modelId='amazon.nova-lite-v1:0',
    body=json.dumps({
            'messages': [{
                'role': 'user',
                'content': [{'text': 'Can you explain the features of Amazon
 Bedrock?'}]
            }],
            'inferenceConfig': {
                'maxTokens': 1024
            }
    })
)
print(json.loads(response['body'].read()))
```

Converse API

```
import boto3

client = boto3.client('bedrock-runtime', region_name='us-east-1')
response = client.converse(
    modelId='amazon.nova-lite-v1:0',
```

```
    messages=[
        {
            'role': 'user',
            'content': [{'text': 'Can you explain the features of Amazon Bedrock?'}]
        }
    ]
)
print(response)
```

Nova Micro

Amazon — Nova Micro

Model Details

Nova Micro is Amazon's fastest text-only model, optimized for speed and low cost in tasks like summarization, translation, and classification. For more information about model development and performance, see the model/service card.

Model launch date: Dec 05, 2024
EOL no sooner than: Dec 05, 2025
Legacy period: at least 6 months
Model lifecycle policy: Model lifecycle (For Models Launched Prior to Sept 7 2026)
Model EOL date: No sooner than 12/4/2025
End User License Agreements and Terms of Use: View
Model lifecycle: Active
Context window: 128K tokens
Max output tokens: 10K
Knowledge cutoff: Oct 2024

Capabilities and Features

Bedrock Features

Features supported using `bedrock-runtime` endpoint

Supported	Not Supported
✓ Response streaming ✓ Guardrails ✓ Client-side tool calling	⊗ Structured outputs ⊗ Watermarking

Implicit and Explicit Prompt Caching using `bedrock-runtime` endpoint

For more information, see Prompt caching for faster model inference.

Explicit Prompt Caching supported	Min tokens per cache checkpoint	Max cache checkpoints per request	Supported TTL	Fields that accept prompt cache checkpoints
Yes	1K*	4	5 minutes	`system` and `messages`

** Amazon Nova models support a maximum of 20K tokens for prompt caching.*

Pricing

For pricing information, see the Amazon Bedrock Pricing page.

Programmatic Access

Use the following model IDs and endpoint URLs to access this model programmatically. For more information about the available APIs and endpoints, see APIs supported and Endpoints supported.

Endpoint	Model ID	In-Region endpoint URL	Geo inference ID	Global inference ID
`bedrock-runtime`	`amazon.nova-micro-v1:0`	`https://bedrock-runtime.{region}.amazonaws.com`	`us.amazon.nova-micro-v1:0` `eu.amazon.nova-micro-v1:0`	Not supported

For example, if region is us-east-1 (N. Virginia), then the bedrock-runtime endpoint URL will be "https://bedrock-runtime.us-east-1.amazonaws.com" and for bedrock-mantle will be "https://bedrock-mantle.us-east-1.api.aws/v1".

Service Tiers

Amazon Bedrock offers multiple service tiers to match your workload requirements. **Standard** provides pay-per-token access with no commitment (set `"service_tier": "default"` or omit

the field). **Priority** delivers the fastest response times for a price premium (set `"service_tier": "priority"`). **Flex** provides lower-cost access for flexible, non-time-sensitive workloads (set `"service_tier": "flex"`). **Reserved** provides dedicated throughput with a term commitment for predictable workloads; it is set at the account level rather than per request (contact your AWS account team to enable). For more information, see service tiers.

Standard	Priority	Flex	Reserved
✓	✗	✗	✗

Regional Availability

Regional availability at a glance

Amazon Bedrock offers three inference options: **In-Region** keeps requests within a single Region for strict compliance, **Geo Cross-Region** routes across Regions within a geography (such as US, EU, and APAC) while respecting data residency, and **Global Cross-Region** routes anywhere worldwide when there are no residency constraints. Refer to the the section called “Regional availability by models” page for more details.

Quotas and Limits

Your AWS account has default quotas to maintain the performance of the service and to ensure appropriate usage of Amazon Bedrock. The default quotas assigned to an account might be updated depending on regional factors, payment history, fraudulent usage, and/or approval of a quota increase request. For more information, see the section called “Quotas” documentation and see the limits for the model.

Sample Code

Step 1 - AWS Account: If you have an AWS account already, skip this step. If you are new to AWS, sign up for an AWS account.

Step 2 - API key: Go to the Amazon Bedrock console and generate a long-term API key.

Step 3 - Get the SDK: To use this getting started guide, you must have Python already installed. Then install the relevant software depending on the APIs you are using.

```
pip install boto3
```

Step 4 - Set environment variables: Configure your environment to use the API key for authentication.

```
AWS_BEARER_TOKEN_BEDROCK="<provide your Bedrock API key>"
```

Step 5 - Run your first inference request: Save the file as `bedrock-first-request.py`

For the complete request and response schema, including all supported parameters such as `system` prompts, `temperature`, `topP`, `stopSequences`, and `toolConfig`, see Complete request schema in the Amazon Nova User Guide.

Invoke API

```
import json
import boto3

client = boto3.client('bedrock-runtime', region_name='us-east-1')
response = client.invoke_model(
    modelId='amazon.nova-micro-v1:0',
    body=json.dumps({
        'messages': [{
            'role': 'user',
            'content': [{'text': 'Can you explain the features of Amazon Bedrock?'}]
        }],
        'inferenceConfig': {
            'maxTokens': 1024
        }
    })
)
print(json.loads(response['body'].read()))
```

Converse API

```
import boto3
```

```
client = boto3.client('bedrock-runtime', region_name='us-east-1')
response = client.converse(
    modelId='amazon.nova-micro-v1:0',
    messages=[
        {
            'role': 'user',
            'content': [{'text': 'Can you explain the features of Amazon Bedrock?'}]
        }
    ]
)
print(response)
```

Nova Pro

Amazon — Nova Pro

Model Details

Nova Pro is Amazon's balanced multimodal model offering strong accuracy, speed, and cost for a wide range of tasks across text, images, and video. For more information about model development and performance, see the model/service card.

Quotas and Limits

Your AWS account has default quotas to maintain the performance of the service and to ensure appropriate usage of Amazon Bedrock. The default quotas assigned to an account might be updated depending on regional factors, payment history, fraudulent usage, and/or approval of a quota increase request. For more information, see the section called “Quotas” documentation and see the limits for the model.

Sample Code

Step 1 - AWS Account: If you have an AWS account already, skip this step. If you are new to AWS, sign up for an AWS account.

Step 2 - API key: Go to the Amazon Bedrock console and generate a long-term API key.

Step 3 - Get the SDK: To use this getting started guide, you must have Python already installed. Then install the relevant software depending on the APIs you are using.

```
pip install boto3
```

Step 4 - Set environment variables: Configure your environment to use the API key for authentication.

```
AWS_BEARER_TOKEN_BEDROCK="<provide your Bedrock API key>"
```

Step 5 - Run your first inference request: Save the file as `bedrock-first-request.py`

Invoke API

```
import json
import boto3

client = boto3.client('bedrock-runtime', region_name='us-east-1')
response = client.invoke_model(
    modelId='amazon.nova-pro-v1:0',
    body=json.dumps({
            'messages': [{
                'role': 'user',
                'content': [{'text': 'Can you explain the features of Amazon
 Bedrock?'}]
            }],
            'inferenceConfig': {
                'maxTokens': 1024
            }
    })
)
print(json.loads(response['body'].read()))
```

Converse API

```
import boto3

client = boto3.client('bedrock-runtime', region_name='us-east-1')
response = client.converse(
    modelId='amazon.nova-pro-v1:0',
    messages=[
        {
            'role': 'user',
            'content': [{'text': 'Can you explain the features of Amazon Bedrock?'}]
        }
    ]
)
print(response)
```

Amazon Nova Multimodal Embeddings

Amazon — Amazon Nova Multimodal Embeddings

Model Details

Amazon Nova Multimodal Embeddings is Amazon's embedding model that converts text, images, and video into vector representations for search and retrieval use cases. For more information about model development and performance, see the model/service card.

Model launch date: Oct 28, 2025
EOL no sooner than: Oct 28, 2026
Legacy period: at least 6 months
Model lifecycle policy: Model lifecycle (For Models Launched Prior to Sept 7 2026)
Model EOL date: N/A
End User License Agreements and Terms of Use: View
Model lifecycle: Active

Input Modalities	Output Modalities	APIs supported	Endpoints supported
✓ Audio	✓ Embedding	✗ `Responses`	✓ `bedrock-runtime`
✓ Image	✗ Image	✗ `Chat Completions`	✗ `bedrock-mantle`
✗ Speech	✗ Speech	✗ `Invoke`	
✓ Text	✗ Text	✗ `Converse`	
✓ Video	✗ Video	✓ `StartAsyncInvoke`	

> **Tip**
>
> Whenever possible, we recommend using the `bedrock-runtime` endpoint for new applications. See the section called "Inference endpoints" for details.

Capabilities and Features

Bedrock Features

Features supported using `bedrock-runtime` endpoint

Supported	Not Supported
—	⊗ Intelligent prompt routing ⊗ Response streaming ⊗ Abuse detection ⊗ Guardrails ⊗ Prompt optimization ⊗ Count tokens ⊗ Knowledge base ⊗ Model evaluation ⊗ Prompt management ⊗ Flows ⊗ Agents

Pricing

For pricing information, see the Amazon Bedrock Pricing page.

Programmatic Access

Use the following model IDs and endpoint URLs to access this model programmatically. For more information about the available APIs and endpoints, see APIs supported and Endpoints supported.

Endpoint	Model ID	In-Region endpoint URL	Geo inference ID	Global inference ID
bedrock-runtime	amazon.nova-2-multimodal-embeddings-v1:0	https://bedrock-runtime.{region}.amazonaws.com	Not supported	Not supported

For example, if region is us-east-1 (N. Virginia), then the bedrock-runtime endpoint URL will be "https://bedrock-runtime.us-east-1.amazonaws.com" and for bedrock-mantle will be "https://bedrock-mantle.us-east-1.api.aws/v1".

Service Tiers

Amazon Bedrock offers multiple service tiers to match your workload requirements. **Standard** provides pay-per-token access with no commitment (set `"service_tier": "default"` or omit the field). **Priority** delivers the fastest response times for a price premium (set `"service_tier": "priority"`). **Flex** provides lower-cost access for flexible, non-time-sensitive workloads (set `"service_tier": "flex"`). **Reserved** provides dedicated throughput with a term commitment for predictable workloads; it is set at the account level rather than per request (contact your AWS account team to enable). For more information, see service tiers.

Standard	Priority	Flex	Reserved
✓	✗	✗	✗

Regional Availability

Regional availability at a glance

Amazon Bedrock offers three inference options: **In-Region** keeps requests within a single Region for strict compliance, **Geo Cross-Region** routes across Regions within a geography (such as US, EU, and APAC) while respecting data residency, and **Global Cross-Region** routes anywhere worldwide when there are no residency constraints. Refer to the the section called “Regional availability by models” page for more details.

Region	In-Region	Geo	Global
us-east-1 (N. Virginia)	✓	✗	✗
us-gov-west-1 (GovCloud)	✓	✗	✗

Quotas and Limits

Your AWS account has default quotas to maintain the performance of the service and to ensure appropriate usage of Amazon Bedrock. The default quotas assigned to an account might be updated depending on regional factors, payment history, fraudulent usage, and/or approval of a quota increase request. For more information, see the section called "Quotas" documentation and see the limits for the model.

Sample Code

Step 1 - AWS Account: If you have an AWS account already, skip this step. If you are new to AWS, sign up for an AWS account.

Step 2 - API key: Go to the Amazon Bedrock console and generate a long-term API key.

Step 3 - Get the SDK:

```
pip install boto3
```

Step 4 - Set environment variables:

```
AWS_BEARER_TOKEN_BEDROCK="<provide your Bedrock API key>"
```

Step 5 - Run your first inference request: This model uses `StartAsyncInvoke`. Save the file as `bedrock-first-request.py`

```
import boto3

client = boto3.client('bedrock-runtime', region_name='us-east-1')
response = client.start_async_invoke(
    modelId='amazon.nova-2-multimodal-embeddings-v1:0',
    modelInput={},
    outputDataConfig={'s3OutputDataConfig': {'s3Uri': 's3://your-bucket/output/'}}
)
```

```
print(response)
```

Nova Canvas

Amazon — Nova Canvas

Model Details

> **Important**
>
> Nova Canvas reached end of life on September 30, 2026 and is no longer available. Requests to this model fail with `ResourceNotFoundException: This model version has reached the end of its life.` For models that are currently available, see Models at a glance. For how model lifecycle stages work, see Model lifecycle.

Nova Canvas was Amazon's image generation model. It added an invisible watermark and content credentials to the images that it generated. For more information about model development and performance, see the model/service card.

Model launch date: Dec 3, 2024

EOL no sooner than: Dec 3, 2025

Legacy period: at least 6 months

Model lifecycle policy: Model lifecycle (For Models Launched Prior to Sept 7 2026)

Use the following model IDs and endpoint URLs to access this model programmatically. For more information about the available APIs and endpoints, see APIs supported and Endpoints supported.

Endpoint	Model ID	In-Region endpoint URL	Geo inference ID	Global inference ID
bedrock-runtime	amazon.titan-embed-image-v1	https://bedrock-runtime.{region}.amazonaws.com	Not supported	Not supported

For example, if region is us-east-1 (N. Virginia), then the bedrock-runtime endpoint URL will be "https://bedrock-runtime.us-east-1.amazonaws.com" and for bedrock-mantle will be "https://bedrock-mantle.us-east-1.api.aws/v1".

Service Tiers

Amazon Bedrock offers multiple service tiers to match your workload requirements. **Standard** provides pay-per-token access with no commitment (set `"service_tier": "default"` or omit the field). **Priority** delivers the fastest response times for a price premium (set `"service_tier": "priority"`). **Flex** provides lower-cost access for flexible, non-time-sensitive workloads (set `"service_tier": "flex"`). **Reserved** provides dedicated throughput with a term commitment for predictable workloads; it is set at the account level rather than per request (contact your AWS account team to enable). For more information, see service tiers.

Standard	Priority	Flex	Reserved
✓	✗	✗	✗

Regional Availability

Regional availability at a glance

Amazon Bedrock offers three inference options: **In-Region** keeps requests within a single Region for strict compliance, **Geo Cross-Region** routes across Regions within a geography (such as US, EU, and APAC) while respecting data residency, and **Global Cross-Region** routes anywhere worldwide when there are no residency constraints. Refer to the the section called “Regional availability by models” page for more details.

Region	In-Region	Geo	Global
us-east-1 (N. Virginia)	✓	✗	✗
us-west-2 (Oregon)	✓	✗	✗
ca-central-1 (Canada)	✓	✗	✗
eu-central-1 (Frankfurt)	✓	✗	✗
eu-west-1 (Ireland)	✓	✗	✗
eu-west-2 (London)	✓	✗	✗
eu-west-3 (Paris)	✓	✗	✗
ap-south-1 (Mumbai)	✓	✗	✗
ap-southeast-2 (Sydney)	✓	✗	✗
sa-east-1 (São Paulo)	✓	✗	✗

Quotas and Limits

Your AWS account has default quotas to maintain the performance of the service and to ensure appropriate usage of Amazon Bedrock. The default quotas assigned to an account might be updated depending on regional factors, payment history, fraudulent usage, and/or approval of a quota increase request. For more information, see the section called "Quotas" documentation and see the limits for the model.

Sample Code

Step 1 - AWS Account: If you have an AWS account already, skip this step. If you are new to AWS, sign up for an AWS account.

Step 2 - API key: Go to the Amazon Bedrock console and generate a long-term API key.

Step 3 - Get the SDK: To use this getting started guide, you must have Python already installed. Then install the relevant software depending on the APIs you are using.

```
pip install boto3
```

Step 4 - Set environment variables: Configure your environment to use the API key for authentication.

```
AWS_BEARER_TOKEN_BEDROCK="<provide your Bedrock API key>"
```

Step 5 - Run your first inference request: Save the file as `bedrock-first-request.py`

Invoke API

```
import json
import boto3

client = boto3.client('bedrock-runtime', region_name='us-east-1')
response = client.invoke_model(
    modelId='amazon.titan-embed-image-v1',
    body=json.dumps({
            'inputText': 'What are the different services that you offer?',
            'embeddingConfig': {
                'outputEmbeddingLength': 1024
            }
    })
)
print(json.loads(response['body'].read()))
```

Titan Embeddings G1 - Text

Amazon — Titan Embeddings G1 - Text

Model Details

Titan Text Embeddings G1 is Amazon's text embeddings model that converts text into numerical vector representations for search, personalization, and clustering. For more information about model development and performance, see the model/service card.

Model launch date: Sep 28, 2023

EOL no sooner than: Sep 28, 2024
Legacy period: at least 6 months
Model lifecycle policy: Model lifecycle (For Models Launched Prior to Sept 7 2026)
Model EOL date: No sooner than 11/29/2024
End User License Agreements and Terms of Use: View
Model lifecycle: Active
Context window: 8K tokens

Whenever possible, we recommend using the `bedrock-runtime` endpoint for new applications. See the section called "Inference endpoints" for details.

Pricing

For pricing information, see the Amazon Bedrock Pricing page.

Programmatic Access

Use the following model IDs and endpoint URLs to access this model programmatically. For more information about the available APIs and endpoints, see APIs supported and Endpoints supported.

Endpoint	Model ID	In-Region endpoint URL	Geo inference ID	Global inference ID
`bedrock-runtime`	`amazon.titan-embed-g1-text-02`	`https://bedrock-runtime.{region}.amazonaws.com`	Not supported	Not supported

For example, if region is us-east-1 (N. Virginia), then the bedrock-runtime endpoint URL will be "https://bedrock-runtime.us-east-1.amazonaws.com" and for bedrock-mantle will be "https://bedrock-mantle.us-east-1.api.aws/v1".

Regional Availability

Regional availability at a glance

Amazon Bedrock offers three inference options: **In-Region** keeps requests within a single Region for strict compliance, **Geo Cross-Region** routes across Regions within a geography (such as US, EU, and APAC) while respecting data residency, and **Global Cross-Region** routes anywhere worldwide when there are no residency constraints. Refer to the the section called "Regional availability by models" page for more details.

Region	In-Region	Geo	Global
`us-east-1` (N. Virginia)	✓	✗	✗
`us-west-2` (Oregon)	✓	✗	✗

Quotas and Limits

Your AWS account has default quotas to maintain the performance of the service and to ensure appropriate usage of Amazon Bedrock. The default quotas assigned to an account might be updated depending on regional factors, payment history, fraudulent usage, and/or approval of a quota increase request. For more information, see the section called "Quotas" documentation and see the limits for the model.

Sample Code

Step 1 - AWS Account: If you have an AWS account already, skip this step. If you are new to AWS, sign up for an AWS account.

Step 2 - API key: Go to the Amazon Bedrock console and generate a long-term API key.

Step 3 - Get the SDK: To use this getting started guide, you must have Python already installed. Then install the relevant software depending on the APIs you are using.

```
pip install boto3
```

Step 4 - Set environment variables: Configure your environment to use the API key for authentication.

```
AWS_BEARER_TOKEN_BEDROCK="<provide your Bedrock API key>"
```

Step 5 - Run your first inference request: Save the file as `bedrock-first-request.py`

Anthropic

The following Anthropic models are available in Amazon Bedrock:

Model	Description
the section called "Claude Fable 5.2"	Claude Fable 5.2 is Anthropic's frontier model for technical work, setting a new bar in coding, finance, and the sciences.
the section called "Claude Mythos 5.2"	Claude Mythos 5.2 is Anthropic's frontier model for cybersecurity and life sciences research, available through Anthropic's verification programs.
the section called "Claude Haiku 5.5"	Claude Haiku 5.5 is the fastest and most efficient model in the Claude 5.5 family, built for high-volume, latency-sensitive work. It's the most capable Haiku model yet, with a clear step up over Claude Haiku 4.5 on coding and agent tasks.
the section called "Claude Sonnet 5.5"	Claude Sonnet 5.5 is a smarter, more efficient Sonnet. It's a clear leap forward from Sonnet 5 on coding and knowledge work, at a much lower cost per task.
the section called "Claude Opus 5.5"	Claude Opus 5.5 is Anthropic's most capable Opus model. Better at coding, knowledge work, and long-running tasks. It's easier to collabora te with and more cost efficient than ever.
the section called "Claude Fable 5.1"	Claude Fable 5.1 is Anthropic's frontier model for ambitious coding, long-horizon agents, and enterprise knowledge work.
the section called "Claude Mythos 5.1"	Claude Mythos 5.1 is Anthropic's most capable model for cybersecu rity defense and life sciences research, including threat intelligence, vulnerability discovery, red teaming, drug discovery, and biodefense screening.

Model	Description
the section called “Claude Opus 5”	Claude Opus 5 is Anthropic's most advanced Opus model, powering long-running agents while delivering improvements in coding and professional work.
the section called “Claude Sonnet 5”	Claude Sonnet 5 is Anthropic's most capable Sonnet model yet, built for coding, agents, and professional work at scale.
the section called “Claude Mythos 5”	Claude Mythos 5 is Anthropic's most capable model for cybersecurity and life sciences, including vulnerability discovery, drug design, and biodefense screening.
the section called “Claude Fable 5”	Claude Fable 5 is Anthropic's next-generation model for complex knowledge work and coding, capable of sustained autonomous operation across multi-day tasks.
the section called “Claude Opus 4.8”	Claude Opus 4.8 is an Anthropic Opus model optimized for coding, agents, and deeper reasoning in enterprise workflows.
the section called “Claude Opus 4.7”	Claude Opus 4.7 is an Anthropic Opus model built for coding, enterpris e workflows, and long-running agentic tasks.
the section called “Claude Sonnet 4.6”	Claude Sonnet 4.6 is a full upgrade of Anthropic's mid-tier model with improved coding, computer use, long-context reasoning, and agent planning with a 1M token context window.
the section called “Claude Opus 4.6”	Claude Opus 4.6 is Anthropic's flagship model that plans more carefully , sustains agentic tasks longer, and operates reliably in massive codebases.
the section called “Claude Opus 4.5”	Claude Opus 4.5 is Anthropic's model for coding, agents, and computer use with improvements for spreadsheets and long-running chats.
the section called “Claude Haiku 4.5”	Claude Haiku 4.5 is Anthropic's lightweight model optimized for speed and efficiency with strong coding and agent performance.

Model	Description
the section called “Claude Sonnet 4.5”	Claude Sonnet 4.5 is Anthropic's model optimized for agents, coding, and computer use with significant improvements across all benchmark s.
the section called “Claude Opus 4.1”	Claude Opus 4.1 is an upgrade to Anthropic's model with improved coding, reasoning, and agentic task capabilities.
the section called “Claude Sonnet 4”	Claude Sonnet 4 is Anthropic's balanced model with strong coding and reasoning capabilities, improved instruction following, and extended thinking with tool use.
the section called “Claude 3 Haiku”	Claude 3 Haiku is Anthropic's fastest and most compact Claude 3 model, optimized for speed and efficiency in near-instant responses.

Billing notes

The following billing behaviors apply specifically to Anthropic models on Amazon Bedrock:

- **Refused requests** – A refused request returns HTTP 200 with `stop_reason: "refusal"`. Whether it's billed depends on when the refusal occurred and on `stop_details.category`. These rules apply on both the `bedrock-runtime` and `bedrock-mantle` endpoints.

  The following table describes each `stop_details.category` value and whether Amazon Bedrock bills a refusal in that category before any output.

`stop_details.category`	What it means	Billed before any output
`"cyber"`	The request could enable cyber harm, such as malware or exploit development. Benign cybersecurity work can also trigger this category.	No

stop_details.category	What it means	Billed before any output
"bio"	The request could enable biological harm, such as dangerous lab methods. Beneficial life sciences work can also trigger this category.	Yes
"frontier_llm"	The request could help with the development of competing AI models, which is restricted under Anthropic's commercial terms. Benign machine learning work can also trigger this category.	Yes
"reasoning_extraction"	The request asks the model to reproduce its internal reasoning in the response text. To get reasoning in a structured form instead, use adaptive thinking. This category has no recommended fallback model, so change the prompt instead of retrying on another model.	Yes
"general_harms"	The request falls under a usage-policy area outside the four named categories. Benign work can also trigger this category.	No
null	The refusal doesn't map to a named category. null is a valid final value, not a placeholder.	No

Amazon Bedrock bills a refusal before any output like any other request, at the refused model's rates. For a refusal that arrives mid-stream, after partial output, Amazon Bedrock bills the input tokens and the output tokens already streamed, in any category. Treat any partial output as incomplete and discard it.

In every case, the response's usage still reports token counts, and the request counts against your quotas. The set of billed categories can change.

Claude Fable 5.2

Anthropic — Claude Fable 5.2

Model Details

Claude Fable 5.2 is Anthropic's frontier model for technical work, setting a new bar in coding, finance, and the sciences. Fable 5.2 takes on ambiguous problems for days, questions and verifies its own work, and orchestrates subagents to optimize results in a loop.

Model launch date: November 9, 2026
EOL no sooner than: November 9, 2027
Legacy period: 6 months
Model lifecycle policy: Model lifecycle
Model EOL date: N/A
End User License Agreements and Terms of Use: View
Model lifecycle: Active
Context window: 1M tokens
Max output tokens: 128K
Sampling parameters: temperature must be 1.0 or unset; top_p must be 0.99 or unset; temperature and top_p cannot be specified together; top_k is not supported
Reasoning: Supported (adaptive thinking is always on and cannot be disabled; effort level configurable — low, medium, high, xhigh, max; default: high) See Adaptive thinking.
Preserved thinking: Thinking blocks are bound to the model and the conversation prefix that produced them. Replay earlier turns unchanged, or a request returns a 400 error. For more information, see Preserved thinking.
Knowledge cutoff: June 2026
Marketplace product ID: prod-m733do2vrmi3o

Endpoints and APIs supported

The following tables show which endpoints and APIs are supported for Claude Fable 5.2. For more information, see the section called “APIs” and the section called “Inference endpoints”.

Endpoint support

Endpoint	Supported
`bedrock-runtime`	⊙

APIs supported on `bedrock-runtime` endpoint

Messages	Responses	Chat Completions	Converse	Invoke
⊙	⊗	⊗	⊙	⊙

> **Tip**
>
> Whenever possible, we recommend using the `bedrock-runtime` endpoint for new applications. See the section called “Inference endpoints” for details.

Capabilities and Features

Bedrock Features

Features supported using `bedrock-runtime` endpoint

Supported	Not Supported
Response streaming Prompt caching Abuse detection Guardrails Prompt optimization Knowledge base Model evaluation Prompt management Flows Agents Computer use Structured outputs Watermarking	Count tokens Intelligent prompt routing Implicit Prompt Caching

Prompt caching using `bedrock-runtime` endpoint

For more information, see Prompt caching for faster model inference.

Prompt caching supported	Min tokens per cache checkpoint	Max cache checkpoints per request	Supported TTL	Fields that accept prompt cache checkpoint
Yes	512	4	5 minutes, 1 hour	`system`, `messages`, and `tools`

Computer use using `bedrock-runtime` endpoint

For more information, see Computer use.

Tool type	Beta header
`computer_20251124`	`computer-use-2025-11-24`

Client tools and toolsets using `bedrock-runtime` endpoint

For more information, see Tool use.

Tool type	Beta header
`computer_toolset_20260801`	None required
`browser_toolset_20260801`	None required
`bash_20250124`	None required
`text_editor_20250728`	None required
`memory_20250818`	None required

Compaction using `bedrock-runtime` endpoint

For more information, see Compaction.

Compaction supported	Beta value
Yes	`compact-2026-09-04` , `compact-2026-01-12`

Content Restrictions

Claude Fable 5.2 includes safety classifiers that block high-risk cybersecurity activities and most research biology tasks. When a classifier blocks a request, the API returns a standard HTTP 200 response with `stop_reason: "refusal"` and a `stop_details` object containing the restriction category. Organizations working in these areas can apply for less restrictive access through Anthropic's Cyber Verification Program and Life Sciences Verification Program.

Customers should handle `stop_reason: "refusal"` as a primary response path. Whether a refused request is billed depends on its category and on whether output had started. For details, see Billing notes.

Fallback credit for refused requests (beta)

When Claude Fable 5.2 refuses a request, the response can include a fallback credit token. Redeem the token when you retry the same request on a fallback model, and the retry is billed for the cached conversation prefix at cache-read rates instead of cache-write rates. Not every refusal carries a token. For more information, see Fallback credit for refused requests (beta).

Supported endpoints	Beta value	Valid fallback models
`bedrock-runtime`	`fallback-credit-2026-07-01`	Claude Opus 5 (`anthropic.claude-opus-5`), Claude Opus 4.8 (`anthropic.claude-opus-4-8`)

Pricing

For pricing information, see the Amazon Bedrock Pricing page.

Programmatic Access

Use the following model IDs and endpoint URLs to access this model programmatically. For more information about the available APIs and endpoints, see APIs supported and Endpoints supported.

Endpoint	Model ID	In-Region endpoint URL	Geo inference ID	Global inference ID
`bedrock-runtime`	`anthropic.claude-fable-5-2`	N/A	`us.anthropic.claude-fable-5-2`	`global.anthropic.claude-fable-5-2`

For example, if region is us-east-1 (N. Virginia), then the bedrock-runtime endpoint URL will be "https://bedrock-runtime.us-east-1.amazonaws.com".

Service Tiers

Amazon Bedrock offers multiple service tiers to match your workload requirements. **Standard** provides pay-per-token access with no commitment (set `"service_tier": "default"` or omit the field). **Priority** delivers the fastest response times for a price premium (set `"service_tier":`

"priority"). **Flex** provides lower-cost access for flexible, non-time-sensitive workloads (set "service_tier": "flex"). **Reserved** provides dedicated throughput with a term commitment for predictable workloads; it is set at the account level rather than per request (contact your AWS account team to enable). For more information, see service tiers.

Standard	Priority	Flex	Reserved

ca-central-1 (Canada)	ca-central-1 (Canada), us-east-1 (N. Virginia), us-east-2 (Ohio), us-west-2 (Oregon)

Source Region	Destination Regions
ca-west-1 (Calgary)	ca-west-1 (Calgary), us-east-1 (N. Virginia), us-east-2 (Ohio), us-west-2 (Oregon)

Data Retention

To use this model, you must opt in to AWS review by setting your data retention mode to `aws_review` via the Data Retention API. For more information, see Amazon Bedrock abuse detection.

Quotas and Limits

Your AWS account has default quotas to maintain the performance of the service and to ensure appropriate usage of Amazon Bedrock. The default quotas assigned to an account might be updated depending on regional factors, payment history, fraudulent usage, and/or approval of a quota increase request. For more information, see the section called "Quotas" documentation and see the limits for the model.

Sample Code

Step 1 - AWS Account: If you have an AWS account already, skip this step. If you are new to AWS, sign up for an AWS account.

Step 2 - API key: Go to the Amazon Bedrock console and generate a long-term API key.

Step 3 - Get the SDK: To use this getting started guide, you must have Python already installed. Then install the relevant software depending on the APIs you are using.

Messages API

```
pip install -U anthropic aws-bedrock-token-generator
```

Invoke/Converse API

```
pip install boto3
```

Step 4 - Set environment variables: Configure your environment to use the API key for authentication.

Messages API

```
AWS_BEARER_TOKEN_BEDROCK="<provide your Bedrock API key>"
```

Invoke/Converse API

```
AWS_BEARER_TOKEN_BEDROCK="<provide your Bedrock API key>"
```

Step 5 - Run your first inference request: Save the file as `bedrock-first-request.py`

Messages API

```
from anthropic import Anthropic
from aws_bedrock_token_generator import provide_token

token = provide_token(region="us-east-1")

client = Anthropic(
    base_url="https://bedrock-runtime.us-east-1.amazonaws.com/anthropic",
    api_key=token,
)

response = client.messages.create(
    model="global.anthropic.claude-fable-5-2",
    max_tokens=16000,
    messages=[{"role": "user", "content": "Can you explain the features of Amazon
 Bedrock?"}],
)

print(response)
```

Invoke API

```
import json
import boto3

client = boto3.client('bedrock-runtime', region_name='us-east-1')
response = client.invoke_model(
    modelId='global.anthropic.claude-fable-5-2',
    body=json.dumps({
            'anthropic_version': 'bedrock-2023-05-31',
```

```
            'messages': [{ 'role': 'user', 'content': 'Can you explain the features
 of Amazon Bedrock?'}],
            'max_tokens': 16000
    })
)
print(json.loads(response['body'].read()))
```

Converse API

```
import boto3

client = boto3.client('bedrock-runtime', region_name='us-east-1')
response = client.converse(
    modelId='global.anthropic.claude-fable-5-2',
    messages=[
        {
            'role': 'user',

print(response)
```

Claude Mythos 5.2

Anthropic — Claude Mythos 5.2

Model Details

Claude Mythos 5.2 is Anthropic's frontier model for cybersecurity and life sciences research, available through Anthropic's verification programs. It is the same underlying model as Claude Fable 5.2; the two differ in safeguards and access.

Access is limited to organizations approved through Anthropic's Cyber Verification Program and Life Sciences Verification Program. Each organization's program tier sets which cybersecurity and biology use cases are allowed.

This model is a Preview and is made available to you as a "Beta Service" as defined in the AWS Service Terms. It is subject to your Agreement with AWS, the AWS Service Terms, and the applicable model EULA.

Model launch date: November 9, 2026

EOL no sooner than: November 9, 2027

Legacy period: 6 months

Model lifecycle policy: Model lifecycle

Model EOL date: N/A

End User License Agreements and Terms of Use: View

Model lifecycle: Active

Context window: 1M tokens

Max output tokens: 128K

Sampling parameters: temperature must be 1.0 or unset; top_p must be 0.99 or unset; temperature and top_p cannot be specified together; top_k is not supported

Reasoning: Supported (adaptive thinking is always on and cannot be disabled; effort level configurable — low, medium, high, xhigh, max; default: high) See Adaptive thinking.

Preserved thinking: Thinking blocks are bound to the model and the conversation prefix that produced them; Claude Fable 5.2 and Claude Mythos 5.2 read each other's blocks. Replay earlier turns unchanged, or a request returns a 400 error. For more information, see Preserved thinking.

Knowledge cutoff: June 2026

Pricing

For pricing information, see the Amazon Bedrock Pricing page.

Programmatic Access

Use the following model IDs and endpoint URLs to access this model programmatically. For more information about the available APIs and endpoints, see APIs supported and Endpoints supported.

Endpoint	Model ID	In-Region endpoint URL	Geo inference ID	Global inference ID
bedrock-runtime	anthropic.claude-mythos-5-2	N/A	us.anthropic.claude-	global.anthropic.claude-

Endpoint	Model ID	In-Region endpoint URL	Geo inference ID	Global inference ID
			`mythos-5-2`	`myt hos-5-2`

For example, if region is us-east-1 (N. Virginia), then the bedrock-runtime endpoint URL will be "https://bedrock-runtime.us-east-1.amazonaws.com".

Service Tiers

Amazon Bedrock offers multiple service tiers to match your workload requirements. **Standard** provides pay-per-token access with no commitment (set `"service_tier": "default"` or omit the field). **Priority** delivers the fastest response times for a price premium (set `"service_tier": "priority"`). **Flex** provides lower-cost access for flexible, non-time-sensitive workloads (set `"service_tier": "flex"`). **Reserved** provides dedicated throughput with a term commitment for predictable workloads; it is set at the account level rather than per request (contact your AWS account team to enable). For more information, see service tiers.

Standard	Priority	Flex	Reserved
✓	✗	✗	✗

Regional Availability

Regional availability at a glance

Amazon Bedrock offers three inference options: **In-Region** keeps requests within a single Region for strict compliance, **Geo Cross-Region** routes across Regions within a geography (such as US, EU, and APAC) while respecting data residency, and **Global Cross-Region** routes anywhere worldwide when there are no residency constraints. Refer to the the section called “Regional availability by models” page for more details.

Geo inference details

The destination Regions available to a geographic inference profile depend on the source Region. To retrieve the current routing configuration, call GetInferenceProfile from the source Region.

Geo: US

Geo inference ID: `us.anthropic.claude-mythos-5-2`

Source Region	Destination Regions
us-east-1 (N. Virginia)	us-east-1 (N. Virginia), us-east-2 (Ohio), us-west-2 (Oregon)
us-east-2 (Ohio)	us-east-1 (N. Virginia), us-east-2 (Ohio), us-west-2 (Oregon)
us-west-1 (N. California)	us-east-1 (N. Virginia), us-east-2 (Ohio), us-west-1 (N. California), us-west-2 (Oregon)
us-west-2 (Oregon)	us-east-1 (N. Virginia), us-east-2 (Ohio), us-west-2 (Oregon)
ca-central-1 (Canada)	ca-central-1 (Canada), us-east-1 (N. Virginia), us-east-2 (Ohio), us-west-2 (Oregon)
ca-west-1 (Calgary)	ca-west-1 (Calgary), us-east-1 (N. Virginia), us-east-2 (Ohio), us-west-2 (Oregon)

Data Retention

To use this model, you must set your data retention mode to `aws_review` or `provider_data_share` via the Data Retention API. For more information, see Amazon Bedrock abuse detection.

Quotas and Limits

Your AWS account has default quotas to maintain the performance of the service and to ensure appropriate usage of Amazon Bedrock. The default quotas assigned to an account might be updated depending on regional factors, payment history, fraudulent usage, and/or approval of a quota increase request. For more information, see the section called “Quotas” documentation and see the limits for the model.

Sample Code

Step 1 - AWS Account: If you have an AWS account already, skip this step. If you are new to AWS, sign up for an AWS account.

Step 2 - API key: Go to the Amazon Bedrock console and generate a long-term API key.

Step 3 - Get the SDK: To use this getting started guide, you must have Python already installed. Then install the relevant software depending on the APIs you are using.

Messages API

```
pip install -U anthropic aws-bedrock-token-generator
```

Invoke/Converse API

```
pip install boto3
```

Step 4 - Set environment variables: Configure your environment to use the API key for authentication.

Messages API

```
AWS_BEARER_TOKEN_BEDROCK="<provide your Bedrock API key>"
```

Invoke/Converse API

```
AWS_BEARER_TOKEN_BEDROCK="<provide your Bedrock API key>"
```

Step 5 - Run your first inference request: Save the file as `bedrock-first-request.py`

Messages API

```
from anthropic import Anthropic
from aws_bedrock_token_generator import provide_token

token = provide_token(region="us-east-1")

client = Anthropic(
    base_url="https://bedrock-runtime.us-east-1.amazonaws.com/anthropic",
    api_key=token,
)

response = client.messages.create(
```

```
    model="global.anthropic.claude-mythos-5-2",
    max_tokens=16000,
    messages=[{"role": "user", "content": "Can you explain the features of Amazon
 Bedrock?"}],
)

print(response)
```

Invoke API

```
import json
import boto3

client = boto3.client('bedrock-runtime', region_name='us-east-1')
response = client.invoke_model(
    modelId='global.anthropic.claude-mythos-5-2',
    body=json.dumps({
            'anthropic_version': 'bedrock-2023-05-31',
            'messages': [{ 'role': 'user', 'content': 'Can you explain the features
 of Amazon Bedrock?'}],
            'max_tokens': 16000
    })
)
print(json.loads(response['body'].read()))
```

Converse API

```
import boto3

client = boto3.client('bedrock-runtime', region_name='us-east-1')
response = client.converse(
    modelId='global.anthropic.claude-mythos-5-2',
    messages=[
        {
            'role': 'user',
            'content': [{'text': 'Can you explain the features of Amazon Bedrock?'}]
        }
    ]
)
print(response)
```

Claude Haiku 5.5

Anthropic — Claude Haiku 5.5

Model Details

Claude Haiku 5.5 is the fastest, most efficient model in the Claude 5.5 family, built for high-volume, latency-sensitive work. It is the most capable Haiku yet, with improved performance over Claude Haiku 4.5 on coding and agent tasks. It is also the first Haiku with effort controls.

Model launch date: October 7, 2026
EOL no sooner than: October 7, 2027
Legacy period: 6 months
Model lifecycle policy: Model lifecycle
Model EOL date: N/A
End User License Agreements and Terms of Use: View
Model lifecycle: Active
Context window: 1M tokens
Max output tokens: 128K
Reasoning: Supported (adaptive thinking is on by default and can be turned off; effort level configurable — low, medium, high, xhigh, max; default: medium; effort capped at high when thinking is disabled) See Adaptive thinking.
Preserved thinking: Thinking blocks are bound to the model and the conversation prefix that produced them. Replay earlier turns unchanged, or a request returns a 400 error. On Claude Haiku 5.5, thinking blocks are also bound to the AWS account that produced them. For more information, see Preserved thinking.
Knowledge cutoff: June 2026

Pricing

This model is a third-party model offered and billed through AWS Marketplace. Charges appear on your AWS bill and in AWS Cost Explorer under the model provider (not under Amazon Bedrock). For pricing, see the Amazon Bedrock Pricing page.

> **Note**
>
> Claude Haiku 5.5 uses tiered long-context pricing. Prompts of 100,000 tokens or fewer are billed at the standard per-token rates. Prompts that exceed 100,000 tokens are billed at higher rates for input, output, and cache read and write operations. The rates for prompts over 100,000 tokens appear in a separate row, labeled **Claude Haiku 5.5 - Long Context**.

Programmatic Access

Use the following model IDs and endpoint URLs to access this model programmatically. For more information about the available APIs and endpoints, see APIs supported and Endpoints supported.

> **Important**
>
> This model is offered through one or more inference profiles designated as inference profiles with limited model selection. These profiles are expected to offer a narrower selection of models, and new models or model versions might not be released for them. Before you take a dependency on one of these inference profiles, review the section called "Inference profiles with limited model selection" and plan for model lifecycle events.

Endpoint	Model ID	In-Region endpoint URL	Geo inference ID	Global inference ID
bedrock-runtime	anthropic.claude-haiku-5-5	N/A	us.anthropic.claude-haiku-5-5 ca.anthropic.claude-haiku-5-5 eu.anthropic.claude-haiku-5-5 au.anthropic.claude-haiku-5-5	global.anthropic.claude-haiku-5-5

Endpoint	Model ID	In-Region endpoint URL	Geo inference ID	Global inference ID
			`jp.anthropic.claude-haiku-5-5`	
`bedrock-mantle`	`anthropic.claude-haiku-5-5`	`https://bedrock-mantle.{region}.api.aws/anthropic/v1/messages`	N/A	N/A

For example, to use Global cross-Region inference from us-east-1 (N. Virginia), use the endpoint URL "https://bedrock-runtime.us-east-1.amazonaws.com" with the inference profile ID "global.anthropic.claude-haiku-5-5".

Service Tiers

Amazon Bedrock offers multiple service tiers to match your workload requirements. **Standard** provides pay-per-token access with no commitment (set `"service_tier": "default"` or omit the field). **Priority** delivers the fastest response times for a price premium (set `"service_tier": "priority"`). **Flex** provides lower-cost access for flexible, non-time-sensitive workloads (set `"service_tier": "flex"`). **Reserved** provides dedicated throughput with a term commitment for predictable workloads; it is set at the account level rather than per request (contact your AWS account team to enable). For more information, see service tiers.

Quotas and Limits

Your AWS account has default quotas for Amazon Bedrock. These quotas might change depending on regional factors, payment history, or approval of a quota increase request. For more details, see the section called "Quotas" and the limits for the model.

Sample Code

Step 1 - AWS Account: If you have an AWS account already, skip this step. If you are new to AWS, sign up for an AWS account.

Step 2 - API key: Open the Amazon Bedrock console and generate a long-term API key.

Step 3 - Get the SDK: To use this getting started guide, you must have Python already installed. Then install the relevant software depending on the APIs you are using.

Messages API

```
pip install -U "anthropic[bedrock]" aws-bedrock-token-generator
```

Invoke/Converse API

```
pip install boto3
```

Step 4 - Set environment variables: Configure your environment to use the API key for authentication.

Messages API

```
AWS_BEARER_TOKEN_BEDROCK="<provide your Bedrock API key>"
```

Invoke/Converse API

```
AWS_BEARER_TOKEN_BEDROCK="<provide your Bedrock API key>"
```

Step 5 - Run your first inference request: Save the file as `bedrock-first-request.py`

Messages API

```
from anthropic import Anthropic
from aws_bedrock_token_generator import provide_token

token = provide_token(region="us-east-1")

client = Anthropic(
```

```
    base_url="https://bedrock-runtime.us-east-1.amazonaws.com/anthropic",
    api_key=token,
)

response = client.messages.create(
    model="global.anthropic.claude-haiku-5-5",
    max_tokens=1024,
    messages=[{"role": "user", "content": "Can you explain the features of Amazon
 Bedrock?"}],
)

print(response)
```

Invoke API

```
import json
import boto3

client = boto3.client('bedrock-runtime', region_name='us-east-1')
response = client.invoke_model(
    modelId='global.anthropic.claude-haiku-5-5',
    body=json.dumps({
            'anthropic_version': 'bedrock-2023-05-31',
            'messages': [{ 'role': 'user', 'content': 'Can you explain the features
 of Amazon Bedrock?'}],
            'max_tokens': 1024
    })
)
print(json.loads(response['body'].read()))
```

Converse API

```
import boto3

client = boto3.client('bedrock-runtime', region_name='us-east-1')
response = client.converse(
    modelId='global.anthropic.claude-haiku-5-5',
    messages=[
        {
            'role': 'user',
            'content': [{'text': 'Can you explain the features of Amazon Bedrock?'}]
        }
    ]
```

```
)
print(response)
```

Anthropic — Claude Sonnet 5.5

Model Details

Claude Sonnet 5.5 is a smarter, more efficient Sonnet. It's a clear leap forward from Sonnet 5 on coding and knowledge work, at a much lower cost per task.

Model launch date: September 28, 2026
EOL no sooner than: September 28, 2027
Legacy period: 6 months
Model lifecycle policy: Model lifecycle
Model EOL date: N/A
End User License Agreements and Terms of Use: View
Model lifecycle: Active
Context window: 1M tokens
Max output tokens: 128K
Reasoning: Supported (adaptive thinking is on by default; `thinking.type: "disabled"` is not supported, so use `"between_tools"` to turn off up-front thinking at `high` effort or below; effort level configurable — low, medium, high, xhigh, max; default: high) See Adaptive thinking.
Preserved thinking: Thinking blocks are bound to the model and the conversation prefix that produced them. Replay earlier turns unchanged, or a request returns a 400 error. On Claude Sonnet 5.5, thinking blocks are also bound to the AWS account that produced them. For more information, see Preserved thinking.
Knowledge cutoff: June 2026
Marketplace product ID: `prod-pjfguoisodbd6`

Endpoints and APIs supported

The following tables show which endpoints and APIs are supported for Claude Sonnet 5.5. For more information, see the section called "APIs" and the section called "Inference endpoints".

Endpoint support

Endpoint	Supported
`bedrock-runtime`	✓
`bedrock-mantle`	✓

APIs supported on `bedrock-runtime` endpoint

Messages	Responses	Chat Completions	Converse	Invoke
✓	✗	✗	✓	✓

APIs supported on `bedrock-mantle` endpoint

Messages	Responses	Chat Completions	Converse	Invoke
✓	✗	✗	✗	✗

> **Tip**
>
> Whenever possible, we recommend using the `bedrock-runtime` endpoint for new applications. See the section called "Inference endpoints" for details.

Capabilities and Features

Bedrock Features

Features supported using `bedrock-runtime` endpoint

Supported	Not Supported
✓ Response streaming ✓ Explicit Prompt Caching ✓ Abuse detection ✓ Guardrails ✓ Prompt optimization ✓ Knowledge base ✓ Model evaluation ✓ Prompt management ✓ Flows ✓ Agents ✓ Computer use ✓ Client-side tool calling (`tool_choice` types `auto` and none only) ✓ Server-side tool use (tool search only) ✓ Application inference profiles ✓ Invocation logs ✓ Structured outputs ✓ Watermarking	✗ Intelligent prompt routing ✗ Count tokens ✗ Implicit Prompt Caching

Features supported using `bedrock-mantle` endpoint

Supported	Not Supported
Response streaming Explicit Prompt Caching Abuse detection Count tokens Computer use Structured outputs Watermarking	Guardrails Prompt optimization Knowledge base Model evaluation Prompt management Flows Agents Intelligent prompt routing Implicit Prompt Caching

Explicit Prompt Caching using `bedrock-runtime` and `bedrock-mantle` endpoints

For more information, see Prompt caching for faster model inference.

Explicit Prompt Caching supported	Min tokens per cache checkpoint	Max cache checkpoints per request	Supported TTL	Fields that accept prompt cache checkpoints
Yes	512	4	5 minutes, 1 hour	`system`, `messages`, and `tools`

Computer use using `bedrock-runtime` and `bedrock-mantle` endpoints

For more information, see Computer use.

Tool type	Beta header
`computer_20251124`	`computer-use-2025-11-24`

Client tools and toolsets using `bedrock-runtime` endpoint

For more information, see Tool use.

Tool type	Beta header
`computer_toolset_20260801`	None required
`browser_toolset_20260801`	None required
`bash_20250124`	None required
`text_editor_20250728`	None required
`memory_20250818`	None required

Compaction using `bedrock-runtime` endpoint

For more information, see Compaction.

Compaction supported	Beta value
Yes	`compact-2026-09-04` , `compact-2026-01-12`

Fallback credit for refused requests (beta)

When Claude Sonnet 5.5 refuses a request, the response can include a fallback credit token. Redeem the token when you retry the same request on a fallback model, and the retry is billed for the cached conversation prefix at cache-read rates instead of cache-write rates. For more information, see Fallback credit for refused requests (beta).

Supported endpoints	Beta value	Valid fallback models
`bedrock-runtime` , `bedrock-mantle`	`fallback-credit-2026-07-01`	Claude Sonnet 5 (`anthropic.claude-sonnet-5`)

Pricing

This model is a third-party model offered and billed through AWS Marketplace. Charges appear on your AWS bill and in AWS Cost Explorer under the model provider (not under Amazon Bedrock). For pricing, see the Amazon Bedrock Pricing page.

Programmatic Access

Use the following model IDs and endpoint URLs to access this model programmatically. For more information about the available APIs and endpoints, see APIs supported and Endpoints supported.

Endpoint	Model ID	In-Region endpoint URL	Geo inference ID	Global inference ID
bedrock-runtime	anthropic.claude-sonnet-5-5	N/A	us.anthropic.claude-sonnet-5-5 eu.anthropic.claude-sonnet-5-5 au.anthropic.claude-sonnet-5-5	global.anthropic.claude-sonnet-5-5
bedrock-mantle	anthropic.claude-sonnet-5-5	https://bedrock-mantle.{region}.api.aws/anthropic/v1/messages	N/A	N/A

For example, to use Global cross-Region inference from us-east-1 (N. Virginia), use the endpoint URL "https://bedrock-runtime.us-east-1.amazonaws.com" with the inference profile ID "global.anthropic.claude-sonnet-5-5".

Service Tiers

Amazon Bedrock offers multiple service tiers to match your workload requirements. **Standard** provides pay-per-token access with no commitment (set `"service_tier": "default"` or omit the field). **Priority** delivers the fastest response times for a price premium (set `"service_tier": "priority"`). **Flex** provides lower-cost access for flexible, non-time-sensitive workloads (set `"service_tier": "flex"`). **Reserved** provides dedicated throughput with a term commitment for predictable workloads; it is set at the account level rather than per request (contact your AWS account team to enable). For more information, see service tiers.

Standard	Priority	Flex	Reserved	Batch
✓	✗	✗	✗	✗

Regional Availability

Regional availability at a glance

Amazon Bedrock offers three inference options: **In-Region** keeps requests within a single Region for strict compliance, **Geo Cross-Region** routes across Regions within a geography (such as US, EU, and APAC) while respecting data residency, and **Global Cross-Region** routes anywhere worldwide when there are no residency constraints. Refer to the the section called “Regional availability by models” page for more details.

Availability differs by endpoint.

Geo inference details

The destination Regions available to a geographic inference profile depend on the source Region. To retrieve the current routing configuration, call GetInferenceProfile from the source Region.

Geo: US

Geo inference ID: `us.anthropic.claude-sonnet-5-5`

Source Region	Destination Regions
us-east-1 (N. Virginia)	us-east-1 (N. Virginia), us-east-2 (Ohio), us-west-2 (Oregon)
us-east-2 (Ohio)	us-east-1 (N. Virginia), us-east-2 (Ohio), us-west-2 (Oregon)
us-west-1 (N. California)	us-east-1 (N. Virginia), us-east-2 (Ohio), us-west-1 (N. California), us-west-2 (Oregon)
us-west-2 (Oregon)	us-east-1 (N. Virginia), us-east-2 (Ohio), us-west-2 (Oregon)
ca-central-1 (Canada)	ca-central-1 (Canada), us-east-1 (N. Virginia), us-east-2 (Ohio), us-west-2 (Oregon)
ca-west-1 (Calgary)	ca-west-1 (Calgary), us-east-1 (N. Virginia), us-east-2 (Ohio), us-west-2 (Oregon)

Geo: EU

Geo inference ID: `eu.anthropic.claude-sonnet-5-5`

Source Region	Destination Regions
eu-central-1 (Frankfurt)	eu-central-1 (Frankfurt), eu-north-1 (Stockholm), eu-south-1 (Milan), eu-south-2 (Spain), eu-west-1 (Ireland), eu-west-3 (Paris)
eu-central-2 (Zurich)	eu-central-1 (Frankfurt), eu-central-2 (Zurich), eu-north-1 (Stockholm), eu-south-1 (Milan), eu-south-2 (Spain), eu-west-1 (Ireland), eu-west-3 (Paris)
eu-north-1 (Stockholm)	eu-central-1 (Frankfurt), eu-north-1 (Stockholm), eu-south-1 (Milan), eu-south-2 (Spain), eu-west-1 (Ireland), eu-west-3 (Paris)

Source Region	Destination Regions
eu-south-1 (Milan)	eu-central-1 (Frankfurt), eu-north-1 (Stockholm), eu-south-1 (Milan), eu-south-2 (Spain), eu-west-1 (Ireland), eu-west-3 (Paris)
eu-south-2 (Spain)	eu-central-1 (Frankfurt), eu-north-1 (Stockholm), eu-south-1 (Milan), eu-south-2 (Spain), eu-west-1 (Ireland), eu-west-3 (Paris)
eu-west-1 (Ireland)	eu-central-1 (Frankfurt), eu-north-1 (Stockholm), eu-south-1 (Milan), eu-south-2 (Spain), eu-west-1 (Ireland), eu-west-3 (Paris)
eu-west-2 (London)	eu-central-1 (Frankfurt), eu-north-1 (Stockholm), eu-south-1 (Milan), eu-south-2 (Spain), eu-west-1 (Ireland), eu-west-2 (London), eu-west-3 (Paris)
eu-west-3 (Paris)	eu-central-1 (Frankfurt), eu-north-1 (Stockholm), eu-south-1 (Milan), eu-south-2 (Spain), eu-west-1 (Ireland), eu-west-3 (Paris)

Geo: AU

Geo inference ID: `au.anthropic.claude-sonnet-5-5`

Source Region	Destination Regions
ap-southeast-2 (Sydney)	ap-southeast-2 (Sydney), ap-southeast-4 (Melbourne)
ap-southeast-4 (Melbourne)	ap-southeast-2 (Sydney), ap-southeast-4 (Melbourne)

Quotas and Limits

Your AWS account has default quotas for Amazon Bedrock. These quotas might change depending on regional factors, payment history, or approval of a quota increase request. For more details, see the section called “Quotas” and the limits for the model.

Sample Code

Step 1 - AWS Account: If you have an AWS account already, skip this step. If you are new to AWS, sign up for an AWS account.

Step 2 - API key: Open the Amazon Bedrock console and generate a long-term API key.

Step 3 - Get the SDK: To use this getting started guide, you must have Python already installed. Then install the relevant software depending on the APIs you are using.

Messages API

```
pip install -U "anthropic[bedrock]" aws-bedrock-token-generator
```

Invoke/Converse API

```
pip install boto3
```

Step 4 - Set environment variables: Configure your environment to use the API key for authentication.

Messages API

```
AWS_BEARER_TOKEN_BEDROCK="<provide your Bedrock API key>"
```

Invoke/Converse API

```
AWS_BEARER_TOKEN_BEDROCK="<provide your Bedrock API key>"
```

Step 5 - Run your first inference request: Save the file as `bedrock-first-request.py`

Messages API

```
from anthropic import Anthropic
from aws_bedrock_token_generator import provide_token

token = provide_token(region="us-east-1")

client = Anthropic(
```

```
    base_url="https://bedrock-runtime.us-east-1.amazonaws.com/anthropic",
    api_key=token,
)

response = client.messages.create(
    model="global.anthropic.claude-sonnet-5-5",
    max_tokens=1024,
    messages=[{"role": "user", "content": "Can you explain the features of Amazon
 Bedrock?"}],
)

print(response)
```

Invoke API

```
import json
import boto3

client = boto3.client('bedrock-runtime', region_name='us-east-1')
response = client.invoke_model(
    modelId='global.anthropic.claude-sonnet-5-5',
    body=json.dumps({
            'anthropic_version': 'bedrock-2023-05-31',
            'messages': [{ 'role': 'user', 'content': 'Can you explain the features
 of Amazon Bedrock?'}],
            'max_tokens': 1024
    })
)
print(json.loads(response['body'].read()))
```

Converse API

```
import boto3

client = boto3.client('bedrock-runtime', region_name='us-east-1')
response = client.converse(
    modelId='global.anthropic.claude-sonnet-5-5',
    messages=[
        {
            'role': 'user',
            'content': [{'text': 'Can you explain the features of Amazon Bedrock?'}]
        }
    ]
```

```
)
print(response)
```

Claude Opus 5.5

Anthropic — Claude Opus 5.5

Model Details

Claude Opus 5.5 is Anthropic's most capable Opus model. Better at coding, knowledge work, and long-running tasks. It's easier to collaborate with and more cost efficient than ever.

Model launch date: September 22, 2026
EOL no sooner than: September 22, 2027
Legacy period: 6 months
Model lifecycle policy: Model lifecycle
Model EOL date: N/A
End User License Agreements and Terms of Use: View
Model lifecycle: Active
Context window: 1M tokens
Max output tokens: 128K
Reasoning: Supported (adaptive thinking is always on and cannot be disabled; effort level configurable — low, medium, high, xhigh, max; default: medium) See Adaptive thinking.
Preserved thinking: Thinking blocks are bound to the model and the conversation prefix that produced them. Replay earlier turns unchanged, or a request returns a 400 error. For more information, see Preserved thinking.
Knowledge cutoff: June 2026
Marketplace product ID: `prod-e5xo6z26ie45g`

> **Tip**
>
> Whenever possible, we recommend using the `bedrock-runtime` endpoint for new applications. See the section called "Inference endpoints" for details.

Capabilities and Features

Bedrock Features

Features supported using `bedrock-runtime` endpoint

Supported	Not Supported
Response streaming Explicit Prompt Caching Abuse detection Guardrails Prompt optimization Knowledge base Model evaluation Prompt management Flows Agents Computer use Client-side tool calling (`tool_choice` types `auto` and none only) Server-side tool use (tool search only; regex and BM25) Application inference profiles Invocation logs Structured outputs Watermarking	Intelligent prompt routing Count tokens Implicit Prompt Caching

Features supported using `bedrock-mantle` endpoint

Supported	Not Supported
✓ Response streaming ✓ Explicit Prompt Caching ✓ Abuse detection ✓ Count tokens ✓ Computer use ✓ Client-side tool calling (`tool_choice` types `auto` and none only) ✓ Server-side tool use (tool search only; regex and BM25) ✓ Structured outputs ✓ Watermarking	✗ Guardrails ✗ Prompt optimization ✗ Knowledge base ✗ Model evaluation ✗ Prompt management ✗ Flows ✗ Agents ✗ Intelligent prompt routing ✗ Application inference profiles ✗ Invocation logs ✗ Implicit Prompt Caching

Explicit Prompt Caching using `bedrock-runtime` and `bedrock-mantle` endpoints

For more information, see Prompt caching for faster model inference.

Explicit Prompt Caching supported	Min tokens per cache checkpoint	Max cache checkpoints per request	Supported TTL	Fields that accept prompt cache checkpoints
Yes	512	4	5 minutes, 1 hour	`system`, `messages`, and `tools`

Computer use using `bedrock-runtime` and `bedrock-mantle` endpoints

For more information, see Computer use.

Tool type	Beta header
`computer_20251124`	`computer-use-2025-11-24`

Client tools and toolsets using `bedrock-runtime` and `bedrock-mantle` endpoints

For more information, see Tool use.

Tool type	Beta header
`computer_toolset_20260801`	None required
`browser_toolset_20260801`	None required
`bash_20250124`	None required
`text_editor_20250728`	None required
`memory_20250818`	None required

Compaction using `bedrock-runtime` endpoint

For more information, see Compaction.

Compaction supported	Beta value
Yes	`compact-2026-09-04` , `compact-2026-01-12`

Fallback credit for refused requests (beta)

When Claude Opus 5.5 refuses a request, the response can include a fallback credit token. Redeem the token when you retry the same request on a fallback model, and the retry is billed for the cached conversation prefix at cache-read rates instead of cache-write rates. For more information, see Fallback credit for refused requests (beta).

Supported endpoints	Beta value	Valid fallback models
`bedrock-runtime` , `bedrock-mantle`	`fallback-credit-2026-07-01`	Claude Opus 5 (`anthropic.claude-opus-5`), Claude Opus 4.8 (`anthropic.claude-opus-4-8`)

Pricing

This model is a third-party model offered and billed through AWS Marketplace. Charges appear on your AWS bill and in AWS Cost Explorer under the model provider (not under Amazon Bedrock). For pricing, see the Amazon Bedrock Pricing page.

Programmatic Access

Use the following model IDs and endpoint URLs to access this model programmatically. For more information about the available APIs and endpoints, see APIs supported and Endpoints supported.

> **Important**
>
> This model is offered through one or more inference profiles designated as inference profiles with limited model selection. These profiles are expected to offer a narrower selection of models, and new models or model versions might not be released for them. Before you take a dependency on one of these inference profiles, review the section called "Inference profiles with limited model selection" and plan for model lifecycle events.

Endpoint	Model ID	In-Region endpoint URL	Geo inference ID	Global inference ID

`bedrock-runtime`	`anthropic.claude-opus-5-5`	`https://bedrock-runtime.eu-west-2.amazonaws.com`
		
		In-Region inference with the bare model ID is available in `eu-west-2` (London) only. From any other Region, use a geo or global inference profile ID.
			`us.anthropic.claude-opus-5-5`
			
			`eu.anthropic.claude-opus-5-5`
			
			`au.anthropic.claude-opus-5-5`
			
			`jp.anthropic.claude-opus-5-5`
				`global.anthropic.claude-opus-5-5`

Endpoint	Model ID	In-Region endpoint URL	Geo inference ID	Global inference ID
bedrock-mantle	anthropic.claude-opus-5-5	https://bedrock-mantle.{region}.api.aws/anthropic/v1/messages	N/A	N/A

For example, if region is us-east-1 (N. Virginia), then the bedrock-runtime endpoint URL will be "https://bedrock-runtime.us-east-1.amazonaws.com" and for bedrock-mantle will be "https://bedrock-mantle.us-east-1.api.aws/anthropic/v1/messages".

Service Tiers

Amazon Bedrock offers multiple service tiers to match your workload requirements. **Standard** provides pay-per-token access with no commitment (set `"service_tier": "default"` or omit the field). **Priority** delivers the fastest response times for a price premium (set `"service_tier": "priority"`). **Flex** provides lower-cost access for flexible, non-time-sensitive workloads (set `"service_tier": "flex"`). **Reserved** provides dedicated throughput with a term commitment for predictable workloads; it is set at the account level rather than per request (contact your AWS account team to enable). For more information, see service tiers.

Standard	Priority	Flex	Reserved	Batch
✓	✗	✗	✗	✗

Regional Availability

Regional availability at a glance

Amazon Bedrock offers three inference options: **In-Region** keeps requests within a single Region for strict compliance, **Geo Cross-Region** routes across Regions within a geography (such as US, EU, and APAC) while respecting data residency, and **Global Cross-Region** routes anywhere worldwide when there are no residency constraints. Refer to the the section called “Regional availability by models” page for more details.

Availability differs by endpoint.

ap-northeast-3 (Osaka)	ap-northeast-1 (Tokyo), ap-northeast-3 (Osaka)

Quotas and Limits

Your AWS account has default quotas for Amazon Bedrock. These quotas might change depending on regional factors, payment history, or approval of a quota increase request. For more details, see the section called "Quotas" and the limits for the model.

Sample Code

Step 1 - AWS Account: If you have an AWS account already, skip this step. If you are new to AWS, sign up for an AWS account.

Step 2 - API key: Go to the Amazon Bedrock console and generate a long-term API key.

Step 3 - Get the SDK: To use this getting started guide, you must have Python already installed. Then install the relevant software depending on the APIs you are using.

Messages API

```
pip install -U anthropic aws-bedrock-token-generator
```

Invoke/Converse API

```
pip install boto3
```

Step 4 - Set environment variables: Configure your environment to use the API key for authentication.

Messages API

```
AWS_BEARER_TOKEN_BEDROCK="<provide your Bedrock API key>"
```

Invoke/Converse API

```
AWS_BEARER_TOKEN_BEDROCK="<provide your Bedrock API key>"
```

Step 5 - Run your first inference request: Save the file as `bedrock-first-request.py`

Messages API

```
from anthropic import Anthropic
from aws_bedrock_token_generator import provide_token

token = provide_token(region="us-east-1")

client = Anthropic(
    base_url="https://bedrock-runtime.us-east-1.amazonaws.com/anthropic",
    api_key=token,
)

response = client.messages.create(
    model="global.anthropic.claude-opus-5-5",
    max_tokens=1024,
    messages=[{"role": "user", "content": "Can you explain the features of Amazon
 Bedrock?"}],
)

print(response)
```

Invoke API

```
import json
import boto3

client = boto3.client('bedrock-runtime', region_name='us-east-1')
response = client.invoke_model(
```

```
    modelId='global.anthropic.claude-opus-5-5',
    body=json.dumps({
            'anthropic_version': 'bedrock-2023-05-31',
            'messages': [{ 'role': 'user', 'content': 'Can you explain the features
 of Amazon Bedrock?'}],
            'max_tokens': 1024
    })
)
print(json.loads(response['body'].read()))
```

Converse API

```
import boto3

client = boto3.client('bedrock-runtime', region_name='us-east-1')
response = client.converse(
    modelId='global.anthropic.claude-opus-5-5',
    messages=[
        {
            'role': 'user',
            'content': [{'text': 'Can you explain the features of Amazon Bedrock?'}]
        }
    ]
)
print(response)
```

Claude Fable 5.1

Anthropic — Claude Fable 5.1

Model Details

Claude Fable 5.1 is Anthropic's frontier model for ambitious coding, long-horizon agents, and enterprise knowledge work. It handles software projects that span an entire codebase, runs multi-hour jobs across many tools inside agent harnesses, and brings best-in-class vision to dense filings, charts, and diagrams.

Model launch date: September 1, 2026
EOL no sooner than: September 1, 2027

Legacy period: at least 6 months

Model lifecycle policy: Model lifecycle (For Models Launched Prior to Sept 7 2026)

Model EOL date: N/A

End User License Agreements and Terms of Use: View

Model lifecycle: Active

Context window: 1M tokens

Max output tokens: 128K

Sampling parameters: temperature must be 1.0 or unset; top_p must be 0.99 or unset; temperature and top_p cannot be specified together; top_k is not supported

Reasoning: Supported (adaptive thinking is always on and cannot be disabled; effort level configurable — low, medium, high, xhigh, max; default: high) See Adaptive thinking.

Preserved thinking: Thinking blocks are bound to the model and the conversation prefix that produced them. Replay earlier turns unchanged, or a request returns a 400 error. For more information, see Preserved thinking.

Knowledge cutoff: June 2026

Marketplace product ID: prod-lt3y75wunrtv4

Endpoints and APIs supported

The following tables show which endpoints and APIs are supported for Claude Fable 5.1. For more information, see the section called “APIs” and the section called “Inference endpoints”.

Endpoint support

Endpoint	Supported
bedrock-runtime	✓
bedrock-mantle	✓

APIs supported on bedrock-runtime endpoint

Messages	Responses	Chat Completions	Converse	Invoke
✓	✗	✗	✓	✓

APIs supported on bedrock-mantle endpoint

Messages	Responses	Chat Completions	Converse	Invoke
✓	✗	✗	✗	✗

Tip

Whenever possible, we recommend using the bedrock-runtime endpoint for new applications. See the section called "Inference endpoints" for details.

Capabilities and Features

Bedrock Features

Features supported using bedrock-runtime endpoint

Supported	Not Supported
✓ Response streaming	✗ Count tokens

Supported	Not Supported
✓ Prompt caching ✓ Abuse detection ✓ Guardrails ✓ Prompt optimization ✓ Knowledge base ✓ Model evaluation ✓ Prompt management ✓ Flows ✓ Agents ✓ Computer use ✓ Structured outputs ✓ Watermarking	✗ Intelligent prompt routing ✗ Implicit Prompt Caching

Bedrock Features

Features supported using `bedrock-mantle` endpoint

Supported	Not Supported
✓ Response streaming ✓ Prompt caching ✓ Abuse detection ✓ Count tokens ✓ Structured outputs ✓ Watermarking	✗ Guardrails ✗ Prompt optimization ✗ Knowledge base ✗ Model evaluation ✗ Prompt management ✗ Flows ✗ Agents ✗ Intelligent prompt routing ✗ Implicit Prompt Caching

Prompt caching using `bedrock-runtime` and `bedrock-mantle` endpoints

For more information, see Prompt caching for faster model inference.

Prompt caching supported	Min tokens per cache checkpoint	Max cache checkpoints per request	Supported TTL	Fields that accept prompt cache checkpoint
Yes	512	4	5 minutes, 1 hour	`system`, `messages`, and `tools`

Computer use using `bedrock-runtime` endpoint

For more information, see Computer use.

Tool type	Beta header
`computer_20251124`	`computer-use-2025-11-24`

Client tools and toolsets using `bedrock-runtime` endpoint

For more information, see Tool use.

Tool type	Beta header
`computer_toolset_20260801`	None required
`browser_toolset_20260801`	None required
`bash_20250124`	None required
`text_editor_20250728`	None required
`memory_20250818`	None required

Compaction using `bedrock-runtime` endpoint

For more information, see Compaction.

Compaction supported	Beta value
Yes	`compact-2026-09-04` ,`compact-2026-01-12`

Content Restrictions

Claude Fable 5.1 includes blocking classifiers for dual-use content in cybersecurity and life sciences. When a classifier blocks a request, the API returns a standard HTTP 200 response with `stop_reason: "refusal"` and a `stop_details` object containing the restriction category. Refusal rates on this model are materially higher than on previous Claude models.

Customers should handle `stop_reason: "refusal"` as a primary response path. Whether a refused request is billed depends on its category and on whether output had started. For details, see Billing notes.

Fallback credit for refused requests (beta)

When Claude Fable 5.1 refuses a request, the response can include a fallback credit token. Redeem the token when you retry the same request on a fallback model, and the retry is billed for the cached conversation prefix at cache-read rates instead of cache-write rates. Not every refusal carries a token. For more information, see Fallback credit for refused requests (beta).

Supported endpoints	Beta value	Valid fallback models
`bedrock-runtime`	`fallback-credit-2026-07-01`	Claude Opus 5 (`anthropic.claude-opus-5`), Claude Opus 4.8 (`anthropic.claude-opus-4-8`)

Pricing

For pricing information, see the Amazon Bedrock Pricing page.

Programmatic Access

Use the following model IDs and endpoint URLs to access this model programmatically. For more information about the available APIs and endpoints, see APIs supported and Endpoints supported.

Endpoint	Model ID	In-Region endpoint URL	Geo inference ID	Global inference ID
bedrock-runtime	anthropic.claude-fable-5-1	N/A	us.anthropic.claude-fable-5-1	global.anthropic.claude-fable-5-1
bedrock-mantle	anthropic.claude-fable-5-1	https://bedrock-mantle.{region}.api.aws/anthropic/v1/messages	N/A	N/A

For example, if region is us-east-1 (N. Virginia), then the bedrock-runtime endpoint URL will be "https://bedrock-runtime.us-east-1.amazonaws.com" and for bedrock-mantle will be "https://bedrock-mantle.us-east-1.api.aws".

Service Tiers

Amazon Bedrock offers multiple service tiers to match your workload requirements. **Standard** provides pay-per-token access with no commitment (set `"service_tier": "default"` or omit the field). **Priority** delivers the fastest response times for a price premium (set `"service_tier": "priority"`). **Flex** provides lower-cost access for flexible, non-time-sensitive workloads (set `"service_tier": "flex"`). **Reserved** provides dedicated throughput with a term commitment for predictable workloads; it is set at the account level rather than per request (contact your AWS account team to enable). For more information, see service tiers.

Standard	Priority	Flex	Reserved
✓	✗	✗	✗

Regional Availability

Regional availability at a glance

Amazon Bedrock offers three inference options: **In-Region** keeps requests within a single Region for strict compliance, **Geo Cross-Region** routes across Regions within a geography (such as US, EU, and APAC) while respecting data residency, and **Global Cross-Region** routes anywhere worldwide when there are no residency constraints. Refer to the the section called “Regional availability by models” page for more details.

Availability differs by endpoint.

Availability using the `bedrock-runtime` endpoint

Region	In-Region	Geo	Global

Availability using the `bedrock-mantle` endpoint

Region	In-Region	Geo	Global
`us-gov-west-1` (GovCloud West)	✓	✗	✗

Geo inference details

The destination Regions available to a geographic inference profile depend on the source Region. To retrieve the current routing configuration, call GetInferenceProfile from the source Region.

Geo: US

Geo inference ID: `us.anthropic.claude-fable-5-1`

Source Region	Destination Regions
us-east-1 (N. Virginia)	us-east-1 (N. Virginia), us-east-2 (Ohio), us-west-2 (Oregon)
us-east-2 (Ohio)	us-east-1 (N. Virginia), us-east-2 (Ohio), us-west-2 (Oregon)
us-west-1 (N. California)	us-east-1 (N. Virginia), us-east-2 (Ohio), us-west-1 (N. California), us-west-2 (Oregon)
us-west-2 (Oregon)	us-east-1 (N. Virginia), us-east-2 (Ohio), us-west-2 (Oregon)
ca-central-1 (Canada)	ca-central-1 (Canada), us-east-1 (N. Virginia), us-east-2 (Ohio), us-west-2 (Oregon)
ca-west-1 (Calgary)	ca-west-1 (Calgary), us-east-1 (N. Virginia), us-east-2 (Ohio), us-west-2 (Oregon)

Data Retention

To use this model, you must opt in to AWS review by setting your data retention mode to `aws_review` via the Data Retention API. For more information, see Amazon Bedrock abuse detection.

Quotas and Limits

Your AWS account has default quotas to maintain the performance of the service and to ensure appropriate usage of Amazon Bedrock. The default quotas assigned to an account might be updated depending on regional factors, payment history, fraudulent usage, and/or approval of a quota increase request. For more information, see the section called "Quotas" documentation and see the limits for the model.

Sample Code

Step 1 - AWS Account: If you have an AWS account already, skip this step. If you are new to AWS, sign up for an AWS account.

Step 2 - API key: Go to the Amazon Bedrock console and generate a long-term API key.

Step 3 - Get the SDK: To use this getting started guide, you must have Python already installed. Then install the relevant software depending on the APIs you are using.

Messages API

```
pip install -U anthropic aws-bedrock-token-generator
```

Invoke/Converse API

```
pip install boto3
```

Step 4 - Set environment variables: Configure your environment to use the API key for authentication.

Messages API

```
AWS_BEARER_TOKEN_BEDROCK="<provide your Bedrock API key>"
```

Invoke/Converse API

```
AWS_BEARER_TOKEN_BEDROCK="<provide your Bedrock API key>"
```

Step 5 - Run your first inference request: Save the file as `bedrock-first-request.py`

Messages API

```
from anthropic import Anthropic
from aws_bedrock_token_generator import provide_token

token = provide_token(region="us-east-1")

client = Anthropic(
    base_url="https://bedrock-runtime.us-east-1.amazonaws.com/anthropic",
    api_key=token,
)

response = client.messages.create(
    model="global.anthropic.claude-fable-5-1",
    max_tokens=16000,
    messages=[{"role": "user", "content": "Can you explain the features of Amazon
 Bedrock?"}],
)

print(response)
```

Invoke API

```
import json
import boto3

client = boto3.client('bedrock-runtime', region_name='us-east-1')
response = client.invoke_model(
    modelId='global.anthropic.claude-fable-5-1',
    body=json.dumps({
            'anthropic_version': 'bedrock-2023-05-31',
            'messages': [{ 'role': 'user', 'content': 'Can you explain the features
 of Amazon Bedrock?'}],
            'max_tokens': 16000
    })
)
```

```
print(json.loads(response['body'].read()))
```

Converse API

```
import boto3

client = boto3.client('bedrock-runtime', region_name='us-east-1')
response = client.converse(
    modelId='global.anthropic.claude-fable-5-1',
    messages=[
        {
            'role': 'user',
            'content': [{'text': 'Can you explain the features of Amazon Bedrock?'}]
        }
    ]
)
print(response)
```

Claude Mythos 5.1

Anthropic — Claude Mythos 5.1

Model Details

Claude Mythos 5.1 is Anthropic's most capable model for cybersecurity defense and life sciences research, including threat intelligence, vulnerability discovery, red teaming, drug discovery, and biodefense screening.

Access is currently gated to a vetted set of organizations through Anthropic's trusted access programs, given the dual-use nature of these domains.

This model is a Preview and is made available to you as a "Beta Service" as defined in the AWS Service Terms. It is subject to your Agreement with AWS, the AWS Service Terms, and the applicable model EULA.

Model launch date: September 1, 2026

EOL no sooner than: September 1, 2027

Legacy period: at least 6 months

Model lifecycle policy: Model lifecycle (For Models Launched Prior to Sept 7 2026)

Model EOL date: N/A

End User License Agreements and Terms of Use: View

Model lifecycle: Active

Context window: 1M tokens

Max output tokens: 128K

Sampling parameters: temperature must be 1.0 or unset; top_p must be 0.99 or unset; temperature and top_p cannot be specified together; top_k is not supported

Reasoning: Supported (adaptive thinking is always on and cannot be disabled; effort level configurable — low, medium, high, xhigh, max; default: high) See Adaptive thinking.

Preserved thinking: Thinking blocks are bound to the model that produced them; Claude Fable 5.1 and Claude Mythos 5.1 read each other's blocks. The conversation prefix isn't checked on Claude Mythos 5.1. For more information, see Preserved thinking.

Geo inference details

The destination Regions available to a geographic inference profile depend on the source Region. To retrieve the current routing configuration, call GetInferenceProfile from the source Region.

Geo: US

Geo inference ID: `us.anthropic.claude-mythos-5-1`

Source Region	Destination Regions
us-east-1 (N. Virginia)	us-east-1 (N. Virginia), us-east-2 (Ohio), us-west-2 (Oregon)
us-east-2 (Ohio)	us-east-1 (N. Virginia), us-east-2 (Ohio), us-west-2 (Oregon)
us-west-1 (N. California)	us-east-1 (N. Virginia), us-east-2 (Ohio), us-west-1 (N. California), us-west-2 (Oregon)
us-west-2 (Oregon)	us-east-1 (N. Virginia), us-east-2 (Ohio), us-west-2 (Oregon)
ca-central-1 (Canada)	ca-central-1 (Canada), us-east-1 (N. Virginia), us-east-2 (Ohio), us-west-2 (Oregon)

Source Region	Destination Regions
ca-west-1 (Calgary)	ca-west-1 (Calgary), us-east-1 (N. Virginia), us-east-2 (Ohio), us-west-2 (Oregon)

Data Retention

To use this model, you must set your data retention mode to `aws_review` or `provider_data_share` via the Data Retention API. For more information, see Amazon Bedrock abuse detection.

Quotas and Limits

Your AWS account has default quotas to maintain the performance of the service and to ensure appropriate usage of Amazon Bedrock. The default quotas assigned to an account might be updated depending on regional factors, payment history, fraudulent usage, and/or approval of a quota increase request. For more information, see the section called "Quotas" documentation and see the limits for the model.

Sample Code

Step 1 - AWS Account: If you have an AWS account already, skip this step. If you are new to AWS, sign up for an AWS account.

Step 2 - API key: Go to the Amazon Bedrock console and generate a long-term API key.

Step 3 - Get the SDK: To use this getting started guide, you must have Python already installed. Then install the relevant software depending on the APIs you are using.

Messages API

```
pip install -U anthropic aws-bedrock-token-generator
```

Invoke/Converse API

```
pip install boto3
```

Step 4 - Set environment variables: Configure your environment to use the API key for authentication.

Messages API

```
AWS_BEARER_TOKEN_BEDROCK="<provide your Bedrock API key>"
```

Invoke/Converse API

```
AWS_BEARER_TOKEN_BEDROCK="<provide your Bedrock API key>"
```

Step 5 - Run your first inference request: Save the file as `bedrock-first-request.py`

Messages API

```
from anthropic import Anthropic
from aws_bedrock_token_generator import provide_token

token = provide_token(region="us-east-1")

client = Anthropic(
    base_url="https://bedrock-runtime.us-east-1.amazonaws.com/anthropic",
    api_key=token,
)

response = client.messages.create(
    model="global.anthropic.claude-mythos-5-1",
    max_tokens=16000,
    messages=[{"role": "user", "content": "Can you explain the features of Amazon
 Bedrock?"}],
)

print(response)
```

Invoke API

```
import json
import boto3

client = boto3.client('bedrock-runtime', region_name='us-east-1')
response = client.invoke_model(
    modelId='global.anthropic.claude-mythos-5-1',
    body=json.dumps({
            'anthropic_version': 'bedrock-2023-05-31',
```

```
            'messages': [{ 'role': 'user', 'content': 'Can you explain the features
 of Amazon Bedrock?'}],
            'max_tokens': 16000
    })
)
print(json.loads(response['body'].read()))
```

Converse API

```
import boto3

client = boto3.client('bedrock-runtime', region_name='us-east-1')
response = client.converse(
    modelId='global.anthropic.claude-mythos-5-1',
    messages=[
        {
            'role': 'user',
            'content': [{'text': 'Can you explain the features of Amazon Bedrock?'}]
        }
    ]
)
print(response)
```

Claude Opus 5

Anthropic — Claude Opus 5

Model Details

Claude Opus 5 is Anthropic's most advanced Opus model, powering long-running agents while delivering improvements in coding and professional work.

Model launch date: July 24, 2026
EOL no sooner than: July 24, 2027
Legacy period: at least 6 months
Model lifecycle policy: Model lifecycle (For Models Launched Prior to Sept 7 2026)
Model EOL date: N/A
End User License Agreements and Terms of Use: View

Model lifecycle: Active

Context window: 1M tokens

Max output tokens: 128K

Reasoning: Supported (adaptive thinking is on by default; can be disabled but effort is capped at high when thinking is disabled) See Adaptive thinking.

Knowledge cutoff: May 2026

Marketplace product ID: `prod-if5d653ow7ehg`

Input Modalities	Output Modalities
⊗ Audio	⊗ Embedding
⊙ Image	⊗ Image
⊗ Speech	⊗ Speech
⊙ Text	⊙ Text
⊗ Video	⊗ Video

Endpoints and APIs supported

The following tables show which endpoints and APIs are supported for Claude Opus 5. For more information, see the section called “APIs” and the section called “Inference endpoints”.

Endpoint support

Endpoint	Supported
`bedrock-runtime`	⊙
`bedrock-mantle`	⊙

APIs supported on `bedrock-runtime` endpoint

Messages	Responses	Chat Completions	Converse	Invoke
✓	✗	✗	✓	✓

APIs supported on `bedrock-mantle` endpoint

Messages	Responses	Chat Completions	Converse	Invoke
✓	✗	✗	✗	✗

> **Tip**
>
> Whenever possible, we recommend using the `bedrock-runtime` endpoint for new applications. See the section called "Inference endpoints" for details.

Capabilities and Features

Bedrock Features

Features supported using `bedrock-runtime` endpoint

Supported	Not Supported
✓ Response streaming ✓ Explicit Prompt Caching ✓ Abuse detection ✓ Guardrails ✓ Prompt optimization ✓ Knowledge base ✓ Model evaluation ✓ Prompt management ✓ Flows ✓ Agents	✗ Intelligent prompt routing ✗ Count tokens ✗ Implicit Prompt Caching

Supported	Not Supported
✓ Computer use ✓ Structured outputs ✓ Watermarking	

Features supported using `bedrock-mantle` endpoint

Supported	Not Supported
✓ Response streaming ✓ Explicit Prompt Caching ✓ Abuse detection ✓ Count tokens ✓ Computer use ✓ Structured outputs ✓ Watermarking	✗ Guardrails ✗ Prompt optimization ✗ Knowledge base ✗ Model evaluation ✗ Prompt management ✗ Flows ✗ Agents ✗ Intelligent prompt routing ✗ Implicit Prompt Caching

Explicit Prompt Caching using `bedrock-runtime` and `bedrock-mantle` endpoints

For more information, see Prompt caching for faster model inference.

Explicit Prompt Caching supported	Min tokens per cache checkpoint	Max cache checkpoints per request	Supported TTL	Fields that accept prompt cache checkpoints
Yes	512	4	5 minutes, 1 hour	`system`, `messages`, and `tools`

Computer use using `bedrock-runtime` and `bedrock-mantle` endpoints

For more information, see Computer use.

Tool type	Beta header
`computer_20251124`	`computer-use-2025-11-24`

Client tools and toolsets using `bedrock-runtime` and `bedrock-mantle` endpoints

For more information, see Tool use.

Tool type	Beta header
`computer_toolset_20260801`	None required
`browser_toolset_20260801`	None required
`bash_20250124`	None required
`text_editor_20250728`	None required
`memory_20250818`	None required

Compaction using `bedrock-runtime` endpoint

For more information, see Compaction.

Compaction supported	Beta value
Yes	`compact-2026-09-04` , `compact-2026-01-12`

Fallback credit for refused requests (beta)

When Claude Opus 5 refuses a request, the response can include a fallback credit token. Redeem the token when you retry the same request on a fallback model, and the retry is billed for the cached conversation prefix at cache-read rates instead of cache-write rates. For more information, see Fallback credit for refused requests (beta).

Supported endpoints	Beta value	Valid fallback models
bedrock-runtime , bedrock-mantle	fallback-credit-2026-07-01	Claude Opus 4.8 (anthropic.claude-opus-4-8)

Pricing

This model is a third-party model offered and billed through AWS Marketplace. Charges appear on your AWS bill and in AWS Cost Explorer under the model provider (not under Amazon Bedrock). For pricing, see the Amazon Bedrock Pricing page.

Programmatic Access

Use the following model IDs and endpoint URLs to access this model programmatically. For more information about the available APIs and endpoints, see APIs supported and Endpoints supported.

> **Important**
>
> This model is offered through one or more inference profiles designated as inference profiles with limited model selection. These profiles are expected to offer a narrower selection of models, and new models or model versions might not be released for them. Before you take a dependency on one of these inference profiles, review the section called "Inference profiles with limited model selection" and plan for model lifecycle events.

Endpoint	Model ID	In-Region endpoint URL	Geo inference ID	Global inference ID
bedrock-runtime	anthropic.claude-opus-5	N/A	us.anthropic.claude-opus-5 eu.anthropic.claude-opus-5	global.anthropic.claude-opus-5

Endpoint	Model ID	In-Region endpoint URL	Geo inference ID	Global inference ID
			au.anthropic.claude-opus-5 in.anthropic.claude-opus-5	
bedrock-mantle	anthropic.claude-opus-5	https://bedrock-mantle.{region}.api.aws/anthropic/v1/messages	N/A	N/A

For example, if region is us-east-1 (N. Virginia), then the bedrock-runtime endpoint URL will be "https://bedrock-runtime.us-east-1.amazonaws.com" and for bedrock-mantle will be "https://bedrock-mantle.us-east-1.api.aws/anthropic/v1/messages".

Service Tiers

Amazon Bedrock offers multiple service tiers to match your workload requirements. **Standard** provides pay-per-token access with no commitment (set `"service_tier": "default"` or omit the field). **Priority** delivers the fastest response times for a price premium (set `"service_tier": "priority"`). **Flex** provides lower-cost access for flexible, non-time-sensitive workloads (set `"service_tier": "flex"`). **Reserved** provides dedicated throughput with a term commitment for predictable workloads; it is set at the account level rather than per request (contact your AWS account team to enable). For more information, see service tiers.

Standard	Priority	Flex	Reserved	Batch
✓	✗	✗	✗	✓

Regional Availability

Regional availability at a glance

Amazon Bedrock offers three inference options: **In-Region** keeps requests within a single Region for strict compliance, **Geo Cross-Region** routes across Regions within a geography (such as US, EU, and APAC) while respecting data residency, and **Global Cross-Region** routes anywhere worldwide when there are no residency constraints. Refer to the the section called “Regional availability by models” page for more details.

Availability differs by endpoint.

eu-west-2 (London)	eu-central-1 (Frankfurt), eu-north-1 (Stockholm), eu-south-1 (Milan), eu-south-2 (Spain), eu-west-1 (Ireland), eu-west-2 (London), eu-west-3 (Paris)
eu-west-3 (Paris)	eu-central-1 (Frankfurt), eu-north-1 (Stockholm), eu-south-1 (Milan), eu-south-2 (Spain), eu-west-1 (Ireland), eu-west-3 (Paris)

Geo: AU

Geo inference ID: `au.anthropic.claude-opus-5`

Source Region	Destination Regions
ap-southeast-2 (Sydney)	ap-southeast-2 (Sydney), ap-southeast-4 (Melbourne)
ap-southeast-4 (Melbourne)	ap-southeast-2 (Sydney), ap-southeast-4 (Melbourne)

Geo: India

Geo inference ID: `in.anthropic.claude-opus-5`

Source Region	Destination Regions
ap-south-1 (Mumbai)	ap-south-1 (Mumbai), ap-south-2 (Hyderabad)
ap-south-2 (Hyderabad)	ap-south-1 (Mumbai), ap-south-2 (Hyderabad)

Quotas and Limits

Your AWS account has default quotas for Amazon Bedrock. These quotas might change depending on regional factors, payment history, or approval of a quota increase request. For more details, see the section called "Quotas" and the limits for the model.

Sample Code

Step 1 - AWS Account: If you have an AWS account already, skip this step. If you are new to AWS, sign up for an AWS account.

Step 2 - API key: Go to the Amazon Bedrock console and generate a long-term API key.

Step 3 - Get the SDK: To use this getting started guide, you must have Python already installed. Then install the relevant software depending on the APIs you are using.

Messages API

```
pip install -U anthropic aws-bedrock-token-generator
```

Invoke/Converse API

```
pip install boto3
```

Step 4 - Set environment variables: Configure your environment to use the API key for authentication.

Messages API

```
AWS_BEARER_TOKEN_BEDROCK="<provide your Bedrock API key>"
```

Invoke/Converse API

```
AWS_BEARER_TOKEN_BEDROCK="<provide your Bedrock API key>"
```

Step 5 - Run your first inference request: Save the file as `bedrock-first-request.py`

Messages API

```
from anthropic import Anthropic
from aws_bedrock_token_generator import provide_token

token = provide_token(region="us-east-1")

client = Anthropic(
    base_url="https://bedrock-runtime.us-east-1.amazonaws.com/anthropic",
    api_key=token,
)

response = client.messages.create(
    model="global.anthropic.claude-opus-5",
    max_tokens=1024,
    messages=[{"role": "user", "content": "Can you explain the features of Amazon
 Bedrock?"}],
)

print(response)
```

Invoke API

```
import json
import boto3

client = boto3.client('bedrock-runtime', region_name='us-east-1')
response = client.invoke_model(
    modelId='global.anthropic.claude-opus-5',
    body=json.dumps({
            'anthropic_version': 'bedrock-2023-05-31',
            'messages': [{ 'role': 'user', 'content': 'Can you explain the features
 of Amazon Bedrock?'}],
            'max_tokens': 1024
    })
)
print(json.loads(response['body'].read()))
```

Converse API

```
import boto3

client = boto3.client('bedrock-runtime', region_name='us-east-1')
```

```
response = client.converse(
    modelId='global.anthropic.claude-opus-5',
    messages=[
        {
            'role': 'user',
            'content': [{'text': 'Can you explain the features of Amazon Bedrock?'}]
        }
    ]
)
print(response)
```

Claude Sonnet 5

Anthropic — Claude Sonnet 5

Model Details

Claude Sonnet 5 is the most capable Sonnet model from Anthropic, built for coding, agents, and professional work at scale. It brings near-Opus intelligence to the model teams run every day, with the same balance of capability, cost, and speed teams already rely on Sonnet for.

Model launch date: June 30, 2026

EOL no sooner than: June 30, 2027

Legacy period: at least 6 months

Model lifecycle policy: Model lifecycle (For Models Launched Prior to Sept 7 2026)

Model EOL date: N/A

End User License Agreements and Terms of Use: Third-party model terms

Model lifecycle: Active

Context window: 1M tokens

Max output tokens: 128K

Reasoning: Supported (adaptive thinking is on by default, including for requests that omit the `thinking` field; effort level is configurable, and thinking can be turned off with `"thinking": {"type": "disabled"}`) See Adaptive thinking.

Knowledge cutoff: January 2026

Marketplace product ID: `prod-4ezhkeia6k2cs`

Input Modalities	Output Modalities
⊗ Audio	⊗ Embedding
⊘ Image	⊗ Image
⊗ Speech	⊗ Speech
⊘ Text	⊘ Text
⊗ Video	⊗ Video

Endpoints and APIs supported

The following tables show which endpoints and APIs are supported for Claude Sonnet 5. For more information, see the section called “APIs” and the section called “Inference endpoints”.

Endpoint support

Endpoint	Supported
`bedrock-runtime`	⊘
`bedrock-mantle`	⊘

APIs supported on `bedrock-runtime` endpoint

Messages	Responses	Chat Completions	Converse	Invoke
⊘	⊗	⊗	⊘	⊘

APIs supported on `bedrock-mantle` endpoint

Messages	Responses	Chat Completions	Converse	Invoke
✓	✗	✗	✗	✗

Tip

Whenever possible, we recommend using the `bedrock-runtime` endpoint for new applications. See the section called "Inference endpoints" for details.

Capabilities and Features

Bedrock Features

Features supported using `bedrock-runtime` endpoint

Supported	Not Supported
✓ Response streaming ✓ Explicit Prompt Caching ✓ Abuse detection ✓ Guardrails ✓ Prompt optimization ✓ Knowledge base ✓ Model evaluation ✓ Prompt management ✓ Flows ✓ Agents ✓ Computer use ✓ Structured outputs ✓ Watermarking	✗ Intelligent prompt routing ✗ Count tokens ✗ Implicit Prompt Caching

Features supported using `bedrock-mantle` endpoint

Supported	Not Supported
Response streaming Explicit Prompt Caching Abuse detection Count tokens Computer use Structured outputs Watermarking	Guardrails Prompt optimization Knowledge base Model evaluation Prompt management Flows Agents Intelligent prompt routing Implicit Prompt Caching

Explicit Prompt Caching using `bedrock-runtime` and `bedrock-mantle` endpoints

For more information, see Prompt caching for faster model inference.

Explicit Prompt Caching supported	Min tokens per cache checkpoint	Max cache checkpoints per request	Supported TTL	Fields that accept prompt cache checkpoints
Yes	1,024	4	5 minutes, 1 hour	`system`, `messages`, and `tools`

Computer use using `bedrock-runtime` and `bedrock-mantle` endpoints

For more information, see Computer use.

Tool type	Beta header
`computer_20251124`	`computer-use-2025-11-24`

Client tools and toolsets using `bedrock-runtime` and `bedrock-mantle` endpoints

For more information, see Tool use.

Tool type	Beta header
`computer_toolset_20260801`	None required
`browser_toolset_20260801`	None required
`bash_20250124`	None required
`text_editor_20250728`	None required
`memory_20250818`	None required

Compaction using `bedrock-runtime` endpoint

For more information, see Compaction.

Compaction supported	Beta value
Yes	`compact-2026-09-04` , `compact-2026-01-12`

Pricing

This model is a third-party model offered and billed through AWS Marketplace. Charges appear on your AWS bill and in AWS Cost Explorer under the model provider (not under Amazon Bedrock). For pricing, see the Amazon Bedrock Pricing page.

Programmatic Access

Use the following model IDs and endpoint URLs to access this model programmatically. For more information about the available APIs and endpoints, see APIs supported and Endpoints supported.

> **Important**
>
> This model is offered through one or more inference profiles designated as inference profiles with limited model selection. These profiles are expected to offer a narrower selection of models, and new models or model versions might not be released for them.

Before you take a dependency on one of these inference profiles, review the section called "Inference profiles with limited model selection" and plan for model lifecycle events.

Endpoint	Model ID	In-Region endpoint URL	Geo inference ID	Global inference ID
bedrock-runtime	anthropic.claude-sonnet-5	N/A	us.anthropic.claude-sonnet-5 eu.anthropic.claude-sonnet-5 au.anthropic.claude-sonnet-5 in.anthropic.claude-sonnet-5	global.anthropic.claude-sonnet-5
bedrock-mantle	anthropic.claude-sonnet-5	https://bedrock-mantle.{region}.api.aws/anthropic/v1/messages	N/A	N/A

For example, to use Global cross-Region inference from us-east-1 (N. Virginia), use the endpoint URL "https://bedrock-runtime.us-east-1.amazonaws.com" with the inference profile ID "global.anthropic.claude-sonnet-5".

Service Tiers

Amazon Bedrock offers multiple service tiers to match your workload requirements. **Standard** provides pay-per-token access with no commitment (set `"service_tier": "default"` or omit

the field). **Priority** delivers the fastest response times for a price premium (set `"service_tier": "priority"`). **Flex** provides lower-cost access for flexible, non-time-sensitive workloads (set `"service_tier": "flex"`). **Reserved** provides dedicated throughput with a term commitment for predictable workloads; it is set at the account level rather than per request (contact your AWS account team to enable). For more information, see service tiers.

Standard	Priority	Flex	Reserved

Quotas and Limits

Your AWS account has default quotas for Amazon Bedrock. These quotas might change depending on regional factors, payment history, or approval of a quota increase request. For more details, see the section called "Quotas" and the limits for the model.

Sample Code

Step 1 - AWS Account: If you have an AWS account already, skip this step. If you are new to AWS, sign up for an AWS account.

Step 2 - API key: Open the Amazon Bedrock console and generate a long-term API key.

Step 3 - Get the SDK: To use this getting started guide, you must have Python already installed. Then install the relevant software depending on the APIs you are using.

Messages API

```
pip install -U "anthropic[bedrock]" aws-bedrock-token-generator
```

Invoke/Converse API

```
pip install boto3
```

Step 4 - Set environment variables: Configure your environment to use the API key for authentication.

Messages API

```
AWS_BEARER_TOKEN_BEDROCK="<provide your Bedrock API key>"
```

Invoke/Converse API

```
AWS_BEARER_TOKEN_BEDROCK="<provide your Bedrock API key>"
```

Step 5 - Run your first inference request: Save the file as `bedrock-first-request.py`

Messages API

```
from anthropic import Anthropic
from aws_bedrock_token_generator import provide_token

token = provide_token(region="us-east-1")

client = Anthropic(
    base_url="https://bedrock-runtime.us-east-1.amazonaws.com/anthropic",
    api_key=token,
)

response = client.messages.create(
    model="global.anthropic.claude-sonnet-5",
    max_tokens=1024,
    messages=[{"role": "user", "content": "Can you explain the features of Amazon
 Bedrock?"}],
)

print(response)
```

Invoke API

```
import json
import boto3

client = boto3.client('bedrock-runtime', region_name='us-east-1')
response = client.invoke_model(
    modelId='us.anthropic.claude-sonnet-5',
    body=json.dumps({
            'anthropic_version': 'bedrock-2023-05-31',
            'messages': [{ 'role': 'user', 'content': 'Can you explain the features
 of Amazon Bedrock?'}],
            'max_tokens': 1024
    })
)
```

```
print(json.loads(response['body'].read()))
```

Converse API

```
import boto3

client = boto3.client('bedrock-runtime', region_name='us-east-1')
response = client.converse(
    modelId='us.anthropic.claude-sonnet-5',
    messages=[
        {
            'role': 'user',
            'content': [{'text': 'Can you explain the features of Amazon Bedrock?'}]
        }
    ]
)
print(response)
```

Claude Mythos 5

Anthropic — Claude Mythos 5

Model Details

Claude Mythos 5 is Anthropic's most capable model for cybersecurity and life sciences, including vulnerability discovery, drug design, and biodefense screening. Access is currently limited due to the dual-use nature of these domains.

This model is a Preview and is made available to you as a "Beta Service" as defined in the AWS Service Terms. It is subject to your Agreement with AWS, the AWS Service Terms, and the applicable model EULA.

Model launch date: June 9, 2026
EOL no sooner than: June 9, 2027
Legacy period: at least 6 months
Model lifecycle policy: Model lifecycle (For Models Launched Prior to Sept 7 2026)
Model EOL date: N/A

End User License Agreements and Terms of Use: View
Model lifecycle: Active
Context window: 1M tokens
Max output tokens: 128K
Sampling parameters: temperature must be 1.0 or unset; top_p must be ≥ 0.99 and < 1.0, or unset; top_k is not supported
Reasoning: Supported (adaptive thinking is always on and cannot be disabled; effort level is configurable) See Adaptive thinking.
Knowledge cutoff: January 2026
Marketplace product ID: prod-kyryzgfmbtwtc

Capabilities and Features

Bedrock Features

Features supported using `bedrock-mantle` endpoint

Supported	Not Supported
⊘ Response streaming ⊘ Explicit Prompt Caching ⊘ Abuse detection ⊘ Count tokens ⊘ Structured outputs	⊗ Guardrails ⊗ Prompt optimization ⊗ Knowledge base ⊗ Model evaluation ⊗ Prompt management ⊗ Flows ⊗ Agents ⊗ Intelligent prompt routing ⊗ Implicit Prompt Caching ⊗ Watermarking

Explicit Prompt Caching using `bedrock-mantle` endpoint

For more information, see Prompt caching for faster model inference.

Explicit Prompt Caching supported	Min tokens per cache checkpoint	Max cache checkpoints per request	Supported TTL	Fields that accept prompt cache checkpoint
Yes	512	4	5 minutes, 1 hour	`system`, `messages`, and `tools`

Pricing

This model is a third-party model offered and billed through AWS Marketplace. Charges appear on your AWS bill and in AWS Cost Explorer under the model provider (not under Amazon Bedrock). For pricing, see the Amazon Bedrock Pricing page.

Programmatic Access

Use the following model IDs and endpoint URLs to access this model programmatically. For more information about the available APIs and endpoints, see APIs supported and Endpoints supported.

Endpoint	Model ID	In-Region endpoint URL	Geo inference ID	Global inference ID
`bedrock-mantle`	`anthropic.claude-mythos-5`	`https://bedrock-mantle.{region}.api.aws/anthropic/v1/messages`	N/A	N/A

For example, if region is us-east-1 (N. Virginia), then the bedrock-mantle endpoint URL will be "https://bedrock-mantle.us-east-1.api.aws/anthropic/v1/messages".

Service Tiers

Amazon Bedrock offers multiple service tiers to match your workload requirements. **Standard** provides pay-per-token access with no commitment (set `"service_tier": "default"` or omit the field). **Priority** delivers the fastest response times for a price premium (set `"service_tier":`

"priority"). **Flex** provides lower-cost access for flexible, non-time-sensitive workloads (set "service_tier": "flex"). **Reserved** provides dedicated throughput with a term commitment for predictable workloads; it is set at the account level rather than per request (contact your AWS account team to enable). For more information, see service tiers.

Standard	Priority	Flex	Reserved
✓	✗	✗	✗

Regional Availability

Regional availability at a glance

Amazon Bedrock offers three inference options: **In-Region** keeps requests within a single Region for strict compliance, **Geo Cross-Region** routes across Regions within a geography (such as US, EU, and APAC) while respecting data residency, and **Global Cross-Region** routes anywhere worldwide when there are no residency constraints. Refer to the the section called "Regional availability by models" page for more details.

Availability differs by endpoint.

Availability using the bedrock-mantle endpoint

Region	In-Region	Geo	Global
us-east-1 (N. Virginia)	✓	✗	✗

Data retention

To use this model, you must opt in to provider data sharing by setting your data retention mode to provider_data_share via the Data Retention API. For more information, see Amazon Bedrock abuse detection.

Quotas and Limits

Your AWS account has default quotas to maintain the performance of the service and to ensure appropriate usage of Amazon Bedrock. The default quotas assigned to an account might be

updated depending on regional factors, payment history, fraudulent usage, and/or approval of a quota increase request. For more information, see the section called "Quotas" documentation and see the limits for the model.

Sample Code

Step 1 - AWS Account: If you have an AWS account already, skip this step. If you are new to AWS, sign up for an AWS account.

Step 2 - API key: Go to the Amazon Bedrock console and generate a long-term API key.

Step 3 - Get the SDK: To use this getting started guide, you must have Python already installed. Then install the relevant software depending on the APIs you are using.

```
pip install -U "anthropic[bedrock]"
```

Step 4 - Set environment variables: Configure your environment to use the API key for authentication.

```
AWS_BEARER_TOKEN_BEDROCK="<provide your Bedrock API key>"
```

Step 5 - Run your first inference request: Save the file as `bedrock-first-request.py`

```
from anthropic import AnthropicBedrockMantle

client = AnthropicBedrockMantle(aws_region="us-east-1")

message = client.messages.create(
    model="anthropic.claude-mythos-5",
    max_tokens=1024,
    messages=[{"role": "user", "content": "Hello, Claude"}],
)

print(message.content[0].text)
```

Claude Fable 5

Anthropic — Claude Fable 5

Model Details

Claude Fable 5 is Anthropic's next-generation model for complex knowledge work and coding, capable of sustained autonomous operation across multi-day tasks. It plans across stages, delegates to sub-agents, and self-verifies its work.

Model launch date: June 9, 2026
EOL no sooner than: June 9, 2027
Legacy period: at least 6 months
Model lifecycle policy: Model lifecycle (For Models Launched Prior to Sept 7 2026)
Model EOL date: N/A
End User License Agreements and Terms of Use: View
Model lifecycle: Active
Context window: 1M tokens
Max output tokens: 128K
Sampling parameters: temperature must be 1.0 or unset; top_p must be ≥ 0.99 and < 1.0, or unset; top_k is not supported
Reasoning: Supported (adaptive thinking is always on and cannot be disabled; effort level is configurable) See Adaptive thinking.

`memory_20250818`	None required

Compaction using `bedrock-runtime` endpoint

For more information, see Compaction.

Compaction supported	Beta value
Yes	`compact-2026-09-04` , `compact-2026-01-12`

Content Restrictions

Claude Fable 5 includes blocking classifiers for dual-use content in cybersecurity and biology. When a classifier blocks a request, the API returns a standard HTTP 200 response with `stop_reason: "refusal"` and a `stop_details` object containing the restriction category. Refusal rates on this model are materially higher than on previous Claude models.

Customers should handle `stop_reason: "refusal"` as a primary response path. Whether a refused request is billed depends on its category and on whether output had started. For details, see Billing notes.

Fallback credit for refused requests (beta)

When Claude Fable 5 refuses a request, the response can include a fallback credit token. Redeem the token when you retry the same request on a fallback model, and the retry is billed for the cached conversation prefix at cache-read rates instead of cache-write rates. For more information, see Fallback credit for refused requests (beta).

Supported endpoints	Beta value	Valid fallback models
`bedrock-runtime` , `bedrock-mantle`	`fallback-credit-2026-07-01`	Claude Opus 5 (`anthropic.claude-opus-5`), Claude Opus 4.8 (`anthropic.claude-opus-4-8`)

Pricing

This model is a third-party model offered and billed through AWS Marketplace. Charges appear on your AWS bill and in AWS Cost Explorer under the model provider (not under Amazon Bedrock). For pricing, see the Amazon Bedrock Pricing page.

Programmatic Access

Use the following model IDs and endpoint URLs to access this model programmatically. For more information about the available APIs and endpoints, see APIs supported and Endpoints supported.

Endpoint	Model ID	In-Region endpoint URL	Geo inference ID	Global inference ID
bedrock-runtime	anthropic.claude-fable-5	N/A	us.anthropic.claude-fable-5	global.anthropic.claude-fable-5
bedrock-mantle	anthropic.claude-fable-5	https://bedrock-mantle.{region}.api.aws/anthropic/v1/messages	N/A	N/A

For example, if region is us-east-1 (N. Virginia), then the bedrock-runtime endpoint URL will be "https://bedrock-runtime.us-east-1.amazonaws.com" and for bedrock-mantle will be "https://bedrock-mantle.us-east-1.api.aws".

Service Tiers

Amazon Bedrock offers multiple service tiers to match your workload requirements. **Standard** provides pay-per-token access with no commitment (set `"service_tier": "default"` or omit the field). **Priority** delivers the fastest response times for a price premium (set `"service_tier": "priority"`). **Flex** provides lower-cost access for flexible, non-time-sensitive workloads (set `"service_tier": "flex"`). **Reserved** provides dedicated throughput with a term commitment for predictable workloads; it is set at the account level rather than per request (contact your AWS account team to enable). For more information, see service tiers.

Standard	Priority	Flex	Reserved
✓	✗	✗	✗

Regional Availability

Regional availability at a glance

Amazon Bedrock offers three inference options: **In-Region** keeps requests within a single Region for strict compliance, **Geo Cross-Region** routes across Regions within a geography (such as US, EU, and APAC) while respecting data residency, and **Global Cross-Region** routes anywhere worldwide when there are no residency constraints. Refer to the the section called “Regional availability by models” page for more details.

Availability using the `bedrock-mantle` endpoint

Region	In-Region	Geo	Global
`us-east-1` (N. Virginia)	✓	✗	✗

Geo inference details

The destination Regions available to a geographic inference profile depend on the source Region. To retrieve the current routing configuration, call GetInferenceProfile from the source Region.

Geo: US

Geo inference ID: `us.anthropic.claude-fable-5`

Source Region	Destination Regions
us-east-1 (N. Virginia)	us-east-1 (N. Virginia), us-east-2 (Ohio), us-west-2 (Oregon)
us-east-2 (Ohio)	us-east-1 (N. Virginia), us-east-2 (Ohio), us-west-2 (Oregon)
us-west-1 (N. California)	us-east-1 (N. Virginia), us-east-2 (Ohio), us-west-1 (N. California), us-west-2 (Oregon)
us-west-2 (Oregon)	us-east-1 (N. Virginia), us-east-2 (Ohio), us-west-2 (Oregon)
ca-central-1 (Canada)	ca-central-1 (Canada), us-east-1 (N. Virginia), us-east-2 (Ohio), us-west-2 (Oregon)
ca-west-1 (Calgary)	ca-west-1 (Calgary), us-east-1 (N. Virginia), us-east-2 (Ohio), us-west-2 (Oregon)

Data Retention

To use this model, you must opt in to AWS review by setting your data retention mode to `aws_review` via the Data Retention API. For more information, see Amazon Bedrock abuse detection.

Quotas and Limits

Your AWS account has default quotas to maintain the performance of the service and to ensure appropriate usage of Amazon Bedrock. The default quotas assigned to an account might be updated depending on regional factors, payment history, fraudulent usage, and/or approval of a quota increase request. For more information, see the section called "Quotas" documentation and see the limits for the model.

Sample Code

Step 1 - AWS Account: If you have an AWS account already, skip this step. If you are new to AWS, sign up for an AWS account.

Step 2 - API key: Go to the Amazon Bedrock console and generate a long-term API key.

Step 3 - Get the SDK: To use this getting started guide, you must have Python already installed. Then install the relevant software depending on the APIs you are using.

Invoke & Converse

```
pip install boto3
```

Step 4 - Set environment variables: Configure your environment to use the API key for authentication.

```
AWS_BEARER_TOKEN_BEDROCK="<provide your Bedrock API key>"
```

Step 5 - Run your first inference request: Save the file as `bedrock-first-request.py`

```
import json
import boto3
```

```
client = boto3.client('bedrock-runtime', region_name='us-east-1')
response = client.invoke_model(
    modelId='anthropic.claude-fable-5',
    body=json.dumps({
        'messages': [{'role': 'user', 'content': 'Can you explain the features of
 Amazon Bedrock?'}],
        'max_tokens': 1024
    })
)
print(json.loads(response['body'].read()))
```

Messages

```
pip install -U anthropic aws-bedrock-token-generator
```

Step 4 - Set environment variables: Configure your environment to use the API key for authentication.

```
AWS_BEARER_TOKEN_BEDROCK="<provide your Bedrock API key>"
```

Step 5 - Run your first inference request: Save the file as `bedrock-first-request.py`

```
from anthropic import Anthropic
from aws_bedrock_token_generator import provide_token

token = provide_token(region="us-east-1")

client = Anthropic(
    base_url="https://bedrock-runtime.us-east-1.amazonaws.com/anthropic",
    api_key=token,
)

response = client.messages.create(
    model="global.anthropic.claude-fable-5",
    max_tokens=1024,
    messages=[{"role": "user", "content": "Hello, Claude"}],
)

print(response)
```

Claude Opus 4.8

Anthropic — Claude Opus 4.8

Model Details

Claude Opus 4.8 is an Anthropic Opus model optimized for coding, agents, and deeper reasoning in enterprise workflows.

Model launch date: May 28, 2026

EOL no sooner than: May 28, 2027

Legacy period: at least 6 months

Model lifecycle policy: Model lifecycle (For Models Launched Prior to Sept 7 2026)

Model EOL date: N/A

End User License Agreements and Terms of Use: View

Model lifecycle: Active

Context window: 1M tokens

Max output tokens: 128K

Reasoning: Supported (off by default; set `thinking.type: "adaptive"` to turn on adaptive thinking; `"disabled"` is also accepted; manual extended thinking with `budget_tokens` is not supported) See Adaptive thinking.

Knowledge cutoff: January 2026

Marketplace product ID: `prod-bk5rjg4eo2pke`

> **Important**
>
> Claude Opus 4.8 only supports `thinking.type: "adaptive"` for extended thinking. Unlike Claude Opus 4.6, `thinking.type: "enabled"` with `budget_tokens` is not supported and will return a 400 error. If you are migrating from Opus 4.6, update your requests to use `thinking.type: "adaptive"`. For more information, see the section called “Adaptive thinking”.

Quotas and Limits

Your AWS account has default quotas for Amazon Bedrock. These quotas might change depending on regional factors, payment history, or approval of a quota increase request. For more details, see the section called “Quotas” and the limits for the model.

Default quotas for Claude Opus 4.8 are 20M input TPM and 4M output TPM on `bedrock-mantle` and 30M TPM on `bedrock-runtime` for each supported region. Claude Opus 4.8 does not have a requests-per-minute (RPM) quota; throttling is governed solely by the token-per-minute (TPM) quotas above.

Sample Code

Step 1 - AWS Account: If you have an AWS account already, skip this step. If you are new to AWS, sign up for an AWS account.

Step 2 - API key: Go to the Amazon Bedrock console and generate a long-term API key.

Step 3 - Get the SDK: To use this getting started guide, you must have Python already installed. Then install the relevant software depending on the APIs you are using.

Messages API

```
pip install -U anthropic aws-bedrock-token-generator
```

Invoke/Converse API

```
pip install boto3
```

Step 4 - Set environment variables: Configure your environment to use the API key for authentication.

Messages API

```
AWS_BEARER_TOKEN_BEDROCK="<provide your Bedrock API key>"
```

Invoke/Converse API

```
AWS_BEARER_TOKEN_BEDROCK="<provide your Bedrock API key>"
```

Step 5 - Run your first inference request: Save the file as `bedrock-first-request.py`

Messages API

```
from anthropic import Anthropic
```

```
from aws_bedrock_token_generator import provide_token

token = provide_token(region="us-east-1")

client = Anthropic(
    base_url="https://bedrock-runtime.us-east-1.amazonaws.com/anthropic",
    api_key=token,
)

response = client.messages.create(
    model="global.anthropic.claude-opus-4-8",
    max_tokens=1024,
    messages=[{"role": "user", "content": "Can you explain the features of Amazon
 Bedrock?"}],
)

print(response)
```

Invoke API

```
import json
import boto3

client = boto3.client('bedrock-runtime', region_name='us-east-1')
response = client.invoke_model(
    modelId='anthropic.claude-opus-4-8',
    body=json.dumps({
            'anthropic_version': 'bedrock-2023-05-31',
            'messages': [{ 'role': 'user', 'content': 'Can you explain the features
 of Amazon Bedrock?'}],
            'max_tokens': 1024
    })
)
print(json.loads(response['body'].read()))
```

Converse API

```
import boto3

client = boto3.client('bedrock-runtime', region_name='us-east-1')
response = client.converse(
    modelId='anthropic.claude-opus-4-8',
    messages=[
```

```
        {
            'role': 'user',
            'content': [{'text': 'Can you explain the features of Amazon Bedrock?'}]
        }
    ]
)
print(response)
```

Claude Opus 4.7

Anthropic — Claude Opus 4.7

Model Details

Claude Opus 4.7 is an Anthropic Opus model built for coding, enterprise workflows, and long-running agentic tasks.

Model launch date: Apr 16, 2026
EOL no sooner than: Apr 16, 2027
Legacy period: at least 6 months
Model lifecycle policy: Model lifecycle (For Models Launched Prior to Sept 7 2026)
Model EOL date: N/A
End User License Agreements and Terms of Use: View
Model lifecycle: Active
Context window: 1M tokens
Max output tokens: 128K
Reasoning: Supported (off by default; set `thinking.type: "adaptive"` to turn on adaptive thinking; `"disabled"` is also accepted; manual extended thinking with `budget_tokens` is not supported) See Adaptive thinking.
Knowledge cutoff: January 2026
Marketplace product ID: `prod-d2ik6zgct5hxi`

> **Important**
>
> Claude Opus 4.7 only supports `thinking.type: "adaptive"` for extended thinking. Unlike Claude Opus 4.6, `thinking.type: "enabled"` with `budget_tokens` is not

supported and will return a 400 error. If you are migrating from Opus 4.6, update your requests to use `thinking.type: "adaptive"`. For more information, see the section called "Adaptive thinking".

Input Modalities	Output Modalities
⊗ Audio	⊗ Embedding
✓ Image	⊗ Image
⊗ Speech	⊗ Speech
✓ Text	✓ Text

Features supported using `bedrock-mantle` endpoint

Supported	Not Supported
✓ Response streaming ✓ Explicit Prompt Caching ✓ Abuse detection ✓ Count tokens ✓ Computer use ✓ Structured outputs	⊗ Guardrails ⊗ Prompt optimization ⊗ Knowledge base ⊗ Model evaluation ⊗ Prompt management ⊗ Flows ⊗ Agents ⊗ Intelligent prompt routing ⊗ Implicit Prompt Caching ⊗ Watermarking

Explicit Prompt Caching using `bedrock-runtime` and `bedrock-mantle` endpoints

For more information, see Prompt caching for faster model inference.

Explicit Prompt Caching supported	Min tokens per cache checkpoint	Max cache checkpoints per request	Supported TTL	Fields that accept prompt cache checkpoints
Yes	4,096	4	5 minutes, 1 hour	`system`, `messages`, and `tools`

Computer use using `bedrock-runtime` and `bedrock-mantle` endpoints

For more information, see Computer use.

Tool type	Beta header
`computer_20251124`	`computer-use-2025-11-24`

Compaction using `bedrock-runtime` endpoint

For more information, see Compaction.

Compaction supported	Beta value
Yes	`compact-2026-09-04` ,`compact-2026-01-12`

Pricing

This model is a third-party model offered and billed through AWS Marketplace. Charges appear on your AWS bill and in AWS Cost Explorer under the model provider (not under Amazon Bedrock). For pricing, see the Amazon Bedrock Pricing page.

Programmatic Access

Use the following model IDs and endpoint URLs to access this model programmatically. For more information about the available APIs and endpoints, see APIs supported and Endpoints supported.

Endpoint	Model ID	In-Region endpoint URL	Geo inference ID	Global inference ID

`bedrock-runtime`	`anthropic.claude-opus-4-7`	N/A	`us.anthropic.claude-opus-4-7`
			`eu.anthropic.claude-opus-4-7`
			`jp.anthropic.claude-opus-4-7`
			`au.anthropic.claude-opus-4-7`
				`global.anthropic.claude-opus-4-7`

`bedrock-mantle`	`anthropic.claude-opus-4-7`	`https://bedrock-mantle.{region}.api.aws/`	N/A	N/A

Endpoint	Model ID	In-Region endpoint URL	Geo inference ID	Global inference ID
		`anthropic/v1/messages`		

For example, if region is us-east-1 (N. Virginia), then the bedrock-runtime endpoint URL will be "https://bedrock-runtime.us-east-1.amazonaws.com" and for bedrock-mantle will be "https://bedrock-mantle.us-east-1.api.aws/anthropic/v1/messages".

Service Tiers

Amazon Bedrock offers multiple service tiers to match your workload requirements. **Standard** provides pay-per-token access with no commitment (set `"service_tier": "default"` or omit the field). **Priority** delivers the fastest response times for a price premium (set `"service_tier": "priority"`). **Flex** provides lower-cost access for flexible, non-time-sensitive workloads (set `"service_tier": "flex"`). **Reserved** provides dedicated throughput with a term commitment for predictable workloads; it is set at the account level rather than per request (contact your AWS account team to enable). For more information, see service tiers.

Standard	Priority	Flex	Reserved
✓	✗	✗	✗

Regional Availability

Regional availability at a glance

Amazon Bedrock offers three inference options: **In-Region** keeps requests within a single Region for strict compliance, **Geo Cross-Region** routes across Regions within a geography (such as US, EU, and APAC) while respecting data residency, and **Global Cross-Region** routes anywhere worldwide when there are no residency constraints. Refer to the the section called “Regional availability by models” page for more details.

Availability differs by endpoint.

Quotas and Limits

Your AWS account has default quotas to maintain the performance of the service and to ensure appropriate usage of Amazon Bedrock. The default quotas assigned to an account might be updated depending on regional factors, payment history, fraudulent usage, and/or approval of a quota increase request. For more information, see the section called “Quotas” documentation and see the limits for the model.

Default quotas for Claude Opus 4.7 are 20M input TPM and 4M output TPM on `bedrock-mantle` and 30M TPM on `bedrock-runtime` for each supported region. Claude Opus 4.7 does not have a requests-per-minute (RPM) quota; throttling is governed solely by the token-per-minute (TPM) quotas above.

Sampling parameters no longer supported

Starting with Claude Opus 4.7, `temperature`, `top_p`, and `top_k` parameters are no longer supported. The recommended migration path is to omit these parameters entirely from your requests and to use prompting to guide the model's behavior. If you previously relied on temperature = 0 for deterministic outputs, note that this setting did not guarantee identical responses across invocations.

Sample Code

Step 1 - AWS Account: If you have an AWS account already, skip this step. If you are new to AWS, sign up for an AWS account.

Step 2 - API key: Go to the Amazon Bedrock console and generate a long-term API key.

Step 3 - Get the SDK: To use this getting started guide, you must have Python already installed. Then install the relevant software depending on the APIs you are using.

Messages API

```
pip install -U anthropic aws-bedrock-token-generator
```

Invoke/Converse API

```
pip install boto3
```

Step 4 - Set environment variables: Configure your environment to use the API key for authentication.

Messages API

```
AWS_BEARER_TOKEN_BEDROCK="<provide your Bedrock API key>"
```

Invoke/Converse API

```
AWS_BEARER_TOKEN_BEDROCK="<provide your Bedrock API key>"
```

Step 5 - Run your first inference request: Save the file as `bedrock-first-request.py`

Messages API

```
from anthropic import Anthropic
from aws_bedrock_token_generator import provide_token

token = provide_token(region="us-east-1")

client = Anthropic(
    base_url="https://bedrock-runtime.us-east-1.amazonaws.com/anthropic",
    api_key=token,
)

response = client.messages.create(
```

```
    model="global.anthropic.claude-opus-4-7",
    max_tokens=1024,
    messages=[{"role": "user", "content": "Can you explain the features of Amazon
 Bedrock?"}],
)

print(response)
```

Invoke API

```
import json
import boto3

client = boto3.client('bedrock-runtime', region_name='us-east-1')
response = client.invoke_model(
    modelId='anthropic.claude-opus-4-7',
    body=json.dumps({
            'anthropic_version': 'bedrock-2023-05-31',
            'messages': [{ 'role': 'user', 'content': 'Can you explain the features
 of Amazon Bedrock?'}],
            'max_tokens': 1024
    })
)
print(json.loads(response['body'].read()))
```

Converse API

```
import boto3

client = boto3.client('bedrock-runtime', region_name='us-east-1')
response = client.converse(
    modelId='anthropic.claude-opus-4-7',
    messages=[
        {
            'role': 'user',
            'content': [{'text': 'Can you explain the features of Amazon Bedrock?'}]
        }
    ]
)
print(response)
```

Claude Sonnet 4.6

Anthropic — Claude Sonnet 4.6

Model Details

Claude Sonnet 4.6 is a full upgrade of Anthropic's mid-tier model with improved coding, computer use, long-context reasoning, and agent planning with a 1M token context window. For more information about model development and performance, see the model/service card.

Model launch date: Feb 17, 2026
EOL no sooner than: Feb 17, 2027
Legacy period: at least 6 months
Model lifecycle policy: Model lifecycle (For Models Launched Prior to Sept 7 2026)
Model EOL date: N/A
End User License Agreements and Terms of Use: View
Model lifecycle: Active
Context window: 1M tokens
Max output tokens: 64K
Reasoning: Supported (off by default; adaptive thinking with `thinking.type: "adaptive"` is recommended; manual extended thinking with `budget_tokens` is deprecated) See Adaptive thinking.
Knowledge cutoff: Aug 2025
Marketplace product ID: `prod-ffvjxvh4ltq64`

`computer_20251124`	`computer-use-2025-11-24`

Compaction using `bedrock-runtime` endpoint

For more information, see Compaction.

Compaction supported	Beta value
Yes	`compact-2026-09-04` , `compact-2026-01-12`

Pricing

This model is a third-party model offered and billed through AWS Marketplace. Charges appear on your AWS bill and in AWS Cost Explorer under the model provider (not under Amazon Bedrock). For pricing, see the Amazon Bedrock Pricing page.

Programmatic Access

Use the following model IDs and endpoint URLs to access this model programmatically. For more information about the available APIs and endpoints, see APIs supported and Endpoints supported.

> **Important**
>
> This model is offered through one or more inference profiles designated as inference profiles with limited model selection. These profiles are expected to offer a narrower selection of models, and new models or model versions might not be released for them. Before you take a dependency on one of these inference profiles, review the section called "Inference profiles with limited model selection" and plan for model lifecycle events.

Endpoint	Model ID	In-Region endpoint URL	Geo inference ID	Global inference ID
bedrock-runtime	anthropic.claude-sonnet-4-6	N/A	us.anthropic.claude-sonnet-4-6 eu.anthropic.claude-sonnet-4-6 au.anthropic.claude-sonnet-4-6 jp.anthropic.claude-sonnet-4-6	global.anthropic.claude-sonnet-4-6

For example, if region is us-east-1 (N. Virginia), then the bedrock-runtime endpoint URL will be "https://bedrock-runtime.us-east-1.amazonaws.com".

Service Tiers

Amazon Bedrock offers multiple service tiers to match your workload requirements. **Standard** provides pay-per-token access with no commitment (set `"service_tier": "default"` or omit the field). **Priority** delivers the fastest response times for a price premium (set `"service_tier": "priority"`). **Flex** provides lower-cost access for flexible, non-time-sensitive workloads (set `"service_tier": "flex"`). **Reserved** provides dedicated throughput with a term commitment for predictable workloads; it is set at the account level rather than per request (contact your AWS account team to enable). For more information, see service tiers.

Standard	Priority	Flex	Reserved
✓	✗	✗	✓

Regional Availability

Regional availability at a glance

Amazon Bedrock offers three inference options: **In-Region** keeps requests within a single Region for strict compliance, **Geo Cross-Region** routes across Regions within a geography (such as US, EU, and APAC) while respecting data residency, and **Global Cross-Region** routes anywhere worldwide when there are no residency constraints. Refer to the the section called “Regional availability by models” page for more details.

Availability differs by endpoint.

Quotas and Limits

Your AWS account has default quotas to maintain the performance of the service and to ensure appropriate usage of Amazon Bedrock. The default quotas assigned to an account might be updated depending on regional factors, payment history, fraudulent usage, and/or approval of a quota increase request. For more information, see the section called “Quotas” documentation and see the limits for the model.

Sample Code

Step 1 - AWS Account: If you have an AWS account already, skip this step. If you are new to AWS, sign up for an AWS account.

Step 2 - API key: Go to the Amazon Bedrock console and generate a long-term API key.

Step 3 - Get the SDK: To use this getting started guide, you must have Python already installed. Then install the relevant software depending on the APIs you are using.

```
pip install boto3
```

Step 4 - Set environment variables: Configure your environment to use the API key for authentication.

```
AWS_BEARER_TOKEN_BEDROCK="<provide your Bedrock API key>"
```

Step 5 - Run your first inference request: Save the file as `bedrock-first-request.py`

Invoke API

```
import json
import boto3

client = boto3.client('bedrock-runtime', region_name='us-east-1')
response = client.invoke_model(
    modelId='global.anthropic.claude-sonnet-4-6',
    body=json.dumps({
            'anthropic_version': 'bedrock-2023-05-31',
            'messages': [{ 'role': 'user', 'content': 'Can you explain the features
 of Amazon Bedrock?'}],
            'max_tokens': 1024
    })
)
print(json.loads(response['body'].read()))
```

Converse API

```
import boto3

client = boto3.client('bedrock-runtime', region_name='us-east-1')
response = client.converse(
    modelId='global.anthropic.claude-sonnet-4-6',
    messages=[
        {
            'role': 'user',
            'content': [{'text': 'Can you explain the features of Amazon Bedrock?'}]
        }
    ]
)
print(response)
```

Claude Opus 4.6

Anthropic — Claude Opus 4.6

Model Details

Claude Opus 4.6 is Anthropic's flagship model that plans more carefully, sustains agentic tasks longer, and operates reliably in massive codebases. For more information about model development and performance, see the model/service card.

Model launch date: Feb 5, 2026
EOL no sooner than: Feb 5, 2027
Legacy period: at least 6 months
Model lifecycle policy: Model lifecycle (For Models Launched Prior to Sept 7 2026)
Model EOL date: N/A
End User License Agreements and Terms of Use: View
Model lifecycle: Active
Context window: 1M tokens
Max output tokens: 128K
Reasoning: Supported (off by default; adaptive thinking with `thinking.type: "adaptive"` is recommended; manual extended thinking with `budget_tokens` is deprecated) See Adaptive thinking.
Knowledge cutoff: May 2025
Marketplace product ID: `prod-5ukwuglpt66kg`

Endpoint	Model ID	In-Region endpoint URL	Geo inference ID	Global inference ID
			`eu.anthropic.claude-opus-4-5-20251101-v1:0`	

For example, if region is us-east-1 (N. Virginia), then the bedrock-runtime endpoint URL will be "https://bedrock-runtime.us-east-1.amazonaws.com" and for bedrock-mantle will be "https://bedrock-mantle.us-east-1.api.aws/v1".

Service Tiers

Amazon Bedrock offers multiple service tiers to match your workload requirements. **Standard** provides pay-per-token access with no commitment (set `"service_tier": "default"` or omit the field). **Priority** delivers the fastest response times for a price premium (set `"service_tier": "priority"`). **Flex** provides lower-cost access for flexible, non-time-sensitive workloads (set `"service_tier": "flex"`). **Reserved** provides dedicated throughput with a term commitment for predictable workloads; it is set at the account level rather than per request (contact your AWS account team to enable). For more information, see service tiers.

Standard	Priority	Flex	Reserved
✓	✗	✗	✓

Regional Availability

Regional availability at a glance

Amazon Bedrock offers three inference options: **In-Region** keeps requests within a single Region for strict compliance, **Geo Cross-Region** routes across Regions within a geography (such as US, EU, and APAC) while respecting data residency, and **Global Cross-Region** routes anywhere worldwide when there are no residency constraints. Refer to the the section called “Regional availability by models” page for more details.

Availability differs by endpoint.

		il-central-1 (Tel Aviv) me-central-1 (UAE) me-south-1 (Bahrain) af-south-1 (Cape Town)	ap-southeast-2 (Sydney) ap-southeast-3 (Jakarta) ap-southeast-4 (Melbourne) ap-southeast-5 (Malaysia) ap-southeast-6 (New Zealand) ap-southeast-7 (Thailand)

Quotas and Limits

Your AWS account has default quotas to maintain the performance of the service and to ensure appropriate usage of Amazon Bedrock. The default quotas assigned to an account might be updated depending on regional factors, payment history, fraudulent usage, and/or approval of a quota increase request. For more information, see the section called "Quotas" documentation and see the limits for the model.

Sample Code

Step 1 - AWS Account: If you have an AWS account already, skip this step. If you are new to AWS, sign up for an AWS account.

Step 2 - API key: Go to the Amazon Bedrock console and generate a long-term API key.

Step 3 - Get the SDK: To use this getting started guide, you must have Python already installed. Then install the relevant software depending on the APIs you are using.

```
pip install boto3
```

Step 4 - Set environment variables: Configure your environment to use the API key for authentication.

```
AWS_BEARER_TOKEN_BEDROCK="<provide your Bedrock API key>"
```

Step 5 - Run your first inference request: Save the file as `bedrock-first-request.py`

Invoke API

```
import json
import boto3

client = boto3.client('bedrock-runtime', region_name='us-east-1')
response = client.invoke_model(
    modelId='anthropic.claude-opus-4-5-20251101-v1:0',
    body=json.dumps({
            'anthropic_version': 'bedrock-2023-05-31',
            'messages': [{ 'role': 'user', 'content': 'Can you explain the features
 of Amazon Bedrock?'}],
            'max_tokens': 1024
    })
)
print(json.loads(response['body'].read()))
```

Converse API

```
import boto3

client = boto3.client('bedrock-runtime', region_name='us-east-1')
response = client.converse(
    modelId='anthropic.claude-opus-4-5-20251101-v1:0',
    messages=[
        {
            'role': 'user',
            'content': [{'text': 'Can you explain the features of Amazon Bedrock?'}]
        }
    ]
)
print(response)
```

Claude Haiku 4.5

Anthropic — Claude Haiku 4.5

Model Details

Claude Haiku 4.5 is Anthropic's lightweight model optimized for speed and efficiency with strong coding and agent performance. For more information about model development and performance, see the model/service card.

Model launch date: Oct 16, 2025
EOL no sooner than: Oct 16, 2026
Legacy period: at least 6 months
Model lifecycle policy: Model lifecycle (For Models Launched Prior to Sept 7 2026)
Model EOL date: N/A
End User License Agreements and Terms of Use: View
Model lifecycle: Active
Context window: 200K tokens
Max output tokens: 64K
Reasoning: Supported
Knowledge cutoff: Feb 2025
Marketplace product ID: `prod-xdkflymybwmvi`

Input Modalities	Output Modalities
⊗ Audio	⊗ Embedding
⊙ Image	⊗ Image

Endpoints and APIs supported

The following tables show which endpoints and APIs are supported for Claude Haiku 4.5. For more information, see the section called "APIs" and the section called "Inference endpoints".

Endpoint support

Endpoint	Supported
`bedrock-runtime`	✓
`bedrock-mantle`	✓

APIs supported on `bedrock-runtime` endpoint

Messages	Responses	Chat Completions	Converse	Invoke
✓	✗	✗	✓	✓

APIs supported on `bedrock-mantle` endpoint

Messages	Responses	Chat Completions	Converse	Invoke
✓	✗	✗	✗	✗

Tip

Whenever possible, we recommend using the `bedrock-runtime` endpoint for new applications. See the section called "Inference endpoints" for details.

Capabilities and Features

Bedrock Features

Features supported using `bedrock-runtime` endpoint

Supported	Not Supported
Response streaming Abuse detection Guardrails Prompt optimization Count tokens Knowledge base Model evaluation Prompt management Flows Agents Structured outputs Client-side tool calling Computer use Explicit Prompt Caching	Intelligent prompt routing Watermarking Implicit Prompt Caching

Features supported using `bedrock-mantle` endpoint

Supported	Not Supported
Response streaming Abuse detection Count tokens Computer use Structured outputs	Guardrails Prompt optimization Knowledge base Model evaluation Prompt management Flows Agents Intelligent prompt routing Watermarking

Explicit Prompt Caching

For more information, see Prompt caching for faster model inference.

Explicit Prompt Caching supported	Min tokens per cache checkpoint	Max cache checkpoints per request	Supported TTL	Fields that accept prompt cache checkpoints
Yes	4,096	4	5 minutes, 1 hour	`system`, `messages`, and `tools`

Computer use using `bedrock-runtime` and `bedrock-mantle` endpoints

For more information, see Computer use.

Tool type	Beta header
`computer_20250124`	`computer-use-2025-01-24`

Compaction using `bedrock-runtime` endpoint

For more information, see Compaction.

Compaction supported	Beta value
No	N/A

Pricing

This model is a third-party model offered and billed through AWS Marketplace. Charges appear on your AWS bill and in AWS Cost Explorer under the model provider (not under Amazon Bedrock). For pricing, see the Amazon Bedrock Pricing page.

Programmatic Access

Use the following model IDs and endpoint URLs to access this model programmatically. For more information about the available APIs and endpoints, see APIs supported and Endpoints supported.

Endpoint	Model ID	In-Region endpoint URL	Geo inference ID	Global inference ID
bedrock-runtime	N/A	N/A	us.anthropic.claude-haiku-4-5-20251001-v1:0 eu.anthropic.claude-haiku-4-5-20251001-v1:0 au.anthropic.claude-haiku-4-5-20251001-v1:0 jp.anthropic.claude-haiku-4-5-20251001-v1:0 in.anthropic.claude-haiku-4-5-20251001-v1:0	global.anthropic.claude-haiku-4-5-20251001-v1:0
bedrock-mantle	anthropic.claude-haiku-4-5	https://bedrock-mantle.{region}.api.aws/	N/A	N/A

Endpoint	Model ID	In-Region endpoint URL	Geo inference ID	Global inference ID
		`anthropic/v1/messages`		

Important

For this model, the `bedrock-runtime` endpoint requires a geo or global inference profile ID. The bare model ID isn't supported for on-demand throughput. Geo and global inference profiles can route requests outside the source Region and don't provide single-Region data residency. For single-Region inference, use the `bedrock-mantle` endpoint with the bare model ID.

For example, to use Global cross-Region inference from us-east-1 (N. Virginia), use the endpoint URL "https://bedrock-runtime.us-east-1.amazonaws.com" with the inference profile ID "global.anthropic.claude-haiku-4-5-20251001-v1:0".

Service Tiers

Amazon Bedrock offers multiple service tiers to match your workload requirements. **Standard** provides pay-per-token access with no commitment (set `"service_tier": "default"` or omit the field). **Priority** delivers the fastest response times for a price premium (set `"service_tier": "priority"`). **Flex** provides lower-cost access for flexible, non-time-sensitive workloads (set `"service_tier": "flex"`). **Reserved** provides dedicated throughput with a term commitment for predictable workloads; it is set at the account level rather than per request (contact your AWS account team to enable). For more information, see service tiers.

Standard	Priority	Flex	Reserved
✓	✗	✗	✓

Regional Availability

Regional availability at a glance

Amazon Bedrock offers three inference options: **In-Region** keeps requests within a single Region for strict compliance, **Geo Cross-Region** routes across Regions within a geography (such as US, EU, and APAC) while respecting data residency, and **Global Cross-Region** routes anywhere worldwide when there are no residency constraints. Refer to the the section called “Regional availability by models” page for more details.

Availability differs by endpoint.

Quotas and Limits

Your AWS account has default quotas to maintain the performance of the service and to ensure appropriate usage of Amazon Bedrock. The default quotas assigned to an account might be updated depending on regional factors, payment history, fraudulent usage, and/or approval of a quota increase request. For more information, see the section called "Quotas" documentation and see the limits for the model.

To view the current input and output token quotas for Claude Haiku 4.5 on the `bedrock-mantle` endpoint, open the Service Quotas console, select **Amazon Bedrock**, and search for `bedrock-mantle endpoint`. For more information, see View quota values.

Sample Code

Step 1 - AWS Account: If you have an AWS account already, skip this step. If you are new to AWS, sign up for an AWS account.

Step 2 - API key: Go to the Amazon Bedrock console and generate a long-term API key.

Step 3 - Get the SDK: To use this getting started guide, you must have Python already installed. Then install the relevant software depending on the APIs you are using.

Messages API

```
pip install -U "anthropic[bedrock]" aws-bedrock-token-generator
```

Invoke/Converse API

```
pip install boto3
```

Step 4 - Set environment variables: Configure your environment to use the API key for authentication.

Messages API

```
AWS_BEARER_TOKEN_BEDROCK="<provide your Bedrock API key>"
```

Invoke/Converse API

```
AWS_BEARER_TOKEN_BEDROCK="<provide your Bedrock API key>"
```

Step 5 - Run your first inference request: Save the file as `bedrock-first-request.py`

Messages API

```
from anthropic import Anthropic
from aws_bedrock_token_generator import provide_token

token = provide_token(region="us-east-1")

client = Anthropic(
    base_url="https://bedrock-runtime.us-east-1.amazonaws.com/anthropic",
    api_key=token,
)

response = client.messages.create(
    model="global.anthropic.claude-haiku-4-5-20251001-v1:0",
    max_tokens=1024,
    messages=[{"role": "user", "content": "Can you explain the features of Amazon
 Bedrock?"}],
)

print(response)
```

Invoke API

```
import json
import boto3

client = boto3.client('bedrock-runtime', region_name='us-east-1')
response = client.invoke_model(
    modelId='us.anthropic.claude-haiku-4-5-20251001-v1:0',
    body=json.dumps({
            'anthropic_version': 'bedrock-2023-05-31',
            'messages': [{ 'role': 'user', 'content': 'Can you explain the features
 of Amazon Bedrock?'}],
            'max_tokens': 1024
    })
)
print(json.loads(response['body'].read()))
```

Converse API

```
import boto3
```

```
client = boto3.client('bedrock-runtime', region_name='us-east-1')
response = client.converse(
    modelId='us.anthropic.claude-haiku-4-5-20251001-v1:0',
    messages=[
        {
            'role': 'user',
            'content': [{'text': 'Can you explain the features of Amazon Bedrock?'}]
        }
    ]
)
print(response)
```

Claude Sonnet 4.5

Anthropic — Claude Sonnet 4.5

Model Details

> **Important**
>
> Claude Sonnet 4.5 is in the Legacy stage in all Regions. It has an upcoming end of life of April 8, 2027, after which requests will fail with `ResourceNotFoundException: This model version has reached the end of its life.` For models that are currently available, see Models at a glance. For how model lifecycle stages work, see Model lifecycle.

Claude Sonnet 4.5 is Anthropic's model optimized for agents, coding, and computer use with significant improvements across all benchmarks. For more information about model development and performance, see the model/service card.

Model launch date: Sep 30, 2025

EOL no sooner than: Sep 30, 2026

Legacy period: at least 6 months

Model lifecycle policy: Model lifecycle (For Models Launched Prior to Sept 7 2026)

Model EOL date: April 8, 2027

End User License Agreements and Terms of Use: View

Model lifecycle: Legacy

Context window: 200K tokens

Max output tokens: 64K

Reasoning: Supported

Knowledge cutoff: Apr 2025

Marketplace product ID: `prod-mxcfnwvpd6kb4`

Pricing

This model is a third-party model offered and billed through AWS Marketplace. Charges appear on your AWS bill and in AWS Cost Explorer under the model provider (not under Amazon Bedrock). For pricing, see the Amazon Bedrock Pricing page.

Programmatic Access

Use the following model IDs and endpoint URLs to access this model programmatically. For more information about the available APIs and endpoints, see APIs supported and Endpoints supported.

Endpoint	Model ID	In-Region endpoint URL	Geo inference ID	Global inference ID
bedrock-runtime	anthropic.claude-sonnet-4-5-20250929-v1:0	N/A	us.anthropic.claude-sonnet-4-5-20250929-v1:0 eu.anthropic.claude-sonnet-4-5-20250929-v1:0 au.anthropic.claude-sonnet-4-5-20250929-v1:0 jp.anthropic.claude-sonnet-4-5-20250929-v1:0	global.anthropic.claude-sonnet-4-5-20250929-v1:0

For example, if region is us-east-1 (N. Virginia), then the bedrock-runtime endpoint URL will be "https://bedrock-runtime.us-east-1.amazonaws.com".

Service Tiers

Amazon Bedrock offers multiple service tiers to match your workload requirements. **Standard** provides pay-per-token access with no commitment (set `"service_tier": "default"` or omit the field). **Priority** delivers the fastest response times for a price premium (set `"service_tier": "priority"`). **Flex** provides lower-cost access for flexible, non-time-sensitive workloads (set `"service_tier": "flex"`). **Reserved** provides dedicated throughput with a term commitment

for predictable workloads; it is set at the account level rather than per request (contact your AWS account team to enable). For more information, see service tiers.

Standard	Priority	Flex	Reserved
✓	✗	✗	✓

Regional Availability

Regional availability at a glance

Amazon Bedrock offers three inference options: **In-Region** keeps requests within a single Region for strict compliance, **Geo Cross-Region** routes across Regions within a geography (such as US, EU, and APAC) while respecting data residency, and **Global Cross-Region** routes anywhere worldwide when there are no residency constraints. Refer to the the section called "Regional availability by models" page for more details.

Availability differs by endpoint.

Quotas and Limits

Your AWS account has default quotas to maintain the performance of the service and to ensure appropriate usage of Amazon Bedrock. The default quotas assigned to an account might be updated depending on regional factors, payment history, fraudulent usage, and/or approval of a quota increase request. For more information, see the section called “Quotas” documentation and see the limits for the model.

Sample Code

Step 1 - AWS Account: If you have an AWS account already, skip this step. If you are new to AWS, sign up for an AWS account.

Step 2 - API key: Go to the Amazon Bedrock console and generate a long-term API key.

Step 3 - Get the SDK: To use this getting started guide, you must have Python already installed. Then install the relevant software depending on the APIs you are using.

```
pip install boto3
```

Step 4 - Set environment variables: Configure your environment to use the API key for authentication.

```
AWS_BEARER_TOKEN_BEDROCK="<provide your Bedrock API key>"
```

Step 5 - Run your first inference request: Save the file as `bedrock-first-request.py`

Invoke API

```
import json
import boto3

client = boto3.client('bedrock-runtime', region_name='us-east-1')
response = client.invoke_model(
    modelId='anthropic.claude-sonnet-4-5-20250929-v1:0',
    body=json.dumps({
            'anthropic_version': 'bedrock-2023-05-31',
            'messages': [{ 'role': 'user', 'content': 'Can you explain the features
 of Amazon Bedrock?'}],
            'max_tokens': 1024
    })
)
print(json.loads(response['body'].read()))
```

Converse API

```
import boto3

client = boto3.client('bedrock-runtime', region_name='us-east-1')
response = client.converse(
    modelId='anthropic.claude-sonnet-4-5-20250929-v1:0',
    messages=[
        {
            'role': 'user',
```

```
            'content': [{'text': 'Can you explain the features of Amazon Bedrock?'}]
        }
    ]
)
print(response)
```

Claude Opus 4.1

Anthropic — Claude Opus 4.1

Model Details

> **Important**
>
> Claude Opus 4.1 is in the Legacy stage in all Regions. It has an upcoming end of life of January 8, 2027, after which requests will fail with `ResourceNotFoundException: This model version has reached the end of its life.` For models that are currently available, see Models at a glance. For how model lifecycle stages work, see Model lifecycle.

Claude Opus 4.1 is an upgrade to Anthropic's model with improved coding, reasoning, and agentic task capabilities. For more information about model development and performance, see the model/service card.

Model launch date: Aug 05, 2025
EOL no sooner than: Aug 05, 2026
Legacy period: at least 6 months
Model lifecycle policy: Model lifecycle (For Models Launched Prior to Sept 7 2026)
Model EOL date: January 8, 2027
End User License Agreements and Terms of Use: View
Model lifecycle: Legacy
Context window: 200K tokens
Max output tokens: 32K
Reasoning: Supported
Knowledge cutoff: Mar 2025

Marketplace product ID: `prod-w3q2d6rfge4tw`

Global Inference ID	Americas	EMEA	Asia Pacific
global.anthropic.claude-sonnet-4-20250514-v1:0	us-east-1 (N. Virginia) us-east-2 (Ohio) us-west-2 (Oregon)	eu-west-1 (Ireland)	ap-northeast-1 (Tokyo)

Quotas and Limits

Your AWS account has default quotas to maintain the performance of the service and to ensure appropriate usage of Amazon Bedrock. The default quotas assigned to an account might be updated depending on regional factors, payment history, fraudulent usage, and/or approval of a quota increase request. For more information, see the section called “Quotas” documentation and see the limits for the model.

Sample Code

Step 1 - AWS Account: If you have an AWS account already, skip this step. If you are new to AWS, sign up for an AWS account.

Step 2 - API key: Go to the Amazon Bedrock console and generate a long-term API key.

Step 3 - Get the SDK: To use this getting started guide, you must have Python already installed. Then install the relevant software depending on the APIs you are using.

```
pip install boto3
```

Step 4 - Set environment variables: Configure your environment to use the API key for authentication.

```
AWS_BEARER_TOKEN_BEDROCK="<provide your Bedrock API key>"
```

Step 5 - Run your first inference request: Save the file as `bedrock-first-request.py`

Invoke API

```
import json
import boto3

client = boto3.client('bedrock-runtime', region_name='us-east-1')
response = client.invoke_model(
    modelId='anthropic.claude-sonnet-4-20250514-v1:0',
    body=json.dumps({
            'anthropic_version': 'bedrock-2023-05-31',
            'messages': [{ 'role': 'user', 'content': 'Can you explain the features
 of Amazon Bedrock?'}],
            'max_tokens': 1024
    })
)
print(json.loads(response['body'].read()))
```

Converse API

```
import boto3

client = boto3.client('bedrock-runtime', region_name='us-east-1')
response = client.converse(
```

```
    modelId='anthropic.claude-sonnet-4-20250514-v1:0',
    messages=[
        {
            'role': 'user',
            'content': [{'text': 'Can you explain the features of Amazon Bedrock?'}]
        }
    ]
)
print(response)
```

Claude 3 Haiku

Anthropic — Claude 3 Haiku

Model Details

> **Important**
>
> Claude 3 Haiku reached end of life on September 10, 2026 in most Regions, where requests now fail with `ResourceNotFoundException: This model version has reached the end of its life.` It remains available in the Legacy stage in `ap-northeast-2` (Seoul), `ap-south-1` (Mumbai), `ap-southeast-1` (Singapore), `ca-central-1` (Canada), `eu-central-2` (Zurich), and `sa-east-1` (São Paulo). These Regions have an upcoming end of life of November 13, 2026 (November 27, 2026 in `ca-central-1`), after which requests in these Regions will also fail. For models that are currently available, see Models at a glance. For how model lifecycle stages work, see Model lifecycle.

Claude 3 Haiku is Anthropic's fastest and most compact Claude 3 model, optimized for speed and efficiency in near-instant responses. For more information about model development and performance, see the model/service card.

Model launch date: Mar 13, 2024
EOL no sooner than: Mar 13, 2025
Legacy period: at least 6 months
Model lifecycle policy: Model lifecycle (For Models Launched Prior to Sept 7 2026)

Model EOL date: September 10, 2026

End User License Agreements and Terms of Use: View

Model lifecycle: EOL: 2026-09-10 (certain regions)

Context window: 200K tokens

Max output tokens: 4K

Knowledge cutoff: Aug 2023

Marketplace product ID: `prod-ozonys2hmmpeu`

Input Modalities	Output Modalities
⊗ Audio	⊗ Embedding
✓ Image	⊗ Image
⊗ Speech	⊗ Speech
✓ Text	✓ Text
⊗ Video	⊗ Video

Endpoints and APIs supported

The following tables show which endpoints and APIs are supported for Claude 3 Haiku. For more information, see the section called “APIs” and the section called “Inference endpoints”.

Endpoint support

Endpoint	Supported
`bedrock-runtime`	✓

APIs supported on `bedrock-runtime` endpoint

Messages	Responses	Chat Completions	Converse	Invoke
⊗	⊗	⊗	✓	✓

Tip

Whenever possible, we recommend using the `bedrock-runtime` endpoint for new applications. See the section called "Inference endpoints" for details.

Pricing

This model is a third-party model offered and billed through AWS Marketplace. Charges appear on your AWS bill and in AWS Cost Explorer under the model provider (not under Amazon Bedrock). For pricing, see the Amazon Bedrock Pricing page.

Programmatic Access

Use the following model IDs and endpoint URLs to access this model programmatically. For more information about the available APIs and endpoints, see APIs supported and Endpoints supported.

Important

This model is offered through one or more inference profiles designated as inference profiles with limited model selection. These profiles are expected to offer a narrower selection of models, and new models or model versions might not be released for them. Before you take a dependency on one of these inference profiles, review the section called "Inference profiles with limited model selection" and plan for model lifecycle events.

Endpoint	Model ID	In-Region endpoint URL	Geo inference ID	Global inference ID
bedrock-runtime	anthropic.claude-3-haiku-20	https://bedrock-runtime.{re	us.anthropic.claude-3-haiku	N/A

Endpoint	Model ID	In-Region endpoint URL	Geo inference ID	Global inference ID
	240307-v1:0	gion}.amazonaws.com	-20240307-v1:0 eu.anthropic.claude-3-haiku-20240307-v1:0	

For example, if region is us-east-1 (N. Virginia), then the bedrock-runtime endpoint URL will be "https://bedrock-runtime.us-east-1.amazonaws.com".

Service Tiers

Amazon Bedrock offers multiple service tiers to match your workload requirements. **Standard** provides pay-per-token access with no commitment (set `"service_tier": "default"` or omit the field). **Priority** delivers the fastest response times for a price premium (set `"service_tier": "priority"`). **Flex** provides lower-cost access for flexible, non-time-sensitive workloads (set `"service_tier": "flex"`). **Reserved** provides dedicated throughput with a term commitment for predictable workloads; it is set at the account level rather than per request (contact your AWS account team to enable). For more information, see service tiers.

Standard	Priority	Flex	Reserved
✓	✗	✗	✗

Regional Availability

Regional availability at a glance

Amazon Bedrock offers three inference options: **In-Region** keeps requests within a single Region for strict compliance, **Geo Cross-Region** routes across Regions within a geography (such as US, EU, and APAC) while respecting data residency, and **Global Cross-Region** routes anywhere worldwide

when there are no residency constraints. Refer to the the section called "Regional availability by models" page for more details.

Availability differs by endpoint.

Availability using the `bedrock-runtime` endpoint

        }
    ]
)
print(response)
```

Cohere

The following Cohere models are available in Amazon Bedrock:

Model	Description
the section called "Embed v4"	Embed v4 is Cohere's unified multimodal embedding model that processes text, images, and mixed content in a single model for search and RAG.
the section called "Rerank 3.5"	Rerank 3.5 is Cohere's relevance scoring model that reorders search results for improved accuracy in RAG pipelines and enterprise search.
the section called "Command R"	Command R is Cohere's scalable LLM optimized for retrieval-augmented generation and tool use in enterprise applications with a 128K context window.
the section called "Command R+"	Command R+ is Cohere's model for complex RAG workflows, multi-step tool use, and enterprise tasks with a 128K context window.
the section called "Embed English"	Embed English is Cohere's English-language text embedding model for search, classification, and clustering with strong retrieval accuracy.
the section called "Embed Multilingual"	Embed Multilingual is Cohere's multilingual text embedding model supporting 100+ languages for cross-lingual search and classification.

Embed v4

Cohere — Embed v4

Model Details

Embed v4 is Cohere's unified multimodal embedding model that processes text, images, and mixed content in a single model for search and RAG. For more information about model development and performance, see the model/service card.

Model launch date: Apr 15, 2025

Quotas and Limits

Your AWS account has default quotas to maintain the performance of the service and to ensure appropriate usage of Amazon Bedrock. The default quotas assigned to an account might be updated depending on regional factors, payment history, fraudulent usage, and/or approval of a quota increase request. For more information, see the section called "Quotas" documentation and see the limits for the model.

Sample Code

Step 1 - AWS Account: If you have an AWS account already, skip this step. If you are new to AWS, sign up for an AWS account.

Step 2 - API key: Go to the Amazon Bedrock console and generate a long-term API key.

Step 3 - Get the SDK: To use this getting started guide, you must have Python already installed. Then install the relevant software depending on the APIs you are using.

```
pip install boto3
```

Step 4 - Set environment variables: Configure your environment to use the API key for authentication.

```
AWS_BEARER_TOKEN_BEDROCK="<provide your Bedrock API key>"
```

Step 5 - Run your first inference request: Save the file as `bedrock-first-request.py`

Invoke API

```
import json
import boto3

client = boto3.client('bedrock-runtime', region_name='us-east-1')
```

```
response = client.invoke_model(
    modelId='cohere.embed-v4:0',
    body=json.dumps({
            'texts': ['What are the different services that you offer?'],
            'input_type': 'search_document',
            'embedding_types': ['float']
    })
)
print(json.loads(response['body'].read()))
```

Rerank 3.5

Cohere — Rerank 3.5

Model Details

Rerank 3.5 is Cohere's relevance scoring model that reorders search results for improved accuracy in RAG pipelines and enterprise search. For more information about model development and performance, see the model/service card.

Model launch date: Dec 2, 2024

Regional availability at a glance

Amazon Bedrock offers three inference options: **In-Region** keeps requests within a single Region for strict compliance, **Geo Cross-Region** routes across Regions within a geography (such as US, EU, and APAC) while respecting data residency, and **Global Cross-Region** routes anywhere worldwide when there are no residency constraints. Refer to the the section called “Regional availability by models” page for more details.

Region	In-Region	Geo	Global
`us-east-1` (N. Virginia)	✓	✗	✗
`us-west-2` (Oregon)	✓	✗	✗
`ca-central-1` (Canada)	✓	✗	✗
`eu-central-1` (Frankfurt)	✓	✗	✗

Region	In-Region	Geo	Global
ap-northeast-1 (Tokyo)	✓	✗	✗

Quotas and Limits

Your AWS account has default quotas to maintain the performance of the service and to ensure appropriate usage of Amazon Bedrock. The default quotas assigned to an account might be updated depending on regional factors, payment history, fraudulent usage, and/or approval of a quota increase request. For more information, see the section called "Quotas" documentation and see the limits for the model.

Sample Code

Step 1 - AWS Account: If you have an AWS account already, skip this step. If you are new to AWS, sign up for an AWS account.

Step 2 - API key: Go to the Amazon Bedrock console and generate a long-term API key.

Step 3 - Get the SDK: To use this getting started guide, you must have Python already installed. Then install the relevant software depending on the APIs you are using.

```
pip install boto3
```

Step 4 - Set environment variables: Configure your environment to use the API key for authentication.

```
AWS_BEARER_TOKEN_BEDROCK="<provide your Bedrock API key>"
```

Step 5 - Run your first inference request: Save the file as `bedrock-first-request.py`

Rerank API

```
import boto3

client = boto3.client('bedrock-agent-runtime', region_name='us-east-1')
response = client.rerank(
    queries=[{
        'type': 'TEXT',
        'textQuery': {'text': 'What is Amazon Bedrock?'}
```

```
    }],
    sources=[
        {
            'type': 'INLINE',
            'inlineDocumentSource': {
                'type': 'TEXT',
                'textDocument': {'text': 'Amazon Bedrock is a fully managed service
 for foundation models.'}
            }
        },
        {
            'type': 'INLINE',
            'inlineDocumentSource': {
                'type': 'TEXT',
                'textDocument': {'text': 'Amazon S3 is an object storage service.'}
            }
        }
    ],
    rerankingConfiguration={
        'type': 'BEDROCK_RERANKING_MODEL',
        'bedrockRerankingConfiguration': {
            'modelConfiguration': {
                'modelArn': 'arn:aws:bedrock:us-east-1::foundation-model/
cohere.rerank-v3-5:0'
            },
            'numberOfResults': 2
        }
    }
)
for result in response['results']:
    print(f'Index: {result["index"]}, Score: {result["relevanceScore"]}')
```

Command R

Cohere — Command R

Model Details

> **Important**
>
> Command R reached end of life on August 19, 2026 and is no longer available. Requests to this model fail with `ResourceNotFoundException: This model version has reached the end of its life.` For models that are currently available, see Models at a glance. For how model lifecycle stages work, see Model lifecycle.

Command R is Cohere's scalable LLM optimized for retrieval-augmented generation and tool use in enterprise applications with a 128K context window. For more information about model development and performance, see the model/service card.

Model launch date: Aug 2024
EOL no sooner than: Aug 2025
Legacy period: at least 6 months
Model lifecycle policy: Model lifecycle (For Models Launched Prior to Sept 7 2026)
Model EOL date: August 19, 2026
End User License Agreements and Terms of Use: View
Model lifecycle: EOL: 2026-08-19
Context window: 128K tokens
Max output tokens: 4K
Knowledge cutoff: Mar 2024
Marketplace product ID: `prod-tukx4z3hrewle`

Input Modalities	Output Modalities	APIs supported	Endpoints supported
⊗ Audio	⊗ Embedding	⊗ `Responses`	⊙ `bedrock-runtime`

Input Modalities	Output Modalities	APIs supported	Endpoints supported
⊗ Image	⊗ Image	⊗ `Chat Completions`	⊗ `bedrock-mantle`

Tip

Whenever possible, we recommend using the `bedrock-runtime` endpoint for new applications. See the section called "Inference endpoints" for details.

Capabilities and Features

Bedrock Features

Features supported using `bedrock-runtime` endpoint

Supported	Not Supported
✓ Response streaming ✓ Guardrails ✓ Client-side tool calling	—

Pricing

This model is a third-party model offered and billed through AWS Marketplace. Charges appear on your AWS bill and in AWS Cost Explorer under the model provider (not under Amazon Bedrock). For pricing, see the Amazon Bedrock Pricing page.

Programmatic Access

Use the following model IDs and endpoint URLs to access this model programmatically. For more information about the available APIs and endpoints, see APIs supported and Endpoints supported.

Endpoint	Model ID	In-Region endpoint URL	Geo inference ID	Global inference ID
bedrock-runtime	cohere.command-r-v1:0	https://bedrock-runtime.{region}.amazonaws.com	Not supported	Not supported

For example, if region is us-east-1 (N. Virginia), then the bedrock-runtime endpoint URL will be "https://bedrock-runtime.us-east-1.amazonaws.com" and for bedrock-mantle will be "https://bedrock-mantle.us-east-1.api.aws/v1".

Service Tiers

Amazon Bedrock offers multiple service tiers to match your workload requirements. **Standard** provides pay-per-token access with no commitment (set `"service_tier": "default"` or omit the field). **Priority** delivers the fastest response times for a price premium (set `"service_tier": "priority"`). **Flex** provides lower-cost access for flexible, non-time-sensitive workloads (set `"service_tier": "flex"`). **Reserved** provides dedicated throughput with a term commitment for predictable workloads; it is set at the account level rather than per request (contact your AWS account team to enable). For more information, see service tiers.

Standard	Priority	Flex	Reserved
✓	✗	✗	✗

Regional Availability

Regional availability at a glance

Amazon Bedrock offers three inference options: **In-Region** keeps requests within a single Region for strict compliance, **Geo Cross-Region** routes across Regions within a geography (such as US, EU,

and APAC) while respecting data residency, and **Global Cross-Region** routes anywhere worldwide when there are no residency constraints. Refer to the the section called "Regional availability by models" page for more details.

Region	In-Region	Geo	Global
`us-east-1` (N. Virginia)	✓	✗	✗
`us-west-2` (Oregon)	✓	✗	✗

Quotas and Limits

Your AWS account has default quotas to maintain the performance of the service and to ensure appropriate usage of Amazon Bedrock. The default quotas assigned to an account might be updated depending on regional factors, payment history, fraudulent usage, and/or approval of a quota increase request. For more information, see the section called "Quotas" documentation and see the limits for the model.

Sample Code

Step 1 - AWS Account: If you have an AWS account already, skip this step. If you are new to AWS, sign up for an AWS account.

Step 2 - API key: Go to the Amazon Bedrock console and generate a long-term API key.

Step 3 - Get the SDK: To use this getting started guide, you must have Python already installed. Then install the relevant software depending on the APIs you are using.

```
pip install boto3
```

Step 4 - Set environment variables: Configure your environment to use the API key for authentication.

```
AWS_BEARER_TOKEN_BEDROCK="<provide your Bedrock API key>"
```

Step 5 - Run your first inference request: Save the file as `bedrock-first-request.py`

Invoke API

```
import json
import boto3

client = boto3.client('bedrock-runtime', region_name='us-east-1')
response = client.invoke_model(
    modelId='cohere.command-r-v1:0',
    body=json.dumps({
            'message': 'Can you explain the features of Amazon Bedrock?',
            'max_tokens': 1024
    })
)
print(json.loads(response['body'].read()))
```

Converse API

```
import boto3

client = boto3.client('bedrock-runtime', region_name='us-east-1')
response = client.converse(
    modelId='cohere.command-r-v1:0',
    messages=[
        {
            'role': 'user',
            'content': [{'text': 'Can you explain the features of Amazon Bedrock?'}]
        }
    ]
)
print(response)
```

Command R+

Cohere — Command R+

Model Details

For example, if region is us-east-1 (N. Virginia), then the bedrock-runtime endpoint URL will be "https://bedrock-runtime.us-east-1.amazonaws.com" and for bedrock-mantle will be "https://bedrock-mantle.us-east-1.api.aws/v1".

Service Tiers

Amazon Bedrock offers multiple service tiers to match your workload requirements. **Standard** provides pay-per-token access with no commitment (set `"service_tier": "default"` or omit the field). **Priority** delivers the fastest response times for a price premium (set `"service_tier": "priority"`). **Flex** provides lower-cost access for flexible, non-time-sensitive workloads (set `"service_tier": "flex"`). **Reserved** provides dedicated throughput with a term commitment for predictable workloads; it is set at the account level rather than per request (contact your AWS account team to enable). For more information, see service tiers.

Standard	Priority	Flex	Reserved
✓	✓	✓	✗

Regional Availability

Regional availability at a glance

Amazon Bedrock offers three inference options: **In-Region** keeps requests within a single Region for strict compliance, **Geo Cross-Region** routes across Regions within a geography (such as US, EU,

and APAC) while respecting data residency, and **Global Cross-Region** routes anywhere worldwide when there are no residency constraints. Refer to the the section called "Regional availability by models" page for more details.

Region	In-Region	Geo	Global
us-east-1 (N. Virginia)	✓	✗	✗
us-east-2 (Ohio)	✓	✗	✗
us-west-2 (Oregon)	✓	✗	✗
eu-north-1 (Stockholm)	✓	✗	✗
eu-west-2 (London)	✓	✗	✗
ap-northeast-1 (Tokyo)	✓	✗	✗
ap-south-1 (Mumbai)	✓	✗	✗
ap-southeast-2 (Sydney)	✓	✗	✗
ap-southeast-3 (Jakarta)	✓	✗	✗
ap-northeast-2 (Seoul)	✓	✗	✗
ap-southeast-1 (Singapore)	✓	✗	✗
ap-southeast-4 (Melbourne)	✓	✗	✗
sa-east-1 (São Paulo)	✓	✗	✗

Quotas and Limits

Your AWS account has default quotas to maintain the performance of the service and to ensure appropriate usage of Amazon Bedrock. The default quotas assigned to an account might be updated depending on regional factors, payment history, fraudulent usage, and/or approval of a quota increase request. For more information, see the section called "Quotas" documentation and see the limits for the model.

Sample Code

Step 1 - AWS Account: If you have an AWS account already, skip this step. If you are new to AWS, sign up for an AWS account.

Step 2 - API key: Go to the Amazon Bedrock console and generate a long-term API key.

Step 3 - Get the SDK: To use this getting started guide, you must have Python already installed. Then install the relevant software depending on the APIs you are using.

Chat Completions API

```
pip install boto3 openai
```

Invoke/Converse API

```
pip install boto3
```

Step 4 - Set environment variables: Configure your environment to use the API key for authentication.

Chat Completions API

```
OPENAI_API_KEY="<provide your Bedrock API key>"
OPENAI_BASE_URL="https://bedrock-runtime.<your-region>.amazonaws.com/openai/v1"
```

Invoke/Converse API

```
AWS_BEARER_TOKEN_BEDROCK="<provide your Bedrock API key>"
```

Step 5 - Run your first inference request: Save the file as `bedrock-first-request.py`

Chat Completions API

```
from openai import OpenAI

client = OpenAI()
```

```
response = client.chat.completions.create(
    model="deepseek.v3.2",
    messages=[{"role": "user", "content": "Can you explain the features of Amazon
 Bedrock?"}]
    )
print(response)
```

Invoke API

```
import json
import boto3

client = boto3.client('bedrock-runtime', region_name='us-east-1')
response = client.invoke_model(
    modelId='deepseek.v3.2',
    body=json.dumps({
            'messages': [{ 'role': 'user', 'content': 'Can you explain the features
 of Amazon Bedrock?'}],
            'max_tokens': 1024
    })
)
print(json.loads(response['body'].read()))
```

Converse API

```
import boto3

client = boto3.client('bedrock-runtime', region_name='us-east-1')
response = client.converse(
    modelId='deepseek.v3.2',
    messages=[
        {
            'role': 'user',
            'content': [{'text': 'Can you explain the features of Amazon Bedrock?'}]
        }
    ]
)
print(response)
```

DeepSeek-V3.1

DeepSeek — DeepSeek-V3.1

Model Details

DeepSeek-V3.1 is DeepSeek's 685B parameter mixture-of-experts model with strong performance across coding, math, and general reasoning tasks. For more information about model development and performance, see the model/service card.

Model launch date: Aug 21, 2025
EOL no sooner than: Aug 21, 2026
Legacy period: at least 6 months
Model lifecycle policy: Model lifecycle (For Models Launched Prior to Sept 7 2026)
Model EOL date: March 30, 2027
End User License Agreements and Terms of Use: View
Model lifecycle: Legacy
Context window: 128K tokens
Max output tokens: 8K
Knowledge cutoff: Jan 2025

        {
            'role': 'user',
            'content': [{'text': 'Can you explain the features of Amazon Bedrock?'}]
```

```
        }
    ]
)
print(response)
```

Google

The following Google models are available in Amazon Bedrock:

Model	Description
the section called "Gemma 4 31B"	Gemma 4 31B is Google's 30.7-billion parameter dense model with built-in reasoning, native function calling, and multimodal input across text and image, supporting a 256K token context window.
the section called "Gemma 4 26B-A4B"	Gemma 4 26B-A4B is Google's mixture-of-experts model with 25.2 billion total parameters and 3.8 billion active per token, delivering cost-efficient inference with built-in reasoning, native function calling, and multimodal input across text and image, supporting a 256K token context window.
the section called "Gemma 4 E2B"	Gemma 4 E2B is Google's compact model with 5.1 billion total parameters and 2.3 billion effective parameters, designed for low-latency workloads with built-in reasoning, native function calling, and multimodal input across text and image, supporting a 128K token context window.
the section called "Gemma 3 12B IT"	Gemma 3 12B IT is Google's 12-billion parameter open model with instruction tuning, supporting text and image inputs with a 128K context window.
the section called "Gemma 3 27B PT"	Gemma 3 27B PT is Google's 27-billion parameter open model, the largest in the Gemma 3 family, with multimodal capabilities and a 128K context window.
the section called "Gemma 3 4B IT"	Gemma 3 4B IT is Google's compact 4-billion parameter open model with instruction tuning, designed for on-device and edge deployment.

Gemma 4 31B

Google — Gemma 4 31B

Model Details

Gemma 4 31B is Google's 30.7-billion parameter dense model with instruction tuning, built-in reasoning, native function calling, and multimodal input across text and image, supporting a 256K token context window. For more information about model development and performance, see the model/service card.

Model launch date: March 31, 2026
EOL no sooner than: March 31, 2027
Legacy period: at least 6 months
Model lifecycle policy: Model lifecycle (For Models Launched Prior to Sept 7 2026)
Model EOL date: N/A
End User License Agreements and Terms of Use: View
Model lifecycle: Active
Context window: 256K tokens

Input Modalities	Output Modalities	APIs supported	Endpoints supported
⊗ Audio	⊗ Embedding	⊙ `Responses`	⊗ `bedrock-runtime`

Region	In-Region	Geo	Global
us-east-2 (Ohio)	✓	✗	✗
us-west-2 (Oregon)	✓	✗	✗
us-gov-west-1 (GovCloud West)	✓	✗	✗
eu-central-1 (Frankfurt)	✓	✗	✗

Quotas and Limits

Your AWS account has default quotas to maintain the performance of the service and to ensure appropriate usage of Amazon Bedrock. The default quotas assigned to an account might be updated depending on regional factors, payment history, fraudulent usage, and/or approval of a quota increase request. For more information, see the section called "Quotas" documentation and see the limits for the model.

When consuming on-demand throughput on the `bedrock-mantle` endpoint, available throughput scales over time. Not all requests within your quota are guaranteed to succeed during periods of high demand, so ramping gradually is important. For this model, default limits aren't surfaced directly through Service Quotas, so we recommend following the ramp as your guide.

Sample Code

Step 1 - AWS Account: If you have an AWS account already, skip this step. If you are new to AWS, sign up for an AWS account.

Step 2 - API key: Go to the Amazon Bedrock console and generate a long-term API key.

Step 3 - Get the SDK: To use this getting started guide, you must have Python already installed. Then install the relevant software depending on the APIs you are using.

```
pip install openai
```

Step 4 - Set environment variables: Configure your environment to use the API key for authentication.

```
OPENAI_API_KEY="<provide your Bedrock API key>"
```

```
OPENAI_BASE_URL="https://bedrock-mantle.<your-region>.api.aws/openai/v1"
```

Step 5 - Run your first inference request: Save the file as `bedrock-first-request.py`

Chat Completions API

```
from openai import OpenAI

client = OpenAI()

response = client.chat.completions.create(
    model="google.gemma-4-31b",
    messages=[{"role": "user", "content": "Can you explain the features of Amazon
 Bedrock?"}]
    )
print(response)
```

Responses API

```
from openai import OpenAI

client = OpenAI()

response = client.responses.create(
    model="google.gemma-4-31b",
    input="Explain the benefits of mixture-of-experts architectures for production
 inference.",
    max_output_tokens=512,
)
print(response.output_text)
```

Usage Considerations and Limitations

- **Reasoning mode** — Reasoning effort is honored on both the Chat Completions and Responses APIs, and the model performs the extended reasoning in both cases. However, the reasoning content is returned only by the Responses API. The Chat Completions API does not return the reasoning tokens, because the OpenAI Chat Completions specification does not support returning them.
- **Parallel tool calls** — Requesting more than one tool call in a single turn is not currently supported. Request tool calls one at a time.

- **Request payload size** — The total request body payload for Gemma 4 31B, including images and video, supports a maximum size of 3.5 MB.

Gemma 4 26B-A4B

Google — Gemma 4 26B-A4B

Model Details

Gemma 4 26B-A4B is Google's mixture-of-experts model with 25.2 billion total parameters and 3.8 billion active per token, delivering cost-efficient inference with instruction tuning, built-in reasoning, native function calling, and multimodal input across text and image, supporting a 256K token context window. Regional Availability

Regional availability at a glance

Amazon Bedrock offers three inference options: **In-Region** keeps requests within a single Region for strict compliance, **Geo Cross-Region** routes across Regions within a geography (such as US, EU, and APAC) while respecting data residency, and **Global Cross-Region** routes anywhere worldwide

when there are no residency constraints. Refer to the the section called “Regional availability by models” page for more details.

Region	In-Region	Geo	Global
us-east-1 (N. Virginia)	✓	✗	✗
us-east-2 (Ohio)	✓	✗	✗
us-west-2 (Oregon)	✓	✗	✗
us-gov-west-1 (GovCloud West)	✓	✗	✗
eu-central-1 (Frankfurt)	✓	✗	✗

Quotas and Limits

Your AWS account has default quotas to maintain the performance of the service and to ensure appropriate usage of Amazon Bedrock. The default quotas assigned to an account might be updated depending on regional factors, payment history, fraudulent usage, and/or approval of a quota increase request. For more information, see the section called “Quotas” documentation and see the limits for the model.

When consuming on-demand throughput on the `bedrock-mantle` endpoint, available throughput scales over time. Not all requests within your quota are guaranteed to succeed during periods of high demand, so ramping gradually is important. For this model, default limits aren't surfaced directly through Service Quotas, so we recommend following the ramp as your guide.

Sample Code

Step 1 - AWS Account: If you have an AWS account already, skip this step. If you are new to AWS, sign up for an AWS account.

Step 2 - API key: Go to the Amazon Bedrock console and generate a long-term API key.

Step 3 - Get the SDK: To use this getting started guide, you must have Python already installed. Then install the relevant software depending on the APIs you are using.

```
pip install openai
```

Step 4 - Set environment variables: Configure your environment to use the API key for authentication.

```
OPENAI_API_KEY="<provide your Bedrock API key>"
OPENAI_BASE_URL="https://bedrock-mantle.<your-region>.api.aws/openai/v1"
```

Step 5 - Run your first inference request: Save the file as `bedrock-first-request.py`

Chat Completions API

```
from openai import OpenAI

client = OpenAI()

response = client.chat.completions.create(
    model="google.gemma-4-26b-a4b",
    messages=[{"role": "user", "content": "Can you explain the features of Amazon
 Bedrock?"}]
    )
print(response)
```

Responses API

```
from openai import OpenAI

client = OpenAI()

response = client.responses.create(
    model="google.gemma-4-26b-a4b",
    input="Explain the benefits of mixture-of-experts architectures for production
 inference.",
    max_output_tokens=512,
)
print(response.output_text)
```

Usage Considerations and Limitations

- **Reasoning mode** — Reasoning effort is honored on both the Chat Completions and Responses APIs, and the model performs the extended reasoning in both cases. However, the reasoning content is returned only by the Responses API. The Chat Completions API does not return

the reasoning tokens, because the OpenAI Chat Completions specification does not support returning them.

- **Parallel tool calls** — Requesting more than one tool call in a single turn is not currently supported. Request tool calls one at a time.
- **Request payload size** — The total request body payload for Gemma 4 26B-A4B, including images and video, supports a maximum size of 3.5 MB.

Gemma 4 E2B

Google — Gemma 4 E2B

Model Details

Gemma 4 E2B is Google's compact model with 5.1 billion total parameters and 2.3 billion effective parameters using Per-Layer Embeddings (PLE), designed for low-latency workloads with instruction tuning, built-in reasoning, native function calling, and multimodal input across text and image, supporting a 128K token context window. For more information about model development and performance, see the model/service card.

Model launch date: March 31, 2026
EOL no sooner than: March 31, 2027
Legacy period: at least 6 months
Model lifecycle policy: Model lifecycle (For Models Launched Prior to Sept 7 2026)
Model EOL date: N/A
End User License Agreements and Terms of Use: View
Model lifecycle: Active
Context window: 128K tokens

Input Modalities	Output Modalities	APIs supported	Endpoints supported
✓ Audio	✗ Embedding	✓ Responses	✗ bedrock-runtime

Input Modalities	Output Modalities	APIs supported	Endpoints supported
✓ Image	✗ Image	✓ `Chat Completions`	✓ `bedrock-mantle`
✗ Speech	✗ Speech	✗ `Invoke`	
✓ Text	✓ Text	✗ `Converse`	
✓ Video	✗ Video	✗ `Messages`	

Note

Gemma 4 models are available only on the `bedrock-mantle` endpoint.
On `bedrock-mantle`, Gemma 4 models are served under the `/openai/v1` path prefix, not the `/v1` prefix that most other models on this endpoint use. Use `/openai/v1/chat/completions` and `/openai/v1/responses`, and set your client's base URL to `https://bedrock-mantle.{region}.api.aws/openai/v1`. A request to `/v1/chat/completions` or `/v1/responses` is rejected with `model `google.gemma-4-e2b` isn't supported on this route`.

Pricing

For pricing information, see the Amazon Bedrock Pricing page.

Programmatic Access

Use the following model IDs and endpoint URLs to access this model programmatically. For more information about the available APIs and endpoints, see APIs supported and Endpoints supported.

Endpoint	Model ID	In-Region endpoint URL	Geo inference ID	Global inference ID
bedrock-mantle	google.gemma-4-e2b	https://bedrock-mantle.{region}.api.aws/openai/v1	Not supported	Not supported

For example, if region is us-east-1 (N. Virginia), then the bedrock-mantle endpoint URL will be "https://bedrock-mantle.us-east-1.api.aws/openai/v1".

Service Tiers

Amazon Bedrock offers multiple service tiers to match your workload requirements. **Standard** provides pay-per-token access with no commitment (set `"service_tier": "default"` or omit the field). **Priority** delivers the fastest response times for a price premium (set `"service_tier": "priority"`). **Flex** provides lower-cost access for flexible, non-time-sensitive workloads (set `"service_tier": "flex"`). **Reserved** provides dedicated throughput with a term commitment for predictable workloads; it is set at the account level rather than per request (contact your AWS account team to enable). For more information, see service tiers.

Standard	Priority	Flex	Reserved

`us-west-2` (Oregon)	✓	✗	✗
`us-gov-west-1` (GovCloud West)	✓	✗	✗
`eu-central-1` (Frankfurt)	✓	✗	✗

Quotas and Limits

Your AWS account has default quotas to maintain the performance of the service and to ensure appropriate usage of Amazon Bedrock. The default quotas assigned to an account might be updated depending on regional factors, payment history, fraudulent usage, and/or approval of a quota increase request. For more information, see the section called "Quotas" documentation and see the limits for the model.

When consuming on-demand throughput on the `bedrock-mantle` endpoint, available throughput scales over time. Not all requests within your quota are guaranteed to succeed during periods of high demand, so ramping gradually is important. For this model, default limits aren't surfaced directly through Service Quotas, so we recommend following the ramp as your guide.

Sample Code

Step 1 - AWS Account: If you have an AWS account already, skip this step. If you are new to AWS, sign up for an AWS account.

Step 2 - API key: Go to the Amazon Bedrock console and generate a long-term API key.

Step 3 - Get the SDK: To use this getting started guide, you must have Python already installed. Then install the relevant software depending on the APIs you are using.

```
pip install openai
```

Step 4 - Set environment variables: Configure your environment to use the API key for authentication.

```
OPENAI_API_KEY="<provide your Bedrock API key>"
OPENAI_BASE_URL="https://bedrock-mantle.<your-region>.api.aws/openai/v1"
```

Step 5 - Run your first inference request: Save the file as `bedrock-first-request.py`

Chat Completions API

```
from openai import OpenAI

client = OpenAI()

response = client.chat.completions.create(
    model="google.gemma-4-e2b",
    messages=[{"role": "user", "content": "Can you explain the features of Amazon
 Bedrock?"}]
    )
print(response)
```

Responses API

```
from openai import OpenAI

client = OpenAI()

response = client.responses.create(
    model="google.gemma-4-e2b",
    input="Explain the benefits of mixture-of-experts architectures for production
 inference.",
    max_output_tokens=512,
)
print(response.output_text)
```

Usage Considerations and Limitations

- **Reasoning mode** — Reasoning effort is honored on both the Chat Completions and Responses APIs, and the model performs the extended reasoning in both cases. However, the reasoning content is returned only by the Responses API. The Chat Completions API does not return the reasoning tokens, because the OpenAI Chat Completions specification does not support returning them.
- **Reasoning effort** — For Gemma 4 E2B, we recommend setting `reasoning_effort` to `high`, which enables thinking mode. This variant tends to reason extensively by default, and a high reasoning effort keeps that reasoning in the dedicated reasoning channel, which improves output quality and prevents reasoning text from appearing in the final response.
- **Parallel tool calls** — Requesting more than one tool call in a single turn is not currently supported. Request tool calls one at a time.
- **Request payload size** — The total request body payload for Gemma 4 E2B, including images and video, supports a maximum size of 3.5 MB.

updated depending on regional factors, payment history, fraudulent usage, and/or approval of a quota increase request. For more information, see the section called "Quotas" documentation and see the limits for the model.

Sample Code

Step 1 - AWS Account: If you have an AWS account already, skip this step. If you are new to AWS, sign up for an AWS account.

Step 2 - API key: Go to the Amazon Bedrock console and generate a long-term API key.

Step 3 - Get the SDK: To use this getting started guide, you must have Python already installed. Then install the relevant software depending on the APIs you are using.

Responses/Chat Completions API

```
pip install boto3 openai
```

Invoke/Converse API

```
pip install boto3
```

Step 4 - Set environment variables: Configure your environment to use the API key for authentication.

Responses/Chat Completions API

```
OPENAI_API_KEY="<provide your Bedrock API key>"
OPENAI_BASE_URL="https://bedrock-runtime.<your-region>.amazonaws.com/openai/v1"
```

Invoke/Converse API

```
AWS_BEARER_TOKEN_BEDROCK="<provide your Bedrock API key>"
```

Step 5 - Run your first inference request: Save the file as `bedrock-first-request.py`

Chat Completions API

```
from openai import OpenAI
```

```
client = OpenAI()

response = client.chat.completions.create(
    model="google.gemma-3-4b-it",
    messages=[{"role": "user", "content": "Can you explain the features of Amazon
 Bedrock?"}]
    )
print(response)
```

Invoke API

```
import json
import boto3

client = boto3.client('bedrock-runtime', region_name='us-east-1')
response = client.invoke_model(
    modelId='google.gemma-3-4b-it',
    body=json.dumps({
            'messages': [{ 'role': 'user', 'content': 'Can you explain the features
 of Amazon Bedrock?'}],
            'max_tokens': 1024
    })
)
print(json.loads(response['body'].read()))
```

Converse API

```
import boto3

client = boto3.client('bedrock-runtime', region_name='us-east-1')
response = client.converse(
    modelId='google.gemma-3-4b-it',
    messages=[
        {
            'role': 'user',
            'content': [{'text': 'Can you explain the features of Amazon Bedrock?'}]
        }
    ]
)
print(response)
```

Luma AI

The following Luma AI model is available in Amazon Bedrock:

Model	Description
the section called "Ray2"	Ray2 is Luma AI's large-scale video-generation model for creating realistic video clips with natural, coherent motion from text prompts and images.

Ray2

Luma AI — Ray2

Model Details

Ray2 is Luma AI's large-scale video generation model creating realistic video clips with natural, coherent motion from text prompts and images. For more information about model development and performance, see the model/service card.

Model launch date: Jan 23, 2025
EOL no sooner than: Jan 23, 2026
Legacy period: at least 6 months
Model lifecycle policy: Model lifecycle (For Models Launched Prior to Sept 7 2026)
Model EOL date: N/A
End User License Agreements and Terms of Use: View
Model lifecycle: Active
Marketplace product ID: `prod-bi33bxqeqavl6`

Input Modalities	Output Modalities	APIs supported	Endpoints supported
⊗ Audio	⊗ Embedding	⊗ Responses	⊙ bedrock-runtime

Input Modalities	Output Modalities	APIs supported	Endpoints supported
✓ Image	✗ Image	✗ Chat Completions	✗ bedrock-mantle
✗ Speech	✗ Speech	✗ Invoke	
✓ Text	✗ Text	✗ Converse	
✗ Video	✓ Video	✓ StartAsyncInvoke	

Tip

Whenever possible, we recommend using the `bedrock-runtime` endpoint for new applications. See the section called "Inference endpoints" for details.

Pricing

This model is a third-party model offered and billed through AWS Marketplace. Charges appear on your AWS bill and in AWS Cost Explorer under the model provider (not under Amazon Bedrock). For pricing, see the Amazon Bedrock Pricing page.

Programmatic Access

Use the following model ID and endpoint URL to access this model programmatically. Ray2 uses the StartAsyncInvoke operation. For more information about the available APIs and endpoints, see APIs supported and Endpoints supported.

Endpoint	Model ID	In-Region endpoint URL	Geo inference ID	Global inference ID
bedrock-runtime	luma.ray-v2:0	https://bedrock-runtime.us-west-2.amazonaws.com	Not supported	Not supported

Service Tiers

Amazon Bedrock offers multiple service tiers to match your workload requirements. For more information, see service tiers.

Standard	Priority	Flex	Reserved
✓	✗	✗	✗

Regional Availability

Regional availability at a glance

Amazon Bedrock offers three inference options: **In-Region** keeps requests within a single Region for strict compliance, **Geo Cross-Region** routes across Regions within a geography while respecting data residency, and **Global Cross-Region** routes worldwide when there are no residency constraints. Refer to the the section called "Regional availability by models" page for more details.

Region	In-Region	Geo	Global
`us-west-2` (Oregon)	✓	✗	✗

Quotas and Limits

The `prompt` request field accepts 1–5,000 characters. Ray2 also has a maximum model input of 300 tokens, so prompts must satisfy both limits.

Your AWS account has default quotas to maintain the performance of the service and to ensure appropriate usage of Amazon Bedrock. For more information, see the section called "Quotas" and the Amazon Bedrock endpoints and quotas.

Sample Code

Step 1 - AWS Account: If you have an AWS account already, skip this step. If you are new to AWS, sign up for an AWS account.

Step 2 - API key: Go to the Amazon Bedrock console and generate a long-term API key.

Step 3 - Get the SDK:

```
pip install boto3
```

Step 4 - Set environment variables:

```
AWS_BEARER_TOKEN_BEDROCK="<provide your Bedrock API key>"
```

Step 5 - Run your first inference request: This model uses `StartAsyncInvoke`. Replace the S3 URI with a bucket that you own, and save the file as `bedrock-first-request.py`.

```
import boto3

client = boto3.client('bedrock-runtime', region_name='us-west-2')
response = client.start_async_invoke(
    modelId='luma.ray-v2:0',
    modelInput={
        'prompt': 'a whale swimming through space particles',
        'duration': '5s',
        'resolution': '720p',
        'aspect_ratio': '16:9',
        'loop': False
    },
    outputDataConfig={
        's3OutputDataConfig': {
            's3Uri': 's3://your-bucket/output/'
        }
    }
)
print(response['invocationArn'])
```

For complete request parameters, image-to-video examples, and instructions for checking job status, see the section called “Luma AI models”.

Meta

The following Meta models are available in Amazon Bedrock:

Model	Description
the section called “Llama 4 Maverick 17B Instruct”	Llama 4 Maverick is Meta's 17-billion active parameter mixture-of-experts model with 128 experts, optimized for multimodal chat and instruction following.
the section called “Llama 4 Scout 17B Instruct”	Llama 4 Scout is Meta's 17-billion active parameter mixture-of-experts model with 16 experts and a 10M token context window for long-document tasks.
the section called “Llama 3.3 70B Instruct”	Llama 3.3 70B Instruct is Meta's 70-billion parameter model with improved efficiency, delivering strong reasoning and coding performance with a 128K context window.
the section called “Llama 3.2 11B Instruct”	Llama 3.2 11B Instruct is Meta's 11-billion parameter multimodal model that processes both text and images with a 128K context window.
the section called “Llama 3.2 1B Instruct”	Llama 3.2 1B Instruct is Meta's ultra-lightweight 1-billion parameter model optimized for on-device and edge deployment.
the section called “Llama 3.2 3B Instruct”	Llama 3.2 3B Instruct is Meta's 3-billion parameter lightweight model designed for on-device tasks like summarization and instruction following.
the section called “Llama 3.2 90B Instruct”	Llama 3.2 90B Instruct is Meta's 90-billion parameter multimodal model that processes text and images for visual reasoning and document understanding.
the section called “Llama 3.1 405B Instruct”	Llama 3.1 405B Instruct is Meta's largest open model with 405 billion parameters and a 128K context window, supporting tool use and multilingual tasks.
the section called “Llama 3.1 70B Instruct”	Llama 3.1 70B Instruct is Meta's 70-billion parameter model with an extended 128K context window and support for tool use and code generation.

Model	Description
the section called "Llama 3.1 8B Instruct"	Llama 3.1 8B Instruct is Meta's compact 8-billion parameter model with a 128K context window, suitable for edge deployment and fine-tuning.
the section called "Llama 3 70B Instruct"	Llama 3 70B Instruct is Meta's 70-billion parameter instruction-tuned model with an 8K context window, optimized for dialogue and assistant -like tasks.
the section called "Llama 3 8B Instruct"	Llama 3 8B Instruct is Meta's 8-billion parameter instruction-tuned model with an 8K context window, designed for efficient deployment on smaller infrastructure.

Llama 4 Maverick 17B Instruct

Meta — Llama 4 Maverick 17B Instruct

Model Details

Llama 4 Maverick is Meta's 17-billion active parameter mixture-of-experts model with 128 experts, optimized for multimodal chat and instruction following. For more information about model development and performance, see the model/service card.

Model launch date: Apr 05, 2025
EOL no sooner than: Apr 05, 2026
Legacy period: at least 6 months
Model lifecycle policy: Model lifecycle (For Models Launched Prior to Sept 7 2026)
Model EOL date: March 30, 2027
End User License Agreements and Terms of Use: View
Model lifecycle: Legacy
Context window: 1M tokens
Max output tokens: 8K
Knowledge cutoff: Aug 2024

Input Modalities	Output Modalities	APIs supported	Endpoints supported
⊗ Audio	⊗ Embedding	⊗ Responses	✓ bedrock-runtime
✓ Image	⊗ Image	⊗ Chat Completions	⊗ bedrock-mantle
⊗ Speech	⊗ Speech	✓ Invoke	
✓ Text	✓ Text	✓ Converse	
⊗ Video	⊗ Video		

Tip

Whenever possible, we recommend using the `bedrock-runtime` endpoint for new applications. See the section called "Inference endpoints" for details.

Capabilities and Features

Bedrock Features

Features supported using `bedrock-runtime` endpoint

Supported	Not Supported
✓ Response streaming	⊗ Intelligent prompt routing
✓ Guardrails	⊗ Abuse detection
✓ Client-side tool calling	⊗ Prompt optimization
✓ Prompt management	⊗ Count tokens
✓ Flows	⊗ Knowledge base
✓ Agents	⊗ Model evaluation
	⊗ Structured outputs
	⊗ Watermarking

> **Note**
>
> Tool use and response streaming are supported separately, but not together. A `ConverseStream` request that includes a `toolConfig` field fails with `This model doesn't support tool use in streaming mode.` Use the non-streaming `Converse` operation when you need tool use.

Pricing

For pricing information, see the Amazon Bedrock Pricing page.

Programmatic Access

Use the following model IDs and endpoint URLs to access this model programmatically. For more information about the available APIs and endpoints, see APIs supported and Endpoints supported.

Endpoint	Model ID	In-Region endpoint URL	Geo inference ID	Global inference ID
`bedrock-runtime`	`meta.llama4-maverick-17b-instruct-v1:0`	`https://bedrock-runtime.{region}.amazonaws.com`	`us.meta.llama4-maverick-17b-instruct-v1:0`	Not supported

For example, if region is us-east-1 (N. Virginia), then the bedrock-runtime endpoint URL will be "https://bedrock-runtime.us-east-1.amazonaws.com" and for bedrock-mantle will be "https://bedrock-mantle.us-east-1.api.aws/v1".

Service Tiers

Amazon Bedrock offers multiple service tiers to match your workload requirements. **Standard** provides pay-per-token access with no commitment (set `"service_tier": "default"` or omit the field). **Priority** delivers the fastest response times for a price premium (set `"service_tier": "priority"`). **Flex** provides lower-cost access for flexible, non-time-sensitive workloads (set `"service_tier": "flex"`). **Reserved** provides dedicated throughput with a term commitment

for predictable workloads; it is set at the account level rather than per request (contact your AWS account team to enable). For more information, see service tiers.

Standard	Priority	Flex	Reserved
✓	✗	✗	✗

Regional Availability

Regional availability at a glance

Amazon Bedrock offers three inference options: **In-Region** keeps requests within a single Region for strict compliance, **Geo Cross-Region** routes across Regions within a geography (such as US, EU, and APAC) while respecting data residency, and **Global Cross-Region** routes anywhere worldwide when there are no residency constraints. Refer to the the section called "Regional availability by models" page for more details.

Region	In-Region	Geo	Global

Geo: US

Geo Inference ID: `us.meta.llama4-maverick-17b-instruct-v1:0`

Source Region	Destination Regions
us-east-1 (N. Virginia)	us-east-1 (N. Virginia), us-east-2 (Ohio), us-west-2 (Oregon)

Source Region	Destination Regions
us-east-2 (Ohio)	us-east-1 (N. Virginia), us-east-2 (Ohio), us-west-2 (Oregon)
us-west-1 (N. California)	us-east-1 (N. Virginia), us-east-2 (Ohio), us-west-1 (N. California), us-west-2 (Oregon)
us-west-2 (Oregon)	us-east-1 (N. Virginia), us-east-2 (Ohio), us-west-2 (Oregon)

Quotas and Limits

Your AWS account has default quotas to maintain the performance of the service and to ensure appropriate usage of Amazon Bedrock. The default quotas assigned to an account might be updated depending on regional factors, payment history, fraudulent usage, and/or approval of a quota increase request. For more information, see the section called "Quotas" documentation and see the limits for the model.

Sample Code

Step 1 - AWS Account: If you have an AWS account already, skip this step. If you are new to AWS, sign up for an AWS account.

Step 2 - API key: Go to the Amazon Bedrock console and generate a long-term API key.

Step 3 - Get the SDK: To use this getting started guide, you must have Python already installed. Then install the relevant software depending on the APIs you are using.

```
pip install boto3
```

Step 4 - Set environment variables: Configure your environment to use the API key for authentication.

```
AWS_BEARER_TOKEN_BEDROCK="<provide your Bedrock API key>"
```

Step 5 - Run your first inference request: Save the file as `bedrock-first-request.py`

Invoke API

```
import json
import boto3

client = boto3.client('bedrock-runtime', region_name='us-east-1')
response = client.invoke_model(
    modelId='meta.llama4-maverick-17b-instruct-v1:0',
    body=json.dumps({
            'messages': [{ 'role': 'user', 'content': 'Can you explain the features
 of Amazon Bedrock?'}],
            'max_tokens': 1024
    })
)
print(json.loads(response['body'].read()))
```

Converse API

```
import boto3

client = boto3.client('bedrock-runtime', region_name='us-east-1')
response = client.converse(
    modelId='meta.llama4-maverick-17b-instruct-v1:0',
    messages=[
        {
            'role': 'user',
            'content': [{'text': 'Can you explain the features of Amazon Bedrock?'}]
        }
    ]
)
print(response)
```

Llama 4 Scout 17B Instruct

Meta — Llama 4 Scout 17B Instruct

Model Details

Llama 4 Scout is Meta's 17-billion active parameter mixture-of-experts model with 16 experts and a 10M token context window for long-document tasks. For more information about model development and performance, see the model/service card.

Model launch date: Apr 05, 2025
EOL no sooner than: Apr 05, 2026

Llama 3.2 11B Instruct

Meta — Llama 3.2 11B Instruct

Model Details

> **Important**
>
> Llama 3.2 11B Instruct reached end of life on July 7, 2026 and is no longer available. Requests to this model fail with `ResourceNotFoundException: This model version has reached the end of its life.` For models that are currently available, see Models at a glance. For how model lifecycle stages work, see Model lifecycle.

Llama 3.2 11B Instruct is Meta's 11-billion parameter multimodal model that processes both text and images with a 128K context window. For more information about model development and performance, see the model/service card.

Model launch date: Sep 25, 2024
EOL no sooner than: Sep 25, 2025
Legacy period: at least 6 months
Model lifecycle policy: Model lifecycle (For Models Launched Prior to Sept 7 2026)
Model EOL date: July 7, 2026
End User License Agreements and Terms of Use: View
Model lifecycle: EOL: 2026-07-07
Context window: 128K tokens
Max output tokens: 4K
Knowledge cutoff: Dec 2023

Input Modalities	Output Modalities	APIs supported	Endpoints supported
⊗ Audio	⊗ Embedding	⊗ `Responses`	⊙ `bedrock-runtime`

Input Modalities	Output Modalities	APIs supported	Endpoints supported
✓ Image	✗ Image	✗ `Chat Completions`	✗ `bedrock-mantle`
✗ Speech	✗ Speech	✓ `Invoke`	
✓ Text	✓ Text	✓ `Converse`	
✗ Video	✗ Video		

Tip

Whenever possible, we recommend using the `bedrock-runtime` endpoint for new applications. See the section called "Inference endpoints" for details.

Capabilities and Features

Bedrock Features

Features supported using `bedrock-runtime` endpoint

Supported	Not Supported
✓ Response streaming	✗ Intelligent prompt routing
✓ Guardrails	✗ Abuse detection
✓ Prompt management	✗ Prompt optimization
✓ Flows	✗ Count tokens
✓ Agents	✗ Knowledge base
	✗ Model evaluation
	✗ Structured outputs

Pricing

For pricing information, see the Amazon Bedrock Pricing page.

Programmatic Access

Use the following model IDs and endpoint URLs to access this model programmatically. For more information about the available APIs and endpoints, see APIs supported and Endpoints supported.

Endpoint	Model ID	In-Region endpoint URL	Geo inference ID	Global inference ID
bedrock-runtime	meta.llama3-2-11b-instruct-v1:0	https://bedrock-runtime.{region}.amazonaws.com	us.meta.llama3-2-11b-instruct-v1:0	Not supported

For example, if region is us-east-1 (N. Virginia), then the bedrock-runtime endpoint URL will be "https://bedrock-runtime.us-east-1.amazonaws.com" and for bedrock-mantle will be "https://bedrock-mantle.us-east-1.api.aws/v1".

Service Tiers

Amazon Bedrock offers multiple service tiers to match your workload requirements. **Standard** provides pay-per-token access with no commitment (set `"service_tier": "default"` or omit the field). **Priority** delivers the fastest response times for a price premium (set `"service_tier": "priority"`). **Flex** provides lower-cost access for flexible, non-time-sensitive workloads (set `"service_tier": "flex"`). **Reserved** provides dedicated throughput with a term commitment for predictable workloads; it is set at the account level rather than per request (contact your AWS account team to enable). For more information, see service tiers.

Standard	Priority	Flex	Reserved
✓	✗	✗	✗

Regional Availability

Regional availability at a glance

Amazon Bedrock offers three inference options: **In-Region** keeps requests within a single Region for strict compliance, **Geo Cross-Region** routes across Regions within a geography (such as US, EU,

and APAC) while respecting data residency, and **Global Cross-Region** routes anywhere worldwide when there are no residency constraints. Refer to the the section called "Regional availability by models" page for more details.

Region	In-Region	Geo	Global
`us-east-1` (N. Virginia)	⊗	✓	⊗
`us-east-2` (Ohio)	⊗	✓	⊗
`us-west-2` (Oregon)	⊗	✓	⊗

Geo inference details

Geo: US

Geo Inference ID: `us.meta.llama3-2-11b-instruct-v1:0`

Source Region	Destination Regions
us-east-1 (N. Virginia)	us-east-1 (N. Virginia), us-west-2 (Oregon)
us-east-2 (Ohio)	us-east-1 (N. Virginia), us-east-2 (Ohio), us-west-2 (Oregon)
us-west-2 (Oregon)	us-east-1 (N. Virginia), us-west-2 (Oregon)

Quotas and Limits

Your AWS account has default quotas to maintain the performance of the service and to ensure appropriate usage of Amazon Bedrock. The default quotas assigned to an account might be updated depending on regional factors, payment history, fraudulent usage, and/or approval of a quota increase request. For more information, see the section called "Quotas" documentation and see the limits for the model.

Sample Code

Step 1 - AWS Account: If you have an AWS account already, skip this step. If you are new to AWS, sign up for an AWS account.

Step 2 - API key: Go to the Amazon Bedrock console and generate a long-term API key.

Step 3 - Get the SDK: To use this getting started guide, you must have Python already installed. Then install the relevant software depending on the APIs you are using.

```
pip install boto3
```

Step 4 - Set environment variables: Configure your environment to use the API key for authentication.

```
AWS_BEARER_TOKEN_BEDROCK="<provide your Bedrock API key>"
```

Step 5 - Run your first inference request: Save the file as `bedrock-first-request.py`

Invoke API

```
import json
import boto3

client = boto3.client('bedrock-runtime', region_name='us-east-1')
response = client.invoke_model(
    modelId='meta.llama3-2-11b-instruct-v1:0',
    body=json.dumps({
            'messages': [{ 'role': 'user', 'content': 'Can you explain the features
 of Amazon Bedrock?'}],
            'max_tokens': 1024
    })
)
print(json.loads(response['body'].read()))
```

Converse API

```
import boto3

client = boto3.client('bedrock-runtime', region_name='us-east-1')
response = client.converse(
    modelId='meta.llama3-2-11b-instruct-v1:0',
    messages=[
        {
            'role': 'user',
            'content': [{'text': 'Can you explain the features of Amazon Bedrock?'}]
```

```
        }
    ]
)
print(response)
```

Llama 3.2 1B Instruct

Meta — Llama 3.2 1B Instruct

Model Details

> **Important**
>
> Llama 3.2 1B Instruct reached end of life on July 7, 2026 and is no longer available. Requests to this model fail with `ResourceNotFoundException: This model version has reached the end of its life.` For models that are currently available, see Models at a glance. For how model lifecycle stages work, see Model lifecycle.

Llama 3.2 1B Instruct is Meta's ultra-lightweight 1-billion parameter model optimized for on-device and edge deployment. For more information about model development and performance, see the model/service card.

Model launch date: Sep 25, 2024

EOL no sooner than: Sep 25, 2025

Legacy period: at least 6 months

Model lifecycle policy: Model lifecycle (For Models Launched Prior to Sept 7 2026)

Model EOL date: July 7, 2026

Model lifecycle: EOL: 2026-07-07

Context window: 128K tokens

Max output tokens: 4K

Knowledge cutoff: Dec 2023

Input Modalities	Output Modalities	APIs supported	Endpoints supported
⊗ Audio	⊗ Embedding	⊗ Responses	⊙ bedrock-runtime
⊗ Image	⊗ Image	⊗ Chat Completions	⊗ bedrock-mantle
⊗ Speech	⊗ Speech	⊗ Invoke	
⊙ Text	⊙ Text	⊙ Converse	
⊗ Video	⊗ Video		

Tip

Whenever possible, we recommend using the `bedrock-runtime` endpoint for new applications. See the section called "Inference endpoints" for details.

Capabilities and Features

Bedrock Features

Features supported using `bedrock-runtime` endpoint

Supported	Not Supported
⊙ Response streaming ⊙ Guardrails ⊙ Client-side tool calling ⊙ Prompt management ⊙ Flows ⊙ Agents	⊗ Intelligent prompt routing ⊗ Abuse detection ⊗ Prompt optimization ⊗ Count tokens ⊗ Knowledge base ⊗ Model evaluation ⊗ Structured outputs

Pricing

For pricing information, see the Amazon Bedrock Pricing page.

Programmatic Access

Use the following model IDs and endpoint URLs to access this model programmatically. For more information about the available APIs and endpoints, see APIs supported and Endpoints supported.

Endpoint	Model ID	In-Region endpoint URL	Geo inference ID	Global inference ID
bedrock-runtime	meta.llama3-1-405b-instruct-v1:0	https://bedrock-runtime.{region}.amazonaws.com	us.meta.llama3-1-405b-instruct-v1:0	Not supported

For example, if region is us-east-1 (N. Virginia), then the bedrock-runtime endpoint URL will be "https://bedrock-runtime.us-east-1.amazonaws.com" and for bedrock-mantle will be "https://bedrock-mantle.us-east-1.api.aws/v1".

Service Tiers

Amazon Bedrock offers multiple service tiers to match your workload requirements. **Standard** provides pay-per-token access with no commitment (set `"service_tier": "default"` or omit the field). **Priority** delivers the fastest response times for a price premium (set `"service_tier": "priority"`). **Flex** provides lower-cost access for flexible, non-time-sensitive workloads (set `"service_tier": "flex"`). **Reserved** provides dedicated throughput with a term commitment for predictable workloads; it is set at the account level rather than per request (contact your AWS account team to enable). For more information, see service tiers.

Standard	Priority	Flex	Reserved
✓	✗	✗	✗

Regional Availability

Regional availability at a glance

Amazon Bedrock offers three inference options: **In-Region** keeps requests within a single Region for strict compliance, **Geo Cross-Region** routes across Regions within a geography (such as US, EU, and APAC) while respecting data residency, and **Global Cross-Region** routes anywhere worldwide when there are no residency constraints. Refer to the the section called "Regional availability by models" page for more details.

Region	In-Region	Geo	Global
`us-east-2` (Ohio)	⊗	✓	⊗
`us-west-2` (Oregon)	✓	⊗	⊗

Geo inference details

Geo: US

Geo Inference ID: `us.meta.llama3-1-405b-instruct-v1:0`

Source Region	Destination Regions
us-east-2 (Ohio)	us-east-1 (N. Virginia), us-east-2 (Ohio), us-west-2 (Oregon)

Sample Code

Step 1 - AWS Account: If you have an AWS account already, skip this step. If you are new to AWS, sign up for an AWS account.

Step 2 - API key: Go to the Amazon Bedrock console and generate a long-term API key.

Step 3 - Get the SDK: To use this getting started guide, you must have Python already installed. Then install the relevant software depending on the APIs you are using.

```
pip install boto3
```

Step 4 - Set environment variables: Configure your environment to use the API key for authentication.

```
AWS_BEARER_TOKEN_BEDROCK="<provide your Bedrock API key>"
```

Step 5 - Run your first inference request: Save the file as `bedrock-first-request.py`

Converse API

```
import boto3

client = boto3.client('bedrock-runtime', region_name='us-east-1')
response = client.converse(
    modelId='meta.llama3-1-405b-instruct-v1:0',
    messages=[
        {
            'role': 'user',
            'content': [{'text': 'Can you explain the features of Amazon Bedrock?'}]
        }
    ]
)
print(response)
```

Llama 3.1 70B Instruct

Meta — Llama 3.1 70B Instruct

Model Details

Llama 3.1 70B Instruct is Meta's 70-billion parameter model with an extended 128K context window and support for tool use and code generation. For more information about model development and performance, see the model/service card.

Model launch date: Jul 23, 2024
EOL no sooner than: Jul 23, 2025
Legacy period: at least 6 months
Model lifecycle policy: Model lifecycle (For Models Launched Prior to Sept 7 2026)
Model EOL date: March 30, 2027

End User License Agreements and Terms of Use: View
Model lifecycle: Legacy
Context window: 128K tokens
Max output tokens: 4K
Knowledge cutoff: Dec 2023

Input Modalities	Output Modalities	APIs supported	Endpoints supported
⊗ Audio	⊗ Embedding	⊗ `Responses`	⊙ `bedrock-runtime`
⊗ Image	⊗ Image	⊗ `Chat Completions`	⊗ `bedrock-mantle`
⊗ Speech	⊗ Speech	⊙ `Invoke`	
⊙ Text	⊙ Text	⊙ `Converse`	
⊗ Video	⊗ Video		

Tip

Whenever possible, we recommend using the `bedrock-runtime` endpoint for new applications. See the section called "Inference endpoints" for details.

Capabilities and Features

Bedrock Features

Features supported using `bedrock-runtime` endpoint

Supported	Not Supported
⊙ Response streaming	⊗ Intelligent prompt routing
⊙ Guardrails	⊗ Abuse detection

Supported	Not Supported
Client-side tool calling Prompt management Flows Agents	Prompt optimization Count tokens Knowledge base Model evaluation Structured outputs Watermarking

Note

Tool use and response streaming are supported separately, but not together. A `ConverseStream` request that includes a `toolConfig` field fails with `This model doesn't support tool use in streaming mode.` Use the non-streaming `Converse` operation when you need tool use.

Pricing

For pricing information, see the Amazon Bedrock Pricing page.

Programmatic Access

Use the following model IDs and endpoint URLs to access this model programmatically. For more information about the available APIs and endpoints, see APIs supported and Endpoints supported.

Endpoint	Model ID	In-Region endpoint URL	Geo inference ID	Global inference ID
`bedrock-runtime`	`meta.llama3-1-70b-instruct-v1:0`	`https://bedrock-runtime.{region}.amazonaws.com`	`us.meta.llama3-1-70b-instruct-v1:0`	Not supported

For example, if region is us-east-1 (N. Virginia), then the bedrock-runtime endpoint URL will be "https://bedrock-runtime.us-east-1.amazonaws.com" and for bedrock-mantle will be "https://bedrock-mantle.us-east-1.api.aws/v1".

Service Tiers

Amazon Bedrock offers multiple service tiers to match your workload requirements. **Standard** provides pay-per-token access with no commitment (set `"service_tier": "default"` or omit the field). **Priority** delivers the fastest response times for a price premium (set `"service_tier": "priority"`). **Flex** provides lower-cost access for flexible, non-time-sensitive workloads (set `"service_tier": "flex"`). **Reserved** provides dedicated throughput with a term commitment for predictable workloads; it is set at the account level rather than per request (contact your AWS account team to enable). Geo inference details

Geo: US

Geo Inference ID: `us.meta.llama3-1-70b-instruct-v1:0`

Source Region	Destination Regions
us-east-1 (N. Virginia)	us-east-1 (N. Virginia), us-east-2 (Ohio), us-west-2 (Oregon)
us-east-2 (Ohio)	us-east-1 (N. Virginia), us-east-2 (Ohio), us-west-2 (Oregon)
us-west-2 (Oregon)	us-east-1 (N. Virginia), us-east-2 (Ohio), us-west-2 (Oregon)

Quotas and Limits

Your AWS account has default quotas to maintain the performance of the service and to ensure appropriate usage of Amazon Bedrock. The default quotas assigned to an account might be updated depending on regional factors, payment history, fraudulent usage, and/or approval of a quota increase request. For more information, see the section called "Quotas" documentation and see the limits for the model.

Sample Code

Step 1 - AWS Account: If you have an AWS account already, skip this step. If you are new to AWS, sign up for an AWS account.

Step 2 - API key: Go to the Amazon Bedrock console and generate a long-term API key.

Step 3 - Get the SDK: To use this getting started guide, you must have Python already installed. Then install the relevant software depending on the APIs you are using.

```
pip install boto3
```

Step 4 - Set environment variables: Configure your environment to use the API key for authentication.

```
AWS_BEARER_TOKEN_BEDROCK="<provide your Bedrock API key>"
```

Step 5 - Run your first inference request: Save the file as `bedrock-first-request.py`

Invoke API

```
import json
import boto3

client = boto3.client('bedrock-runtime', region_name='us-east-1')
response = client.invoke_model(
    modelId='meta.llama3-1-70b-instruct-v1:0',
    body=json.dumps({
            'messages': [{ 'role': 'user', 'content': 'Can you explain the features
 of Amazon Bedrock?'}],
            'max_tokens': 1024
    })
)
print(json.loads(response['body'].read()))
```

Converse API

```
import boto3

client = boto3.client('bedrock-runtime', region_name='us-east-1')
response = client.converse(
    modelId='meta.llama3-1-70b-instruct-v1:0',
    messages=[
        {
            'role': 'user',
            'content': [{'text': 'Can you explain the features of Amazon Bedrock?'}]
        }
    ]
)
print(response)
```

Llama 3.1 8B Instruct

Meta — Llama 3.1 8B Instruct

Model Details

Llama 3.1 8B Instruct is Meta's compact 8-billion parameter model with a 128K context window, suitable for edge deployment and fine-tuning. For more information about model development and performance, see the model/service card.

Model launch date: Jul 23, 2024
EOL no sooner than: Jul 23, 2025
Legacy period: at least 6 months
Model lifecycle policy: Model lifecycle (For Models Launched Prior to Sept 7 2026)
Model EOL date: March 30, 2027
End User License Agreements and Terms of Use: View
Model lifecycle: Legacy
Context window: 128K tokens
Max output tokens: 4K

Quotas and Limits

Your AWS account has default quotas to maintain the performance of the service and to ensure appropriate usage of Amazon Bedrock. The default quotas assigned to an account might be updated depending on regional factors, payment history, fraudulent usage, and/or approval of a quota increase request. For more information, see the section called "Quotas" documentation and see the limits for the model.

Sample Code

Step 1 - AWS Account: If you have an AWS account already, skip this step. If you are new to AWS, sign up for an AWS account.

Step 2 - API key: Go to the Amazon Bedrock console and generate a long-term API key.

Step 3 - Get the SDK: To use this getting started guide, you must have Python already installed. Then install the relevant software depending on the APIs you are using.

```
pip install boto3
```

Step 4 - Set environment variables: Configure your environment to use the API key for authentication.

```
AWS_BEARER_TOKEN_BEDROCK="<provide your Bedrock API key>"
```

Step 5 - Run your first inference request: Save the file as `bedrock-first-request.py`

Invoke API

```
import json
import boto3
```

```
client = boto3.client('bedrock-runtime', region_name='us-east-1')
response = client.invoke_model(
    modelId='meta.llama3-8b-instruct-v1:0',
    body=json.dumps({
            'messages': [{ 'role': 'user', 'content': 'Can you explain the features
 of Amazon Bedrock?'}],
            'max_tokens': 1024
    })
)
print(json.loads(response['body'].read()))
```

Converse API

```
import boto3

client = boto3.client('bedrock-runtime', region_name='us-east-1')
response = client.converse(
    modelId='meta.llama3-8b-instruct-v1:0',
    messages=[
        {
            'role': 'user',
            'content': [{'text': 'Can you explain the features of Amazon Bedrock?'}]
        }
    ]
)
print(response)
```

MiniMax

The following MiniMax models are available in Amazon Bedrock:

Model	Description
the section called “MiniMax M2”	MiniMax M2 is MiniMax's large language model with strong multilingual capabilities and solid performance on reasoning and coding benchmarks.
the section called “MiniMax M2.1”	MiniMax M2.1 is MiniMax's updated model with improved reasoning, coding, and instruction following over M2.

Model	Description
the section called "MiniMax M2.5"	MiniMax M2.5 is an agent-native frontier model trained to reason efficiently, decompose tasks optimally, and complete complex workflows under real-world time and cost constraints.

MiniMax M2

MiniMax — MiniMax M2

Model Details

MiniMax M2 is MiniMax's large language model with strong multilingual capabilities and solid performance on reasoning and coding benchmarks. For more information about model development and performance, see the model/service card.

Model launch date: Oct 23, 2025
EOL no sooner than: Oct 23, 2026
Legacy period: at least 6 months
Model lifecycle policy: Model lifecycle (For Models Launched Prior to Sept 7 2026)
Model EOL date: March 30, 2027
End User License Agreements and Terms of Use: View
Model lifecycle: Legacy
Context window: 1M tokens
Max output tokens: 8K

Pricing

For pricing information, see the Amazon Bedrock Pricing page.

Programmatic Access

Use the following model IDs and endpoint URLs to access this model programmatically. For more information about the available APIs and endpoints, see APIs supported and Endpoints supported.

Endpoint	Model ID	In-Region endpoint URL	Geo inference ID	Global inference ID
bedrock-runtime	minimax.minimax-m2	https://bedrock-runtime.{region}.amazonaws.com	Not supported	Not supported
bedrock-mantle	minimax.minimax-m2	https://bedrock-mantle.{region}.api.aws/v1	Not supported	Not supported

For example, if region is us-east-1 (N. Virginia), then the bedrock-runtime endpoint URL will be "https://bedrock-runtime.us-east-1.amazonaws.com" and for bedrock-mantle will be "https://bedrock-mantle.us-east-1.api.aws/v1".

Service Tiers

Amazon Bedrock offers multiple service tiers to match your workload requirements. **Standard** provides pay-per-token access with no commitment (set `"service_tier": "default"` or omit the field). **Priority** delivers the fastest response times for a price premium (set `"service_tier": "priority"`). **Flex** provides lower-cost access for flexible, non-time-sensitive workloads (set `"service_tier": "flex"`). **Reserved** provides dedicated throughput with a term commitment for predictable workloads; it is set at the account level rather than per request (contact your AWS account team to enable). For more information, see service tiers.

Standard	Priority	Flex	Reserved
✓	✓	✓	✗

Regional Availability

Regional availability at a glance

Amazon Bedrock offers three inference options: **In-Region** keeps requests within a single Region for strict compliance, **Geo Cross-Region** routes across Regions within a geography (such as US, EU, and APAC) while respecting data residency, and **Global Cross-Region** routes anywhere worldwide when there are no residency constraints. Refer to the the section called "Regional availability by models" page for more details.

Region	In-Region	Geo	Global
`us-east-1` (N. Virginia)	✓	✗	✗
`us-east-2` (Ohio)	✓	✗	✗

Quotas and Limits

Your AWS account has default quotas to maintain the performance of the service and to ensure appropriate usage of Amazon Bedrock. The default quotas assigned to an account might be updated depending on regional factors, payment history, fraudulent usage, and/or approval of a quota increase request. For more information, see the section called "Quotas" documentation and see the limits for the model.

Sample Code

Step 1 - AWS Account: If you have an AWS account already, skip this step. If you are new to AWS, sign up for an AWS account.

Step 2 - API key: Go to the Amazon Bedrock console and generate a long-term API key.

Step 3 - Get the SDK: To use this getting started guide, you must have Python already installed. Then install the relevant software depending on the APIs you are using.

Chat Completions API

```
pip install boto3 openai
```

Invoke/Converse API

```
pip install boto3
```

Step 4 - Set environment variables: Configure your environment to use the API key for authentication.

Chat Completions API

```
OPENAI_API_KEY="<provide your Bedrock API key>"
OPENAI_BASE_URL="https://bedrock-runtime.<your-region>.amazonaws.com/openai/v1"
```

Invoke/Converse API

```
AWS_BEARER_TOKEN_BEDROCK="<provide your Bedrock API key>"
```

Step 5 - Run your first inference request: Save the file as `bedrock-first-request.py`

Chat Completions API

```
from openai import OpenAI

client = OpenAI()

response = client.chat.completions.create(
    model="minimax.minimax-m2",
    messages=[{"role": "user", "content": "Can you explain the features of Amazon
 Bedrock?"}]
    )
print(response)
```

Invoke API

```
import json
import boto3

client = boto3.client('bedrock-runtime', region_name='us-east-1')
response = client.invoke_model(
    modelId='minimax.minimax-m2',
    body=json.dumps({
            'messages': [{ 'role': 'user', 'content': 'Can you explain the features
 of Amazon Bedrock?'}],
            'max_tokens': 1024
    })
)
print(json.loads(response['body'].read()))
```

Converse API

```
import boto3

client = boto3.client('bedrock-runtime', region_name='us-east-1')
response = client.converse(
    modelId='minimax.minimax-m2',
    messages=[
        {
            'role': 'user',
            'content': [{'text': 'Can you explain the features of Amazon Bedrock?'}]
        }
    ]
)
print(response)
```

MiniMax M2.1

MiniMax — MiniMax M2.1

Model Details

MiniMax M2.1 is MiniMax's updated model with improved reasoning, coding, and instruction following over M2. For more information about model development and performance, see the model/service card.

MiniMax M2.5

MiniMax — MiniMax M2.5

Model Details

MiniMax M2.5 is an agent-native frontier model trained explicitly to reason efficiently, decompose tasks optimally, and complete complex workflows under real-world time and cost constraints. It achieves task completion speeds comparable to or faster than leading proprietary frontier models by combining high inference throughput with reinforcement learning focused on token-efficient

reasoning and better decision-making in agentic scaffolds. For more information about model development and performance, see the model/service card.

Model launch date: Feb 12, 2026

Mistral AI

The following Mistral AI models are available in Amazon Bedrock:

Model	Description
the section called “Mistral Small”	Mistral Small is Mistral AI's cost-efficient model optimized for low-latency tasks like classification, translation, and customer support.
the section called “Ministral 14B 3.0”	Ministral 14B 3.0 is Mistral AI's 14-billion parameter edge model optimized for on-device deployment with strong performance on knowledge and reasoning tasks.
the section called “Ministral 3 8B”	Ministral 3 8B is Mistral AI's 8-billion parameter compact model for edge and mobile deployment with efficient inference.
the section called “Ministral 3B”	Ministral 3B is Mistral AI's ultra-compact 3-billion parameter model for on-device tasks requiring minimal compute.
the section called “Mistral Large 3”	Mistral Large 3 is Mistral AI's 675-billion parameter model with strong performance on coding, reasoning, and multilingual tasks.
the section called “Voxtral Small 24B 2507”	Voxtral Small 24B is Mistral AI's speech-to-text model with 24 billion parameters for high-accuracy transcription and voice understanding.
the section called “Magistral Small 2509”	Magistral Small 2509 is Mistral AI's reasoning model that uses chain-of-thought to solve complex math, coding, and logic problems.
the section called “Voxtral Mini 3B 2507”	Voxtral Mini 3B is Mistral AI's compact speech-to-text model for real-time transcription and voice understanding on edge devices.
the section called “Devstral 2 123B”	Devstral 2 123B is Mistral AI's 123-billion parameter coding model optimized for software engineering tasks including code generation, debugging, and refactoring.

Model	Description
the section called "Pixtral Large"	Pixtral Large is Mistral AI's 124-billion parameter multimodal model that processes text and images for visual reasoning and document understanding.
the section called "Mistral Large"	Mistral Large is Mistral AI's flagship model with strong reasoning, multilingual support, and a 32K context window for complex enterprise tasks.
the section called "Mixtral 8x7B Instruct"	Mixtral 8x7B Instruct is Mistral AI's sparse mixture-of-experts model with 8 experts and 7B parameters each, delivering strong performance at faster inference speeds.
the section called "Mistral 7B Instruct"	Mistral 7B Instruct is Mistral AI's 7-billion parameter instruction-tuned model with grouped-query attention and sliding window attention for efficient long-context inference.

Mistral Small

Mistral AI — Mistral Small

Model Details

Mistral Small is Mistral AI's cost-efficient model optimized for low-latency tasks like classification, translation, and customer support. For more information about model development and performance, see the model/service card.

Ministral 14B 3.0

Mistral AI — Ministral 14B 3.0

Model Details

Ministral 14B 3.0 is Mistral AI's 14-billion parameter edge model optimized for on-device deployment with strong performance on knowledge and reasoning tasks. For more information about model development and performance, see the model/service card.

Model launch date: Dec 2, 2025
EOL no sooner than: Dec 2, 2026
Legacy period: at least 6 months
Model lifecycle policy: Model lifecycle (For Models Launched Prior to Sept 7 2026)
Model EOL date: N/A
End User License Agreements and Terms of Use: View
Model lifecycle: Active
Context window: 128K tokens
Max output tokens: 8K

Input Modalities	Output Modalities	APIs supported	Endpoints supported

Structured outputs	

Pricing

For pricing information, see the Amazon Bedrock Pricing page.

Programmatic Access

Use the following model IDs and endpoint URLs to access this model programmatically. For more information about the available APIs and endpoints, see APIs supported and Endpoints supported.

Endpoint	Model ID	In-Region endpoint URL	Geo inference ID	Global inference ID
bedrock-runtime	mistral.ministral-3-14b-instruct	https://bedrock-runtime.{region}.amazonaws.com	Not supported	Not supported
bedrock-mantle	mistral.ministral-3-14b-instruct	https://bedrock-mantle.{region}.api.aws/v1	Not supported	Not supported

For example, if region is us-east-1 (N. Virginia), then the bedrock-runtime endpoint URL will be "https://bedrock-runtime.us-east-1.amazonaws.com" and for bedrock-mantle will be "https://bedrock-mantle.us-east-1.api.aws/v1".

Service Tiers

Amazon Bedrock offers multiple service tiers to match your workload requirements. **Standard** provides pay-per-token access with no commitment (set `"service_tier": "default"` or omit the field). **Priority** delivers the fastest response times for a price premium (set `"service_tier": "priority"`). **Flex** provides lower-cost access for flexible, non-time-sensitive workloads (set `"service_tier": "flex"`). **Reserved** provides dedicated throughput with a term commitment for predictable workloads; it is set at the account level rather than per request (contact your AWS account team to enable). For more information, see service tiers.

Standard	Priority	Flex	Reserved
✓	✓	✓	✗

Regional Availability

Regional availability at a glance

Amazon Bedrock offers three inference options: **In-Region** keeps requests within a single Region for strict compliance, **Geo Cross-Region** routes across Regions within a geography (such as US, EU,

and APAC) while respecting data residency, and **Global Cross-Region** routes anywhere worldwide when there are no residency constraints. Refer to the the section called “Regional availability by models” page for more details.

Region	In-Region	Geo	Global
`us-east-1` (N. Virginia)	✓	✗	✗
`us-east-2` (Ohio)	✓	✗	✗
`us-west-2` (Oregon)	✓	✗	✗
`eu-south-1` (Milan)	✓	✗	✗
`eu-west-1` (Ireland)	✓	✗	✗
`eu-west-2` (London)	✓	✗	✗
`ap-northeast-1` (Tokyo)	✓	✗	✗
`ap-south-1` (Mumbai)	✓	✗	✗
`ap-southeast-2` (Sydney)	✓	✗	✗
`sa-east-1` (São Paulo)	✓	✗	✗
`ap-southeast-3` (Jakarta)	✓	✗	✗
`ap-southeast-4` (Melbourne)	✓	✗	✗
`ap-northeast-2` (Seoul)	✓	✗	✗
`ap-southeast-1` (Singapore)	✓	✗	✗
`eu-central-1` (Frankfurt)	✓	✗	✗
`eu-north-1` (Stockholm)	✓	✗	✗

Quotas and Limits

Your AWS account has default quotas to maintain the performance of the service and to ensure appropriate usage of Amazon Bedrock. The default quotas assigned to an account might be updated depending on regional factors, payment history, fraudulent usage, and/or approval of a quota increase request. For more information, see the section called "Quotas" documentation and see the limits for the model.

Sample Code

Step 1 - AWS Account: If you have an AWS account already, skip this step. If you are new to AWS, sign up for an AWS account.

Step 2 - API key: Go to the Amazon Bedrock console and generate a long-term API key.

Step 3 - Get the SDK: To use this getting started guide, you must have Python already installed. Then install the relevant software depending on the APIs you are using.

Chat Completions API

```
pip install boto3 openai
```

Invoke/Converse API

```
pip install boto3
```

Step 4 - Set environment variables: Configure your environment to use the API key for authentication.

Chat Completions API

```
OPENAI_API_KEY="<provide your Bedrock API key>"
OPENAI_BASE_URL="https://bedrock-runtime.<your-region>.amazonaws.com/openai/v1"
```

Invoke/Converse API

```
AWS_BEARER_TOKEN_BEDROCK="<provide your Bedrock API key>"
```

Step 5 - Run your first inference request: Save the file as `bedrock-first-request.py`

Chat Completions API

```
from openai import OpenAI

client = OpenAI()

response = client.chat.completions.create(
    model="mistral.ministral-3-14b-instruct",
    messages=[{"role": "user", "content": "Can you explain the features of Amazon
 Bedrock?"}]
    )
print(response)
```

Invoke API

```
import json
import boto3

client = boto3.client('bedrock-runtime', region_name='us-east-1')
response = client.invoke_model(
    modelId='mistral.ministral-3-14b-instruct',
    body=json.dumps({
            'messages': [{ 'role': 'user', 'content': 'Can you explain the features
 of Amazon Bedrock?'}],
            'max_tokens': 1024
    })
)
print(json.loads(response['body'].read()))
```

Converse API

```
import boto3

client = boto3.client('bedrock-runtime', region_name='us-east-1')
response = client.converse(
    modelId='mistral.ministral-3-14b-instruct',
    messages=[
        {
            'role': 'user',
            'content': [{'text': 'Can you explain the features of Amazon Bedrock?'}]
        }
    ]
)
```

```
print(response)
```

Ministral 3 8B

Mistral AI — Ministral 3 8B

Model Details

Ministral 3 8B is Mistral AI's 8-billion parameter compact model for edge and mobile deployment with efficient inference. For more information about model development and performance, see the model/service card.

Model launch date: Dec 02, 2025
EOL no sooner than: Dec 02, 2026
Legacy period: at least 6 months
Model lifecycle policy: Model lifecycle (For Models Launched Prior to Sept 7 2026)
Model EOL date: N/A
End User License Agreements and Terms of Use: View
Model lifecycle: Active
Context window: 128K tokens
Max output tokens: 8K

Voxtral Small 24B 2507

Mistral AI — Voxtral Small 24B 2507

Model Details

Voxtral Small 24B is Mistral AI's speech-to-text model with 24 billion parameters for high-accuracy transcription and voice understanding. For more information about model development and performance, see the model/service card.

Model launch date: Oct 30, 2025
EOL no sooner than: Oct 30, 2026
Legacy period: at least 6 months
Model lifecycle policy: Model lifecycle (For Models Launched Prior to Sept 7 2026)
Model EOL date: March 30, 2027
End User License Agreements and Terms of Use: View
Model lifecycle: Legacy
Context window: 32K tokens

Input Modalities	Output Modalities	APIs supported	Endpoints supported
⊗ Audio	⊗ Embedding	⊗ `Responses`	⊙ `bedrock-runtime`

> **Tip**
>
> Whenever possible, we recommend using the `bedrock-runtime` endpoint for new applications. See the section called "Inference endpoints" for details.

Capabilities and Features

Bedrock Features

Features supported using `bedrock-mantle` endpoint

Supported	Not Supported
Projects Client-side tool calling	Server-side tool calling Watermarking

Features supported using `bedrock-runtime` endpoint

Supported	Not Supported
Response streaming Guardrails Model evaluation Prompt management Flows Agents Structured outputs	Intelligent prompt routing Abuse detection Prompt optimization Count tokens Knowledge base Watermarking

Pricing

For pricing information, see the Amazon Bedrock Pricing page.

Programmatic Access

Use the following model IDs and endpoint URLs to access this model programmatically. For more information about the available APIs and endpoints, see APIs supported and Endpoints supported.

Endpoint	Model ID	In-Region endpoint URL	Geo inference ID	Global inference ID
bedrock-runtime	mistral.voxtral-small-24b-2507	https://bedrock-runtime.{region}.amazonaws.com	Not supported	Not supported
bedrock-mantle	mistral.voxtral-small-24b-2507	https://bedrock-mantle.{region}.api.aws/v1	Not supported	Not supported

For example, if region is us-east-1 (N. Virginia), then the bedrock-runtime endpoint URL will be "https://bedrock-runtime.us-east-1.amazonaws.com" and for bedrock-mantle will be "https://bedrock-mantle.us-east-1.api.aws/v1".

Service Tiers

Amazon Bedrock offers multiple service tiers to match your workload requirements. **Standard** provides pay-per-token access with no commitment (set `"service_tier": "default"` or omit the field). **Priority** delivers the fastest response times for a price premium (set `"service_tier": "priority"`). **Flex** provides lower-cost access for flexible, non-time-sensitive workloads (set `"service_tier": "flex"`). **Reserved** provides dedicated throughput with a term commitment for predictable workloads; it is set at the account level rather than per request (contact your AWS account team to enable). For more information, see service tiers.

Standard	Priority	Flex	Reserved
✓	✓	✓	✗

Regional Availability

Regional availability at a glance

Amazon Bedrock offers three inference options: **In-Region** keeps requests within a single Region for strict compliance, **Geo Cross-Region** routes across Regions within a geography (such as US, EU,

and APAC) while respecting data residency, and **Global Cross-Region** routes anywhere worldwide when there are no residency constraints. Refer to the the section called "Regional availability by models" page for more details.

Region	In-Region	Geo	Global
us-east-1 (N. Virginia)	✓	✗	✗
us-east-2 (Ohio)	✓	✗	✗
us-west-2 (Oregon)	✓	✗	✗
eu-south-1 (Milan)	✓	✗	✗
eu-west-1 (Ireland)	✓	✗	✗
eu-west-2 (London)	✓	✗	✗
ap-northeast-1 (Tokyo)	✓	✗	✗
ap-south-1 (Mumbai)	✓	✗	✗
ap-southeast-2 (Sydney)	✓	✗	✗
sa-east-1 (São Paulo)	✓	✗	✗
ap-southeast-3 (Jakarta)	✓	✗	✗
ap-southeast-4 (Melbourne)	✓	✗	✗
ap-northeast-2 (Seoul)	✓	✗	✗
ap-southeast-1 (Singapore)	✓	✗	✗
eu-central-1 (Frankfurt)	✓	✗	✗
eu-north-1 (Stockholm)	✓	✗	✗

Quotas and Limits

Your AWS account has default quotas to maintain the performance of the service and to ensure appropriate usage of Amazon Bedrock. The default quotas assigned to an account might be updated depending on regional factors, payment history, fraudulent usage, and/or approval of a quota increase request. For more information, see the section called "Quotas" documentation and see the limits for the model.

Sample Code

Step 1 - AWS Account: If you have an AWS account already, skip this step. If you are new to AWS, sign up for an AWS account.

Step 2 - API key: Go to the Amazon Bedrock console and generate a long-term API key.

Step 3 - Get the SDK: To use this getting started guide, you must have Python already installed. Then install the relevant software depending on the APIs you are using.

Responses/Chat Completions API

```
pip install boto3 openai
```

Invoke/Converse API

```
pip install boto3
```

Step 4 - Set environment variables: Configure your environment to use the API key for authentication.

Responses/Chat Completions API

```
OPENAI_API_KEY="<provide your Bedrock API key>"
OPENAI_BASE_URL="https://bedrock-runtime.<your-region>.amazonaws.com/openai/v1"
```

Invoke/Converse API

```
AWS_BEARER_TOKEN_BEDROCK="<provide your Bedrock API key>"
```

Step 5 - Run your first inference request: Save the file as `bedrock-first-request.py`

Responses API

```
from openai import OpenAI

client = OpenAI()

response = client.responses.create(
    model="mistral.voxtral-small-24b-2507",
    input="Can you explain the features of Amazon Bedrock?"
    )
print(response)
```

Chat Completions API

```
from openai import OpenAI

client = OpenAI()

response = client.chat.completions.create(
    model="mistral.voxtral-small-24b-2507",
    messages=[{"role": "user", "content": "Can you explain the features of Amazon
 Bedrock?"}]
    )
print(response)
```

Invoke API

```
import json
import boto3

client = boto3.client('bedrock-runtime', region_name='us-east-1')
response = client.invoke_model(
    modelId='mistral.voxtral-small-24b-2507',
    body=json.dumps({
            'messages': [{ 'role': 'user', 'content': 'Can you explain the features
 of Amazon Bedrock?'}],
            'max_tokens': 1024
    })
)
print(json.loads(response['body'].read()))
```

Converse API

```
import boto3

client = boto3.client('bedrock-runtime', region_name='us-east-1')
response = client.converse(
    modelId='mistral.voxtral-small-24b-2507',
    messages=[
        {
            'role': 'user',
            'content': [{'text': 'Can you explain the features of Amazon Bedrock?'}]
        }
    ]
)
print(response)
```

Magistral Small 2509

Mistral AI — Magistral Small 2509

Model Details

Magistral Small 2509 is Mistral AI's reasoning model that uses chain-of-thought to solve complex math, coding, and logic problems. For more information about model development and performance, see the model/service card.

Model launch date: Sep 2025
EOL no sooner than: Sep 2026
Legacy period: at least 6 months
Model lifecycle policy: Model lifecycle (For Models Launched Prior to Sept 7 2026)
Model EOL date: N/A
End User License Agreements and Terms of Use: View
Model lifecycle: Active
Context window: 128K tokens
Max output tokens: 40K
Reasoning: Supported

Mistral AI — Pixtral Large

Model Details

Pixtral Large is Mistral AI's 124-billion parameter multimodal model that processes text and images for visual reasoning and document understanding. For more information about model development and performance, see the model/service card.

Model launch date: Nov 19, 2024
EOL no sooner than: Nov 19, 2025
Legacy period: at least 6 months
Model lifecycle policy: Model lifecycle (For Models Launched Prior to Sept 7 2026)
Model EOL date: No sooner than 4/8/2026
End User License Agreements and Terms of Use: View
Model lifecycle: Active
Context window: 128K tokens
Max output tokens: 16K

Input Modalities	Output Modalities	APIs supported	Endpoints supported
⊗ Audio	⊗ Embedding	⊗ Responses	⊙ bedrock-runtime
⊙ Image	⊗ Image	⊗ Chat Completions	⊗ bedrock-mantle
⊗ Speech	⊗ Speech	⊙ Invoke	
⊙ Text	⊙ Text	⊙ Converse	
⊗ Video	⊗ Video		

> **Tip**
>
> Whenever possible, we recommend using the `bedrock-runtime` endpoint for new applications. See the section called "Inference endpoints" for details.

Capabilities and Features

Bedrock Features

Features supported using `bedrock-runtime` endpoint

Supported	Not Supported
Response streaming Guardrails Client-side tool calling Prompt management Flows Agents	Intelligent prompt routing Abuse detection Prompt optimization Count tokens Knowledge base Model evaluation Structured outputs Watermarking

Pricing

For pricing information, see the Amazon Bedrock Pricing page.

Programmatic Access

Use the following model IDs and endpoint URLs to access this model programmatically. For more information about the available APIs and endpoints, see APIs supported and Endpoints supported.

Endpoint	Model ID	In-Region endpoint URL	Geo inference ID	Global inference ID
bedrock-runtime	mistral.pixtral-la	https://bedrock-runtime.{re	us.mistral.pixtral-	Not supported

Endpoint	Model ID	In-Region endpoint URL	Geo inference ID	Global inference ID
	rge-2502-v1:0	gion}.amazonaws.com	large-2502-v1:0 eu.mistral.pixtral-large-2502-v1:0	

For example, if region is us-east-1 (N. Virginia), then the bedrock-runtime endpoint URL will be "https://bedrock-runtime.us-east-1.amazonaws.com" and for bedrock-mantle will be "https://bedrock-mantle.us-east-1.api.aws/v1".

Service Tiers

Amazon Bedrock offers multiple service tiers to match your workload requirements. **Standard** provides pay-per-token access with no commitment (set `"service_tier": "default"` or omit the field). **Priority** delivers the fastest response times for a price premium (set `"service_tier": "priority"`). **Flex** provides lower-cost access for flexible, non-time-sensitive workloads (set `"service_tier": "flex"`). **Reserved** provides dedicated throughput with a term commitment for predictable workloads; it is set at the account level rather than per request (contact your AWS account team to enable). For more information, see service tiers.

Standard	Priority	Flex	Reserved
✓	✓	✓	✗

Regional Availability

Regional availability at a glance

Amazon Bedrock offers three inference options: **In-Region** keeps requests within a single Region for strict compliance, **Geo Cross-Region** routes across Regions within a geography (such as US, EU, and APAC) while respecting data residency, and **Global Cross-Region** routes anywhere worldwide

when there are no residency constraints. Refer to the the section called "Regional availability by models" page for more details.

Region	In-Region	Geo	Global
us-east-1 (N. Virginia)	⊗	✓	⊗
us-east-2 (Ohio)	⊗	✓	⊗
us-west-2 (Oregon)	⊗	✓	⊗
eu-central-1 (Frankfurt)	⊗	✓	⊗
eu-north-1 (Stockholm)	⊗	✓	⊗
eu-west-1 (Ireland)	⊗	✓	⊗
eu-west-3 (Paris)	⊗	✓	⊗

Geo inference details

Geo: US

Geo Inference ID: `us.mistral.pixtral-large-2502-v1:0`

Source Region	Destination Regions
us-east-1 (N. Virginia)	us-east-1 (N. Virginia), us-east-2 (Ohio), us-west-2 (Oregon)
us-east-2 (Ohio)	us-east-1 (N. Virginia), us-east-2 (Ohio), us-west-2 (Oregon)
us-west-2 (Oregon)	us-east-1 (N. Virginia), us-east-2 (Ohio), us-west-2 (Oregon)

Geo: EU

Geo Inference ID: `eu.mistral.pixtral-large-2502-v1:0`

Source Region	Destination Regions
eu-central-1 (Frankfurt)	eu-central-1 (Frankfurt), eu-north-1 (Stockholm), eu-west-1 (Ireland), eu-west-3 (Paris)
eu-north-1 (Stockholm)	eu-central-1 (Frankfurt), eu-north-1 (Stockholm), eu-west-1 (Ireland), eu-west-3 (Paris)
eu-west-1 (Ireland)	eu-central-1 (Frankfurt), eu-north-1 (Stockholm), eu-west-1 (Ireland), eu-west-3 (Paris)
eu-west-3 (Paris)	eu-central-1 (Frankfurt), eu-north-1 (Stockholm), eu-west-1 (Ireland), eu-west-3 (Paris)

Quotas and Limits

Your AWS account has default quotas to maintain the performance of the service and to ensure appropriate usage of Amazon Bedrock. The default quotas assigned to an account might be updated depending on regional factors, payment history, fraudulent usage, and/or approval of a quota increase request. For more information, see the section called “Quotas” documentation and see the limits for the model.

Sample Code

Step 1 - AWS Account: If you have an AWS account already, skip this step. If you are new to AWS, sign up for an AWS account.

Step 2 - API key: Go to the Amazon Bedrock console and generate a long-term API key.

Step 3 - Get the SDK: To use this getting started guide, you must have Python already installed. Then install the relevant software depending on the APIs you are using.

```
pip install boto3
```

Step 4 - Set environment variables: Configure your environment to use the API key for authentication.

```
AWS_BEARER_TOKEN_BEDROCK="<provide your Bedrock API key>"
```

Step 5 - Run your first inference request: Save the file as `bedrock-first-request.py`

Invoke API

```
import json
import boto3

client = boto3.client('bedrock-runtime', region_name='us-east-1')
response = client.invoke_model(
    modelId='mistral.pixtral-large-2502-v1:0',
    body=json.dumps({
            'messages': [{ 'role': 'user', 'content': 'Can you explain the features
 of Amazon Bedrock?'}],
            'max_tokens': 1024
    })
)
print(json.loads(response['body'].read()))
```

Converse API

```
import boto3

client = boto3.client('bedrock-runtime', region_name='us-east-1')
response = client.converse(
    modelId='mistral.pixtral-large-2502-v1:0',
    messages=[
        {
            'role': 'user',
            'content': [{'text': 'Can you explain the features of Amazon Bedrock?'}]
        }
    ]
)
print(response)
```

Mistral Large

Mistral AI — Mistral Large

Model Details

Mistral Large is Mistral AI's flagship model with strong reasoning, multilingual support, and a 32K context window for complex enterprise tasks. For more information about model development and performance, see the model/service card.

Model launch date: Feb 26, 2024
EOL no sooner than: Feb 26, 2025
Legacy period: at least 6 months
Model lifecycle policy: Model lifecycle (For Models Launched Prior to Sept 7 2026)
Model EOL date: No sooner than 4/3/2025
End User License Agreements and Terms of Use: View
Model lifecycle: Active
Context window: 32K tokens
Max output tokens: 4K

Input Modalities	Output Modalities	APIs supported	Endpoints supported
⊗ Audio	⊗ Embedding	⊗ Responses	⊙ bedrock-runtime
⊗ Image	⊗ Image	⊗ Chat Completions	⊗ bedrock-mantle
⊗ Speech	⊗ Speech	⊙ Invoke

Quotas and Limits

Your AWS account has default quotas to maintain the performance of the service and to ensure appropriate usage of Amazon Bedrock. The default quotas assigned to an account might be updated depending on regional factors, payment history, fraudulent usage, and/or approval of a quota increase request. For more information, see the section called "Quotas" documentation and see the limits for the model.

Sample Code

Step 1 - AWS Account: If you have an AWS account already, skip this step. If you are new to AWS, sign up for an AWS account.

Step 2 - API key: Go to the Amazon Bedrock console and generate a long-term API key.

Step 3 - Get the SDK: To use this getting started guide, you must have Python already installed. Then install the relevant software depending on the APIs you are using.

```
pip install boto3
```

Step 4 - Set environment variables: Configure your environment to use the API key for authentication.

```
AWS_BEARER_TOKEN_BEDROCK="<provide your Bedrock API key>"
```

Step 5 - Run your first inference request: Save the file as `bedrock-first-request.py`

Invoke API

```
import json
import boto3

client = boto3.client('bedrock-runtime', region_name='us-east-1')
response = client.invoke_model(
    modelId='mistral.mistral-large-2402-v1:0',
    body=json.dumps({
            'messages': [{ 'role': 'user', 'content': 'Can you explain the features
 of Amazon Bedrock?'}],
            'max_tokens': 1024
    })
)
print(json.loads(response['body'].read()))
```

Converse API

```
import boto3

client = boto3.client('bedrock-runtime', region_name='us-east-1')
response = client.converse(
    modelId='mistral.mistral-large-2402-v1:0',
    messages=[
        {
            'role': 'user',
            'content': [{'text': 'Can you explain the features of Amazon Bedrock?'}]
        }
    ]
)
print(response)
```

Mixtral 8x7B Instruct

Mistral AI — Mixtral 8x7B Instruct

Model Details

Mixtral 8x7B Instruct is Mistral AI's sparse mixture-of-experts model with 8 experts and 7B parameters each, delivering strong performance at faster inference speeds. For more information about model development and performance, see the model/service card.

Model launch date: Dec 10, 2023
EOL no sooner than: Dec 10, 2024
Legacy period: at least 6 months

Quotas and Limits

Your AWS account has default quotas to maintain the performance of the service and to ensure appropriate usage of Amazon Bedrock. The default quotas assigned to an account might be updated depending on regional factors, payment history, fraudulent usage, and/or approval of a quota increase request. For more information, see the section called "Quotas" documentation and see the limits for the model.

Sample Code

Step 1 - AWS Account: If you have an AWS account already, skip this step. If you are new to AWS, sign up for an AWS account.

Step 2 - API key: Go to the Amazon Bedrock console and generate a long-term API key.

Step 3 - Get the SDK: To use this getting started guide, you must have Python already installed. Then install the relevant software depending on the APIs you are using.

```
pip install boto3
```

Step 4 - Set environment variables: Configure your environment to use the API key for authentication.

```
AWS_BEARER_TOKEN_BEDROCK="<provide your Bedrock API key>"
```

Step 5 - Run your first inference request: Save the file as `bedrock-first-request.py`

Invoke API

```
import json
import boto3

client = boto3.client('bedrock-runtime', region_name='us-east-1')
response = client.invoke_model(
    modelId='mistral.mixtral-8x7b-instruct-v0:1',
    body=json.dumps({
            'messages': [{ 'role': 'user', 'content': 'Can you explain the features
 of Amazon Bedrock?'}],
            'max_tokens': 1024
    })
)
print(json.loads(response['body'].read()))
```

Converse API

```
import boto3

client = boto3.client('bedrock-runtime', region_name='us-east-1')
response = client.converse(
    modelId='mistral.mixtral-8x7b-instruct-v0:1',
    messages=[
        {
            'role': 'user',
            'content': [{'text': 'Can you explain the features of Amazon Bedrock?'}]
        }
    ]
)
print(response)
```

Mistral 7B Instruct

Mistral AI — Mistral 7B Instruct

Model Details

Mistral 7B Instruct is Mistral AI's 7-billion parameter instruction-tuned model with grouped-query attention and sliding window attention for efficient long-context inference. For more information about model development and performance, see the model/service card.

Model launch date: Sep 28, 2023
EOL no sooner than: Sep 28, 2024

Quotas and Limits

Your AWS account has default quotas to maintain the performance of the service and to ensure appropriate usage of Amazon Bedrock. The default quotas assigned to an account might be updated depending on regional factors, payment history, fraudulent usage, and/or approval of a quota increase request. For more information, see the section called "Quotas" documentation and see the limits for the model.

Sample Code

Step 1 - AWS Account: If you have an AWS account already, skip this step. If you are new to AWS, sign up for an AWS account.

Step 2 - API key: Go to the Amazon Bedrock console and generate a long-term API key.

Step 3 - Get the SDK: To use this getting started guide, you must have Python already installed. Then install the relevant software depending on the APIs you are using.

```
pip install boto3
```

Step 4 - Set environment variables: Configure your environment to use the API key for authentication.

```
AWS_BEARER_TOKEN_BEDROCK="<provide your Bedrock API key>"
```

Step 5 - Run your first inference request: Save the file as `bedrock-first-request.py`

Invoke API

```
import json
import boto3

client = boto3.client('bedrock-runtime', region_name='us-east-1')
response = client.invoke_model(
    modelId='mistral.mistral-7b-instruct-v0:2',
    body=json.dumps({
            'messages': [{ 'role': 'user', 'content': 'Can you explain the features
 of Amazon Bedrock?'}],
            'max_tokens': 1024
    })
)
print(json.loads(response['body'].read()))
```

Converse API

```
import boto3

client = boto3.client('bedrock-runtime', region_name='us-east-1')
response = client.converse(
    modelId='mistral.mistral-7b-instruct-v0:2',
    messages=[
        {
            'role': 'user',
            'content': [{'text': 'Can you explain the features of Amazon Bedrock?'}]
        }
    ]
)
print(response)
```

Moonshot AI

The following Moonshot AI models are available in Amazon Bedrock:

Model	Description
the section called “Kimi K3.1 Pro - Highspeed”	Kimi K3.1 is Moonshot AI's most capable open-weight model, combining native vision with a 1-million-token context window for long-running coding and knowledge workflows.
the section called “Kimi K3”	Kimi K3 is Moonshot AI's most capable open-weight model, combining native vision with a 1-million-token context window for long-running coding and knowledge workflows.
the section called “Kimi K2.5”	Kimi K2.5 is Moonshot AI's multimodal model with improved reasoning, coding, and multilingual capabilities.
the section called “Kimi K2 Thinking”	Kimi K2 Thinking is Moonshot AI's reasoning model with chain-of-thought capabilities for complex problem solving in math, coding, and logic.

Kimi K3.1 Pro - Highspeed

Moonshot AI — Kimi K3.1 Pro - Highspeed

Model Details

Kimi K3.1 Pro - Highspeed is Moonshot AI's most capable open-weight model, combining native vision with a 1-million-token context window for long-running coding and knowledge workflows that sustain context across large repositories, documents, and images. For more information about model development and performance, see the model/service card.

Model launch date: 4th Nov 2026
EOL no sooner than: Not Applicable, at least 45 day EOL Notice will be provided
Legacy period: at least 45 days
Model lifecycle policy: Bedrock Model Lifecycle

Model EOL date: N/A
Model lifecycle: Active
Context window: 1M tokens
End User License Agreements and Terms of Use: View *(Note- Access through Amazon Bedrock is considered access through "**Certified Inference Partners**")*

Input Modalities	Output Modalities	APIs supported	Endpoints supported
⊗ Audio	⊗ Embedding	⊙ Responses	⊙ bedrock-runtime
⊙ Image	⊗ Image	⊙ Chat Completions	⊗ bedrock-mantle
⊗ Speech	⊗ Speech	⊙ Converse	
⊙ Text	⊙ Text	⊙ Invoke	
⊗ Video	⊗ Video		

Tip

Whenever possible, we recommend using the `bedrock-runtime` endpoint for new applications. For Kimi K3.1 Pro - Highspeed, we recommend using the Chat Completions API. See the section called "Inference endpoints" for details.

Capabilities and Features

Bedrock Features

Features supported using `bedrock-runtime` endpoint

Supported	Not Supported
⊙ Response streaming	⊗ Intelligent prompt routing

Supported	Not Supported
Implicit Prompt Caching Explicit Prompt Caching (Responses, Chat Completions, and InvokeModel APIs; not supported with Converse) Client-side tool calling Structured outputs Invocation logs Guardrails Reasoning (effort configurable; see Reasoning effort below) Application inference profiles	Knowledge base Count tokens Watermarking

Explicit prompt caching using `bedrock-runtime` endpoint

For more information, see Prompt caching for faster model inference.

Explicit Prompt Caching supported	Min tokens per cache checkpoint	Cache retention (TTL)
Yes	256	At least 30 minutes

> **Note**
>
> By default, Kimi K3.1 Pro - Highspeed supports implicit (automatic) prompt caching. Configuring explicit cache controls can improve your cache hit rate, and therefore reduce latency and cost, so we recommend using explicit prompt caching. Explicit prompt caching is supported on the Responses, Chat Completions, and `InvokeModel` APIs. Converse doesn't support explicit caching for this model. See the prompt caching guide for more details.

Reasoning effort

Kimi K3.1 Pro - Highspeed reasons by default. You can trade latency and token consumption against task performance by setting the reasoning effort. The supported values are none, `low`,

`medium`, `high`, `xhigh`, and `max`. If you don't set a value, the model uses `max`. Use `none` to turn reasoning off for a request. The value `minimal` is not supported for this model.

Set the effort with the parameter for the API that you call:

- Responses API — `reasoning.effort`
- Chat Completions API — `reasoning_effort`
- InvokeModel API — `reasoning_effort` in the request body

> **Note**
>
> Converse accepts `reasoning_effort` in `additionalModelRequestFields` but doesn't validate it for this model, including values that the other APIs reject. Set the reasoning effort through one of the APIs listed above.

Pricing

Inference option	Input	Output	Cache read	Cache write (30 min)
Global CRIS	$4.00	$20.00	$0.20	$5.00
US CRIS	$4.40	$22.00	$0.22	$5.50
IN CRIS	$4.40	$22.00	$0.22	$5.50

All prices are per 1 million tokens. Pricing shown is for the Standard tier.

Priority and Flex tier support: In addition to Standard, Kimi K3.1 Pro - Highspeed supports the Priority and Flex service tiers. Priority is billed at **1.75x** the Standard per-token rate (a 75% premium) and Flex at **0.5x** the Standard rate (a 50% discount); apply these multipliers to whichever Standard base rate (Global or US CRIS) applies to your request. For details on each service tier, see service tiers.

Programmatic Access

Use the following model ID and endpoint URL to access this model programmatically. Kimi K3.1 Pro - Highspeed is available through US and India Geo, and Global cross-Region inference. For more information about the available APIs and endpoints, see APIs supported and Endpoints supported.

Endpoint	Model ID	In-Region endpoint URL	Geo inference ID	Global inference ID
`bedrock-runtime`	`moonshotai.kimi-k3.1`	`https://bedrock-runtime.{region}.amazonaws.com`	`us.moonshotai.kimi-k3.1` in the commercial AWS Regions, `in.moonshotai.kimi-k3.1` in the India Regions	`global.moonshotai.kimi-k3.1`

For example, if region is us-east-1 (N. Virginia), then the bedrock-runtime endpoint URL will be "https://bedrock-runtime.us-east-1.amazonaws.com".

Service Tiers

Amazon Bedrock offers multiple service tiers to match your workload requirements. **Standard** provides pay-per-token access with no commitment (set `"service_tier": "default"` or omit the field). **Priority** delivers the fastest response times for a price premium (set `"service_tier": "priority"`). **Flex** provides lower-cost access for flexible, non-time-sensitive workloads (set `"service_tier": "flex"`). For more information, see service tiers.

Standard	Priority	Flex	Reserved
✓	✓	✓	✗

Note

Kimi K3.1 Pro - Highspeed supports service tiers on the Responses, Chat Completions, Converse, and `InvokeModel` APIs. The parameter differs by API: Converse takes `serviceTier` as an object, `"serviceTier": {"type": "priority"}`, while the Responses, Chat Completions, and `InvokeModel` APIs take `"service_tier": "priority"`. Service tier support varies by model, so check the model card for the model that you are calling.

Regional Availability

Regional availability at a glance

Amazon Bedrock offers three inference options: **In-Region** keeps requests within a single Region for strict compliance, **Geo Cross-Region** routes across Regions within a geography (such as US, EU, and APAC) while respecting data residency, and **Global Cross-Region** routes anywhere worldwide when there are no residency constraints. Refer to the the section called “Regional availability by models” page for more details.

Kimi K3.1 Pro - Highspeed is available through US Geo cross-Region inference (using the `us.moonshotai.kimi-k3.1` profile, which routes requests only among US-geography Regions to respect US data residency), India geographic cross-Region inference (using the `in.moonshotai.kimi-k3.1` profile, which routes requests only among India-geography Regions (Mumbai and Hyderabad) to respect India data residency), and Global cross-Region inference (using the `global.moonshotai.kimi-k3.1` profile, which routes to any supported commercial AWS Region worldwide). You choose the AWS Region you send requests to, and Amazon Bedrock routes each request accordingly.

Geo inference details

The destination Regions available to a geographic inference profile depend on the source Region. To retrieve the current routing configuration, call GetInferenceProfile from the source Region.

Geo: US

Geo inference ID: `us.moonshotai.kimi-k3.1`

Source Region	Destination Regions
us-east-1 (N. Virginia)	us-east-1 (N. Virginia), us-east-2 (Ohio), us-west-2 (Oregon)
us-east-2 (Ohio)	us-east-1 (N. Virginia), us-east-2 (Ohio), us-west-2 (Oregon)
us-west-1 (N. California)	us-east-1 (N. Virginia), us-east-2 (Ohio), us-west-1 (N. California), us-west-2 (Oregon)

Source Region	Destination Regions
us-west-2 (Oregon)	us-east-1 (N. Virginia), us-east-2 (Ohio), us-west-2 (Oregon)
ca-central-1 (Canada)	ca-central-1 (Canada), us-east-1 (N. Virginia), us-east-2 (Ohio), us-west-2 (Oregon)
ca-west-1 (Calgary)	ca-west-1 (Calgary), us-east-1 (N. Virginia), us-east-2 (Ohio), us-west-2 (Oregon)

Geo: India

Geo inference ID: `in.moonshotai.kimi-k3.1`

Source Region	Destination Regions
ap-south-1 (Mumbai)	ap-south-1 (Mumbai), ap-south-2 (Hyderabad)
ap-south-2 (Hyderabad)	ap-south-1 (Mumbai), ap-south-2 (Hyderabad)

Quotas and Limits

Your AWS account has default quotas to maintain the performance of the service and to ensure appropriate usage of Amazon Bedrock. The default quotas assigned to an account might be updated depending on regional factors, payment history, fraudulent usage, and/or approval of a quota increase request. See your default quotas in Service Quotas and request limit increases as necessary.

The burndown rate for Moonshot AI Kimi K3.1 Pro - Highspeed on the `bedrock-runtime` endpoint is 10x for output tokens (1 output token consumes 10 tokens from your quotas).

Usage Considerations and Limitations

Keep the following considerations and limitations in mind when you use Kimi K3.1 Pro - Highspeed:

- **Prefer the OpenAI-compatible APIs over Converse** — Although Kimi K3.1 Pro - Highspeed can be called through the Converse and ConverseStream APIs, we recommend using the

OpenAI-compatible Responses or Chat Completions APIs where possible. Converse has known limitations with this model, including a failure (`InternalServerException`) when reasoning content from earlier turns is included in a multi-turn request, which affects frameworks such as LangChain and Strands Agents in their default configurations, and rejection of attached document inputs such as PDF and HTML. To use Converse for multi-turn requests, remove reasoning blocks from prior turns.

- **Video inputs are not supported** — Amazon Bedrock does not support attaching video inputs to Kimi K3.1 Pro - Highspeed requests.
- **Place images before text for combined inputs** — For requests that combine text and images, Kimi K3.1 Pro - Highspeed can produce higher-quality answers when image content blocks are placed before text content blocks. This behavior is prompt-dependent, so test both orderings for your own workload.
- **Image detail parameter** — The `detail` parameter that controls image input fidelity (`low` for lower cost or `high` for higher-fidelity understanding) is honored only on the Chat Completions API. On the Responses API, images are always processed at high detail.

Sample Code

Step 1 - AWS Account: If you have an AWS account already, skip this step. If you are new to AWS, sign up for an AWS account.

Step 2 - API key: Go to the Amazon Bedrock console and generate a long-term API key.

Step 3 - Get the SDK: To use this getting started guide, you must have Python already installed. Then install the relevant software depending on the APIs you are using.

Responses / Chat Completions API

```
pip install -U openai aws-bedrock-token-generator
```

Invoke/Converse API

```
pip install boto3
```

Step 4 - Run your first inference request: Save the file as `bedrock-first-request.py`

Responses API

```
from aws_bedrock_token_generator import provide_token
from openai import OpenAI

region = "us-west-2"
client = OpenAI(
    api_key=provide_token(region=region),
    base_url=f"https://bedrock-runtime.{region}.amazonaws.com/openai/v1",
)

resp = client.responses.create(
    input="Can you explain the features of Amazon Bedrock?",
    model="global.moonshotai.kimi-k3.1",
)
print(resp.output_text)
```

Converse API

```
import boto3

client = boto3.client('bedrock-runtime', region_name='us-west-2')
response = client.converse(
    modelId='global.moonshotai.kimi-k3.1',
    messages=[
        {
            'role': 'user',
            'content': [{'text': 'Can you explain the features of Amazon Bedrock?'}]
        }
    ]
)
print(response)
```

Invoke API

```
import json
import boto3

client = boto3.client('bedrock-runtime', region_name='us-west-2')
response = client.invoke_model(
    modelId='global.moonshotai.kimi-k3.1',
    body=json.dumps({
```

```
            'messages': [{ 'role': 'user', 'content': 'Can you explain the features
 of Amazon Bedrock?'}],
            'max_tokens': 1024
    })
)
print(json.loads(response['body'].read()))
```

Kimi K3

Moonshot AI — Kimi K3

Model Details

Kimi K3 is Moonshot AI's most capable open-weight model, combining native vision with a 1-million-token context window for long-running coding and knowledge workflows that sustain context across large repositories, documents, and images. For more information about model development and performance, see the model/service card.

Model launch date: 18th Sept 2026

EOL no sooner than: Not Applicable, at least 45 day EOL Notice will be provided

Legacy period: at least 45 days

Model lifecycle policy: Bedrock Model Lifecycle

Model EOL date: N/A

Model lifecycle: Active

Context window: 1M tokens

End User License Agreements and Terms of Use: View *(Note- Access through Amazon Bedrock is considered access through "**Certified Inference Partners**")*

Input Modalities	Output Modalities	APIs supported	Endpoints supported
✓ Image	✗ Image	✓ `Chat Completions`	✗ `bedrock-mantle`
✗ Speech	✗ Speech	✓ `Converse`	
✓ Text	✓ Text	✓ `Invoke`	
✗ Video	✗ Video		

Tip

Whenever possible, we recommend using the `bedrock-runtime` endpoint for new applications. For Kimi K3, we recommend using the Chat Completions API. See the section called "Inference endpoints" for details.

Capabilities and Features

Bedrock Features

Features supported using `bedrock-runtime` endpoint

Supported	Not Supported
✓ Response streaming ✓ Implicit Prompt Caching ✓ Explicit Prompt Caching (Responses, Chat Completions, and InvokeModel APIs; not supported with Converse) ✓ Client-side tool calling ✓ Structured outputs ✓ Invocation logs ✓ Guardrails ✓ Reasoning (effort configurable; see Reasoning effort below)	✗ Intelligent prompt routing ✗ Knowledge base ✗ Count tokens ✗ Watermarking

Supported	Not Supported
Application inference profiles	

Explicit prompt caching using `bedrock-runtime` endpoint

For more information, see Prompt caching for faster model inference.

Explicit Prompt Caching supported	Min tokens per cache checkpoint	Cache retention (TTL)
Yes	256	At least 30 minutes

> **Note**
>
> By default, Kimi K3 supports implicit (automatic) prompt caching. Configuring explicit cache controls can improve your cache hit rate, and therefore reduce latency and cost, so we recommend using explicit prompt caching. Explicit prompt caching is supported on the Responses, Chat Completions, and `InvokeModel` APIs. Converse doesn't support explicit caching for this model. See the prompt caching guide for more details.

Reasoning effort

Kimi K3 reasons by default. You can trade latency and token consumption against task performance by setting the reasoning effort. The supported values are none, `low`, `medium`, `high`, `xhigh`, and `max`. If you don't set a value, the model uses `max`. Use none to turn reasoning off for a request. The value `minimal` is not supported for this model.

Set the effort with the parameter for the API that you call:

- Responses API — `reasoning.effort`
- Chat Completions API — `reasoning_effort`
- InvokeModel API — `reasoning_effort` in the request body

> **Note**
>
> Converse accepts `reasoning_effort` in `additionalModelRequestFields` but doesn't validate it for this model, including values that the other APIs reject. Set the reasoning effort through one of the APIs listed above.

Pricing

Inference option	Input	Output	Cache read	Cache write (30 min)
Global CRIS	$3.00	$15.00	$0.30	$3.75
US CRIS	$3.30	$16.50	$0.33	$4.125
IN CRIS	$3.30	$16.50	$0.33	$4.125

All prices are per 1 million tokens. Pricing shown is for the Standard tier.

Priority and Flex tier support: In addition to Standard, Kimi K3 supports the Priority and Flex service tiers. Priority is billed at **1.75x** the Standard per-token rate (a 75% premium) and Flex at **0.5x** the Standard rate (a 50% discount); apply these multipliers to whichever Standard base rate (Global or US CRIS) applies to your request. For details on each service tier, see service tiers.

Programmatic Access

Use the following model ID and endpoint URL to access this model programmatically. Kimi K3 is available through US and India Geo, and Global cross-Region inference. For more information about the available APIs and endpoints, see APIs supported and Endpoints supported.

Endpoint	Model ID	In-Region endpoint URL	Geo inference ID	Global inference ID
`bedrock-runtime`	`moonshotai.kimi-k3`	`https://bedrock-runtime.{re`	`us.moonshotai.kimi-k3` in the	`global.moonshotai.kimi-k3`

Endpoint	Model ID	In-Region endpoint URL	Geo inference ID	Global inference ID
		`gion}.amazonaws.com`	commercial AWS Regions, `in.moonshotai.kimi-k3` in the India Regions	

For example, if region is us-east-1 (N. Virginia), then the bedrock-runtime endpoint URL will be "https://bedrock-runtime.us-east-1.amazonaws.com".

Service Tiers

Amazon Bedrock offers multiple service tiers to match your workload requirements. **Standard** provides pay-per-token access with no commitment (set `"service_tier": "default"` or omit the field). **Priority** delivers the fastest response times for a price premium (set `"service_tier": "priority"`). **Flex** provides lower-cost access for flexible, non-time-sensitive workloads (set `"service_tier": "flex"`). For more information, see service tiers.

Standard	Priority	Flex	Reserved
✓	✓	✓	✗

Note

Kimi K3 supports service tiers on the Responses, Chat Completions, Converse, and `InvokeModel` APIs. The parameter differs by API: Converse takes `serviceTier` as an object, `"serviceTier": {"type": "priority"}`, while the Responses, Chat Completions, and `InvokeModel` APIs take `"service_tier": "priority"`. Service tier support varies by model, so check the model card for the model that you are calling.

Regional Availability

Regional availability at a glance

Amazon Bedrock offers three inference options: **In-Region** keeps requests within a single Region for strict compliance, **Geo Cross-Region** routes across Regions within a geography (such as US, EU, and APAC) while respecting data residency, and **Global Cross-Region** routes anywhere worldwide when there are no residency constraints. Refer to the the section called "Regional availability by models" page for more details.

Kimi K3 is available through US Geo cross-Region inference (using the `us.moonshotai.kimi-k3` profile, which routes requests only among US-geography Regions to respect US data residency), India geographic cross-Region inference (using the `in.moonshotai.kimi-k3` profile, which routes requests only among India-geography Regions (Mumbai and Hyderabad) to respect India data residency), and Global cross-Region inference (using the `global.moonshotai.kimi-k3` profile, which routes to any supported commercial AWS Region worldwide). You choose the AWS Region you send requests to, and Amazon Bedrock routes each request accordingly.

Quotas and Limits

Your AWS account has default quotas to maintain the performance of the service and to ensure appropriate usage of Amazon Bedrock. The default quotas assigned to an account might be updated depending on regional factors, payment history, fraudulent usage, and/or approval of a quota increase request. See your default quotas in Service Quotas and request limit increases as necessary.

The burndown rate for Moonshot AI Kimi K3 on the `bedrock-runtime` endpoint is 10x for output tokens (1 output token consumes 10 tokens from your quotas).

Usage Considerations and Limitations

Keep the following considerations and limitations in mind when you use Kimi K3:

- **Prefer the OpenAI-compatible APIs over Converse** — Although Kimi K3 can be called through the Converse and ConverseStream APIs, we recommend using the OpenAI-compatible Responses or Chat Completions APIs where possible. Converse has known limitations with this model, including a failure (`InternalServerException`) when reasoning content from earlier turns is included in a multi-turn request, which affects frameworks such as LangChain and Strands Agents in their default configurations, and rejection of attached document inputs such as PDF and HTML. To use Converse for multi-turn requests, remove reasoning blocks from prior turns.
- **Video inputs are not supported** — Amazon Bedrock does not support attaching video inputs to Kimi K3 requests.
- **Place images before text for combined inputs** — For requests that combine text and images, Kimi K3 can produce higher-quality answers when image content blocks are placed before text content blocks. This behavior is prompt-dependent, so test both orderings for your own workload.
- **Image detail parameter** — The `detail` parameter that controls image input fidelity (`low` for lower cost or `high` for higher-fidelity understanding) is honored only on the Chat Completions API. On the Responses API, images are always processed at high detail.

Sample Code

Step 1 - AWS Account: If you have an AWS account already, skip this step. If you are new to AWS, sign up for an AWS account.

Step 2 - API key: Go to the Amazon Bedrock console and generate a long-term API key.

Step 3 - Get the SDK: To use this getting started guide, you must have Python already installed. Then install the relevant software depending on the APIs you are using.

            'messages': [{ 'role': 'user', 'content': 'Can you explain the features
 of Amazon Bedrock?'}],
            'max_tokens': 1024
    })
)
print(json.loads(response['body'].read()))
```

Kimi K2.5

Moonshot AI — Kimi K2.5

Model Details

Kimi K2.5 is Moonshot AI's multimodal model with improved reasoning, coding, and multilingual capabilities. For more information about model development and performance, see the model/service card.

Model launch date: Jan 27, 2026

EOL no sooner than: Jan 27, 2027
Legacy period: at least 6 months
Model lifecycle policy: Model lifecycle (For Models Launched Prior to Sept 7 2026)
Model EOL date: N/A
Model lifecycle: Active
Context window: 256K tokens
Max output tokens: 16K
Max image payload size: 3 MB
End User License Agreements and Terms of Use: View *(Note- Access through Amazon Bedrock is considered access through "**Certified Inference Partners**")*

Pricing

For pricing information, see the Amazon Bedrock Pricing page.

Programmatic Access

Use the following model IDs and endpoint URLs to access this model programmatically. For more information about the available APIs and endpoints, see APIs supported and Endpoints supported.

Endpoint	Model ID	In-Region endpoint URL	Geo inference ID	Global inference ID
`bedrock-runtime`	`moonshotai.kimi-k2.5`	`https://bedrock-runtime.{region}.amazonaws.com`	Not supported	Not supported

Endpoint	Model ID	In-Region endpoint URL	Geo inference ID	Global inference ID
bedrock-mantle	moonshotai.kimi-k2.5	https://bedrock-mantle.{region}.api.aws/v1	Not supported	Not supported

For example, if region is us-east-1 (N. Virginia), then the bedrock-runtime endpoint URL will be "https://bedrock-runtime.us-east-1.amazonaws.com" and for bedrock-mantle will be "https://bedrock-mantle.us-east-1.api.aws/v1".

Service Tiers

Amazon Bedrock offers multiple service tiers to match your workload requirements. **Standard** provides pay-per-token access with no commitment (set `"service_tier": "default"` or omit the field). **Priority** delivers the fastest response times for a price premium (set `"service_tier": "priority"`). **Flex** provides lower-cost access for flexible, non-time-sensitive workloads (set `"service_tier": "flex"`). **Reserved** provides dedicated throughput with a term commitment for predictable workloads; it is set at the account level rather than per request (contact your AWS account team to enable). For more information, see service tiers.

Standard	Priority	Flex	Reserved
✓	✓	✓	✗

Regional Availability

Regional availability at a glance

Amazon Bedrock offers three inference options: **In-Region** keeps requests within a single Region for strict compliance, **Geo Cross-Region** routes across Regions within a geography (such as US, EU, and APAC) while respecting data residency, and **Global Cross-Region** routes anywhere worldwide when there are no residency constraints. Refer to the the section called “Regional availability by models” page for more details.

Quotas and Limits

Your AWS account has default quotas to maintain the performance of the service and to ensure appropriate usage of Amazon Bedrock. The default quotas assigned to an account might be updated depending on regional factors, payment history, fraudulent usage, and/or approval of a quota increase request. For more information, see the section called “Quotas” documentation and see the limits for the model.

Sample Code

Step 1 - AWS Account: If you have an AWS account already, skip this step. If you are new to AWS, sign up for an AWS account.

Step 2 - API key: Go to the Amazon Bedrock console and generate a long-term API key.

Step 3 - Get the SDK: To use this getting started guide, you must have Python already installed. Then install the relevant software depending on the APIs you are using.

Chat Completions API

```
pip install boto3 openai
```

Invoke/Converse API

```
pip install boto3
```

Step 4 - Set environment variables: Configure your environment to use the API key for authentication.

Chat Completions API

```
OPENAI_API_KEY="<provide your Bedrock API key>"
OPENAI_BASE_URL="https://bedrock-runtime.<your-region>.amazonaws.com/openai/v1"
```

Invoke/Converse API

```
AWS_BEARER_TOKEN_BEDROCK="<provide your Bedrock API key>"
```

Step 5 - Run your first inference request: Save the file as `bedrock-first-request.py`

Chat Completions API

```
from openai import OpenAI

client = OpenAI()

response = client.chat.completions.create(
    model="moonshotai.kimi-k2.5",
    messages=[{"role": "user", "content": "Can you explain the features of Amazon
 Bedrock?"}]
    )
print(response)
```

Invoke API

```
import json
import boto3

client = boto3.client('bedrock-runtime', region_name='us-east-1')
response = client.invoke_model(
    modelId='moonshotai.kimi-k2.5',
    body=json.dumps({
            'messages': [{ 'role': 'user', 'content': 'Can you explain the features
 of Amazon Bedrock?'}],
            'max_tokens': 1024
    })
)
print(json.loads(response['body'].read()))
```

Converse API

```
import boto3

client = boto3.client('bedrock-runtime', region_name='us-east-1')
response = client.converse(
    modelId='moonshotai.kimi-k2.5',
    messages=[
        {
            'role': 'user',
            'content': [{'text': 'Can you explain the features of Amazon Bedrock?'}]
        }
    ]
)
print(response)
```

Kimi K2 Thinking

Moonshot AI — Kimi K2 Thinking

Model Details

Kimi K2 Thinking is Moonshot AI's reasoning model with chain-of-thought capabilities for complex problem solving in math, coding, and logic. For more information about model development and performance, see the model/service card.

Model launch date: Nov 06, 2025
EOL no sooner than: Nov 06, 2026
Legacy period: at least 6 months
Model lifecycle policy: Model lifecycle (For Models Launched Prior to Sept 7 2026)
Model EOL date: March 30, 2027
Model lifecycle: Legacy
Context window: 256K tokens
Max output tokens: 16K
Reasoning: Supported
End User License Agreements and Terms of Use: View *(Note- Access through Amazon Bedrock is considered access through "**Certified Inference Partners**")*

Input Modalities	Output Modalities	APIs supported	Endpoints supported
⊗ Audio	⊗ Embedding	⊗ Responses	⊙ bedrock-runtime
⊗ Image	⊗ Image	⊙ Chat Completions	⊙ bedrock-mantle

Capabilities and Features

Bedrock Features

Features supported using `bedrock-mantle` endpoint

Supported	Not Supported
Projects Client-side tool calling	Server-side tool calling Watermarking

Features supported using `bedrock-runtime` endpoint

Supported	Not Supported
Response streaming Guardrails Model evaluation Prompt management Flows Agents Structured outputs	Intelligent prompt routing Abuse detection Prompt optimization Count tokens Knowledge base Watermarking

Pricing

For pricing information, see the Amazon Bedrock Pricing page.

Programmatic Access

Use the following model IDs and endpoint URLs to access this model programmatically. For more information about the available APIs and endpoints, see APIs supported and Endpoints supported.

Endpoint	Model ID	In-Region endpoint URL	Geo inference ID	Global inference ID
bedrock-runtime	moonshot.kimi-k2-thinking	https://bedrock-runtime.{region}.amazonaws.com	Not supported	Not supported
bedrock-mantle	moonshotai.kimi-k2-thinking	https://bedrock-mantle.{region}.api.aws/v1	Not supported	Not supported

For example, if region is us-east-1 (N. Virginia), then the bedrock-runtime endpoint URL will be "https://bedrock-runtime.us-east-1.amazonaws.com" and for bedrock-mantle will be "https://bedrock-mantle.us-east-1.api.aws/v1".

Service Tiers

Amazon Bedrock offers multiple service tiers to match your workload requirements. **Standard** provides pay-per-token access with no commitment (set `"service_tier": "default"` or omit the field). **Priority** delivers the fastest response times for a price premium (set `"service_tier": "priority"`). **Flex** provides lower-cost access for flexible, non-time-sensitive workloads (set `"service_tier": "flex"`). **Reserved** provides dedicated throughput with a term commitment for predictable workloads; it is set at the account level rather than per request (contact your AWS account team to enable). For more information, see service tiers.

Standard	Priority	Flex	Reserved
✓	✓	✓	✗

Regional Availability

Regional availability at a glance

Amazon Bedrock offers three inference options: **In-Region** keeps requests within a single Region for strict compliance, **Geo Cross-Region** routes across Regions within a geography (such as US, EU,

and APAC) while respecting data residency, and **Global Cross-Region** routes anywhere worldwide when there are no residency constraints. Refer to the the section called "Regional availability by models" page for more details.

Region	In-Region	Geo	Global
us-east-1 (N. Virginia)	✓	✗	✗
us-east-2 (Ohio)	✓	✗	✗
us-west-2 (Oregon)	✓	✗	✗
ap-northeast-1 (Tokyo)	✓	✗	✗
ap-south-1 (Mumbai)	✓	✗	✗
ap-southeast-2 (Sydney)	✓	✗	✗
sa-east-1 (São Paulo)	✓	✗	✗
ap-southeast-3 (Jakarta)	✓	✗	✗
ap-southeast-4 (Melbourne)	✓	✗	✗
ap-northeast-2 (Seoul)	✓	✗	✗
ap-southeast-1 (Singapore)	✓	✗	✗
eu-north-1 (Stockholm)	✓	✗	✗
eu-west-2 (London)	✓	✗	✗

Quotas and Limits

Your AWS account has default quotas to maintain the performance of the service and to ensure appropriate usage of Amazon Bedrock. The default quotas assigned to an account might be updated depending on regional factors, payment history, fraudulent usage, and/or approval of a quota increase request. For more information, see the section called "Quotas" documentation and see the limits for the model.

Sample Code

Step 1 - AWS Account: If you have an AWS account already, skip this step. If you are new to AWS, sign up for an AWS account.

Step 2 - API key: Go to the Amazon Bedrock console and generate a long-term API key.

Step 3 - Get the SDK: To use this getting started guide, you must have Python already installed. Then install the relevant software depending on the APIs you are using.

Chat Completions API

```
pip install boto3 openai
```

Invoke/Converse API

```
pip install boto3
```

Step 4 - Set environment variables: Configure your environment to use the API key for authentication.

Chat Completions API

```
OPENAI_API_KEY="<provide your Bedrock API key>"
OPENAI_BASE_URL="https://bedrock-runtime.<your-region>.amazonaws.com/openai/v1"
```

Invoke/Converse API

```
AWS_BEARER_TOKEN_BEDROCK="<provide your Bedrock API key>"
```

Step 5 - Run your first inference request: Save the file as `bedrock-first-request.py`

Chat Completions API

```
from openai import OpenAI

client = OpenAI()

response = client.chat.completions.create(
```

```
    model="moonshotai.kimi-k2-thinking",
    messages=[{"role": "user", "content": "Can you explain the features of Amazon
 Bedrock?"}]
    )
print(response)
```

Invoke API

```
import json
import boto3

client = boto3.client('bedrock-runtime', region_name='us-east-1')
response = client.invoke_model(
    modelId='moonshot.kimi-k2-thinking',
    body=json.dumps({
            'messages': [{ 'role': 'user', 'content': 'Can you explain the features
 of Amazon Bedrock?'}],
            'max_tokens': 1024
    })
)
print(json.loads(response['body'].read()))
```

Converse API

```
import boto3

client = boto3.client('bedrock-runtime', region_name='us-east-1')
response = client.converse(
    modelId='moonshot.kimi-k2-thinking',
    messages=[
        {
            'role': 'user',
            'content': [{'text': 'Can you explain the features of Amazon Bedrock?'}]
        }
    ]
)
print(response)
```

NVIDIA

The following NVIDIA models are available in Amazon Bedrock:

Model	Description
the section called "NVIDIA Nemotron Nano 9B v2"	Nemotron Nano 9B v2 is NVIDIA's 9-billion parameter model optimized for efficient text generation, reasoning, and coding on NVIDIA hardware.
the section called "NVIDIA Nemotron Nano 12B v2 VL BF16"	Nemotron Nano 12B v2 VL is NVIDIA's 12-billion parameter vision-language model for multimodal tasks including image understanding and visual Q&A.
the section called "Nemotron Nano 3 30B"	Nemotron Nano 3 30B is NVIDIA's 30-billion parameter model with strong reasoning and coding performance, optimized for deployment on NVIDIA GPUs.
the section called "NVIDIA Nemotron 3 Super 120B"	NVIDIA Nemotron 3 Super 120B is NVIDIA's open hybrid MoE model with 120B total parameters and 12B active, designed for complex multi-agent applications with a 1M token context window.

NVIDIA Nemotron Nano 9B v2

NVIDIA — NVIDIA Nemotron Nano 9B v2

Model Details

Nemotron Nano 9B v2 is NVIDIA's 9-billion parameter model optimized for efficient text generation, reasoning, and coding on NVIDIA hardware. For more information about model development and performance, see the model/service card.

Model launch date: Aug 18, 2025
EOL no sooner than: Aug 18, 2026

Geo CRIS inference details

US GovCloud CRIS

US GovCloud CRIS Inference ID: `us-gov.nvidia.nemotron-nano-3-30b`

Source Region	Destination Regions
us-gov-west-1 (GovCloud West)	us-gov-west-1 (GovCloud West), us-gov-east-1 (GovCloud East)
us-gov-east-1 (GovCloud East)	us-gov-west-1 (GovCloud West), us-gov-east-1 (GovCloud East)

Quotas and Limits

Your AWS account has default quotas to maintain the performance of the service and to ensure appropriate usage of Amazon Bedrock. The default quotas assigned to an account might be updated depending on regional factors, payment history, fraudulent usage, and/or approval of a quota increase request. For more information, see the section called "Quotas" documentation and see the limits for the model.

Sample Code

Step 1 - AWS Account: If you have an AWS account already, skip this step. If you are new to AWS, sign up for an AWS account.

Step 2 - API key: Go to the Amazon Bedrock console and generate a long-term API key.

Step 3 - Get the SDK: To use this getting started guide, you must have Python already installed. Then install the relevant software depending on the APIs you are using.

Chat Completions API

```
pip install boto3 openai
```

Invoke/Converse API

```
pip install boto3
```

Step 4 - Set environment variables: Configure your environment to use the API key for authentication.

Chat Completions API

```
OPENAI_API_KEY="<provide your Bedrock API key>"
OPENAI_BASE_URL="https://bedrock-runtime.<your-region>.amazonaws.com/openai/v1"
```

Invoke/Converse API

```
AWS_BEARER_TOKEN_BEDROCK="<provide your Bedrock API key>"
```

Step 5 - Run your first inference request: Save the file as `bedrock-first-request.py`

Chat Completions API

```
from openai import OpenAI

client = OpenAI()

response = client.chat.completions.create(
    model="nvidia.nemotron-nano-3-30b",
    messages=[{"role": "user", "content": "Can you explain the features of Amazon
 Bedrock?"}]
    )
print(response)
```

Invoke API

```
import json
import boto3

client = boto3.client('bedrock-runtime', region_name='us-east-1')
response = client.invoke_model(
    modelId='nvidia.nemotron-nano-3-30b',
    body=json.dumps({
            'messages': [{ 'role': 'user', 'content': 'Can you explain the features
 of Amazon Bedrock?'}],
            'max_tokens': 1024
    })
)
print(json.loads(response['body'].read()))
```

Converse API

```
import boto3

client = boto3.client('bedrock-runtime', region_name='us-east-1')
response = client.converse(
    modelId='nvidia.nemotron-nano-3-30b',
    messages=[
        {
            'role': 'user',
            'content': [{'text': 'Can you explain the features of Amazon Bedrock?'}]
        }
    ]
)
print(response)
```

NVIDIA Nemotron 3 Super 120B

NVIDIA — NVIDIA Nemotron 3 Super 120B

Model Details

NVIDIA Nemotron 3 Super is a 120B-parameter open hybrid MoE model, activating just 12B parameters for maximum compute efficiency and accuracy in complex multi-agent applications. It delivers up to 7x higher throughput, providing fast, cost-efficient inference for agentic tasks. A long context window gives the model long-term memory, preventing AI agents from losing focus on long, multi-step tasks and ensuring high-accuracy results. Fully open with weights, datasets, and recipes, it allows easy customization and secure deployment. For more information about model development and performance, see the model/service card.

Model launch date: Mar 11, 2026

EOL no sooner than: Mar 11, 2027

Legacy period: at least 6 months

Model lifecycle policy: Model lifecycle (For Models Launched Prior to Sept 7 2026)

Model EOL date: N/A

End User License Agreements and Terms of Use: View

Model lifecycle: Active

Context window: 256K tokens

Max output tokens: 32K

Reasoning: Supported (effort configurable: none, low, medium, high)

Input Modalities	Output Modalities	APIs supported	Endpoints supported
⊗ Audio	⊗ Embedding	⊗ `Responses`	⊙ `bedrock-runtime`
⊗ Image	⊗ Image	⊙ `Chat Completions`	⊙ `bedrock-mantle`
⊗ Speech	⊗ Speech	⊙ `Invoke`	
⊙ Text	⊙ Text	⊙ `Converse`	
⊗ Video	⊗ Video		

> **Tip**
>
> Whenever possible, we recommend using the `bedrock-runtime` endpoint for new applications. See the section called "Inference endpoints" for details.

Capabilities and Features

Bedrock Features

Features supported using `bedrock-mantle` endpoint

Supported	Not Supported
⊙ Projects	⊗ Server-side tool calling
⊙ Client-side tool calling	⊗ Watermarking

Features supported using `bedrock-runtime` endpoint

Supported	Not Supported

Pricing

For pricing information, see the Amazon Bedrock Pricing page.

Programmatic Access

Use the following model IDs and endpoint URLs to access this model programmatically. For more information about the available APIs and endpoints, see APIs supported and Endpoints supported.

Endpoint	Model ID	In-Region endpoint URL	Geo inference ID	Global inference ID
`bedrock-runtime`	`nvidia.nemotron-super-3-120b`	`https://bedrock-runtime.{region}.amazonaws.com`	`us-gov.nvidia.nemotron-super-3-120b`	Not supported
`bedrock-mantle`	`nvidia.nemotron-super-3-120b`	`https://bedrock-mantle.{region}.api.aws/v1`	Not supported	Not supported

For example, if region is us-east-1 (N. Virginia), then the bedrock-runtime endpoint URL will be "https://bedrock-runtime.us-east-1.amazonaws.com" and for bedrock-mantle will be "https://bedrock-mantle.us-east-1.api.aws/v1".

Service Tiers

Amazon Bedrock offers multiple service tiers to match your workload requirements. **Standard** provides pay-per-token access with no commitment (set `"service_tier": "default"` or omit the field). **Priority** delivers the fastest response times for a price premium (set `"service_tier": "priority"`). **Flex** provides lower-cost access for flexible, non-time-sensitive workloads (set `"service_tier": "flex"`). **Reserved** provides dedicated throughput with a term commitment for predictable workloads; it is set at the account level rather than per request (contact your AWS account team to enable). For more information, see service tiers.

Standard	Priority	Flex	Reserved
✓	✓	✓	✗

Regional Availability

Regional availability at a glance

Amazon Bedrock offers three inference options: **In-Region** keeps requests within a single Region for strict compliance, **Geo Cross-Region** routes across Regions within a geography (such as US, EU, and APAC) while respecting data residency, and **Global Cross-Region** routes anywhere worldwide when there are no residency constraints. Refer to the the section called “Regional availability by models” page for more details.

Region	In-Region	Geo	Global
`us-east-1` (N. Virginia)	✓	✗	✗
`us-east-2` (Ohio)	✓	✗	✗

ap-southeast-3 (Jakarta)	✓	✗	✗
us-gov-west-1 (GovCloud)	✓	✗	✗

Geo CRIS inference details

US GovCloud CRIS

US GovCloud CRIS Inference ID: `us-gov.nvidia.nemotron-super-3-120b`

Source Region	Destination Regions
us-gov-west-1 (GovCloud West)	us-gov-west-1 (GovCloud West), us-gov-east-1 (GovCloud East)
us-gov-east-1 (GovCloud East)	us-gov-west-1 (GovCloud West), us-gov-east-1 (GovCloud East)

Quotas and Limits

Your AWS account has default quotas to maintain the performance of the service and to ensure appropriate usage of Amazon Bedrock. The default quotas assigned to an account might be updated depending on regional factors, payment history, fraudulent usage, and/or approval of a quota increase request. For more information, see the section called "Quotas" documentation and see the limits for the model.

Sample Code

Step 1 - AWS Account: If you have an AWS account already, skip this step. If you are new to AWS, sign up for an AWS account.

Step 2 - API key: Go to the Amazon Bedrock console and generate a long-term API key.

Step 3 - Get the SDK: To use this getting started guide, you must have Python already installed. Then install the relevant software depending on the APIs you are using.

Chat Completions API

```
pip install boto3 openai
```

Invoke/Converse API

```
pip install boto3
```

Step 4 - Set environment variables: Configure your environment to use the API key for authentication.

Chat Completions API

```
OPENAI_API_KEY="<provide your Bedrock API key>"
OPENAI_BASE_URL="https://bedrock-runtime.<your-region>.amazonaws.com/openai/v1"
```

Invoke/Converse API

```
AWS_BEARER_TOKEN_BEDROCK="<provide your Bedrock API key>"
```

Step 5 - Run your first inference request: Save the file as `bedrock-first-request.py`

Chat Completions API

```
from openai import OpenAI

client = OpenAI()

response = client.chat.completions.create(
    model="nvidia.nemotron-super-3-120b",
    messages=[{"role": "user", "content": "Can you explain the features of Amazon
 Bedrock?"}]
    )
print(response)
```

Invoke API

```
import json
import boto3

client = boto3.client('bedrock-runtime', region_name='us-east-1')
response = client.invoke_model(
    modelId='nvidia.nemotron-super-3-120b',
    body=json.dumps({
            'messages': [{ 'role': 'user', 'content': 'Can you explain the features
 of Amazon Bedrock?'}],
            'max_tokens': 1024
    })
)
print(json.loads(response['body'].read()))
```

Converse API

```
import boto3

client = boto3.client('bedrock-runtime', region_name='us-east-1')
response = client.converse(
    modelId='nvidia.nemotron-super-3-120b',
    messages=[
        {
            'role': 'user',
            'content': [{'text': 'Can you explain the features of Amazon Bedrock?'}]
        }
    ]
)
```

```
print(response)
```

OpenAI

You can use all models on this page with both the Responses API and the Chat Completions API on `bedrock-mantle`. See each model card for details.

The following OpenAI models are available in Amazon Bedrock:

Model	Description
the section called "GPT-6 Astra"	OpenAI's most capable model, built for complex reasoning, coding, computer use, research, and document creation.
the section called "GPT-6.1 Sol"	OpenAI GPT-6.1 Sol brings performance approaching GPT-6 Astra on several demanding evaluations at Sol pricing. It advances coding, professional work, and agentic workflows for teams balancing capabilit y and cost.
the section called "GPT-6.1 Terra"	A Terra-line model offering balanced performance with detailed visual reasoning, accurate computer use, and improved factuality at a low price.
the section called "GPT-6 Sol"	GPT-6 Sol supports complex coding and agentic workflows.
the section called "GPT-6 Luna"	GPT-6 Luna is designed for focused, high-volume tasks.
the section called "GPT-5.6 Sol"	The most capable OpenAI model yet, delivering frontier reasoning and state-of-the-art agentic performance across coding, cybersecurity, and scientific research.
the section called "GPT-5.6 Terra"	Balanced performance competitive with GPT-5.5 at half the cost, built for everyday production workloads at scale.
the section called "GPT-5.6 Luna"	Fast and affordable inference at OpenAI's lowest cost, built for high-volume tasks where speed and efficiency matter.

Model	Description
the section called "Daybreak Red: GPT-5.6 Cyber"	A highly specialized model for advanced tasks like vulnerability research, exploit reproduction, and mitigation development. Requires Trusted Access for Cyber enrollment.
the section called "Daybreak Blue: GPT-5.6 Sol"	A specialized model for verified defenders conducting advanced, authorized cybersecurity work. Requires Trusted Access for Cyber enrollment.
the section called "GPT-5.5"	GPT-5.5 is OpenAI's most capable model for complex professional work, designed for advanced coding, research, analysis, software operation, document workflows, and long-running agentic tasks.
the section called "GPT-5.4"	GPT-5.4 brings frontier reasoning, coding, computer use, long-context workflows, and tool use to Amazon Bedrock for professional workflows that require reliable reasoning and action across complex business systems.
the section called "GPT OSS Safeguard 120B"	GPT OSS Safeguard 120B is OpenAI's 120-billion parameter open-sour ce safety model for content moderation and guardrail enforcement in AI applications.
the section called "GPT OSS Safeguard 20B"	GPT OSS Safeguard 20B is OpenAI's compact 20-billion parameter open-source safety model for lightweight content moderation and guardrail tasks.
the section called "gpt-oss-120b"	GPT OSS 120B is OpenAI's 120-billion parameter open-source general-purpose model for text generation, coding, and reasoning tasks.
the section called "gpt-oss-20b"	GPT OSS 20B is OpenAI's 20-billion parameter open-source model for efficient text generation and coding at lower compute cost.

GPT-6 Astra

OpenAI — GPT-6 Astra

Model Details

GPT-6 Astra is OpenAI's most capable model. It handles the hardest end-to-end work. Use it for complex reasoning, coding, computer use, research, and document creation. To learn more, see the OpenAI Deployment Safety Hub.

Model launch date: September 8, 2026
EOL no sooner than: September 8, 2027
Legacy period: at least 6 months
Model lifecycle policy: Model lifecycle
Model EOL date: N/A
End User License Agreements and Terms of Use: View
Model lifecycle: Active
Context window: 1,050,000 tokens
Max output tokens: 128,000
Knowledge cutoff: April 30, 2026
Marketplace product ID: `prod-hqau7gqhlqsrg`

Input Modalities	Output Modalities
⊗ Audio	⊗ Embedding
✓ Image	⊗ Image
⊗ Speech	⊗ Speech

⊗ Video	⊗ Video

Endpoints and APIs supported

The following tables show which endpoints and APIs GPT-6 Astra supports. For more information, see the section called "APIs" and the section called "Inference endpoints".

Endpoint support

Endpoint	Supported
`bedrock-runtime`	✓
`bedrock-mantle`	✓

APIs supported on `bedrock-runtime`

Messages	Responses	Chat Completions	Converse	Invoke
✗	✓	✓	✓	✓

APIs supported on `bedrock-mantle`

Messages	Responses	Chat Completions	Converse	Invoke
✗	✓	✓	✗	✗

Note

On `bedrock-mantle`, both APIs use the `/openai/v1` base path, not `/v1`. Use either API with this model:

- For Responses, use `/openai/v1/responses`.
- For Chat Completions, use `/openai/v1/chat/completions`.

Capabilities and Features

Bedrock Features

Features supported using `bedrock-runtime`

Supported	Not Supported
✓ Projects (default project only) ✓ Invocation logs ✓ Response streaming ✓ Abuse detection ✓ Guardrails (Converse API only) ✓ Application inference profiles (InvokeModel and Converse APIs only; not supported with Responses or Chat Completions) ✓ Implicit Prompt Caching (Responses, Chat Completions, InvokeModel, and Converse APIs) ✓ Explicit Prompt Caching (Responses, Chat Completions, and InvokeModel APIs; not supported with Converse) ✓ Structured outputs (JSON Schema; see API configuration) ✓ Reasoning Summaries (Responses, Converse, and ConverseStream APIs; on Converse, set `additionalModelRequestFields.reasoning.summary`)	✗ Server-side tool use ✗ Intelligent prompt routing ✗ Count tokens ✗ Watermarking

Features supported using `bedrock-mantle`

Supported	Not Supported
✓ Server-side tool calling ✓ Projects ✓ Implicit Prompt Caching (Responses and Chat Completions APIs)	✗ Application inference profiles ✗ Watermarking

Supported	Not Supported
Explicit Prompt Caching (Responses and Chat Completions APIs) Reasoning Summaries (Responses API only) Structured outputs (JSON Schema; Responses and Chat Completions APIs)	

JSON Schema output on bedrock-runtime

Use JSON Schema to set the format of the model response. These settings apply to non-streaming calls on the `bedrock-runtime` endpoint. Choose a profile ID from Programmatic access.

- For Chat Completions, set `response_format.type` to `json_schema`. Put `name`, `schema`, and `strict: true` in `response_format.json_schema`.
- For Responses, set `text.format.type` to `json_schema`. Put `name`, `schema`, and `strict: true` in `text.format`.
- For Converse, set `outputConfig.textFormat.type` to `json_schema`. In `outputConfig.textFormat.structure.jsonSchema`, set `name` and `schema`. Encode the schema as a JSON string. Then set `additionalModelRequestFields.text.format.strict` to `true`.

Use an object schema. Put all fields in `required`. Set `additionalProperties` to `false`. Validate your schema before you send it. Check for refusals or incomplete responses before you parse the output.

Important

For JSON Schema output with the Converse API, you must set `additionalModelRequestFields.text.format.strict` to `true`, in addition to specifying the schema in `outputConfig`. Include the following field in your request.

```
{
  "additionalModelRequestFields": {
    "text": {
      "format": { "strict": true }
```

```
    }
  }
}
```

Converse content blocks

On the `bedrock-runtime` endpoint, Converse accepts `text` and `image` content blocks in user messages. This model doesn't accept `document` content blocks, and it doesn't accept an `image` content block inside a `toolResult`. A request that includes either is rejected with a `ValidationException`. To send a document to this model, use the Responses API with an `input_file` content part instead.

Pricing

All prices are in USD per 1 million tokens. The following tables list Standard and Ultrafast prices.

The **Input — 30-minute cache write** column is the price per 1 million tokens written to the prompt cache. The 30-minute figure is how long a cached prompt prefix is retained, not a quantity of tokens. For more information, see prompt caching.

Commercial In-Region and Geo CRIS prices include a 10% premium over the corresponding OpenAI rates for the same service tier. You do not need to add this premium.

Priority and Flex tiers are not supported for this model.

Standard — Commercial Regions, short context (272K input tokens or fewer)

Inference option	Input	Input — 30-minute cache write	Input — cache read	Output
In-Region	$11.00	$13.75	$1.10	$55.00
Geo CRIS	$11.00	$13.75	$1.10	$55.00
Global CRIS	$10.00	$12.50	$1.00	$50.00

Standard — Commercial Regions, long context (more than 272K input tokens)

Inference option	Input	Input — 30-minute cache write	Input — cache read	Output
In-Region	$22.00	$27.50	$2.20	$82.50
Geo CRIS	$22.00	$27.50	$2.20	$82.50
Global CRIS	$20.00	$25.00	$2.00	$75.00

Ultrafast prices are six times the corresponding Standard prices. On `bedrock-runtime`, Ultrafast is available through both US geographic CRIS and Global CRIS. On `bedrock-mantle`, Ultrafast is available in `us-east-1`. Short-context prices apply to requests with at most 272,000 input tokens. When input exceeds this threshold, long-context prices apply to the entire request.

Ultrafast — Commercial Regions, short context (272K input tokens or fewer)

Inference option	Input	Input — 30-minute cache write	Input — cache read	Output
In-Region (us-east-1)	$66.00	$82.50	$6.60	$330.00
Geo CRIS (US)	$66.00	$82.50	$6.60	$330.00
Global CRIS	$60.00	$75.00	$6.00	$300.00

Ultrafast — Commercial Regions, long context (more than 272K input tokens)

Inference option	Input	Input — 30-minute cache write	Input — cache read	Output
In-Region (us-east-1)	$132.00	$165.00	$13.20	$495.00
Geo CRIS (US)	$132.00	$165.00	$13.20	$495.00
Global CRIS	$120.00	$150.00	$12.00	$450.00

Programmatic Access

To call this model from code, use the following model IDs and endpoint URLs. For more information, see the section called “APIs” and the section called “Inference endpoints”.

Endpoint	Model ID	In-Region endpoint URL	Geo inference ID	Global inference ID
`bedrock-mantle`	`openai.gpt-6-astra`	`https://bedrock-mantle.us-east-1.api.aws/openai/v1` `https://bedrock-mantle.us-west-2.api.aws/openai/v1` (Standard only)	Not supported	Not supported
`bedrock-runtime`	`openai.gpt-6-astra`	Not supported	`us.openai.gpt-6-astra`	`global.openai.gpt-6-astra`

The `bedrock-mantle` endpoint is available in `us-east-1` (N. Virginia) and `us-west-2` (Oregon). Ultrafast is available only in `us-east-1` on this endpoint. On `bedrock-runtime`, the base URL is `https://bedrock-runtime.{region}.amazonaws.com/openai/v1`. Name `us.openai.gpt-6-astra` for US geographic cross-Region inference or `global.openai.gpt-6-astra` for global cross-Region inference.

Service Tiers

Amazon Bedrock offers several service tiers for different workloads. **Standard** gives you pay-per-token access with no commitment. To use it, set `"service_tier": "default"` or omit the field. For more information, see service tiers.

Ultrafast is a speed tier for GPT-6 Astra. OpenAI reports API speeds up to six times faster than Standard. To request it with the Responses API, set `"service_tier": "ultrafast"`.

Standard	Ultrafast	Priority	Flex	Reserved
✓	✓	✗	✗	✗

Use one of these routes for Ultrafast:

- `bedrock-mantle` in `us-east-1`, with model ID `openai.gpt-6-astra`.
- `bedrock-runtime`, with `us.openai.gpt-6-astra` for US geographic CRIS or `global.openai.gpt-6-astra` for Global CRIS.

> **Note**
>
> Ultrafast does not support regional Mantle access in `us-west-2`. If an existing session is pinned to Oregon capacity, start a new session using an Ultrafast-supported route.

Regional Availability

Regional availability at a glance

Amazon Bedrock offers three inference options. **In-Region** keeps requests in one Region for strict compliance. **Geo Cross-Region** routes requests across Regions in one geography. It respects data residency. **Global Cross-Region** routes requests anywhere in the world. Use it when you have no data residency needs. For more information, see the the section called “Regional availability by models” page.

Availability using the `bedrock-mantle` endpoint

Region	In-Region	Geo	Global
`us-east-1` (N. Virginia)	✓	✗	✗
`us-west-2` (Oregon)	✓	✗	✗

Ultrafast is available through regional Mantle in `us-east-1`. Regional Mantle in `us-west-2` supports Standard only.

Availability using the `bedrock-runtime` endpoint

Region	In-Region	Geo	Global
`us-east-1` (N. Virginia)	⊗	⊘	⊘
`us-east-2` (Ohio)	⊗	⊘	⊘

Geo inference details

The destination Regions available to a geographic inference profile depend on the source Region. To retrieve the current routing configuration, call GetInferenceProfile from the source Region.

Geo: US

Geo inference ID: `us.openai.gpt-6-astra`

Source Region	Destination Regions
us-east-1 (N. Virginia)	us-east-1 (N. Virginia), us-east-2 (Ohio), us-west-2 (Oregon)
us-east-2 (Ohio)	us-east-1 (N. Virginia), us-east-2 (Ohio), us-west-2 (Oregon)
us-west-1 (N. California)	us-east-1 (N. Virginia), us-east-2 (Ohio), us-west-1 (N. California), us-west-2 (Oregon)
us-west-2 (Oregon)	us-east-1 (N. Virginia), us-east-2 (Ohio), us-west-2 (Oregon)
ca-central-1 (Canada)	ca-central-1 (Canada), us-east-1 (N. Virginia), us-east-2 (Ohio), us-west-2 (Oregon)
ca-west-1 (Calgary)	ca-west-1 (Calgary), us-east-1 (N. Virginia), us-east-2 (Ohio), us-west-2 (Oregon)

Quotas and Limits

Your AWS account has default quotas. These quotas help keep Amazon Bedrock running well. A few things can change your quotas. These include Region, payment history, fraudulent use, or an approved quota increase request. For more information, see the the section called “Quotas” documentation and the limits for the model.

On the `bedrock-runtime` endpoint, limits are managed as tokens per minute (TPM) with a 10x burndown rate, where 1 output token consumes 10 tokens.

Sample Code

Step 1 - AWS Account: If you already have an AWS account, skip this step. If you are new to AWS, sign up for an AWS account.

Step 2 - API key: Go to the Amazon Bedrock console and generate a long-term API key.

Step 3 - Get the SDK: You must have Python installed to use this guide. Then install the OpenAI SDK.

```
pip install openai
```

Step 4 - Set environment variables

Set up your environment to use the API key for authentication.

bedrock-mantle

```
OPENAI_API_KEY="<provide your Bedrock API key>"
OPENAI_BASE_URL="https://bedrock-mantle.us-west-2.api.aws/openai/v1"
```

bedrock-runtime

```
OPENAI_API_KEY="<provide your Bedrock API key>"
OPENAI_BASE_URL="https://bedrock-runtime.us-west-2.amazonaws.com/openai/v1"
```

> **Note**
>
> On `bedrock-runtime`, name a cross-Region inference profile as the model: `us.openai.gpt-6-astra` or `global.openai.gpt-6-astra`. This model is not available for in-Region inference on that endpoint.

Step 5 - Run your first inference request

Save the file as `bedrock-first-request.py`.

bedrock-mantle

Use the settings from Step 4 - Set environment variables. Choose the `bedrock-mantle` tab. The Chat tab uses the Chat Completions API.

Responses API

```
from openai import OpenAI

client = OpenAI()

response = client.responses.create(
    model="openai.gpt-6-astra",
    input="Can you explain the features of Amazon Bedrock?"
)
print(response)
```

Chat

```
from openai import OpenAI

client = OpenAI()

response = client.chat.completions.create(
    model="openai.gpt-6-astra",
    messages=[{"role": "user", "content": "Can you explain the features of Amazon
 Bedrock?"}]
)
print(response)
```

bedrock-runtime: OpenAI SDK

Use the settings from Step 4 - Set environment variables. Choose the `bedrock-runtime` tab. Send your request with the Responses API.

Responses API

```
from openai import OpenAI

client = OpenAI()
```

```
response = client.responses.create(
    model="us.openai.gpt-6-astra",
    input="Can you explain the features of Amazon Bedrock?"
)
print(response)
```

Ultrafast example

Set `OPENAI_API_KEY` to your Amazon Bedrock API key. This example uses the `bedrock-mantle` endpoint in `us-east-1`.

```
export OPENAI_API_KEY="<your Amazon Bedrock API key>"
```

```
from openai import OpenAI

client = OpenAI(
    base_url="https://bedrock-mantle.us-east-1.api.aws/openai/v1",
)
response = client.responses.create(
    model="openai.gpt-6-astra",
    service_tier="ultrafast",
    input="Explain how Amazon Bedrock cross-Region inference works.",
)
print(response.output_text)
```

For `bedrock-runtime`, use the OpenAI-compatible base URL from Programmatic Access. Set the model to `us.openai.gpt-6-astra` for US geographic CRIS or `global.openai.gpt-6-astra` for Global CRIS, and keep `service_tier="ultrafast"`.

GPT-6.1 Sol

OpenAI — GPT-6.1 Sol

Model Details

OpenAI GPT-6.1 Sol brings advanced capabilities to workloads where both performance and cost matter. GPT-6.1 Sol helps agents investigate codebases and iterate on solutions. Agents can also

use it to understand complex documents and complete business and computer use workflows across multiple steps.

Model launch date: September 29, 2026
Model lifecycle policy: OpenAI model deprecation notice periods. This model follows OpenAI first-party lifecycle terms, with at least 6 months of deprecation notice for generally available models, unless safety or compliance concerns require a faster timeline.
Model EOL date: Not announced.
End User License Agreements and Terms of Use: OpenAI models on Amazon Bedrock terms
Model lifecycle: Active
Context window: 1M tokens
Max output tokens: 131,072 tokens
Marketplace product ID: `prod-qco655ut2vn54`

Input Modalities	Output Modalities
⊗ Audio	⊗ Embedding
⊙ Image	⊗ Image
⊗ Speech	⊗ Speech
⊙ Text	⊙ Text
⊗ Video	⊗ Video

Endpoints and APIs supported

The following tables show which endpoints and APIs GPT-6.1 Sol supports. For more information, see the section called “APIs” and the section called “Inference endpoints”.

Endpoint support

Endpoint	Supported
`bedrock-runtime`	⊙
`bedrock-mantle`	⊙

APIs supported on `bedrock-runtime`

Messages	Responses	Chat Completions	Converse	Invoke
⊗	✓	✓	✓	✓

APIs supported on `bedrock-mantle`

Messages	Responses	Chat Completions	Converse	Invoke
⊗	✓	✓	⊗	⊗

Note

On `bedrock-mantle`, both APIs use the `/openai/v1` base path, not `/v1`. Use either API with this model:

- For Responses, use `/openai/v1/responses`.
- For Chat Completions, use `/openai/v1/chat/completions`.

Capabilities and Features

Bedrock Features

Features supported using `bedrock-runtime`

Supported	Not Supported
✓ Projects (default project only) ✓ Invocation logs ✓ Response streaming ✓ Abuse detection	⊗ Server-side system tools ⊗ Intelligent prompt routing ⊗ Count tokens ⊗ Knowledge Bases ⊗ Prompt optimization

Supported	Not Supported
Guardrails (Chat Completions, InvokeModel, and Converse APIs; not supported with Responses) Application inference profiles (InvokeModel and Converse APIs only; not supported with Responses or Chat Completions) Implicit Prompt Caching (Responses, Chat Completions, InvokeModel, and Converse APIs) Explicit Prompt Caching (Responses, Chat Completions, and InvokeModel APIs; not supported with Converse) Structured outputs (Responses, Chat Completions, InvokeModel, and Converse APIs) Reasoning Summaries (Responses, Converse, and ConverseStream APIs; on Converse, set `additionalModelRequestFields.reasoning.summary`)	Watermarking

Features supported using `bedrock-mantle`

Supported	Not Supported
Projects Response streaming Implicit Prompt Caching (Responses and Chat Completions APIs) Explicit Prompt Caching (Responses and Chat Completions APIs) Structured outputs (Responses and Chat Completions APIs) Reasoning Summaries (Responses API only)	Guardrails Invocation logs Application inference profiles Server-side system tools Intelligent prompt routing Count tokens Knowledge Bases Prompt optimization Watermarking

Prompt caching

GPT-6.1 Sol supports both Implicit Prompt Caching and Explicit Prompt Caching. API support differs by endpoint:

- Responses and Chat Completions support both caching types on the `bedrock-runtime` and `bedrock-mantle` endpoints.
- InvokeModel supports both caching types on the `bedrock-runtime` endpoint.
- Converse supports implicit caching on the `bedrock-runtime` endpoint. The native `cachePoint` field isn't supported for explicit caching with this model.

For explicit caching, set `prompt_cache_options.mode` to `explicit`. Set `prompt_cache_options.ttl` to `30m`, the only supported TTL and the default. In Responses requests, add `"prompt_cache_breakpoint": {"mode": "explicit"}` to an `input_text` content block. In Chat Completions and InvokeModel requests, add it to a `text` content part.

A cacheable prompt prefix must contain at least 1,024 tokens. You can include multiple explicit breakpoints, and each request can create up to four cache writes. Check the cache usage fields in the response to determine whether tokens were written to or read from the cache.

JSON Schema output

Use JSON Schema to set the format of the model response for streaming and non-streaming requests. Chat Completions and Responses support JSON Schema output on both the `bedrock-runtime` and `bedrock-mantle` endpoints. InvokeModel, InvokeModelWithResponseStream, Converse, and ConverseStream support JSON Schema output on the `bedrock-runtime` endpoint. Choose a model ID or inference profile ID from Programmatic access.

- For Chat Completions, set `response_format.type` to `json_schema`. Put `name`, `schema`, and `strict: true` in `response_format.json_schema`.
- For Responses, set `text.format.type` to `json_schema`. Put `name`, `schema`, and `strict: true` in `text.format`.
- For InvokeModel and InvokeModelWithResponseStream, use the same `response_format` fields as Chat Completions.
- For Converse and ConverseStream, set `outputConfig.textFormat.type` to `json_schema`. In `outputConfig.textFormat.structure.jsonSchema`, set `name` and `schema`. Encode the

schema as a JSON string. Then set `additionalModelRequestFields.text.format.strict` to `true`.

Use an object schema. Put all fields in `required`. Set `additionalProperties` to `false`. Validate your schema before you send it. Check for refusals or incomplete responses before you parse the output.

Important

For JSON Schema output with Converse and ConverseStream, you must set `additionalModelRequestFields.text.format.strict` to `true`, in addition to specifying the schema in `outputConfig`. Include the following field in your request.

```
{
  "additionalModelRequestFields": {
    "text": {
      "format": { "strict": true }
    }
  }
}
```

Converse content blocks

On the `bedrock-runtime` endpoint, Converse accepts `text` and `image` content blocks in user messages. This model doesn't accept `document` content blocks, and it doesn't accept an `image` content block inside a `toolResult`. A request that includes either is rejected with a `ValidationException`. To send a document to this model, use the Responses API with an `input_file` content part instead.

Pricing

All prices are in USD per 1 million tokens. The following tables list Standard and Ultrafast prices. Global CRIS rates match OpenAI first-party pricing for the same service tier.

The **Input — 30-minute cache write** column is the price per 1 million tokens written to the prompt cache. The 30-minute figure is how long a cached prompt prefix is retained, not a quantity of tokens. For more information, see prompt caching.

In-Region access on `bedrock-mantle` costs 10% more than Global CRIS. US geographic cross-Region inference (US CRIS) on `bedrock-runtime` has the same premium. This applies to both service tiers. The tables include this premium.

GPT-6.1 Sol supports both implicit and explicit prompt caching. Cache-write tokens are billed at 1.25× the uncached input-token rate, and cache-read tokens are billed at 0.05× the uncached input-token rate. For configuration and API support, see Prompt caching.

Long-context rates apply to the full request when input exceeds 272,000 tokens.

Priority and Flex tiers are not supported for this model.

Standard — Commercial Regions, short context (272K input tokens or fewer)

Inference option	Input	Input — cache write	Input — cache read	Output
Regional (`bedrock-mantle` in US East (N. Virginia))	$2.20	$2.75	$0.11	$11.00
US CRIS (bedrock-runtime)	$2.20	$2.75	$0.11	$11.00
Global CRIS (bedrock-runtime)	$2.00	$2.50	$0.10	$10.00

Standard — Commercial Regions, long context (more than 272K input tokens)

Inference option	Input	Input — cache write	Input — cache read	Output
Regional (`bedrock-mantle` in US East (N. Virginia))	$4.40	$5.50	$0.22	$16.50
US CRIS (bedrock-runtime)	$4.40	$5.50	$0.22	$16.50
Global CRIS (bedrock-runtime)	$4.00	$5.00	$0.20	$15.00

Ultrafast costs six times as much as Standard. Global CRIS rates match OpenAI first-party Ultrafast pricing. On `bedrock-runtime`, use Ultrafast through US CRIS or Global CRIS. On `bedrock-mantle`, use Ultrafast in `us-east-1`. Short-context prices apply to requests with up to 272,000 input tokens. Above that limit, long-context prices apply to the full request.

Ultrafast — Commercial Regions, short context (272K input tokens or fewer)

Inference option	Input	Input — 30-minute cache write	Input — cache read	Output
In-Region (`bedrock-mantle` in `us-east-1`)	$13.20	$16.50	$0.66	$66.00
US CRIS (`bedrock-runtime`)	$13.20	$16.50	$0.66	$66.00
Global CRIS (`bedrock-runtime`)	$12.00	$15.00	$0.60	$60.00

Ultrafast — Commercial Regions, long context (more than 272K input tokens)

Inference option	Input	Input — 30-minute cache write	Input — cache read	Output
In-Region (`bedrock-mantle` in `us-east-1`)	$26.40	$33.00	$1.32	$99.00
US CRIS (`bedrock-runtime`)	$26.40	$33.00	$1.32	$99.00
Global CRIS (`bedrock-runtime`)	$24.00	$30.00	$1.20	$90.00

Programmatic Access

To call this model from code, use the following model IDs and endpoint URLs. For more information, see the section called "APIs" and the section called "Inference endpoints".

Endpoint	Model ID	In-Region endpoint URL	Geo inference ID	Global inference ID
bedrock-mantle	openai.gpt-6.1-sol	https://bedrock-mantle.us-east-1.api.aws/openai/v1	Not supported	Not supported
bedrock-runtime	openai.gpt-6.1-sol	Not supported	us.openai.gpt-6.1-sol	global.openai.gpt-6.1-sol

For in-Region access, use `bedrock-mantle` in `us-east-1` (N. Virginia). On `bedrock-runtime`, the OpenAI-compatible base URL is `https://bedrock-runtime.{region}.amazonaws.com/openai/v1`. Use `us.openai.gpt-6.1-sol` for US geographic cross-Region inference or `global.openai.gpt-6.1-sol` for global cross-Region inference. Direct in-Region invocation is not supported on `bedrock-runtime`. Use a source Region enabled for the profile you choose; see the section called "Cross-Region inference".

Service Tiers

Amazon Bedrock offers several service tiers for different workloads. **Standard** gives you pay-per-token access with no commitment. To use it, set `"service_tier": "default"` or omit the field. For more information, see service tiers.

Ultrafast is a premium speed tier for GPT-6.1 Sol. Use it for workloads where response speed matters most. To request it with the Responses API, set `"service_tier": "ultrafast"`.

Standard	Ultrafast	Priority	Flex	Reserved
✓	✓	✗	✗	✗

Use one of these routes for Ultrafast:

- `bedrock-mantle` in `us-east-1`, with model ID `openai.gpt-6.1-sol`.
- `bedrock-runtime`, with `us.openai.gpt-6.1-sol` for US CRIS or `global.openai.gpt-6.1-sol` for Global CRIS.

Regional Availability

Regional availability at a glance

Standard and Ultrafast are available on `bedrock-mantle` in `us-east-1` (N. Virginia). Both tiers support US geographic and global inference profiles on `bedrock-runtime`. For more information, see the section called “Regional availability by models”.

Availability using the `bedrock-mantle` endpoint

Region	In-Region	Geo	Global
`us-east-1` (N. Virginia)	✓	✗	✗

Availability using the `bedrock-runtime` endpoint

Scope	In-Region	Geo	Global
US geographic and global inference	✗	✓	✓

Geo inference details

The destination Regions available to a geographic inference profile depend on the source Region. To retrieve the current routing configuration, call GetInferenceProfile from the source Region.

Geo: US

Geo inference ID: `us.openai.gpt-6.1-sol`

Source Region	Destination Regions
us-east-1 (N. Virginia)	us-east-1 (N. Virginia), us-east-2 (Ohio), us-west-2 (Oregon)
us-east-2 (Ohio)	us-east-1 (N. Virginia), us-east-2 (Ohio), us-west-2 (Oregon)
us-west-1 (N. California)	us-east-1 (N. Virginia), us-east-2 (Ohio), us-west-1 (N. California), us-west-2 (Oregon)
us-west-2 (Oregon)	us-east-1 (N. Virginia), us-east-2 (Ohio), us-west-2 (Oregon)
ca-central-1 (Canada)	ca-central-1 (Canada), us-east-1 (N. Virginia), us-east-2 (Ohio), us-west-2 (Oregon)
ca-west-1 (Calgary)	ca-west-1 (Calgary), us-east-1 (N. Virginia), us-east-2 (Ohio), us-west-2 (Oregon)

Quotas and Limits

Quotas vary by account and Region. See the section called “Quotas” and the model's service quota settings.

The output-token burndown rate is 10: each output token consumes 10 tokens of quota.

Sample Code

Step 1 - AWS Account: If you already have an AWS account, skip this step. If you are new to AWS, sign up for an AWS account.

Step 2 - API key: Go to the Amazon Bedrock console and generate a long-term API key.

Step 3 - Get the SDK: You must have Python installed to use this guide. Then install the OpenAI SDK.

```
python3 -m pip install openai
```

Step 4 - Set environment variables

Set up your environment to use the API key for authentication.

bedrock-mantle

```
export OPENAI_API_KEY="<provide your Bedrock API key>"
export OPENAI_BASE_URL="https://bedrock-mantle.us-east-1.api.aws/openai/v1"
```

bedrock-runtime

```
export OPENAI_API_KEY="<provide your Bedrock API key>"
export OPENAI_BASE_URL="https://bedrock-runtime.us-east-1.amazonaws.com/openai/v1"
```

> **Note**
>
> On `bedrock-runtime`, set the model to `us.openai.gpt-6.1-sol` for US CRIS or `global.openai.gpt-6.1-sol` for Global CRIS. Direct in-Region invocation is not supported on this endpoint.

Step 5 - Run your first inference request

Save the file as `bedrock-first-request.py`.

bedrock-mantle

Use the settings from Step 4 - Set environment variables. Choose the `bedrock-mantle` tab. The Chat tab uses the Chat Completions API.

Responses API

```
from openai import OpenAI

client = OpenAI()
```

```
response = client.responses.create(
    model="openai.gpt-6.1-sol",
    input="Can you explain the features of Amazon Bedrock?",
    max_output_tokens=512,
)
print(response.output_text)
```

Chat

```
from openai import OpenAI

client = OpenAI()

response = client.chat.completions.create(
    model="openai.gpt-6.1-sol",
    messages=[{"role": "user", "content": "Can you explain the features of Amazon
 Bedrock?"}]
)
print(response.choices[0].message.content)
```

bedrock-runtime: OpenAI SDK

Use the settings from Step 4 - Set environment variables. Choose the `bedrock-runtime` tab. Send your request with the Responses API. The example uses the US CRIS profile. For Global CRIS, replace `us.openai.gpt-6.1-sol` with `global.openai.gpt-6.1-sol`.

Responses API

```
from openai import OpenAI

client = OpenAI()

response = client.responses.create(
    model="us.openai.gpt-6.1-sol",
    input="Can you explain the features of Amazon Bedrock?",
    max_output_tokens=512,
)
print(response.output_text)
```

Ultrafast example

Set `OPENAI_API_KEY` to your Amazon Bedrock API key. This example uses the `bedrock-mantle` endpoint in `us-east-1`.

```
export OPENAI_API_KEY="<your Amazon Bedrock API key>"
```

```
from openai import OpenAI

client = OpenAI(
    base_url="https://bedrock-mantle.us-east-1.api.aws/openai/v1",
)
response = client.responses.create(
    model="openai.gpt-6.1-sol",
    service_tier="ultrafast",
    input="Explain how Amazon Bedrock cross-Region inference works.",
)
print(response.output_text)
```

For `bedrock-runtime`, use the OpenAI-compatible base URL from Programmatic Access. Set the model to `us.openai.gpt-6.1-sol` for US CRIS or `global.openai.gpt-6.1-sol` for Global CRIS, and keep `service_tier="ultrafast"`.

GPT-6.1 Terra

OpenAI — GPT-6.1 Terra

Model Details

As the newest model in the Terra line, GPT-6.1 Terra combines detailed visual reasoning, accurate computer use, and improved factuality and natural writing over GPT-5.6 Terra for complex workflows. In OpenAI's Agents' Last Exam evaluation, it scored 15 percentage points higher than GPT-5.6 Terra, performed on par with GPT-6 Astra, and completed tasks more than three times faster than GPT-6 Astra and GPT-6.1 Sol. GPT-6.1 Terra offers balanced performance with input and output token prices at least 50% lower than those of GPT-6.1 Sol and GPT-5.6 Terra. For more information about model development and performance, see the model/service card.

Model launch date: October 26, 2026

EOL no sooner than: October 26, 2027
Legacy period: at least 6 months
Model lifecycle policy: Model lifecycle (For Models Launched Prior to Sept 7 2026)
Model EOL date: N/A
End User License Agreements and Terms of Use: View
Model lifecycle: Active
Context window: 1,050,000 tokens
Max output tokens: 128,000
Marketplace product ID: `prod-xynumvnbsn34g`

Input Modalities	Output Modalities
⊗ Audio	⊗ Embedding
⊙ Image	⊗ Image
⊗ Speech	⊗ Speech
⊙ Text	⊙ Text
⊗ Video	⊗ Video

Endpoints and APIs supported

The following tables show which endpoints and APIs are supported for GPT-6.1 Terra. For more information, see the section called “APIs” and the section called “Inference endpoints”.

Endpoint support

Endpoint	Supported
`bedrock-runtime`	⊙
`bedrock-mantle`	⊙

APIs supported on `bedrock-runtime` endpoint

Messages	Responses	Chat Completions	Converse	Invoke
⊗	⊙	⊙	⊙	⊙

APIs supported on `bedrock-mantle` endpoint

Messages	Responses	Chat Completions	Converse	Invoke
⊗	⊙	⊙	⊗	⊗

Note

On `bedrock-mantle`, both APIs use the `/openai/v1` base path, not `/v1`. Use either API with this model:

- For Responses, use `/openai/v1/responses`.
- For Chat Completions, use `/openai/v1/chat/completions`.

Tip

Whenever possible, we recommend using the `bedrock-runtime` endpoint for new applications. See the section called “Inference endpoints” for details.

Capabilities and Features

Bedrock Features

Features supported using `bedrock-runtime` endpoint

Supported	Not Supported
⊙ Projects (default project only)	⊗ Server-side tool use

Supported	Not Supported
✓ Invocation logs ✓ Response streaming ✓ Abuse detection ✓ Guardrails (Converse API only) ✓ Application inference profiles (Converse API only; not supported with Responses or Chat Completions APIs) ✓ Implicit Prompt Caching (Responses, Chat Completions, InvokeModel, and Converse APIs) ✓ Explicit Prompt Caching (Responses API only) ✓ Structured outputs (JSON Schema; see API configuration) ✓ Reasoning Summaries (Responses, Converse, and ConverseStream APIs; on Converse, set `additionalModelRequestFields.reasoning.summary`)	✗ Intelligent prompt routing ✗ Count tokens ✗ Watermarking

Features supported using `bedrock-mantle` endpoint

Supported	Not Supported
✓ Server-side tool calling ✓ Projects ✓ Implicit Prompt Caching (Responses API only) ✓ Explicit Prompt Caching (Responses API only) ✓ Reasoning Summaries (Responses API only)	✗ Application inference profiles (Responses and Chat Completions APIs only) ✗ Watermarking

JSON Schema output on bedrock-runtime

Use JSON Schema to set the format of the model response. These settings apply to non-streaming calls on the `bedrock-runtime` endpoint. Choose a profile ID from Programmatic access.

- For Chat Completions, set `response_format.type` to `json_schema`. Put `name`, `schema`, and `strict: true` in `response_format.json_schema`.
- For Responses, set `text.format.type` to `json_schema`. Put `name`, `schema`, and `strict: true` in `text.format`.
- For Converse, set `outputConfig.textFormat.type` to `json_schema`. In `outputConfig.textFormat.structure.jsonSchema`, set `name` and `schema`. Encode the schema as a JSON string. Then set `additionalModelRequestFields.text.format.strict` to `true`.

Use an object schema. Put all fields in `required`. Set `additionalProperties` to `false`. Validate your schema before you send it. Check for refusals or incomplete responses before you parse the output.

Important

For JSON Schema output with the Converse API, you must set `additionalModelRequestFields.text.format.strict` to `true`, in addition to specifying the schema in `outputConfig`. Include the following field in your request.

```
{
  "additionalModelRequestFields": {
    "text": {
      "format": { "strict": true }
    }
  }
}
```

Converse content blocks

On the `bedrock-runtime` endpoint, Converse accepts `text` and `image` content blocks in user messages. This model doesn't accept `document` content blocks, and it doesn't accept an `image` content block inside a `toolResult`. A request that includes either is rejected with a

`ValidationException`. To send a document to this model, use the Responses API with an `input_file` content part instead.

Pricing

All prices are in USD per 1 million tokens for the Standard tier.

The **Input — 30-minute cache write** column is the price per 1 million tokens written to the prompt cache. The 30-minute figure is how long a cached prompt prefix is retained, not a quantity of tokens. For more information, see prompt caching.

Commercial In-Region prices include a 10% fee over OpenAI rates. You do not need to add this fee.

Priority and Flex tiers are not supported for this model.

Commercial Regions — short context (272K input tokens or fewer)

Inference option	Input	Input — 30-minute cache write	Input — cache read	Output
In-Region	$1.10	$1.375	$0.055	$5.50
Geo CRIS	$1.10	$1.375	$0.055	$5.50
Global CRIS	$1.00	$1.25	$0.05	$5.00

Commercial Regions — long context (more than 272K input tokens)

Inference option	Input	Input — 30-minute cache write	Input — cache read	Output
In-Region	$2.20	$2.75	$0.11	$8.25
Geo CRIS	$2.20	$2.75	$0.11	$8.25
Global CRIS	$2.00	$2.50	$0.10	$7.50

Programmatic Access

Use the following model IDs and endpoint URLs to access this model programmatically. For more information about the available APIs and endpoints, see APIs supported and Endpoints supported.

Endpoint	Model ID	In-Region endpoint URL	Geo inference ID	Global inference ID
bedrock-mantle	openai.gpt-6.1-terra	https://bedrock-mantle.{region}.api.aws/openai/v1	Not supported	Not supported
bedrock-runtime	openai.gpt-6.1-terra	Not supported	us.openai.gpt-6.1-terra	global.openai.gpt-6.1-terra

For example, if region is us-east-1 (N. Virginia), then the bedrock-mantle endpoint URL will be "https://bedrock-mantle.us-east-1.api.aws/openai/v1". On `bedrock-runtime`, the base URL is "https://bedrock-runtime.{region}.amazonaws.com/openai/v1" and requests must name the geographic cross-Region inference ID `us.openai.gpt-6.1-terra` as the model.

Service Tiers

Amazon Bedrock offers multiple service tiers to match your workload requirements. **Standard** provides pay-per-token access with no commitment (set `"service_tier": "default"` or omit the field). **Priority** delivers the fastest response times for a price premium (set `"service_tier": "priority"`). **Flex** provides lower-cost access for flexible, non-time-sensitive workloads (set `"service_tier": "flex"`). **Reserved** provides dedicated throughput with a term commitment for predictable workloads; it is set at the account level rather than per request (contact your AWS account team to enable). For more information, see service tiers.

Standard	Priority	Flex	Reserved
✓	✗	✗	✗

Regional Availability

Regional availability at a glance

Amazon Bedrock offers three inference options: **In-Region** keeps requests within a single Region for strict compliance, **Geo Cross-Region** routes across Regions within a geography (such as US, EU, and APAC) while respecting data residency, and **Global Cross-Region** routes anywhere worldwide when there are no residency constraints. Refer to the the section called “Regional availability by models” page for more details.

Availability differs by endpoint.

Availability using the `bedrock-mantle` endpoint

Region	In-Region	Geo	Global
`us-east-1` (N. Virginia)	✓	✗	✗
`us-east-2` (Ohio)	✗	✗	✗
`us-west-2` (Oregon)	✗	✗	✗
`us-gov-west-1` (GovCloud West)	✗	✗	✗
`us-gov-east-1` (GovCloud East)	✗	✗	✗

Geo inference details

The destination Regions available to a geographic inference profile depend on the source Region. To retrieve the current routing configuration, call GetInferenceProfile from the source Region.

Geo: US

Geo inference ID: `us.openai.gpt-6.1-terra`

Source Region	Destination Regions
us-east-1 (N. Virginia)	us-east-1 (N. Virginia), us-east-2 (Ohio), us-west-2 (Oregon)
us-east-2 (Ohio)	us-east-1 (N. Virginia), us-east-2 (Ohio), us-west-2 (Oregon)
us-west-1 (N. California)	us-east-1 (N. Virginia), us-east-2 (Ohio), us-west-1 (N. California), us-west-2 (Oregon)
us-west-2 (Oregon)	us-east-1 (N. Virginia), us-east-2 (Ohio), us-west-2 (Oregon)

Source Region	Destination Regions
ca-central-1 (Canada)	ca-central-1 (Canada), us-east-1 (N. Virginia), us-east-2 (Ohio), us-west-2 (Oregon)
ca-west-1 (Calgary)	ca-west-1 (Calgary), us-east-1 (N. Virginia), us-east-2 (Ohio), us-west-2 (Oregon)

Quotas and Limits

Your AWS account has default quotas to maintain the performance of the service and to ensure appropriate usage of Amazon Bedrock. The default quotas assigned to an account might be updated depending on regional factors, payment history, fraudulent usage, and/or approval of a quota increase request. For more information, see the section called "Quotas" documentation and see the limits for the model.

On Amazon Bedrock, each request can contain a maximum of 100 image inputs.

On the `bedrock-runtime` endpoint, limits are managed as tokens per minute (TPM) with a 10x burndown rate, where 1 output token consumes 10 tokens.

Sample Code

Step 1 - AWS Account: If you have an AWS account already, skip this step. If you are new to AWS, sign up for an AWS account.

Step 2 - API key: Go to the Amazon Bedrock console and generate a long-term API key.

Step 3 - Get the SDK: To use this getting started guide, you must have Python already installed. Then install the relevant software depending on the APIs you are using.

For both APIs, choose the OpenAI SDK tab.

OpenAI SDK

```
pip install openai
```

Step 4 - Set environment variables

Configure your environment to use the API key for authentication.

bedrock-mantle

```
OPENAI_API_KEY="<provide your Bedrock API key>"
OPENAI_BASE_URL="https://bedrock-mantle.us-east-1.api.aws/openai/v1"
```

Note

On `bedrock-runtime`, name a cross-Region inference profile as the model — `us.openai.gpt-6.1-terra` or `global.openai.gpt-6.1-terra`. This model is not available for in-Region inference on that endpoint. Your IAM identity also needs `bedrock:InvokeModel` on your account's default project (`arn:aws:bedrock:{region}:{account-id}:project/default`) in addition to the inference profile.

Step 5 - Run your first inference request

Save the file as `bedrock-first-request.py`

bedrock-mantle

Use the settings from Step 4 - Set environment variables. Choose the `bedrock-mantle` tab. Send your request with the Responses API.

Responses API

```
from openai import OpenAI

client = OpenAI()

response = client.responses.create(
    model="openai.gpt-6.1-terra",
    input="Can you explain the features of Amazon Bedrock?"
)
print(response)
```

bedrock-runtime: OpenAI SDK

Use the settings from Step 4 - Set environment variables. Choose the `bedrock-runtime` tab. Send your request with the Responses API.

Responses API

```
from openai import OpenAI

client = OpenAI()

response = client.responses.create(
    model="us.openai.gpt-6.1-terra",
    input="Can you explain the features of Amazon Bedrock?"
)
print(response)
```

GPT-6 Sol

OpenAI — GPT-6 Sol

Model details

GPT-6 Sol is designed for demanding development work. It can build features, debug and refactor code, and review code. It supports multi-step work across tools and apps. It accepts text and images and returns text, including code.

Model launch date: September 22, 2026
EOL no sooner than: September 22, 2027
Legacy period: at least 6 months
Model lifecycle policy: Model lifecycle
Model EOL date: N/A
End User License Agreements and Terms of Use: View
Model lifecycle: Active
Context window: 1,050,000 tokens
Max output tokens: 128,000
Knowledge cutoff: April 20, 2026
Marketplace product ID: `prod-zpwu74hhojefo`

Input modalities	Output modalities
⊗ Audio	⊗ Embedding
⊙ Image	⊗ Image
⊗ Speech	⊗ Speech
⊙ Text	⊙ Text
⊗ Video	⊗ Video

Endpoints and APIs supported

These tables show the endpoints and APIs that GPT-6 Sol supports. See the section called “APIs” and the section called “Inference endpoints”.

Endpoint support

Endpoint	Supported
`bedrock-runtime`	⊙
`bedrock-mantle`	⊙

APIs supported on the `bedrock-runtime` endpoint

Messages	Responses	Chat Completions	Converse	Invoke
⊗	⊙	⊙	⊙	⊙

APIs supported on the `bedrock-mantle` endpoint

Messages	Responses	Chat Completions	Converse	Invoke
⊗	✓	✓	⊗	⊗

Note

On `bedrock-mantle`, both APIs use the `/openai/v1` base path. Do not use `/v1`. Use either API with this model:

- For Responses, use `/openai/v1/responses`.
- For Chat Completions, use `/openai/v1/chat/completions`.

Tip

For new applications, use the `bedrock-runtime` endpoint when possible. See the section called "Inference endpoints" for details.

Capabilities and features

Amazon Bedrock features

Features supported on the `bedrock-runtime` endpoint

Supported	Not Supported
✓ Projects (default project only) ✓ Invocation logs ✓ Response streaming ✓ Abuse detection ✓ Guardrails (Responses, Chat Completions, InvokeModel, and Converse APIs) ✓ Application inference profiles (InvokeModel and Converse APIs only; not supported with Responses or Chat Completions)	⊗ Server-side tool use ⊗ Intelligent prompt routing ⊗ Count tokens ⊗ Knowledge Bases

Supported	Not Supported
✓ Implicit Prompt Caching (Responses, Chat Completions, InvokeModel, and Converse APIs) ✓ Explicit Prompt Caching (Responses, Chat Completions, and InvokeModel APIs; not supported with Converse) ✓ Structured outputs (Responses, Chat Completions, InvokeModel, and Converse APIs) ✓ Reasoning Summaries (Responses, Converse, and ConverseStream APIs; on Converse, set `additionalModelRequestFields.reasoning.summary`)	

Features supported on the `bedrock-mantle` endpoint

Supported	Not Supported
✓ Server-side tool calling ✓ Projects ✓ Response streaming ✓ Implicit Prompt Caching (Responses and Chat Completions APIs) ✓ Explicit Prompt Caching (Responses and Chat Completions APIs) ✓ Structured outputs (Responses and Chat Completions APIs) ✓ Reasoning Summaries (Responses API only)	⊗ Guardrails ⊗ Invocation logs ⊗ Application inference profiles ⊗ Intelligent prompt routing ⊗ Count tokens ⊗ Knowledge Bases ⊗ Prompt optimization

Prompt caching

GPT-6 Sol supports both Implicit Prompt Caching and Explicit Prompt Caching. API support differs by endpoint:

- Responses and Chat Completions support both caching types on the `bedrock-runtime` and `bedrock-mantle` endpoints.
- InvokeModel supports both caching types on the `bedrock-runtime` endpoint.
- Converse supports implicit caching on the `bedrock-runtime` endpoint. The native `cachePoint` field isn't supported for explicit caching with this model.

For explicit caching, set `prompt_cache_options.mode` to `explicit`. Set `prompt_cache_options.ttl` to `30m`, the only supported TTL and the default. In Responses requests, add `"prompt_cache_breakpoint": {"mode": "explicit"}` to an `input_text` content block. In Chat Completions and InvokeModel requests, add it to a `text` content part.

A cacheable prompt prefix must contain at least 1,024 tokens. You can include multiple explicit breakpoints, and each request can create up to four cache writes. Check `cached_tokens` and `cache_write_tokens` in the response to determine whether tokens were read from or written to the cache.

Reasoning effort

Set reasoning effort to none, `low`, `medium`, `high`, `xhigh`, or `max`. The default is `medium`.

JSON Schema output

Use JSON Schema to set the format of the model response for non-streaming requests. Chat Completions and Responses support JSON Schema output on the `bedrock-runtime` and `bedrock-mantle` endpoints. InvokeModel and Converse support JSON Schema output on the `bedrock-runtime` endpoint. Choose a model ID or inference profile ID from Programmatic access.

- For Chat Completions, set `response_format.type` to `json_schema`. Put `name`, `schema`, and `strict: true` in `response_format.json_schema`.
- For Responses, set `text.format.type` to `json_schema`. Put `name`, `schema`, and `strict: true` in `text.format`.
- For InvokeModel, use the same `response_format` fields as Chat Completions.
- For Converse, set `outputConfig.textFormat.type` to `json_schema`. In `outputConfig.textFormat.structure.jsonSchema`, set `name` and `schema`. Encode the schema as a JSON string. Then set `additionalModelRequestFields.text.format.strict` to `true`.

Use an object schema. Put all fields in `required`. Set `additionalProperties` to `false`. Validate your schema before you send it. Check for refusals or incomplete responses before you parse the output.

Important

For JSON Schema output with the Converse API, you must set `additionalModelRequestFields.text.format.strict` to `true`, in addition to specifying the schema in `outputConfig`. Include the following field in your request.

```
{
  "additionalModelRequestFields": {
    "text": {
      "format": { "strict": true }
    }
  }
}
```

Converse content blocks

On the `bedrock-runtime` endpoint, Converse accepts `text` and `image` content blocks in user messages. This model doesn't accept `document` content blocks, and it doesn't accept an `image` content block inside a `toolResult`. A request that includes either is rejected with a `ValidationException`. To send a document to this model, use the Responses API with an `input_file` content part instead.

Pricing

All prices are in USD per 1 million tokens for the Standard tier.

Mantle in-Region and US geographic cross-Region inference include a 10% premium. The base rates are OpenAI first-party Standard rates. Global cross-Region inference uses those rates with no premium. The prices below already include any premium.

Priority and Flex tiers are not supported for these inference options.

Commercial Regions — short context (272K input tokens or fewer)

Inference option	Input	Input — cache write	Input — cache read	Output
Mantle in-Region	$2.20	$2.75	$0.22	$11.00
US Geo CRIS	$2.20	$2.75	$0.22	$11.00
Global CRIS	$2.00	$2.50	$0.20	$10.00

Commercial Regions — long context (more than 272K input tokens)

Inference option	Input	Input — cache write	Input — cache read	Output
Mantle in-Region	$4.40	$5.50	$0.44	$16.50
US Geo CRIS	$4.40	$5.50	$0.44	$16.50
Global CRIS	$4.00	$5.00	$0.40	$15.00

Long-context rates apply to the full request when input exceeds 272,000 tokens.

> **Note**
>
> Prices are subject to change. For current prices, see Amazon Bedrock pricing.

Call the model

Use these model IDs and endpoint URLs to call the model. See APIs supported and Endpoints supported.

Endpoint	Model ID	In-Region endpoint URL	Geo inference ID	Global inference ID
bedrock-runtime	openai.gpt-6-sol	Not supported	us.openai.gpt-6-sol	global.openai.gpt-6-sol
bedrock-mantle	openai.gpt-6-sol	https://bedrock-mantle.{region}.api.aws/openai/v1	Not supported	Not supported

Configure your client for the `bedrock-runtime` endpoint as follows:

- Use this base URL: `https://bedrock-runtime.{region}.amazonaws.com/openai/v1`.
- Set the model ID to `us.openai.gpt-6-sol` or `global.openai.gpt-6-sol`.
- Choose a profile that is available in your source Region.
- You cannot use the base model ID for in-Region calls on this endpoint.

On `bedrock-mantle`, use `openai.gpt-6-sol` with the `/openai/v1` base path. Use the US East (N. Virginia) (`us-east-1`) Region for this model on this endpoint.

Service tiers

This model supports only the **Standard** tier in Amazon Bedrock. You pay per token with no commitment. Set `"service_tier": "default"` or omit the field. Priority, Flex, and Reserved are not supported. For more information, see service tiers.

Standard	Priority	Flex	Reserved
✓	✗	✗	✗

Supported Regions

Each endpoint supports a different set of Regions. See the section called “Regional availability by models”.

The `bedrock-mantle` endpoint

Region	In-Region	Geo	Global
`us-east-1` (US East (N. Virginia))	Supported	Not supported	Not supported

mx-central-1	Not supported	Not supported	Supported

Geo inference details

The destination Regions available to a geographic inference profile depend on the source Region. To retrieve the current routing configuration, call GetInferenceProfile from the source Region.

Geo: US

Geo inference ID: `us.openai.gpt-6-sol`

Source Region	Destination Regions
us-east-1 (N. Virginia)	us-east-1 (N. Virginia), us-east-2 (Ohio), us-west-2 (Oregon)
us-east-2 (Ohio)	us-east-1 (N. Virginia), us-east-2 (Ohio), us-west-2 (Oregon)
us-west-1 (N. California)	us-east-1 (N. Virginia), us-east-2 (Ohio), us-west-1 (N. California), us-west-2 (Oregon)
us-west-2 (Oregon)	us-east-1 (N. Virginia), us-east-2 (Ohio), us-west-2 (Oregon)
ca-central-1 (Canada)	ca-central-1 (Canada), us-east-1 (N. Virginia), us-east-2 (Ohio), us-west-2 (Oregon)
ca-west-1 (Calgary)	ca-west-1 (Calgary), us-east-1 (N. Virginia), us-east-2 (Ohio), us-west-2 (Oregon)

Quotas and limits

Quotas vary by account and Region. To review your quotas or request an increase, see the section called “Quotas” and Request an increase to a quota.

On `bedrock-runtime`, the quota counts output tokens at a 10-to-1 rate. Each output token uses 10 tokens of quota.

Sample code

Step 1 - Create an AWS account: If you already have an AWS account, skip this step. Otherwise, sign up for an AWS account.

Step 2 - Create an API key: Open the Amazon Bedrock console. Create a long-term API key.

Step 3 - Install the SDK: You need Python to run these examples. Install the OpenAI SDK with the command below. Both APIs use this SDK.

OpenAI SDK

```
python3 -m pip install openai
```

Step 4 - Set environment variables

Choose the tab for your endpoint. Set your API key and the base URL shown there.

bedrock-runtime

```
export OPENAI_API_KEY="<provide your Bedrock API key>"
export OPENAI_BASE_URL="https://bedrock-runtime.us-east-1.amazonaws.com/openai/v1"
```

bedrock-mantle

```
export OPENAI_API_KEY="<provide your Bedrock API key>"
export OPENAI_BASE_URL="https://bedrock-mantle.us-east-1.api.aws/openai/v1"
```

Note

On `bedrock-runtime`, use a cross-Region inference profile as the model: `us.openai.gpt-6-sol` or `global.openai.gpt-6-sol`. This model does not support in-Region calls on this endpoint.
Your IAM identity needs `bedrock:InvokeModel` permission for both resources:

- The inference profile.
- Your AWS account's default project: `arn:aws:bedrock:{region}:{account-id}:project/default`.

Step 5 - Send your first request

Save one of the examples below as `bedrock-first-request.py`.

bedrock-runtime: OpenAI SDK

Use the settings from Step 4 - Set environment variables. Choose the `bedrock-runtime` tab. Both examples use the global system inference profile.

Responses API

```
import os
from openai import OpenAI

client = OpenAI(base_url=os.environ["OPENAI_BASE_URL"])

response = client.responses.create(
    model="global.openai.gpt-6-sol",
    input="Can you explain the features of Amazon Bedrock?"
)
print(response)
```

Chat Completions API

```
import os
from openai import OpenAI

client = OpenAI(base_url=os.environ["OPENAI_BASE_URL"])

response = client.chat.completions.create(
    model="global.openai.gpt-6-sol",
    messages=[{"role": "user", "content": "Can you explain the features of Amazon
 Bedrock?"}]
)
print(response)
```

bedrock-mantle

Use the settings from Step 4 - Set environment variables. Choose the `bedrock-mantle` tab.

Responses API

```
import os
from openai import OpenAI

client = OpenAI(base_url=os.environ["OPENAI_BASE_URL"])

response = client.responses.create(
    model="openai.gpt-6-sol",
    input="Can you explain the features of Amazon Bedrock?"
)
```

```
print(response)
```

Chat Completions API

```
import os
from openai import OpenAI

client = OpenAI(base_url=os.environ["OPENAI_BASE_URL"])

response = client.chat.completions.create(
    model="openai.gpt-6-sol",
    messages=[{"role": "user", "content": "Can you explain the features of Amazon
 Bedrock?"}]
)
print(response)
```

GPT-6 Luna

OpenAI — GPT-6 Luna

Model details

GPT-6 Luna is designed for repeatable work at scale. It can summarize documents, extract information, and answer focused questions. It accepts text and images and returns text, including code. You can adjust its reasoning effort to fit your workload.

Model launch date: September 22, 2026
EOL no sooner than: September 22, 2027
Legacy period: at least 6 months
Model lifecycle policy: Model lifecycle
Model EOL date: N/A
End User License Agreements and Terms of Use: View
Model lifecycle: Active
Context window: 1,050,000 tokens
Max output tokens: 128,000
Knowledge cutoff: May 18, 2026

Marketplace product ID: `prod-fiwlckcpwkwli`

Input modalities	Output modalities
⊗ Audio	⊗ Embedding
✓ Image	⊗ Image

Features supported on the `bedrock-mantle` endpoint

Supported	Not Supported
✓ Server-side tool calling ✓ Projects ✓ Response streaming ✓ Implicit Prompt Caching (Responses and Chat Completions APIs) ✓ Explicit Prompt Caching (Responses and Chat Completions APIs) ✓ Structured outputs (Responses and Chat Completions APIs) ✓ Reasoning Summaries (Responses API only)	✗ Guardrails ✗ Invocation logs ✗ Application inference profiles ✗ Intelligent prompt routing ✗ Count tokens ✗ Knowledge Bases ✗ Prompt optimization

Prompt caching

GPT-6 Luna supports both Implicit Prompt Caching and Explicit Prompt Caching. API support differs by endpoint:

- Responses and Chat Completions support both caching types on the `bedrock-runtime` and `bedrock-mantle` endpoints.
- InvokeModel supports both caching types on the `bedrock-runtime` endpoint.
- Converse supports implicit caching on the `bedrock-runtime` endpoint. The native `cachePoint` field isn't supported for explicit caching with this model.

For explicit caching, set `prompt_cache_options.mode` to `explicit`. Set `prompt_cache_options.ttl` to `30m`, the only supported TTL and the default. In Responses requests, add `"prompt_cache_breakpoint": {"mode": "explicit"}` to an `input_text` content block. In Chat Completions and InvokeModel requests, add it to a `text` content part.

A cacheable prompt prefix must contain at least 1,024 tokens. You can include multiple explicit breakpoints, and each request can create up to four cache writes. Check `cached_tokens` and `cache_write_tokens` in the response to determine whether tokens were read from or written to the cache.

Reasoning effort

Set reasoning effort to none, `low`, `medium`, `high`, `xhigh`, or `max`. The default is `medium`.

JSON Schema output

Use JSON Schema to set the format of the model response for non-streaming requests. Chat Completions and Responses support JSON Schema output on the `bedrock-runtime` and `bedrock-mantle` endpoints. InvokeModel and Converse support JSON Schema output on the `bedrock-runtime` endpoint. Choose a model ID or inference profile ID from Programmatic access.

- For Chat Completions, set `response_format.type` to `json_schema`. Put `name`, `schema`, and `strict: true` in `response_format.json_schema`.
- For Responses, set `text.format.type` to `json_schema`. Put `name`, `schema`, and `strict: true` in `text.format`.
- For InvokeModel, use the same `response_format` fields as Chat Completions.
- For Converse, set `outputConfig.textFormat.type` to `json_schema`. In `outputConfig.textFormat.structure.jsonSchema`, set `name` and `schema`. Encode the schema as a JSON string. Then set `additionalModelRequestFields.text.format.strict` to `true`.

Use an object schema. Put all fields in `required`. Set `additionalProperties` to `false`. Validate your schema before you send it. Check for refusals or incomplete responses before you parse the output.

Important

For JSON Schema output with the Converse API, you must set `additionalModelRequestFields.text.format.strict` to `true`, in addition to specifying the schema in `outputConfig`. Include the following field in your request.

```
{
  "additionalModelRequestFields": {
    "text": {
      "format": { "strict": true }
    }
  }
}
```

Converse content blocks

On the `bedrock-runtime` endpoint, Converse accepts `text` and `image` content blocks in user messages. This model doesn't accept `document` content blocks, and it doesn't accept an `image` content block inside a `toolResult`. A request that includes either is rejected with a `ValidationException`. To send a document to this model, use the Responses API with an `input_file` content part instead.

Pricing

All prices are in USD per 1 million tokens for the Standard tier.

Mantle in-Region and US geographic cross-Region inference include a 10% premium. The base rates are OpenAI first-party Standard rates. Global cross-Region inference uses those rates with no premium. The prices below already include any premium.

Priority and Flex tiers are not supported for these inference options.

Commercial Regions — short context (272K input tokens or fewer)

Inference option	Input	Input — cache write	Input — cache read	Output
Mantle in-Region	$0.11	$0.1375	$0.011	$0.55
US Geo CRIS	$0.11	$0.1375	$0.011	$0.55
Global CRIS	$0.10	$0.125	$0.01	$0.50

Commercial Regions — long context (more than 272K input tokens)

Inference option	Input	Input — cache write	Input — cache read	Output
Mantle in-Region	$0.22	$0.275	$0.022	$0.825
US Geo CRIS	$0.22	$0.275	$0.022	$0.825
Global CRIS	$0.20	$0.25	$0.02	$0.75

Long-context rates apply to the full request when input exceeds 272,000 tokens.

> **Note**
>
> Prices are subject to change. For current prices, see Amazon Bedrock pricing.

Call the model

Use these model IDs and endpoint URLs to call the model. See APIs supported and Endpoints supported.

Endpoint	Model ID	In-Region endpoint URL	Geo inference ID	Global inference ID
bedrock-mantle	openai.gpt-6-luna	https://bedrock-mantle.{region}.api.aws/openai/v1	Not supported	Not supported
bedrock-runtime	openai.gpt-6-luna	Not supported	us.openai.gpt-6-luna	global.openai.gpt-6-luna

Configure your client for the `bedrock-runtime` endpoint as follows:

- Use this base URL: `https://bedrock-runtime.{region}.amazonaws.com/openai/v1`.
- Set the model ID to `us.openai.gpt-6-luna` or `global.openai.gpt-6-luna`.
- Choose a profile that is available in your source Region.
- You cannot use the base model ID for in-Region calls on this endpoint.

On `bedrock-mantle`, use `openai.gpt-6-luna` with the `/openai/v1` base path. Use the US East (N. Virginia) (`us-east-1`) Region for this model on this endpoint.

Service tiers

This model supports only the **Standard** tier in Amazon Bedrock. You pay per token with no commitment. Set `"service_tier": "default"` or omit the field. Priority, Flex, and Reserved are not supported. For more information, see service tiers.

Standard	Priority	Flex	Reserved
✓	✗	✗	✗

Supported Regions

Each endpoint supports a different set of Regions. See the section called “Regional availability by models”.

The `bedrock-mantle` endpoint

Region	In-Region	Geo	Global
`us-east-1` (US East (N. Virginia))	Supported	Not supported	Not supported

The `bedrock-runtime` endpoint

Source Region	In-Region	US Geo CRIS	Global CRIS
`us-east-1`	Not supported	Supported	Supported
`us-east-2`	Not supported	Supported	Supported
`us-west-1`	Not supported	Supported	Supported

Geo inference details

The destination Regions available to a geographic inference profile depend on the source Region. To retrieve the current routing configuration, call GetInferenceProfile from the source Region.

Geo: US

Geo inference ID: `us.openai.gpt-6-luna`

Source Region	Destination Regions
us-east-1 (N. Virginia)	us-east-1 (N. Virginia), us-east-2 (Ohio), us-west-2 (Oregon)
us-east-2 (Ohio)	us-east-1 (N. Virginia), us-east-2 (Ohio), us-west-2 (Oregon)
us-west-1 (N. California)	us-east-1 (N. Virginia), us-east-2 (Ohio), us-west-1 (N. California), us-west-2 (Oregon)
us-west-2 (Oregon)	us-east-1 (N. Virginia), us-east-2 (Ohio), us-west-2 (Oregon)
ca-central-1 (Canada)	ca-central-1 (Canada), us-east-1 (N. Virginia), us-east-2 (Ohio), us-west-2 (Oregon)
ca-west-1 (Calgary)	ca-west-1 (Calgary), us-east-1 (N. Virginia), us-east-2 (Ohio), us-west-2 (Oregon)

Quotas and limits

Quotas vary by account and Region. To review your quotas or request an increase, see the section called "Quotas" and Request an increase to a quota.

On `bedrock-runtime`, the quota counts output tokens at a 10-to-1 rate. Each output token uses 10 tokens of quota.

Sample code

Step 1 - Create an AWS account: If you already have an AWS account, skip this step. Otherwise, sign up for an AWS account.

Step 2 - Create an API key: Open the Amazon Bedrock console. Create a long-term API key.

Step 3 - Install the SDK: You need Python to run these examples. Install the OpenAI SDK with the command below. Both APIs use this SDK.

OpenAI SDK

```
python3 -m pip install openai
```

Step 4 - Set environment variables

Choose the tab for your endpoint. Set your API key and the base URL shown there.

bedrock-mantle

```
export OPENAI_API_KEY="<provide your Bedrock API key>"
export OPENAI_BASE_URL="https://bedrock-mantle.us-east-1.api.aws/openai/v1"
```

bedrock-runtime

```
export OPENAI_API_KEY="<provide your Bedrock API key>"
export OPENAI_BASE_URL="https://bedrock-runtime.us-east-1.amazonaws.com/openai/v1"
```

Note

On `bedrock-runtime`, use a cross-Region inference profile as the model: `us.openai.gpt-6-luna` or `global.openai.gpt-6-luna`. This model does not support in-Region calls on this endpoint.
Your IAM identity needs `bedrock:InvokeModel` permission for both resources:

- The inference profile.
- Your AWS account's default project: `arn:aws:bedrock:{region}:{account-id}:project/default`.

Step 5 - Send your first request

Save one of the examples below as `bedrock-first-request.py`.

bedrock-mantle

Use the settings from Step 4 - Set environment variables. Choose the `bedrock-mantle` tab.

Responses API

```
import os
from openai import OpenAI

client = OpenAI(base_url=os.environ["OPENAI_BASE_URL"])

response = client.responses.create(
    model="openai.gpt-6-luna",
    input="Can you explain the features of Amazon Bedrock?"
)
print(response)
```

Chat Completions API

```
import os
from openai import OpenAI

client = OpenAI(base_url=os.environ["OPENAI_BASE_URL"])

response = client.chat.completions.create(
    model="openai.gpt-6-luna",
    messages=[{"role": "user", "content": "Can you explain the features of Amazon
 Bedrock?"}]
)
print(response)
```

bedrock-runtime: OpenAI SDK

Use the settings from Step 4 - Set environment variables. Choose the `bedrock-runtime` tab. Use either API. Both examples use the US system inference profile.

Responses API

```
import os
from openai import OpenAI

client = OpenAI(base_url=os.environ["OPENAI_BASE_URL"])

response = client.responses.create(
    model="us.openai.gpt-6-luna",
    input="Can you explain the features of Amazon Bedrock?"
```

```
)
print(response)
```

Chat Completions API

```
import os
from openai import OpenAI

client = OpenAI(base_url=os.environ["OPENAI_BASE_URL"])
response = client.chat.completions.create(
    model="us.openai.gpt-6-luna",
    messages=[{"role": "user", "content": "Can you explain the features of Amazon
 Bedrock?"}]
)
print(response)
```

GPT-5.6 Sol

OpenAI — GPT-5.6 Sol

Model Details

GPT-5.6 Sol is the most capable OpenAI model yet, delivering frontier reasoning and state-of-the-art agentic performance across coding, cybersecurity, and scientific research. For more information about model development and performance, see the model/service card.

Model launch date: July 13, 2026
EOL no sooner than: July 13, 2027
Legacy period: at least 6 months
Model lifecycle policy: Model lifecycle (For Models Launched Prior to Sept 7 2026)
Model EOL date: N/A
End User License Agreements and Terms of Use: View
Model lifecycle: Active
Context window: 1,050,000 tokens
Max output tokens: 128,000
Marketplace product ID: `prod-k5bywj2464j7c`

Input Modalities	Output Modalities
⊗ Audio	⊗ Embedding
⊘ Image	⊗ Image
⊗ Speech	⊗ Speech
⊘ Text	⊘ Text
⊗ Video	⊗ Video

Endpoints and APIs supported

The following tables show which endpoints and APIs are supported for GPT-5.6 Sol. For more information, see the section called “APIs” and the section called “Inference endpoints”.

Endpoint support

Endpoint	Supported
`bedrock-runtime`	⊘
`bedrock-mantle`	⊘

APIs supported on `bedrock-runtime` endpoint

Messages	Responses	Chat Completions	Converse	Invoke
⊗	⊘	⊘	⊘	⊗

APIs supported on `bedrock-mantle` endpoint

Messages	Responses	Chat Completions	Converse	Invoke
⊗	✓	✓	⊗	⊗

Note

On `bedrock-mantle`, both APIs use the `/openai/v1` base path, not `/v1`. Use either API with this model:

- For Responses, use `/openai/v1/responses`.
- For Chat Completions, use `/openai/v1/chat/completions`.

Tip

Whenever possible, we recommend using the `bedrock-runtime` endpoint for new applications. See the section called "Inference endpoints" for details.

Capabilities and Features

Bedrock Features

Features supported using `bedrock-runtime` endpoint

Supported	Not Supported
✓ Projects (default project only) ✓ Invocation logs ✓ Response streaming ✓ Abuse detection ✓ Guardrails (Converse API only) ✓ Application inference profiles (Converse API only; not supported with Responses or Chat Completions APIs)	⊗ Server-side tool use ⊗ Intelligent prompt routing ⊗ Count tokens ⊗ Watermarking

Supported	Not Supported
Implicit Prompt Caching (Responses, Chat Completions, InvokeModel, and Converse APIs) Explicit Prompt Caching (Responses API only) Structured outputs (JSON Schema; see API configuration) Reasoning Summaries (Responses, Converse, and ConverseStream APIs; on Converse, set `additionalModelRequestFields.reasoning.summary`)	

Features supported using `bedrock-mantle` endpoint

Supported	Not Supported
Server-side tool calling Projects Implicit Prompt Caching (Responses API only) Explicit Prompt Caching (Responses API only) Reasoning Summaries (Responses API only)	Application inference profiles (Responses and Chat Completions APIs only) Watermarking

JSON Schema output on bedrock-runtime

Use JSON Schema to set the format of the model response. These settings apply to non-streaming calls on the `bedrock-runtime` endpoint. Choose a profile ID from Programmatic access.

- For Chat Completions, set `response_format.type` to `json_schema`. Put `name`, `schema`, and `strict: true` in `response_format.json_schema`.
- For Responses, set `text.format.type` to `json_schema`. Put `name`, `schema`, and `strict: true` in `text.format`.

- For Converse, set `outputConfig.textFormat.type` to `json_schema`. In `outputConfig.textFormat.structure.jsonSchema`, set `name` and `schema`. Encode the schema as a JSON string. Then set `additionalModelRequestFields.text.format.strict` to `true`.

Use an object schema. Put all fields in `required`. Set `additionalProperties` to `false`. Validate your schema before you send it. Check for refusals or incomplete responses before you parse the output.

Important

For JSON Schema output with the Converse API, you must set `additionalModelRequestFields.text.format.strict` to `true`, in addition to specifying the schema in `outputConfig`. Include the following field in your request.

```
{
  "additionalModelRequestFields": {
    "text": {
      "format": { "strict": true }
    }
  }
}
```

Converse content blocks

On the `bedrock-runtime` endpoint, Converse accepts `text` and `image` content blocks in user messages. This model doesn't accept `document` content blocks, and it doesn't accept an `image` content block inside a `toolResult`. A request that includes either is rejected with a `ValidationException`. To send a document to this model, use the Responses API with an `input_file` content part instead.

Pricing

All prices are in USD per 1 million tokens for the Standard tier.

The **Input — 30-minute cache write** column is the price per 1 million tokens written to the prompt cache. The 30-minute figure is how long a cached prompt prefix is retained, not a quantity of tokens. For more information, see prompt caching.

Commercial In-Region prices include a 10% fee over OpenAI rates. You do not need to add this fee.

Priority and Flex tiers are not supported for this model.

Commercial Regions — short context (272K input tokens or fewer)

Inference option	Input	Input — 30-minute cache write	Input — cache read	Output
In-Region	$4.40	$5.50	$0.44	$22.00
Geo CRIS	$4.40	$5.50	$0.44	$22.00
Global CRIS	$4.00	$5.00	$0.40	$20.00

Commercial Regions — long context (more than 272K input tokens)

Inference option	Input	Input — 30-minute cache write	Input — cache read	Output
In-Region	$8.80	$11.00	$0.88	$33.00
Geo CRIS	$8.80	$11.00	$0.88	$33.00
Global CRIS	$8.00	$10.00	$0.80	$30.00

Programmatic Access

Use the following model IDs and endpoint URLs to access this model programmatically. For more information about the available APIs and endpoints, see APIs supported and Endpoints supported.

Endpoint	Model ID	In-Region endpoint URL	Geo inference ID	Global inference ID
`bedrock-runtime`	`openai.gpt-5.6-sol`	Not supported	`us.openai.gpt-5.6-sol`	`global.openai.gpt-5.6-sol`

Endpoint	Model ID	In-Region endpoint URL	Geo inference ID	Global inference ID
bedrock-mantle	openai.gpt-5.6-sol	https://bedrock-mantle.{region}.api.aws/openai/v1	Not supported	Not supported

For example, if region is us-east-1 (N. Virginia), then the bedrock-mantle endpoint URL will be "https://bedrock-mantle.us-east-1.api.aws/openai/v1". On `bedrock-runtime`, the base URL is "https://bedrock-runtime.{region}.amazonaws.com/openai/v1" and requests must name the geographic cross-Region inference ID `us.openai.gpt-5.6-sol` as the model.

Service Tiers

Amazon Bedrock offers multiple service tiers to match your workload requirements. **Standard** provides pay-per-token access with no commitment (set `"service_tier": "default"` or omit the field). **Priority** delivers the fastest response times for a price premium (set `"service_tier": "priority"`). **Flex** provides lower-cost access for flexible, non-time-sensitive workloads (set `"service_tier": "flex"`). **Reserved** provides dedicated throughput with a term commitment for predictable workloads; it is set at the account level rather than per request (contact your AWS account team to enable). For more information, see service tiers.

Standard	Priority	Flex	Reserved
✓	✗	✗	✗

Regional Availability

Regional availability at a glance

Amazon Bedrock offers three inference options: **In-Region** keeps requests within a single Region for strict compliance, **Geo Cross-Region** routes across Regions within a geography (such as US, EU, and APAC) while respecting data residency, and **Global Cross-Region** routes anywhere worldwide when there are no residency constraints. Refer to the the section called “Regional availability by models” page for more details.

Availability differs by endpoint.

Availability using the `bedrock-mantle` endpoint

Region	In-Region	Geo	Global
`us-east-1` (N. Virginia)	✓	✗	✗
`us-east-2` (Ohio)	✓	✗	✗

Availability using the `bedrock-runtime` endpoint

Region	In-Region	Geo	Global
`us-east-1` (N. Virginia)	✗	✓	✓
`us-east-2` (Ohio)	✗	✓	✓
`us-west-1` (N. California)	✗	✓	✓
`us-west-2` (Oregon)	✗	✓	✓
`ca-central-1` (Canada)	✗	✓	✓
`ca-west-1` (Calgary)	✗	✓	✓

Geo inference details

The destination Regions available to a geographic inference profile depend on the source Region. To retrieve the current routing configuration, call GetInferenceProfile from the source Region.

Geo: US

Geo inference ID: `us.openai.gpt-5.6-sol`

Source Region	Destination Regions
us-east-1 (N. Virginia)	us-east-1 (N. Virginia), us-east-2 (Ohio), us-west-2 (Oregon)
us-east-2 (Ohio)	us-east-1 (N. Virginia), us-east-2 (Ohio), us-west-2 (Oregon)
us-west-1 (N. California)	us-east-1 (N. Virginia), us-east-2 (Ohio), us-west-1 (N. California), us-west-2 (Oregon)
us-west-2 (Oregon)	us-east-1 (N. Virginia), us-east-2 (Ohio), us-west-2 (Oregon)
ca-central-1 (Canada)	ca-central-1 (Canada), us-east-1 (N. Virginia), us-east-2 (Ohio), us-west-2 (Oregon)
ca-west-1 (Calgary)	ca-west-1 (Calgary), us-east-1 (N. Virginia), us-east-2 (Ohio), us-west-2 (Oregon)

Quotas and Limits

Your AWS account has default quotas to maintain the performance of the service and to ensure appropriate usage of Amazon Bedrock. The default quotas assigned to an account might be updated depending on regional factors, payment history, fraudulent usage, and/or approval of a quota increase request. For more information, see the section called “Quotas” documentation and see the limits for the model.

On Amazon Bedrock, each request can contain a maximum of 100 image inputs.

On the `bedrock-runtime` endpoint, limits are managed as tokens per minute (TPM) with a 10x burndown rate, where 1 output token consumes 10 tokens.

Sample Code

Step 1 - AWS Account: If you have an AWS account already, skip this step. If you are new to AWS, sign up for an AWS account.

Step 2 - API key: Go to the Amazon Bedrock console and generate a long-term API key.

Step 3 - Get the SDK: To use this getting started guide, you must have Python already installed. Then install the relevant software depending on the APIs you are using.

For both APIs, choose the OpenAI SDK tab.

OpenAI SDK

```
pip install openai
```

Step 4 - Set environment variables

Configure your environment to use the API key for authentication.

bedrock-runtime

```
OPENAI_API_KEY="<provide your Bedrock API key>"
OPENAI_BASE_URL="https://bedrock-runtime.us-east-1.amazonaws.com/openai/v1"
```

bedrock-mantle

```
OPENAI_API_KEY="<provide your Bedrock API key>"
OPENAI_BASE_URL="https://bedrock-mantle.us-east-1.api.aws/openai/v1"
```

> **Note**
>
> On `bedrock-runtime`, name a cross-Region inference profile as the model — `us.openai.gpt-5.6-sol` or `global.openai.gpt-5.6-sol`. This model is not available for in-Region inference on that endpoint. Your IAM identity also needs `bedrock:InvokeModel` on your account's default project (`arn:aws:bedrock:{region}:{account-id}:project/default`) in addition to the inference profile.

Step 5 - Run your first inference request

Save the file as `bedrock-first-request.py`

bedrock-runtime: OpenAI SDK

Use the settings from Step 4 - Set environment variables. Choose the `bedrock-runtime` tab. Both examples use the global system inference profile.

Responses API

```
from openai import OpenAI

client = OpenAI()

response = client.responses.create(
    model="global.openai.gpt-5.6-sol",
    input="Can you explain the features of Amazon Bedrock?"
)
print(response)
```

Chat

```
from openai import OpenAI

client = OpenAI()

response = client.chat.completions.create(
    model="global.openai.gpt-5.6-sol",
    messages=[{"role": "user", "content": "Can you explain the features of Amazon
 Bedrock?"}]
)
print(response)
```

bedrock-mantle

Use the settings from Step 4 - Set environment variables. Choose the `bedrock-mantle` tab. The Chat tab uses the Chat Completions API.

Responses API

```
from openai import OpenAI
```

```
client = OpenAI()

response = client.responses.create(
    model="openai.gpt-5.6-sol",
    input="Can you explain the features of Amazon Bedrock?"
)
print(response)
```

Chat

```
from openai import OpenAI

client = OpenAI()

response = client.chat.completions.create(
    model="openai.gpt-5.6-sol",
    messages=[{"role": "user", "content": "Can you explain the features of Amazon
 Bedrock?"}]
)
print(response)
```

GPT-5.6 Terra

OpenAI — GPT-5.6 Terra

Model Details

GPT-5.6 Terra is the balanced model for everyday production work. It delivers superior performance to GPT-5.5 at a lower cost, completing tasks with fewer output tokens for stronger performance per dollar. Use Terra for code generation, content workflows, structured data extraction, and general-purpose agentic tasks. For more information about model development and performance, see the model/service card.

Model launch date: July 13, 2026
EOL no sooner than: July 13, 2027
Legacy period: at least 6 months
Model lifecycle policy: Model lifecycle (For Models Launched Prior to Sept 7 2026)

Model EOL date: N/A

End User License Agreements and Terms of Use: View

Model lifecycle: Active

Context window: 1,050,000 tokens

Max output tokens: 128,000

Marketplace product ID: `prod-oxu3iqwrwktjm`

Input Modalities	Output Modalities
⊗ Audio	⊗ Embedding
✓ Image	⊗ Image
⊗ Speech	⊗ Speech
✓ Text	✓ Text
⊗ Video	⊗ Video

Endpoints and APIs supported

The following tables show which endpoints and APIs are supported for GPT-5.6 Terra. For more information, see the section called “APIs” and the section called “Inference endpoints”.

Endpoint support

Endpoint	Supported
`bedrock-runtime`	✓
`bedrock-mantle`	✓

APIs supported on `bedrock-runtime` endpoint

Messages	Responses	Chat Completions	Converse	Invoke
⊗	⊙	⊙	⊙	⊗

APIs supported on `bedrock-mantle` endpoint

Messages	Responses	Chat Completions	Converse	Invoke
⊗	⊙	⊙	⊗	⊗

Note

On `bedrock-mantle`, both APIs use the `/openai/v1` base path, not `/v1`. Use either API with this model:

- For Responses, use `/openai/v1/responses`.
- For Chat Completions, use `/openai/v1/chat/completions`.

Tip

Whenever possible, we recommend using the `bedrock-runtime` endpoint for new applications. See the section called “Inference endpoints” for details.

Capabilities and Features

Bedrock Features

Features supported using `bedrock-runtime` endpoint

Supported	Not Supported
⊙ Projects (default project only)	⊗ Server-side tool use

Supported	Not Supported
✓ Invocation logs ✓ Response streaming ✓ Abuse detection ✓ Guardrails (Converse API only) ✓ Application inference profiles (Converse API only; not supported with Responses or Chat Completions APIs) ✓ Implicit Prompt Caching (Responses, Chat Completions, InvokeModel, and Converse APIs) ✓ Explicit Prompt Caching (Responses API only) ✓ Structured outputs (JSON Schema; see API configuration) ✓ Reasoning Summaries (Responses, Converse, and ConverseStream APIs; on Converse, set `additionalModelRequestFields.reasoning.summary`)	✗ Intelligent prompt routing ✗ Count tokens ✗ Watermarking

Features supported using `bedrock-mantle` endpoint

Supported	Not Supported
✓ Server-side tool calling ✓ Projects ✓ Implicit Prompt Caching (Responses API only) ✓ Explicit Prompt Caching (Responses API only) ✓ Reasoning Summaries (Responses API only)	✗ Application inference profiles (Responses and Chat Completions APIs only) ✗ Watermarking

JSON Schema output on bedrock-runtime

Use JSON Schema to set the format of the model response. These settings apply to non-streaming calls on the `bedrock-runtime` endpoint. Choose a profile ID from Programmatic access.

- For Chat Completions, set `response_format.type` to `json_schema`. Put `name`, `schema`, and `strict: true` in `response_format.json_schema`.
- For Responses, set `text.format.type` to `json_schema`. Put `name`, `schema`, and `strict: true` in `text.format`.
- For Converse, set `outputConfig.textFormat.type` to `json_schema`. In `outputConfig.textFormat.structure.jsonSchema`, set `name` and `schema`. Encode the schema as a JSON string. Then set `additionalModelRequestFields.text.format.strict` to `true`.

Use an object schema. Put all fields in `required`. Set `additionalProperties` to `false`. Validate your schema before you send it. Check for refusals or incomplete responses before you parse the output.

Important

For JSON Schema output with the Converse API, you must set `additionalModelRequestFields.text.format.strict` to `true`, in addition to specifying the schema in `outputConfig`. Include the following field in your request.

```
{
  "additionalModelRequestFields": {
    "text": {
      "format": { "strict": true }
    }
  }
}
```

Converse content blocks

On the `bedrock-runtime` endpoint, Converse accepts `text` and `image` content blocks in user messages. This model doesn't accept `document` content blocks, and it doesn't accept an `image` content block inside a `toolResult`. A request that includes either is rejected with a

`ValidationException`. To send a document to this model, use the Responses API with an `input_file` content part instead.

Pricing

All prices are in USD per 1 million tokens for the Standard tier.

The **Input — 30-minute cache write** column is the price per 1 million tokens written to the prompt cache. The 30-minute figure is how long a cached prompt prefix is retained, not a quantity of tokens. For more information, see prompt caching.

Commercial In-Region prices include a 10% fee over OpenAI rates. You do not need to add this fee.

Priority and Flex tiers are not supported for this model.

Commercial Regions — short context (272K input tokens or fewer)

Inference option	Input	Input — 30-minute cache write	Input — cache read	Output
In-Region	$2.20	$2.75	$0.22	$13.20
Geo CRIS	$2.20	$2.75	$0.22	$13.20
Global CRIS	$2.00	$2.50	$0.20	$12.00

Commercial Regions — long context (more than 272K input tokens)

Inference option	Input	Input — 30-minute cache write	Input — cache read	Output
In-Region	$4.40	$5.50	$0.44	$19.80
Geo CRIS	$4.40	$5.50	$0.44	$19.80
Global CRIS	$4.00	$5.00	$0.40	$18.00

AWS GovCloud (US-East and US-West)

Short context (272K input tokens or fewer)

Inference option	Input	Input — 30-minute cache write	Input — cache read	Output
In-Region (`bedrock-mantle`)	$2.70	$3.375	$0.27	$16.20
Geo CRIS	$2.70	$3.375	$0.27	$16.20

Long context (more than 272K input tokens)

Inference option	Input	Input — 30-minute cache write	Input — cache read	Output
In-Region (`bedrock-mantle`)	$5.40	$6.75	$0.54	$24.30
Geo CRIS	$5.40	$6.75	$0.54	$24.30

Programmatic Access

Use the following model IDs and endpoint URLs to access this model programmatically. For more information about the available APIs and endpoints, see APIs supported and Endpoints supported.

Endpoint	Model ID	In-Region endpoint URL	Geo inference ID	Global inference ID
`bedrock-mantle`	`openai.gpt-5.6-terra`	`https://bedrock-mantle.{region}.api.aws/openai/v1`	Not supported	Not supported

Endpoint	Model ID	In-Region endpoint URL	Geo inference ID	Global inference ID
`bedrock-runtime`	`openai.gpt-5.6-terra`	Not supported	`us.openai.gpt-5.6-terra` in the commercial AWS Regions, `in.openai.gpt-5.6-terra` in the India Regions, `us-gov.openai.gpt-5.6-terra` in the AWS GovCloud (US) Regions	`global.openai.gpt-5.6-terra`

For example, if region is us-east-1 (N. Virginia), then the bedrock-mantle endpoint URL will be "https://bedrock-mantle.us-east-1.api.aws/openai/v1". On `bedrock-runtime`, the base URL is "https://bedrock-runtime.{region}.amazonaws.com/openai/v1" and requests must name the geographic cross-Region inference ID `us.openai.gpt-5.6-terra` as the model.

Service Tiers

Amazon Bedrock offers multiple service tiers to match your workload requirements. **Standard** provides pay-per-token access with no commitment (set `"service_tier": "default"` or omit the field). **Priority** delivers the fastest response times for a price premium (set `"service_tier": "priority"`). **Flex** provides lower-cost access for flexible, non-time-sensitive workloads (set `"service_tier": "flex"`). **Reserved** provides dedicated throughput with a term commitment for predictable workloads; it is set at the account level rather than per request (contact your AWS account team to enable). For more information, see service tiers.

Standard	Priority	Flex	Reserved
✓	✗	✗	✗

Regional Availability

Regional availability at a glance

Amazon Bedrock offers three inference options: **In-Region** keeps requests within a single Region for strict compliance, **Geo Cross-Region** routes across Regions within a geography (such as US, EU, and APAC) while respecting data residency, and **Global Cross-Region** routes anywhere worldwide when there are no residency constraints. Refer to the the section called “Regional availability by models” page for more details.

Availability differs by endpoint.

Availability using the `bedrock-mantle` endpoint

Region	In-Region	Geo	Global
`us-east-1` (N. Virginia)	✓	✗	✗
`us-east-2` (Ohio)	✓	✗	✗
`us-west-2` (Oregon)	✓	✗	✗
`us-gov-west-1` (GovCloud West)	✓	✗	✗
`us-gov-east-1` (GovCloud East)	✓	✗	✗

Availability using the `bedrock-runtime` endpoint

Geo inference details

The destination Regions available to a geographic inference profile depend on the source Region. To retrieve the current routing configuration, call GetInferenceProfile from the source Region.

Geo: US

Geo inference ID: `us.openai.gpt-5.6-terra`

Source Region	Destination Regions
us-east-1 (N. Virginia)	us-east-1 (N. Virginia), us-east-2 (Ohio), us-west-2 (Oregon)
us-east-2 (Ohio)	us-east-1 (N. Virginia), us-east-2 (Ohio), us-west-2 (Oregon)
us-west-1 (N. California)	us-east-1 (N. Virginia), us-east-2 (Ohio), us-west-1 (N. California), us-west-2 (Oregon)
us-west-2 (Oregon)	us-east-1 (N. Virginia), us-east-2 (Ohio), us-west-2 (Oregon)
ca-central-1 (Canada)	ca-central-1 (Canada), us-east-1 (N. Virginia), us-east-2 (Ohio), us-west-2 (Oregon)
ca-west-1 (Calgary)	ca-west-1 (Calgary), us-east-1 (N. Virginia), us-east-2 (Ohio), us-west-2 (Oregon)

Geo: India

Geo inference ID: `in.openai.gpt-5.6-terra`

Source Region	Destination Regions
ap-south-1 (Mumbai)	ap-south-1 (Mumbai), ap-south-2 (Hyderabad)
ap-south-2 (Hyderabad)	ap-south-1 (Mumbai), ap-south-2 (Hyderabad)

Geo: US-GOV

Geo inference ID: `us-gov.openai.gpt-5.6-terra`

Source Region	Destination Regions
us-gov-east-1 (AWS GovCloud (US-East))	us-gov-east-1 (AWS GovCloud (US-East)), us-gov-west-1 (AWS GovCloud (US-West))

Source Region	Destination Regions
us-gov-west-1 (AWS GovCloud (US-West))	us-gov-east-1 (AWS GovCloud (US-East)), us-gov-west-1 (AWS GovCloud (US-West))

Quotas and Limits

Your AWS account has default quotas to maintain the performance of the service and to ensure appropriate usage of Amazon Bedrock. The default quotas assigned to an account might be updated depending on regional factors, payment history, fraudulent usage, and/or approval of a quota increase request. For more information, see the section called "Quotas" documentation and see the limits for the model.

On Amazon Bedrock, each request can contain a maximum of 100 image inputs.

On the `bedrock-runtime` endpoint, limits are managed as tokens per minute (TPM) with a 10x burndown rate, where 1 output token consumes 10 tokens.

Sample Code

Step 1 - AWS Account: If you have an AWS account already, skip this step. If you are new to AWS, sign up for an AWS account.

Step 2 - API key: Go to the Amazon Bedrock console and generate a long-term API key.

Step 3 - Get the SDK: To use this getting started guide, you must have Python already installed. Then install the relevant software depending on the APIs you are using.

For both APIs, choose the OpenAI SDK tab.

OpenAI SDK

```
pip install openai
```

Step 4 - Set environment variables

Configure your environment to use the API key for authentication.

bedrock-mantle

```
OPENAI_API_KEY="<provide your Bedrock API key>"
OPENAI_BASE_URL="https://bedrock-mantle.us-east-1.api.aws/openai/v1"
```

bedrock-runtime

```
OPENAI_API_KEY="<provide your Bedrock API key>"
OPENAI_BASE_URL="https://bedrock-runtime.us-east-1.amazonaws.com/openai/v1"
```

Note

On `bedrock-runtime`, name a cross-Region inference profile as the model — `us.openai.gpt-5.6-terra` or `global.openai.gpt-5.6-terra` (in the AWS GovCloud (US) Regions, `us-gov.openai.gpt-5.6-terra`). This model is not available for in-Region inference on that endpoint. Your IAM identity also needs `bedrock:InvokeModel` on your account's default project (`arn:aws:bedrock:{region}:{account-id}:project/default`, or `arn:aws-us-gov:bedrock:{region}:{account-id}:project/default` in the AWS GovCloud (US) Regions) in addition to the inference profile.

Step 5 - Run your first inference request

Save the file as `bedrock-first-request.py`

bedrock-mantle

Use the settings from Step 4 - Set environment variables. Choose the `bedrock-mantle` tab. The Chat tab uses the Chat Completions API.

Responses API

```
from openai import OpenAI

client = OpenAI()

response = client.responses.create(
```

```
    model="openai.gpt-5.6-terra",
    input="Can you explain the features of Amazon Bedrock?"
)
print(response)
```

Chat

```
from openai import OpenAI

client = OpenAI()

response = client.chat.completions.create(
    model="openai.gpt-5.6-terra",
    messages=[{"role": "user", "content": "Can you explain the features of Amazon
 Bedrock?"}]
)
print(response)
```

bedrock-runtime: OpenAI SDK

Use the settings from Step 4 - Set environment variables. Choose the `bedrock-runtime` tab. Send your request with the Responses API.

Responses API

```
from openai import OpenAI

client = OpenAI()

response = client.responses.create(
    model="us.openai.gpt-5.6-terra",
    input="Can you explain the features of Amazon Bedrock?"
)
print(response)
```

GPT-5.6 Luna

OpenAI — GPT-5.6 Luna

Model Details

GPT-5.6 Luna is the fast and affordable model from OpenAI. Use Luna for high-volume inference tasks like classification, summarization, routing, and real-time applications where latency and cost per token matter most. For more information about model development and performance, see the model/service card.

Model launch date: July 13, 2026
EOL no sooner than: July 13, 2027
Legacy period: at least 6 months
Model lifecycle policy: Model lifecycle (For Models Launched Prior to Sept 7 2026)
Model EOL date: N/A
End User License Agreements and Terms of Use: View
Model lifecycle: Active
Context window: 1,050,000 tokens
Max output tokens: 128,000
Marketplace product ID: `prod-bpeu2ptegwjfa`

Input Modalities	Output Modalities
⊗ Audio	⊗ Embedding
⊙ Image	⊗ Image
⊗ Speech	⊗ Speech
⊙ Text	⊙ Text
⊗ Video	⊗ Video

Endpoints and APIs supported

The following tables show which endpoints and APIs are supported for GPT-5.6 Luna. For more information, see the section called “APIs” and the section called “Inference endpoints”.

Endpoint support

Endpoint	Supported
`bedrock-runtime`	✓
`bedrock-mantle`	✓

APIs supported on `bedrock-runtime` endpoint

Messages	Responses	Chat Completions	Converse	Invoke
✗	✓	✓	✓	✗

APIs supported on `bedrock-mantle` endpoint

Messages	Responses	Chat Completions	Converse	Invoke
✗	✓	✓	✗	✗

Note

On `bedrock-mantle`, both APIs use the `/openai/v1` base path, not `/v1`. Use either API with this model:

- For Responses, use `/openai/v1/responses`.
- For Chat Completions, use `/openai/v1/chat/completions`.

> **Tip**
>
> Whenever possible, we recommend using the `bedrock-runtime` endpoint for new applications. See the section called "Inference endpoints" for details.

Capabilities and Features

Bedrock Features

Features supported using `bedrock-runtime` endpoint

Supported	Not Supported
Projects (default project only) Invocation logs Response streaming Abuse detection Guardrails (Converse API only) Application inference profiles (Converse API only; not supported with Responses or Chat Completions APIs) Implicit Prompt Caching (Responses, Chat Completions, InvokeModel, and Converse APIs) Explicit Prompt Caching (Responses API only) Structured outputs (JSON Schema; see API configuration) Reasoning Summaries (Responses, Converse, and ConverseStream APIs; on Converse, set `additionalModelRequestFields.reasoning.summary`)	Server-side tool use Intelligent prompt routing Count tokens Watermarking

Features supported using `bedrock-mantle` endpoint

Supported	Not Supported
Server-side tool calling Projects Implicit Prompt Caching (Responses API only) Explicit Prompt Caching (Responses API only) Reasoning Summaries (Responses API only)	Application inference profiles (Responses and Chat Completions APIs only) Watermarking

JSON Schema output on bedrock-runtime

Use JSON Schema to set the format of the model response. These settings apply to non-streaming calls on the `bedrock-runtime` endpoint. Choose a profile ID from Programmatic access.

- For Chat Completions, set `response_format.type` to `json_schema`. Put `name`, `schema`, and `strict: true` in `response_format.json_schema`.
- For Responses, set `text.format.type` to `json_schema`. Put `name`, `schema`, and `strict: true` in `text.format`.
- For Converse, set `outputConfig.textFormat.type` to `json_schema`. In `outputConfig.textFormat.structure.jsonSchema`, set `name` and `schema`. Encode the schema as a JSON string. Then set `additionalModelRequestFields.text.format.strict` to `true`.

Use an object schema. Put all fields in `required`. Set `additionalProperties` to `false`. Validate your schema before you send it. Check for refusals or incomplete responses before you parse the output.

Important

For JSON Schema output with the Converse API, you must set `additionalModelRequestFields.text.format.strict` to `true`, in addition to specifying the schema in `outputConfig`. Include the following field in your request.

```
{
```

```
  "additionalModelRequestFields": {
    "text": {
      "format": { "strict": true }
    }
  }
}
```

Converse content blocks

On the `bedrock-runtime` endpoint, Converse accepts `text` and `image` content blocks in user messages. This model doesn't accept `document` content blocks, and it doesn't accept an `image` content block inside a `toolResult`. A request that includes either is rejected with a `ValidationException`. To send a document to this model, use the Responses API with an `input_file` content part instead.

Pricing

All prices are in USD per 1 million tokens for the Standard tier.

The **Input — 30-minute cache write** column is the price per 1 million tokens written to the prompt cache. The 30-minute figure is how long a cached prompt prefix is retained, not a quantity of tokens. For more information, see prompt caching.

Commercial In-Region prices include a 10% fee over OpenAI rates. You do not need to add this fee.

Priority and Flex tiers are not supported for this model.

Commercial Regions — short context (272K input tokens or fewer)

Inference option	Input	Input — 30-minute cache write	Input — cache read	Output
In-Region	$0.22	$0.275	$0.022	$1.32
Geo CRIS	$0.22	$0.275	$0.022	$1.32
Global CRIS	$0.20	$0.25	$0.02	$1.20

Commercial Regions — long context (more than 272K input tokens)

Inference option	Input	Input — 30-minute cache write	Input — cache read	Output
In-Region	$0.44	$0.55	$0.044	$1.98
Geo CRIS	$0.44	$0.55	$0.044	$1.98
Global CRIS	$0.40	$0.50	$0.04	$1.80

AWS GovCloud (US-East and US-West)

Short context (272K input tokens or fewer)

Inference option	Input	Input — 30-minute cache write	Input — cache read	Output
In-Region (`bedrock-mantle`)	$0.27	$0.3375	$0.027	$1.62
Geo CRIS	$0.27	$0.3375	$0.027	$1.62

Long context (more than 272K input tokens)

Inference option	Input	Input — 30-minute cache write	Input — cache read	Output
In-Region (`bedrock-mantle`)	$0.54	$0.675	$0.054	$2.43
Geo CRIS	$0.54	$0.675	$0.054	$2.43

Programmatic Access

Use the following model IDs and endpoint URLs to access this model programmatically. For more information about the available APIs and endpoints, see APIs supported and Endpoints supported.

Endpoint	Model ID	In-Region endpoint URL	Geo inference ID	Global inference ID
bedrock-mantle	openai.gpt-5.6-luna	https://bedrock-mantle.{region}.api.aws/openai/v1	Not supported	Not supported
bedrock-runtime	openai.gpt-5.6-luna	Not supported	us.openai.gpt-5.6-luna in the commercial AWS Regions, in.openai.gpt-5.6-luna in the India Regions, us-gov.openai.gpt-5.6-luna in the AWS GovCloud (US) Regions	global.openai.gpt-5.6-luna

For example, if region is us-east-1 (N. Virginia), then the bedrock-mantle endpoint URL will be "https://bedrock-mantle.us-east-1.api.aws/openai/v1". On `bedrock-runtime`, the base URL is "https://bedrock-runtime.{region}.amazonaws.com/openai/v1" and requests must name the geographic cross-Region inference ID `us.openai.gpt-5.6-luna` as the model.

Service Tiers

Amazon Bedrock offers multiple service tiers to match your workload requirements. **Standard** provides pay-per-token access with no commitment (set `"service_tier": "default"` or omit the field). **Priority** delivers the fastest response times for a price premium (set `"service_tier": "priority"`). **Flex** provides lower-cost access for flexible, non-time-sensitive workloads (set `"service_tier": "flex"`). **Reserved** provides dedicated throughput with a term commitment

for predictable workloads; it is set at the account level rather than per request (contact your AWS account team to enable). For more information, see service tiers.

Standard	Priority	Flex	Reserved
✓	✗	✗	✗

Regional Availability

Regional availability at a glance

Amazon Bedrock offers three inference options: **In-Region** keeps requests within a single Region for strict compliance, **Geo Cross-Region** routes across Regions within a geography (such as US, EU, and APAC) while respecting data residency, and **Global Cross-Region** routes anywhere worldwide when there are no residency constraints. Refer to the the section called "Regional availability by models" page for more details.

Availability differs by endpoint.

Geo inference ID: `in.openai.gpt-5.6-luna`

Source Region	Destination Regions
ap-south-1 (Mumbai)	ap-south-1 (Mumbai), ap-south-2 (Hyderabad)
ap-south-2 (Hyderabad)	ap-south-1 (Mumbai), ap-south-2 (Hyderabad)

Geo: US-GOV

Geo inference ID: `us-gov.openai.gpt-5.6-luna`

Source Region	Destination Regions
us-gov-east-1 (AWS GovCloud (US-East))	us-gov-east-1 (AWS GovCloud (US-East)), us-gov-west-1 (AWS GovCloud (US-West))

Source Region	Destination Regions
us-gov-west-1 (AWS GovCloud (US-West))	us-gov-east-1 (AWS GovCloud (US-East)), us-gov-west-1 (AWS GovCloud (US-West))

Quotas and Limits

Your AWS account has default quotas to maintain the performance of the service and to ensure appropriate usage of Amazon Bedrock. The default quotas assigned to an account might be updated depending on regional factors, payment history, fraudulent usage, and/or approval of a quota increase request. For more information, see the section called "Quotas" documentation and see the limits for the model.

On Amazon Bedrock, each request can contain a maximum of 100 image inputs.

On the `bedrock-runtime` endpoint, limits are managed as tokens per minute (TPM) with a 10x burndown rate, where 1 output token consumes 10 tokens.

Sample Code

Step 1 - AWS Account: If you have an AWS account already, skip this step. If you are new to AWS, sign up for an AWS account.

Step 2 - API key: Go to the Amazon Bedrock console and generate a long-term API key.

Step 3 - Get the SDK: To use this getting started guide, you must have Python already installed. Then install the relevant software depending on the APIs you are using.

For both APIs, choose the OpenAI SDK tab.

OpenAI SDK

```
pip install openai
```

Step 4 - Set environment variables

Configure your environment to use the API key for authentication.

bedrock-mantle

```
OPENAI_API_KEY="<provide your Bedrock API key>"
OPENAI_BASE_URL="https://bedrock-mantle.us-east-1.api.aws/openai/v1"
```

bedrock-runtime

```
OPENAI_API_KEY="<provide your Bedrock API key>"
OPENAI_BASE_URL="https://bedrock-runtime.us-east-1.amazonaws.com/openai/v1"
```

Note

On `bedrock-runtime`, name a cross-Region inference profile as the model — `us.openai.gpt-5.6-luna` or `global.openai.gpt-5.6-luna` (in the AWS GovCloud (US) Regions, `us-gov.openai.gpt-5.6-luna`). This model is not available for in-Region inference on that endpoint. Your IAM identity also needs `bedrock:InvokeModel` on your account's default project (`arn:aws:bedrock:{region}:{account-id}:project/default`, or `arn:aws-us-gov:bedrock:{region}:{account-id}:project/default` in the AWS GovCloud (US) Regions) in addition to the inference profile.

Step 5 - Run your first inference request

Save the file as `bedrock-first-request.py`

bedrock-mantle

Use the settings from Step 4 - Set environment variables. Choose the `bedrock-mantle` tab. The Chat tab uses the Chat Completions API.

Responses API

```
from openai import OpenAI

client = OpenAI()

response = client.responses.create(
    model="openai.gpt-5.6-luna",
    input="Can you explain the features of Amazon Bedrock?"
```

```
)
print(response)
```

Chat

```
from openai import OpenAI

client = OpenAI()

response = client.chat.completions.create(
    model="openai.gpt-5.6-luna",
    messages=[{"role": "user", "content": "Can you explain the features of Amazon
 Bedrock?"}]
)
print(response)
```

bedrock-runtime: OpenAI SDK

Use the settings from Step 4 - Set environment variables. Choose the `bedrock-runtime` tab. Send your request with the Responses API.

Responses API

```
from openai import OpenAI

client = OpenAI()

response = client.responses.create(
    model="us.openai.gpt-5.6-luna",
    input="Can you explain the features of Amazon Bedrock?"
)
print(response)
```

Daybreak Red: GPT-5.6 Cyber

OpenAI — Daybreak Red: GPT-5.6 Cyber

Model Details

Daybreak Red: GPT-5.6 Cyber is a highly specialized OpenAI model for advanced tasks such as vulnerability research, exploit reproduction, and mitigation development.

> **Note**
>
> Access to this model is limited to eligible customers. To learn more, see Accelerate cyber defense with OpenAI and AWS.

Model launch date: August 12, 2026
EOL no sooner than: August 12, 2027
Legacy period: at least 6 months
Model lifecycle policy: Model lifecycle (For Models Launched Prior to Sept 7 2026)
Model EOL date: N/A
End User License Agreements and Terms of Use: View
Model lifecycle: Active
Context window: 1,050,000 tokens
Languages: English, Spanish, French, German, Portuguese, Italian, Dutch, Russian, Chinese (Simplified and Traditional), Japanese, Korean, Arabic, Hindi, Turkish, Polish, Ukrainian, and other languages.
Fine-tuning supported: No
Supported use cases: Vulnerability research, exploit reproduction, and mitigation development.
Marketplace product ID: `prod-vhjvg2xnjhr44`

Endpoints and APIs supported

The following tables show which endpoints and APIs are supported for Daybreak Red: GPT-5.6 Cyber. For more information, see the section called "APIs" and the section called "Inference endpoints".

Endpoint support

Endpoint	Supported
`bedrock-runtime`	⊙
`bedrock-mantle`	⊙

APIs supported on `bedrock-runtime` endpoint

Messages	Responses	Chat Completions	Converse	Invoke
⊗	⊙	⊙	⊙	⊗

APIs supported on `bedrock-mantle` endpoint

Messages	Responses	Chat Completions	Converse	Invoke
⊗	⊙	⊙	⊗	⊗

Note

On `bedrock-mantle`, both APIs use the `/openai/v1` base path, not `/v1`. Use either API with this model:

- For Responses, use `/openai/v1/responses`.
- For Chat Completions, use `/openai/v1/chat/completions`.

Tip

Whenever possible, we recommend using the `bedrock-runtime` endpoint for new applications. See the section called "Inference endpoints" for details.

Capabilities and Features

Bedrock Features

Features supported using `bedrock-runtime` endpoint

Supported	Not Supported
Projects (default project only) Invocation logs Response streaming Abuse detection Guardrails (Converse API only) Application inference profiles (Converse API only; not supported with Responses or Chat Completions APIs) Implicit Prompt Caching (Responses, Chat Completions, InvokeModel, and Converse APIs) Explicit Prompt Caching (Responses API only) Structured outputs (JSON Schema; see API configuration)	Server-side tool use Intelligent prompt routing Count tokens Watermarking

Supported	Not Supported
Reasoning Summaries (Responses, Converse, and ConverseStream APIs; on Converse, set `additionalModelRequestFields.reasoning.summary`)	

Features supported using `bedrock-mantle` endpoint

Supported	Not Supported
Server-side tool calling Projects Implicit Prompt Caching (Responses API only) Explicit Prompt Caching (Responses API only) Reasoning Summaries (Responses API only)	Watermarking

JSON Schema output on bedrock-runtime

Use JSON Schema to set the format of the model response. These settings apply to non-streaming calls on the `bedrock-runtime` endpoint. Choose a profile ID from Programmatic access.

- For Chat Completions, set `response_format.type` to `json_schema`. Put `name`, `schema`, and `strict: true` in `response_format.json_schema`.
- For Responses, set `text.format.type` to `json_schema`. Put `name`, `schema`, and `strict: true` in `text.format`.
- For Converse, set `outputConfig.textFormat.type` to `json_schema`. In `outputConfig.textFormat.structure.jsonSchema`, set `name` and `schema`. Encode the schema as a JSON string. Then set `additionalModelRequestFields.text.format.strict` to `true`.

Use an object schema. Put all fields in `required`. Set `additionalProperties` to `false`. Validate your schema before you send it. Check for refusals or incomplete responses before you parse the output.

Important

For JSON Schema output with the Converse API, you must set `additionalModelRequestFields.text.format.strict` to `true`, in addition to specifying the schema in `outputConfig`. Include the following field in your request.

```
{
  "additionalModelRequestFields": {
    "text": {
      "format": { "strict": true }
    }
  }
}
```

Converse content blocks

On the `bedrock-runtime` endpoint, Converse accepts `text` and `image` content blocks in user messages. This model doesn't accept `document` content blocks, and it doesn't accept an `image` content block inside a `toolResult`. A request that includes either is rejected with a `ValidationException`. To send a document to this model, use the Responses API with an `input_file` content part instead.

Pricing

All prices are in USD per 1 million tokens for the Standard tier.

The **Input — 30-minute cache write** column is the price per 1 million tokens written to the prompt cache. The 30-minute figure is how long a cached prompt prefix is retained, not a quantity of tokens. For more information, see prompt caching.

Commercial In-Region prices include a 10% fee over OpenAI rates. You do not need to add this fee.

Priority and Flex tiers are not supported for this model.

Commercial Regions — short context (272K input tokens or fewer)

Inference option	Input	Input — 30-minute cache write	Input — cache read	Output
In-Region	$13.75	$17.1875	$1.375	$82.50

AWS GovCloud (US-East) — short context (272K input tokens or fewer)

Inference option	Input	Input — 30-minute cache write	Input — cache read	Output
In-Region	$16.875	$21.09375	$1.6875	$101.25

Programmatic Access

Use the following model IDs and endpoint URLs to access this model programmatically. For more information about the available APIs and endpoints, see APIs supported and Endpoints supported.

Endpoint	Model ID	In-Region endpoint URL	Geo inference ID	Global inference ID
`bedrock-runtime`	`openai.gpt-5.6-cyber`	Not supported	`us.openai.gpt-5.6-cyber`	`global.openai.gpt-5.6-cyber`
`bedrock-mantle`	`openai.gpt-5.6-cyber`	`https://bedrock-mantle.{region}.api.aws/openai/v1`	Not supported	Not supported

For example, if region is us-east-2 (Ohio), then the bedrock-mantle endpoint URL will be "https://bedrock-mantle.us-east-2.api.aws/openai/v1". On `bedrock-runtime`, the base URL is "https://bedrock-runtime.{region}.amazonaws.com/openai/v1" and requests must name the geographic cross-Region inference ID `us.openai.gpt-5.6-cyber` as the model.

Service Tiers

Amazon Bedrock offers multiple service tiers to match your workload requirements. **Standard** provides pay-per-token access with no commitment (set `"service_tier": "default"` or omit the field). **Priority** delivers the fastest response times for a price premium (set `"service_tier": "priority"`). **Flex** provides lower-cost access for flexible, non-time-sensitive workloads (set `"service_tier": "flex"`). **Reserved** provides dedicated throughput with a term commitment for predictable workloads; it is set at the account level rather than per request (contact your AWS account team to enable). For more information, see service tiers.

Standard	Priority	Flex	Reserved
✓	✗	✗	✗

Regional Availability

Regional availability at a glance

Amazon Bedrock offers three inference options: **In-Region** keeps requests within a single Region for strict compliance, **Geo Cross-Region** routes across Regions within a geography (such as US, EU, and APAC) while respecting data residency, and **Global Cross-Region** routes anywhere worldwide when there are no residency constraints. Refer to the the section called “Regional availability by models” page for more details.

Availability differs by endpoint.

Availability using the `bedrock-mantle` endpoint

Region	In-Region	Geo	Global
`us-east-2` (Ohio)	✓	✗	✗
`us-gov-east-1` (AWS GovCloud (US-East))	✓	✗	✗

Geo inference details

The destination Regions available to a geographic inference profile depend on the source Region. To retrieve the current routing configuration, call GetInferenceProfile from the source Region.

Geo: US

Geo inference ID: `us.openai.gpt-5.6-cyber`

Source Region	Destination Regions
us-east-1 (N. Virginia)	us-east-1 (N. Virginia), us-east-2 (Ohio), us-west-2 (Oregon)

Source Region	Destination Regions
us-east-2 (Ohio)	us-east-1 (N. Virginia), us-east-2 (Ohio), us-west-2 (Oregon)
us-west-1 (N. California)	us-east-1 (N. Virginia), us-east-2 (Ohio), us-west-1 (N. California), us-west-2 (Oregon)
us-west-2 (Oregon)	us-east-1 (N. Virginia), us-east-2 (Ohio), us-west-2 (Oregon)
ca-central-1 (Canada)	ca-central-1 (Canada), us-east-1 (N. Virginia), us-east-2 (Ohio), us-west-2 (Oregon)
ca-west-1 (Calgary)	ca-west-1 (Calgary), us-east-1 (N. Virginia), us-east-2 (Ohio), us-west-2 (Oregon)

Quotas and Limits

Model access is available only to eligible customers. Access to this model requires enrollment in Trusted Access for Cyber from OpenAI. To enroll, contact OpenAI or your AWS account team for guidance on eligibility. After approval, work with your account team to request access on AWS.

Your AWS account has default quotas to maintain the performance of the service and to ensure appropriate usage of Amazon Bedrock. The default quotas assigned to an account might be updated depending on regional factors, payment history, fraudulent usage, and/or approval of a quota increase request. For more information, see the section called “Quotas” documentation and see the limits for the model.

On the `bedrock-runtime` endpoint, limits are managed as tokens per minute (TPM) with a 10x burndown rate, where 1 output token consumes 10 tokens.

Sample Code

Step 1 - AWS Account: If you have an AWS account already, skip this step. If you are new to AWS, sign up for an AWS account.

Step 2 - API key: Go to the Amazon Bedrock console and generate a long-term API key.

Step 3 - Get the SDK: To use this getting started guide, you must have Python already installed. Then install the relevant software depending on the APIs you are using.

For both APIs, choose the OpenAI SDK tab.

OpenAI SDK

```
pip install openai
```

Step 4 - Set environment variables

Configure your environment to use the API key for authentication.

bedrock-runtime

```
OPENAI_API_KEY="<provide your Bedrock API key>"
OPENAI_BASE_URL="https://bedrock-runtime.us-east-1.amazonaws.com/openai/v1"
```

bedrock-mantle

```
OPENAI_API_KEY="<provide your Bedrock API key>"
OPENAI_BASE_URL="https://bedrock-mantle.us-east-2.api.aws/openai/v1"
```

Note

On `bedrock-runtime`, name a cross-Region inference profile as the model — `us.openai.gpt-5.6-cyber` or `global.openai.gpt-5.6-cyber`. This model is not available for in-Region inference on that endpoint. Your IAM identity also needs `bedrock:InvokeModel` on your account's default project (`arn:aws:bedrock:{region}:{account-id}:project/default`) in addition to the inference profile.

Step 5 - Run your first inference request

Save the file as `bedrock-first-request.py`

bedrock-runtime: OpenAI SDK

Use the settings from Step 4 - Set environment variables. Choose the `bedrock-runtime` tab. Both examples use the US geographic cross-Region inference profile.

Responses API

```
from openai import OpenAI

client = OpenAI()

response = client.responses.create(
    model="us.openai.gpt-5.6-cyber",
    input="Can you explain the features of Amazon Bedrock?"
)
print(response)
```

Chat

```
from openai import OpenAI

client = OpenAI()

response = client.chat.completions.create(
    model="us.openai.gpt-5.6-cyber",
    messages=[{"role": "user", "content": "Can you explain the features of Amazon
 Bedrock?"}]
)
print(response)
```

bedrock-mantle

Use the settings from Step 4 - Set environment variables. Choose the `bedrock-mantle` tab. The Chat tab uses the Chat Completions API.

Responses API

```
from openai import OpenAI

client = OpenAI()
```

```
response = client.responses.create(
    model="openai.gpt-5.6-cyber",
    input="Can you explain the features of Amazon Bedrock?"
)
print(response)
```

Chat

```
from openai import OpenAI

client = OpenAI()

response = client.chat.completions.create(
    model="openai.gpt-5.6-cyber",
    messages=[{"role": "user", "content": "Can you explain the features of Amazon
 Bedrock?"}]
)
print(response)
```

Daybreak Blue: GPT-5.6 Sol

OpenAI — Daybreak Blue: GPT-5.6 Sol

Model Details

Daybreak Blue: GPT-5.6 Sol is a specialized OpenAI model for verified defenders conducting advanced, authorized cybersecurity work.

> **Note**
>
> Access to this model is limited to eligible customers. For more information, see Accelerate cyber defense with OpenAI and AWS.

Model launch date: August 12, 2026
EOL no sooner than: August 12, 2027
Legacy period: at least 6 months
Model lifecycle policy: Model lifecycle (For Models Launched Prior to Sept 7 2026)

Model EOL date: N/A
End User License Agreements and Terms of Use: View
Model lifecycle: Active
Context window: 1,050,000 tokens
Languages: English, Spanish, French, German, Portuguese, Italian, Dutch, Russian, Chinese (Simplified and Traditional), Japanese, Korean, Arabic, Hindi, Turkish, Polish, Ukrainian, and other languages.
Fine-tuning supported: No
Supported use cases: Vulnerability discovery, detection engineering, and incident response.
Marketplace product ID: `prod-kvlnq5lbvorj4`

Endpoints and APIs supported

The following tables show which endpoints and APIs are supported for Daybreak Blue: GPT-5.6 Sol. For more information, see the section called “APIs” and the section called “Inference endpoints”.

Endpoint support

Endpoint	Supported
`bedrock-runtime`	✓
`bedrock-mantle`	✓

APIs supported on `bedrock-runtime` endpoint

Messages	Responses	Chat Completions	Converse	Invoke
⊗	⊙	⊙	⊙	⊗

APIs supported on `bedrock-mantle` endpoint

Messages	Responses	Chat Completions	Converse	Invoke
⊗	⊙	⊙	⊗	⊗

Note

On `bedrock-mantle`, both APIs use the `/openai/v1` base path, not `/v1`. Use either API with this model:

- For Responses, use `/openai/v1/responses`.
- For Chat Completions, use `/openai/v1/chat/completions`.

Tip

Whenever possible, we recommend using the `bedrock-runtime` endpoint for new applications. See the section called “Inference endpoints” for details.

Server-side tool calling Projects Implicit Prompt Caching (Responses API only) Explicit Prompt Caching (Responses API only) Reasoning Summaries (Responses API only)	Watermarking

JSON Schema output on bedrock-runtime

Use JSON Schema to set the format of the model response. These settings apply to non-streaming calls on the `bedrock-runtime` endpoint. Choose a profile ID from Programmatic access.

- For Chat Completions, set `response_format.type` to `json_schema`. Put `name`, `schema`, and `strict: true` in `response_format.json_schema`.
- For Responses, set `text.format.type` to `json_schema`. Put `name`, `schema`, and `strict: true` in `text.format`.
- For Converse, set `outputConfig.textFormat.type` to `json_schema`. In `outputConfig.textFormat.structure.jsonSchema`, set `name` and `schema`. Encode the schema as a JSON string. Then set `additionalModelRequestFields.text.format.strict` to `true`.

Use an object schema. Put all fields in `required`. Set `additionalProperties` to `false`. Validate your schema before you send it. Check for refusals or incomplete responses before you parse the output.

Important

For JSON Schema output with the Converse API, you must set `additionalModelRequestFields.text.format.strict` to `true`, in addition to specifying the schema in `outputConfig`. Include the following field in your request.

```
{
  "additionalModelRequestFields": {
    "text": {
      "format": { "strict": true }
    }
  }
}
```

Converse content blocks

On the `bedrock-runtime` endpoint, Converse accepts `text` and `image` content blocks in user messages. This model doesn't accept `document` content blocks, and it doesn't accept an `image` content block inside a `toolResult`. A request that includes either is rejected with a

`ValidationException`. To send a document to this model, use the Responses API with an `input_file` content part instead.

Pricing

All prices are in USD per 1 million tokens for the Standard tier.

The **Input — 30-minute cache write** column is the price per 1 million tokens written to the prompt cache. The 30-minute figure is how long a cached prompt prefix is retained, not a quantity of tokens. For more information, see prompt caching.

Commercial In-Region prices include a 10% fee over OpenAI rates. You do not need to add this fee.

Priority and Flex tiers are not supported for this model.

Commercial Regions — short context (272K input tokens or fewer)

Inference option	Input	Input — 30-minute cache write	Input — cache read	Output
In-Region	$4.40	$5.50	$0.44	$22.00

Commercial Regions — long context (more than 272K input tokens)

Inference option	Input	Input — 30-minute cache write	Input — cache read	Output
In-Region	$8.80	$11.00	$0.88	$33.00

Programmatic Access

Use the following model IDs and endpoint URLs to access this model programmatically. For more information about the available APIs and endpoints, see APIs supported and Endpoints supported.

Endpoint	Model ID	In-Region endpoint URL	Geo inference ID	Global inference ID
bedrock-runtime	openai.gpt-daybreak-blue-5.6-sol	Not supported	us.openai.gpt-daybreak-blue-5.6-sol	global.openai.gpt-daybreak-blue-5.6-sol
bedrock-mantle	openai.gpt-daybreak-blue-5.6-sol	https://bedrock-mantle.{region}.api.aws/openai/v1	Not supported	Not supported

For example, if region is us-east-2 (Ohio), then the bedrock-mantle endpoint URL will be "https://bedrock-mantle.us-east-2.api.aws/openai/v1". On `bedrock-runtime`, the base URL is "https://bedrock-runtime.{region}.amazonaws.com/openai/v1" and requests must name the geographic cross-Region inference ID `us.openai.gpt-daybreak-blue-5.6-sol` as the model.

Service Tiers

Amazon Bedrock offers multiple service tiers to match your workload requirements. **Standard** provides pay-per-token access with no commitment (set `"service_tier": "default"` or omit the field). **Priority** delivers the fastest response times for a price premium (set `"service_tier": "priority"`). **Flex** provides lower-cost access for flexible, non-time-sensitive workloads (set `"service_tier": "flex"`). **Reserved** provides dedicated throughput with a term commitment for predictable workloads; it is set at the account level rather than per request (contact your AWS account team to enable). For more information, see service tiers.

print(response)
```

GPT-5.5

OpenAI — GPT-5.5

Model Details

GPT-5.5 is OpenAI's most capable model, designed for advanced coding, research, analysis, software operation, document workflows, and long-running agentic tasks. GPT-5.5 can understand open-ended goals, use tools, reason across longer workflows, navigate ambiguity, and carry complex tasks through to completion with less orchestration. For more information about model development and performance, see the model/service card.

Model launch date: June 1, 2026

EOL no sooner than: June 1, 2027

Legacy period: at least 6 months

Model lifecycle policy: Model lifecycle (For Models Launched Prior to Sept 7 2026)

Model EOL date: N/A

End User License Agreements and Terms of Use: View

Model lifecycle: Active

Context window: 1,050,000 tokens, shared between input and output

Max output tokens: 128,000

Marketplace product ID: `prod-indw4nwkcsyua`

Input Modalities	Output Modalities
⊗ Audio	⊗ Embedding
⊙ Image	⊗ Image
⊗ Speech	⊗ Speech
⊙ Text	⊙ Text
⊗ Video	⊗ Video

Endpoints and APIs supported

The following tables show which endpoints and APIs are supported for GPT-5.5. For more information, see the section called “APIs” and the section called “Inference endpoints”.

Endpoint support

Endpoint	Supported
`bedrock-runtime`	✓
`bedrock-mantle`	✓

APIs supported on `bedrock-runtime` endpoint

Messages	Responses	Chat Completions	Converse	Invoke
✗	✓	✓	✓	✗

APIs supported on `bedrock-mantle` endpoint

Messages	Responses	Chat Completions	Converse	Invoke
✗	✓	✓	✗	✗

Note

On `bedrock-mantle`, both inference APIs use the `/openai/v1` base path, not `/v1`. Use either API with this model:

- For Responses, use `/openai/v1/responses`.
- For Chat Completions, use `/openai/v1/chat/completions`.

This applies to inference only. Model discovery stays on `/v1/models`, as it does for every model on `bedrock-mantle`. A request to `/openai/v1/models` returns `404`. For more information, see the section called "Get list of models".

Tip

Whenever possible, we recommend using the `bedrock-runtime` endpoint for new applications. See the section called "Inference endpoints" for details.

Capabilities and Features

Bedrock Features

Features supported using `bedrock-runtime` endpoint

Supported	Not Supported
✓ Projects (default project only) ✓ Invocation logs ✓ Response streaming ✓ Abuse detection ✓ Guardrails (Converse API only) ✓ Application inference profiles (Converse API only; not supported with Responses or Chat Completions APIs) ✓ Implicit Prompt Caching (Responses API only; automatic, no request parameters) ✓ Structured outputs (JSON Schema; Responses API) ✓ Reasoning Summaries (Responses, Converse, and ConverseStream APIs; on Converse, set `additionalModelRequestFields.reasoning.summary`)	✗ Explicit Prompt Caching ✗ Server-side tool use ✗ Intelligent prompt routing ✗ Count tokens ✗ Watermarking

Features supported using `bedrock-mantle` endpoint

Supported	Not Supported
✓ Server-side tool calling ✓ Projects ✓ Client-side tool calling ✓ Reasoning Summaries (Responses API only)	✗ Watermarking

Converse content blocks

On the `bedrock-runtime` endpoint, Converse accepts `text` and `image` content blocks in user messages. This model doesn't accept `document` content blocks, and it doesn't accept an `image` content block inside a `toolResult`. A request that includes either is rejected with a `ValidationException`. To send a document to this model, use the Responses API with an `input_file` content part instead.

Pricing

All prices are in USD per 1 million tokens for the Standard tier.

The **Input — 30-minute cache write** column is the price per 1 million tokens written to the prompt cache. The 30-minute figure is how long a cached prompt prefix is retained, not a quantity of tokens. For more information, see prompt caching.

Commercial In-Region prices include a 10% fee over OpenAI rates. You do not need to add this fee.

Long-context rates apply to all input and output tokens, not just tokens above 272K.

Priority and Flex tiers are not supported for this model.

Commercial Regions — short context (272K input tokens or fewer)

Inference option	Input	Input — 30-minute cache write	Input — cache read	Output
In-Region	$5.50	—	$0.55	$33.00

Commercial Regions — long context (more than 272K input tokens)

Inference option	Input	Input — 30-minute cache write	Input — cache read	Output
In-Region	$11.00	—	$1.10	$49.50

Programmatic Access

Use the following model IDs and endpoint URLs to access this model programmatically. For more information about the available APIs and endpoints, see APIs supported and Endpoints supported.

Endpoint	Model ID	In-Region endpoint URL	Geo inference ID	Global inference ID
`bedrock-runtime`	`openai.gpt-5.5`	Not supported	`us.openai.gpt-5.5`	`global.openai.gpt-5.5`
`bedrock-mantle`	`openai.gpt-5.5`	`https://bedrock-mantle.{region}.api.aws/openai/v1`	Not supported	Not supported

For example, if region is us-east-1 (N. Virginia), then the bedrock-mantle endpoint URL will be "https://bedrock-mantle.us-east-1.api.aws/openai/v1". On `bedrock-runtime`, the base URL is "https://bedrock-runtime.{region}.amazonaws.com/openai/v1" and requests must name a cross-Region inference ID — `us.openai.gpt-5.5` or `global.openai.gpt-5.5` — as the model.

Service Tiers

Amazon Bedrock offers multiple service tiers to match your workload requirements. **Standard** provides pay-per-token access with no commitment (set `"service_tier": "default"` or omit the field). **Priority** delivers the fastest response times for a price premium (set `"service_tier": "priority"`). **Flex** provides lower-cost access for flexible, non-time-sensitive workloads (set `"service_tier": "flex"`). **Reserved** provides dedicated throughput with a term commitment

for predictable workloads; it is set at the account level rather than per request (contact your AWS account team to enable). For more information, see service tiers.

Standard	Priority	Flex	Reserved
✓	✗	✗	✗

Regional Availability

Regional availability at a glance

Amazon Bedrock offers three inference options: **In-Region** keeps requests within a single Region for strict compliance, **Geo Cross-Region** routes across Regions within a geography (such as US, EU, and APAC) while respecting data residency, and **Global Cross-Region** routes anywhere worldwide when there are no residency constraints. Refer to the the section called "Regional availability by models" page for more details.

Availability differs by endpoint.

Availability using the `bedrock-mantle` endpoint

Region	In-Region	Geo	Global
`us-east-1` (N. Virginia)	✓	✗	✗
`us-east-2` (Ohio)	✓	✗	✗

Quotas and Limits

Your AWS account has default quotas to maintain the performance of the service and to ensure appropriate usage of Amazon Bedrock. The default quotas assigned to an account might be updated depending on regional factors, payment history, fraudulent usage, and/or approval of a quota increase request. For more information, see the section called "Quotas" documentation and see the limits for the model.

Sample Code

Step 1 - AWS Account: If you have an AWS account already, skip this step. If you are new to AWS, sign up for an AWS account.

Step 2 - API key: Go to the Amazon Bedrock console and generate a long-term API key.

Step 3 - Get the SDK: To use this getting started guide, you must have Python already installed. Then install the relevant software depending on the APIs you are using.

For both APIs, choose the OpenAI SDK tab.

OpenAI SDK

```
pip install openai
```

Step 4 - Set environment variables

Configure your environment to use the API key for authentication.

bedrock-runtime

```
OPENAI_API_KEY="<provide your Bedrock API key>"
OPENAI_BASE_URL="https://bedrock-runtime.us-east-2.amazonaws.com/openai/v1"
```

bedrock-mantle

```
OPENAI_API_KEY="<provide your Bedrock API key>"
OPENAI_BASE_URL="https://bedrock-mantle.us-east-2.api.aws/openai/v1"
```

> **Note**
>
> On `bedrock-runtime`, name a cross-Region inference profile as the model — `us.openai.gpt-5.5` or `global.openai.gpt-5.5`. This model is not available for in-Region inference on that endpoint. Your IAM identity also needs `bedrock:InvokeModel` on your account's default project (`arn:aws:bedrock:{region}:{account-id}:project/default`) in addition to the inference profile.

Step 5 - Run your first inference request

Save the file as `bedrock-first-request.py`

bedrock-mantle

Use the settings from Step 4 - Set environment variables. Choose the `bedrock-mantle` tab. The Chat tab uses the Chat Completions API.

Responses API

```
from openai import OpenAI
```

```
client = OpenAI()

response = client.responses.create(
    model="openai.gpt-5.5",
    input="Can you explain the features of Amazon Bedrock?"
)
print(response)
```

Chat

```
from openai import OpenAI

client = OpenAI()

response = client.chat.completions.create(
    model="openai.gpt-5.5",
    messages=[{"role": "user", "content": "Can you explain the features of Amazon
 Bedrock?"}]
)
print(response)
```

GPT-5.4

OpenAI — GPT-5.4

Model Details

GPT-5.4 brings frontier reasoning, coding, computer use, long-context workflows, and tool use to Amazon Bedrock. It helps developers build AI applications and production workflows that can interpret context, interact with tools, operate software environments, and verify outputs across multiple steps. GPT-5.4 is well suited for professional workflows that require reliable reasoning and action across complex business systems. For more information about model development and performance, see the model/service card.

Model launch date: June 1, 2026
EOL no sooner than: June 1, 2027
Legacy period: at least 6 months

Model lifecycle policy: Model lifecycle (For Models Launched Prior to Sept 7 2026)

Model EOL date: N/A

End User License Agreements and Terms of Use: View

Model lifecycle: Active

Context window: 1,050,000 tokens, shared between input and output

Max output tokens: 128,000

Marketplace product ID: `prod-3bbohv3635iau`

Input Modalities	Output Modalities
⊗ Audio	⊗ Embedding
✓ Image	⊗ Image
⊗ Speech	⊗ Speech
✓ Text	✓ Text
⊗ Video	⊗ Video

Endpoints and APIs supported

The following tables show which endpoints and APIs are supported for GPT-5.4. For more information, see the section called "APIs" and the section called "Inference endpoints".

Endpoint support

Endpoint	Supported
`bedrock-runtime`	✓
`bedrock-mantle`	✓

APIs supported on `bedrock-runtime` endpoint

Messages	Responses	Chat Completions	Converse	Invoke
⊗	⊙	⊙	⊙	⊗

APIs supported on `bedrock-mantle` endpoint

Messages	Responses	Chat Completions	Converse	Invoke
⊗	⊙	⊙	⊗	⊗

Note

On `bedrock-mantle`, both APIs use the `/openai/v1` base path, not `/v1`. Use either API with this model:

- For Responses, use `/openai/v1/responses`.
- For Chat Completions, use `/openai/v1/chat/completions`.

Tip

Whenever possible, we recommend using the `bedrock-runtime` endpoint for new applications. See the section called “Inference endpoints” for details.

Capabilities and Features

Bedrock Features

Features supported using `bedrock-runtime` endpoint

Supported	Not Supported
⊙ Projects (default project only)	⊗ Explicit Prompt Caching

Supported	Not Supported
Invocation logs Response streaming Abuse detection Guardrails (Converse API only) Application inference profiles (Converse API only; not supported with Responses or Chat Completions APIs) Implicit Prompt Caching (Responses API only; automatic, no request parameters) Structured outputs (JSON Schema; Responses API) Reasoning Summaries (Responses, Converse, and ConverseStream APIs; on Converse, set `additionalModelRequestFields.reasoning.summary`)	Server-side tool use Intelligent prompt routing Count tokens Watermarking

Features supported using `bedrock-mantle` endpoint

Supported	Not Supported
Server-side tool calling Projects Client-side tool calling Reasoning Summaries (Responses API only)	Watermarking

Converse content blocks

On the `bedrock-runtime` endpoint, Converse accepts `text` and `image` content blocks in user messages. This model doesn't accept `document` content blocks, and it doesn't accept an `image` content block inside a `toolResult`. A request that includes either is rejected with a `ValidationException`. To send a document to this model, use the Responses API with an `input_file` content part instead.

Pricing

All prices are in USD per 1 million tokens for the Standard tier.

The **Input — 30-minute cache write** column is the price per 1 million tokens written to the prompt cache. The 30-minute figure is how long a cached prompt prefix is retained, not a quantity of tokens. For more information, see prompt caching.

Commercial In-Region prices include a 10% fee over OpenAI rates. You do not need to add this fee.

Long-context rates apply to all input and output tokens, not just tokens above 272K.

Priority and Flex tiers are not supported for this model.

Commercial Regions — short context (272K input tokens or fewer)

Inference option	Input	Input — 30-minute cache write	Input — cache read	Output
In-Region	$2.75	—	$0.275	$16.50

Commercial Regions — long context (more than 272K input tokens)

Inference option	Input	Input — 30-minute cache write	Input — cache read	Output
In-Region	$5.50	—	$0.55	$24.75

AWS GovCloud (US-West) — short context (272K input tokens or fewer)

Inference option	Input	Input — 30-minute cache write	Input — cache read	Output
In-Region (`bedrock-mantle`)	$3.375	—	$0.3375	$20.25

Programmatic Access

Use the following model IDs and endpoint URLs to access this model programmatically. For more information about the available APIs and endpoints, see APIs supported and Endpoints supported.

Endpoint	Model ID	In-Region endpoint URL	Geo inference ID	Global inference ID
`bedrock-runtime`	`openai.gpt-5.4`	Not supported	`us.openai.gpt-5.4` in the commercial AWS Regions, `us-gov.openai.gpt-5.4` in the AWS GovCloud (US) Regions	`global.openai.gpt-5.4`
`bedrock-mantle`	`openai.gpt-5.4`	`https://bedrock-mantle.{region}.api.aws/openai/v1`	Not supported	Not supported

For example, if region is us-east-1 (N. Virginia), then the bedrock-mantle endpoint URL will be "https://bedrock-mantle.us-east-1.api.aws/openai/v1". On `bedrock-runtime`, the base URL is "https://bedrock-runtime.{region}.amazonaws.com/openai/v1" and requests must name a cross-Region inference ID — `us.openai.gpt-5.4` or `global.openai.gpt-5.4` (in the AWS GovCloud (US) Regions, `us-gov.openai.gpt-5.4`) — as the model.

Service Tiers

Amazon Bedrock offers multiple service tiers to match your workload requirements. **Standard** provides pay-per-token access with no commitment (set `"service_tier": "default"` or omit the field). **Priority** delivers the fastest response times for a price premium (set `"service_tier": "priority"`). **Flex** provides lower-cost access for flexible, non-time-sensitive workloads (set `"service_tier": "flex"`). **Reserved** provides dedicated throughput with a term commitment

for predictable workloads; it is set at the account level rather than per request (contact your AWS account team to enable). For more information, see service tiers.

Geo inference details

The destination Regions available to a geographic inference profile depend on the source Region. To retrieve the current routing configuration, call GetInferenceProfile from the source Region.

Geo: US-GOV

Geo inference ID: `us-gov.openai.gpt-5.4`

Source Region	Destination Regions
us-gov-east-1 (AWS GovCloud (US-East))	us-gov-east-1 (AWS GovCloud (US-East)), us-gov-west-1 (AWS GovCloud (US-West))
us-gov-west-1 (AWS GovCloud (US-West))	us-gov-east-1 (AWS GovCloud (US-East)), us-gov-west-1 (AWS GovCloud (US-West))

Quotas and Limits

Your AWS account has default quotas to maintain the performance of the service and to ensure appropriate usage of Amazon Bedrock. The default quotas assigned to an account might be updated depending on regional factors, payment history, fraudulent usage, and/or approval of a quota increase request. For more information, see the section called "Quotas" documentation and see the limits for the model.

Sample Code

Step 1 - AWS Account: If you have an AWS account already, skip this step. If you are new to AWS, sign up for an AWS account.

Step 2 - API key: Go to the Amazon Bedrock console and generate a long-term API key.

Step 3 - Get the SDK: To use this getting started guide, you must have Python already installed. Then install the relevant software depending on the APIs you are using.

For both APIs, choose the OpenAI SDK tab.

OpenAI SDK

```
pip install openai
```

Step 4 - Set environment variables

Configure your environment to use the API key for authentication.

bedrock-runtime

```
OPENAI_API_KEY="<provide your Bedrock API key>"
```

```
OPENAI_BASE_URL="https://bedrock-runtime.us-west-2.amazonaws.com/openai/v1"
```

bedrock-mantle

```
OPENAI_API_KEY="<provide your Bedrock API key>"
OPENAI_BASE_URL="https://bedrock-mantle.us-west-2.api.aws/openai/v1"
```

Note

On `bedrock-runtime`, name a cross-Region inference profile as the model — `us.openai.gpt-5.4` or `global.openai.gpt-5.4` (in the AWS GovCloud (US) Regions, `us-gov.openai.gpt-5.4`). This model is not available for in-Region inference on that endpoint. Your IAM identity also needs `bedrock:InvokeModel` on your account's default project (`arn:aws:bedrock:{region}:{account-id}:project/default`, or `arn:aws-us-gov:bedrock:{region}:{account-id}:project/default` in the AWS GovCloud (US) Regions) in addition to the inference profile.

Step 5 - Run your first inference request

Save the file as `bedrock-first-request.py`

bedrock-mantle

Use the settings from Step 4 - Set environment variables. Choose the `bedrock-mantle` tab. The Chat tab uses the Chat Completions API.

Responses API

```
from openai import OpenAI

client = OpenAI()

response = client.responses.create(
    model="openai.gpt-5.4",
    input="Can you explain the features of Amazon Bedrock?"
)
print(response)
```

Chat

```
from openai import OpenAI

client = OpenAI()

response = client.chat.completions.create(
    model="openai.gpt-5.4",
    messages=[{"role": "user", "content": "Can you explain the features of Amazon
 Bedrock?"}]
)
print(response)
```

GPT OSS Safeguard 120B

OpenAI — GPT OSS Safeguard 120B

Model Details

GPT OSS Safeguard 120B is OpenAI's 120-billion parameter open-source safety model for content moderation and guardrail enforcement in AI applications. For more information about model development and performance, see the model/service card.

Model launch date: Oct 29, 2025

EOL no sooner than: Oct 29, 2026

Legacy period: at least 6 months

Model lifecycle policy: Model lifecycle (For Models Launched Prior to Sept 7 2026)

Model EOL date: N/A

End User License Agreements and Terms of Use: View

Model lifecycle: Active

Context window: 128K tokens

Max output tokens: 16K

Reasoning: Supported, on by default (effort configurable: low, medium, high)

Input Modalities	Output Modalities
⊗ Audio	⊗ Embedding
⊗ Image	⊗ Image
⊗ Speech	⊗ Speech
⊙ Text	⊙ Text
⊗ Video	⊗ Video

Endpoints and APIs supported

The following tables show which endpoints and APIs are supported for GPT OSS Safeguard 120B. For more information, see the section called “APIs” and the section called “Inference endpoints”.

Endpoint support

Endpoint	Supported
`bedrock-runtime`	⊙
`bedrock-mantle`	⊙

APIs supported on `bedrock-runtime` endpoint

Messages	Responses	Chat Completions	Converse	Invoke
⊗	⊗	⊙	⊙	⊙

APIs supported on `bedrock-mantle` endpoint

Messages	Responses	Chat Completions	Converse	Invoke
⊗	✓	✓	⊗	⊗

Note

On `bedrock-mantle`, both APIs use the `/v1` base path, not `/openai/v1`. Use either API with this model:

- For Responses, use `/v1/responses`.
- For Chat Completions, use `/v1/chat/completions`.

Tip

Whenever possible, we recommend using the `bedrock-runtime` endpoint for new applications. See the section called "Inference endpoints" for details.

Capabilities and Features

Bedrock Features

Features supported using `bedrock-mantle` endpoint

Quotas and Limits

Your AWS account has default quotas to maintain the performance of the service and to ensure appropriate usage of Amazon Bedrock. The default quotas assigned to an account might be updated depending on regional factors, payment history, fraudulent usage, and/or approval of a quota increase request. For more information, see the section called "Quotas" documentation and see the limits for the model.

Sample Code

Step 1 - AWS Account: If you have an AWS account already, skip this step. If you are new to AWS, sign up for an AWS account.

Step 2 - API key: Go to the Amazon Bedrock console and generate a long-term API key.

Step 3 - Get the SDK: To use this getting started guide, you must have Python already installed. Then install the relevant software depending on the APIs you are using.

For Responses or Chat Completions, choose the OpenAI SDK tab. For Invoke or Converse, choose the Boto3 tab.

OpenAI SDK

```
pip install boto3 openai
```

Boto3

```
pip install boto3
```

Step 4 - Set environment variables

Configure your environment to use the API key for authentication.

Choose the tab for your SDK and endpoint.

bedrock-mantle

```
OPENAI_API_KEY="<provide your Bedrock API key>"
OPENAI_BASE_URL="https://bedrock-mantle.<your-region>.api.aws/v1"
```

bedrock-runtime

```
OPENAI_API_KEY="<provide your Bedrock API key>"
OPENAI_BASE_URL="https://bedrock-runtime.<your-region>.amazonaws.com/openai/v1"
```

Boto3

```
AWS_BEARER_TOKEN_BEDROCK="<provide your Bedrock API key>"
```

Step 5 - Run your first inference request

Save the file as `bedrock-first-request.py`

bedrock-mantle

Use the settings from Step 4 - Set environment variables. Choose the `bedrock-mantle` tab. The Chat tab uses the Chat Completions API.

Responses API

```
from openai import OpenAI
```

```
client = OpenAI()

response = client.responses.create(
    model="openai.gpt-oss-safeguard-120b",
    input="Can you explain the features of Amazon Bedrock?"
)
print(response)
```

Chat

```
from openai import OpenAI

client = OpenAI()

response = client.chat.completions.create(
    model="openai.gpt-oss-safeguard-120b",
    messages=[{"role": "user", "content": "Can you explain the features of Amazon
 Bedrock?"}]
)
print(response)
```

bedrock-runtime: OpenAI SDK

Use the settings from Step 4 - Set environment variables. Choose the `bedrock-runtime` tab. This sample uses the Chat Completions API.

> **Note**
>
> To call the Responses API with this model, use `bedrock-mantle`. You can't call it on `bedrock-runtime`.

```
from openai import OpenAI

client = OpenAI()

response = client.chat.completions.create(
    model="openai.gpt-oss-safeguard-120b",
    messages=[{"role": "user", "content": "Can you explain the features of Amazon
 Bedrock?"}]
```

```
    )
print(response)
```

bedrock-runtime: Boto3

Use the Boto3 settings from Step 4 - Set environment variables. Choose the API for your request.

Invoke API

```
import json
import boto3

client = boto3.client('bedrock-runtime', region_name='us-east-1')
response = client.invoke_model(
    modelId='openai.gpt-oss-safeguard-120b',
    body=json.dumps({
            'messages': [{ 'role': 'user', 'content': 'Can you explain the features
 of Amazon Bedrock?'}],
            'max_tokens': 1024
    })
)
print(json.loads(response['body'].read()))
```

Converse API

```
import boto3

client = boto3.client('bedrock-runtime', region_name='us-east-1')
response = client.converse(
    modelId='openai.gpt-oss-safeguard-120b',
    messages=[
        {
            'role': 'user',
            'content': [{'text': 'Can you explain the features of Amazon Bedrock?'}]
        }
    ]
)
print(response)
```

GPT OSS Safeguard 20B

OpenAI — GPT OSS Safeguard 20B

Model Details

GPT OSS Safeguard 20B is OpenAI's compact 20-billion parameter open-source safety model for lightweight content moderation and guardrail tasks. For more information about model development and performance, see the model/service card.

Model launch date: Oct 29, 2025
EOL no sooner than: Oct 29, 2026
Legacy period: at least 6 months
Model lifecycle policy: Model lifecycle (For Models Launched Prior to Sept 7 2026)
Model EOL date: N/A
End User License Agreements and Terms of Use: View
Model lifecycle: Active
Context window: 128K tokens
Max output tokens: 16K
Reasoning: Supported, on by default (effort configurable: low, medium, high)

Input Modalities	Output Modalities
⊗ Audio	⊗ Embedding
⊗ Image	⊗ Image
⊗ Speech	⊗ Speech
⊙ Text	⊙ Text
⊗ Video	⊗ Video

Endpoints and APIs supported

The following tables show which endpoints and APIs are supported for GPT OSS Safeguard 20B. For more information, see the section called "APIs" and the section called "Inference endpoints".

Endpoint support

Endpoint	Supported
`bedrock-runtime`	✓
`bedrock-mantle`	✓

APIs supported on `bedrock-runtime` endpoint

Messages	Responses	Chat Completions	Converse	Invoke
✗	✗	✓	✓	✓

APIs supported on `bedrock-mantle` endpoint

Messages	Responses	Chat Completions	Converse	Invoke
✗	✓	✓	✗	✗

Note

On `bedrock-mantle`, both APIs use the `/v1` base path, not `/openai/v1`. Use either API with this model:

- For Responses, use `/v1/responses`.
- For Chat Completions, use `/v1/chat/completions`.

> **Tip**
>
> Whenever possible, we recommend using the `bedrock-runtime` endpoint for new applications. See the section called "Inference endpoints" for details.

Capabilities and Features

Bedrock Features

Features supported using `bedrock-mantle` endpoint

Supported	Not Supported
Server-side tool calling Projects Client-side tool calling	Watermarking

Features supported using `bedrock-runtime` endpoint

Supported	Not Supported
Response streaming Guardrails Model evaluation Prompt management Flows Agents Structured outputs	Intelligent prompt routing Abuse detection Prompt optimization Count tokens Knowledge base Watermarking

Pricing

For pricing information, see the Amazon Bedrock Pricing page.

Programmatic Access

Use the following model IDs and endpoint URLs to access this model programmatically. For more information about the available APIs and endpoints, see APIs supported and Endpoints supported.

Endpoint	Model ID	In-Region endpoint URL	Geo inference ID	Global inference ID
bedrock-runtime	openai.gpt-oss-safeguard-20b	https://bedrock-runtime.{region}.amazonaws.com	Not supported	Not supported
bedrock-mantle	openai.gpt-oss-safeguard-20b	https://bedrock-mantle.{region}.api.aws/v1	Not supported	Not supported

For example, if region is us-east-1 (N. Virginia), then the bedrock-runtime endpoint URL will be "https://bedrock-runtime.us-east-1.amazonaws.com" and for bedrock-mantle will be "https://bedrock-mantle.us-east-1.api.aws/v1".

Service Tiers

Amazon Bedrock offers multiple service tiers to match your workload requirements. **Standard** provides pay-per-token access with no commitment (set `"service_tier": "default"` or omit the field). **Priority** delivers the fastest response times for a price premium (set `"service_tier": "priority"`). **Flex** provides lower-cost access for flexible, non-time-sensitive workloads (set `"service_tier": "flex"`). **Reserved** provides dedicated throughput with a term commitment for predictable workloads; it is set at the account level rather than per request (contact your AWS account team to enable). For more information, see service tiers.

Standard	Priority	Flex	Reserved
✓	✓	✓	✗

Regional Availability

Regional availability at a glance

Amazon Bedrock offers three inference options: **In-Region** keeps requests within a single Region for strict compliance, **Geo Cross-Region** routes across Regions within a geography (such as US, EU, and APAC) while respecting data residency, and **Global Cross-Region** routes anywhere worldwide when there are no residency constraints. Refer to the the section called “Regional availability by models” page for more details.

Region	In-Region	Geo	Global
`us-east-1` (N. Virginia)	✓	✗	✗
`us-east-2` (Ohio)	✓	✗	✗
`us-west-2` (Oregon)	✓	✗	✗
`eu-south-1` (Milan)	✓	✗	✗
`eu-west-1` (Ireland)	✓	✗	✗
`eu-west-2` (London)	✓	✗	✗
`ap-northeast-1` (Tokyo)	✓	✗	✗
`ap-south-1` (Mumbai)	✓	✗	✗
`ap-southeast-2` (Sydney)	✓	✗	✗
`sa-east-1` (São Paulo)	✓	✗	✗
`ap-southeast-3` (Jakarta)	✓	✗	✗
`ap-southeast-4` (Melbourne)	✓	✗	✗
`ap-northeast-2` (Seoul)	✓	✗	✗
`ap-southeast-1` (Singapore)	✓	✗	✗
`eu-central-1` (Frankfurt)	✓	✗	✗

Region	In-Region	Geo	Global
eu-north-1 (Stockholm)	✓	✗	✗

Quotas and Limits

Your AWS account has default quotas to maintain the performance of the service and to ensure appropriate usage of Amazon Bedrock. The default quotas assigned to an account might be updated depending on regional factors, payment history, fraudulent usage, and/or approval of a quota increase request. For more information, see the section called "Quotas" documentation and see the limits for the model.

Sample Code

Step 1 - AWS Account: If you have an AWS account already, skip this step. If you are new to AWS, sign up for an AWS account.

Step 2 - API key: Go to the Amazon Bedrock console and generate a long-term API key.

Step 3 - Get the SDK: To use this getting started guide, you must have Python already installed. Then install the relevant software depending on the APIs you are using.

For Responses or Chat Completions, choose the OpenAI SDK tab. For Invoke or Converse, choose the Boto3 tab.

OpenAI SDK

```
pip install boto3 openai
```

Boto3

```
pip install boto3
```

Step 4 - Set environment variables

Configure your environment to use the API key for authentication.

Choose the tab for your SDK and endpoint.

bedrock-mantle

```
OPENAI_API_KEY="<provide your Bedrock API key>"
OPENAI_BASE_URL="https://bedrock-mantle.<your-region>.api.aws/v1"
```

bedrock-runtime

```
OPENAI_API_KEY="<provide your Bedrock API key>"
OPENAI_BASE_URL="https://bedrock-runtime.<your-region>.amazonaws.com/openai/v1"
```

Boto3

```
AWS_BEARER_TOKEN_BEDROCK="<provide your Bedrock API key>"
```

Step 5 - Run your first inference request

Save the file as `bedrock-first-request.py`

bedrock-mantle

Use the settings from Step 4 - Set environment variables. Choose the `bedrock-mantle` tab. The Chat tab uses the Chat Completions API.

Responses API

```
from openai import OpenAI

client = OpenAI()

response = client.responses.create(
    model="openai.gpt-oss-safeguard-20b",
    input="Can you explain the features of Amazon Bedrock?"
)
print(response)
```

Chat

```
from openai import OpenAI

client = OpenAI()
```

```
response = client.chat.completions.create(
    model="openai.gpt-oss-safeguard-20b",
    messages=[{"role": "user", "content": "Can you explain the features of Amazon
 Bedrock?"}]
)
print(response)
```

bedrock-runtime: OpenAI SDK

Use the settings from Step 4 - Set environment variables. Choose the `bedrock-runtime` tab. This sample uses the Chat Completions API.

> **Note**
>
> To call the Responses API with this model, use `bedrock-mantle`. You can't call it on `bedrock-runtime`.

```
from openai import OpenAI

client = OpenAI()

response = client.chat.completions.create(
    model="openai.gpt-oss-safeguard-20b",
    messages=[{"role": "user", "content": "Can you explain the features of Amazon
 Bedrock?"}]
    )
print(response)
```

bedrock-runtime: Boto3

Use the Boto3 settings from Step 4 - Set environment variables. Choose the API for your request.

Invoke API

```
import json
import boto3

client = boto3.client('bedrock-runtime', region_name='us-east-1')
response = client.invoke_model(
    modelId='openai.gpt-oss-safeguard-20b',
```

```
    body=json.dumps({
            'messages': [{ 'role': 'user', 'content': 'Can you explain the features
 of Amazon Bedrock?'}],
            'max_tokens': 1024
    })
)
print(json.loads(response['body'].read()))
```

Converse API

```
import boto3

client = boto3.client('bedrock-runtime', region_name='us-east-1')
response = client.converse(
    modelId='openai.gpt-oss-safeguard-20b',
    messages=[
        {
            'role': 'user',
            'content': [{'text': 'Can you explain the features of Amazon Bedrock?'}]
        }
    ]
)
print(response)
```

gpt-oss-120b

OpenAI — gpt-oss-120b

Model Details

GPT OSS 120B is OpenAI's 120-billion parameter open-source general-purpose model for text generation, coding, and reasoning tasks. For more information about model development and performance, see the model/service card.

Model launch date: Aug 05, 2025
EOL no sooner than: Aug 05, 2026
Legacy period: at least 6 months
Model lifecycle policy: Model lifecycle (For Models Launched Prior to Sept 7 2026)

Model EOL date: N/A

End User License Agreements and Terms of Use: View

Model lifecycle: Active

Context window: 128K tokens

Max output tokens: 16K

Reasoning: Supported, on by default (effort configurable: low, medium, high)

Input Modalities	Output Modalities
⊗ Audio	⊗ Embedding
⊗ Image	⊗ Image
⊗ Speech	⊗ Speech
⊙ Text	⊙ Text
⊗ Video	⊗ Video

Endpoints and APIs supported

The following tables show which endpoints and APIs are supported for gpt-oss-120b. For more information, see the section called “APIs” and the section called “Inference endpoints”.

Endpoint support

Endpoint	Supported
`bedrock-runtime`	⊙
`bedrock-mantle`	⊙

APIs supported on `bedrock-runtime` endpoint

Messages	Responses	Chat Completions	Converse	Invoke
⊗	⊗	⊙	⊙	⊙

Note

On `bedrock-runtime`, this model supports Chat Completions with model ID `openai.gpt-oss-120b-1:0`, but it doesn't support the Responses API. To use the Responses API with this model, use `bedrock-mantle` and model ID `openai.gpt-oss-120b`.

APIs supported on `bedrock-mantle` endpoint

Messages	Responses	Chat Completions	Converse	Invoke
⊗	⊙	⊙	⊗	⊗

Note

On `bedrock-mantle`, both APIs use the `/v1` base path, not `/openai/v1`. Use either API with this model:

- For Responses, use `/v1/responses`.
- For Chat Completions, use `/v1/chat/completions`.

Tip

Whenever possible, we recommend using the `bedrock-runtime` endpoint for new applications. See the section called “Inference endpoints” for details.

Capabilities and Features

Bedrock Features

Features supported using `bedrock-mantle` endpoint

Supported	Not Supported
✓ Server-side tool calling ✓ Projects ✓ Client-side tool calling	✗ Watermarking

Features supported using `bedrock-runtime` endpoint

Supported	Not Supported
✓ Response streaming ✓ Guardrails	✗ Intelligent prompt routing ✗ Abuse detection ✗ Prompt optimization ✗ Count tokens ✗ Knowledge base ✗ Model evaluation ✗ Prompt management ✗ Flows ✗ Agents ✗ Watermarking

Pricing

For pricing information, see the Amazon Bedrock Pricing page.

Programmatic Access

Use the following model IDs and endpoint URLs to access this model programmatically. For more information about the available APIs and endpoints, see APIs supported and Endpoints supported.

Endpoint	Model ID	In-Region endpoint URL	Geo inference ID	Global inference ID
bedrock-runtime	openai.gpt-oss-120b-1:0	https://bedrock-runtime.{region}.amazonaws.com	us-gov.openai.gpt-oss-120b-1:0	Not supported
bedrock-mantle	openai.gpt-oss-120b	https://bedrock-mantle.{region}.api.aws/v1	Not supported	Not supported

For example, if region is us-east-1 (N. Virginia), then the bedrock-runtime endpoint URL will be "https://bedrock-runtime.us-east-1.amazonaws.com" and for bedrock-mantle will be "https://bedrock-mantle.us-east-1.api.aws/v1".

Service Tiers

Amazon Bedrock offers multiple service tiers to match your workload requirements. **Standard** provides pay-per-token access with no commitment (set `"service_tier": "default"` or omit the field). **Priority** delivers the fastest response times for a price premium (set `"service_tier": "priority"`). **Flex** provides lower-cost access for flexible, non-time-sensitive workloads (set `"service_tier": "flex"`). **Reserved** provides dedicated throughput with a term commitment for predictable workloads; it is set at the account level rather than per request (contact your AWS account team to enable). For more information, see service tiers.

Quotas and Limits

Your AWS account has default quotas to maintain the performance of the service and to ensure appropriate usage of Amazon Bedrock. The default quotas assigned to an account might be updated depending on regional factors, payment history, fraudulent usage, and/or approval of a quota increase request. For more information, see the section called "Quotas" documentation and see the limits for the model.

Sample Code

Step 1 - AWS Account: If you have an AWS account already, skip this step. If you are new to AWS, sign up for an AWS account.

Step 2 - API key: Go to the Amazon Bedrock console and generate a long-term API key.

Step 3 - Get the SDK: To use this getting started guide, you must have Python already installed. Then install the relevant software depending on the APIs you are using.

For Responses or Chat Completions, choose the OpenAI SDK tab. For Invoke or Converse, choose the Boto3 tab.

OpenAI SDK

```
pip install boto3 openai
```

Boto3

```
pip install boto3
```

Step 4 - Set environment variables

Configure your environment to use the API key for authentication.

Choose the tab for your SDK and endpoint.

bedrock-runtime

```
OPENAI_API_KEY="<provide your Bedrock API key>"
OPENAI_BASE_URL="https://bedrock-runtime.<your-region>.amazonaws.com/openai/v1"
```

bedrock-mantle

```
OPENAI_API_KEY="<provide your Bedrock API key>"
OPENAI_BASE_URL="https://bedrock-mantle.<your-region>.api.aws/v1"
```

Boto3

```
AWS_BEARER_TOKEN_BEDROCK="<provide your Bedrock API key>"
```

Step 5 - Run your first inference request

Save the file as `bedrock-first-request.py`

bedrock-runtime: OpenAI SDK

Use the settings from Step 4 - Set environment variables. Choose the `bedrock-runtime` tab. This model supports the Chat Completions API, but not the Responses API, on this endpoint.

```
from openai import OpenAI

client = OpenAI()

response = client.chat.completions.create(
    model="openai.gpt-oss-120b-1:0",
    messages=[{"role": "user", "content": "Can you explain the features of Amazon
 Bedrock?"}]
)
print(response)
```

bedrock-mantle

Use the settings from Step 4 - Set environment variables. Choose the `bedrock-mantle` tab. The Chat tab uses the Chat Completions API.

Responses API

```
from openai import OpenAI

client = OpenAI()

response = client.responses.create(
    model="openai.gpt-oss-120b",
    input="Can you explain the features of Amazon Bedrock?"
)
print(response)
```

Chat

```
from openai import OpenAI

client = OpenAI()

response = client.chat.completions.create(
    model="openai.gpt-oss-120b",
    messages=[{"role": "user", "content": "Can you explain the features of Amazon
 Bedrock?"}]
)
print(response)
```

bedrock-runtime: Boto3

Use the Boto3 settings from Step 4 - Set environment variables. Choose the API for your request.

Invoke API

```
import json
import boto3

client = boto3.client('bedrock-runtime', region_name='us-east-1')
response = client.invoke_model(
    modelId='openai.gpt-oss-120b-1:0',
```

```
    body=json.dumps({
            'messages': [{ 'role': 'user', 'content': 'Can you explain the features
 of Amazon Bedrock?'}],
            'max_tokens': 1024
    })
)
print(json.loads(response['body'].read()))
```

Converse API

```
import boto3

client = boto3.client('bedrock-runtime', region_name='us-east-1')
response = client.converse(
    modelId='openai.gpt-oss-120b-1:0',
    messages=[
        {
            'role': 'user',
            'content': [{'text': 'Can you explain the features of Amazon Bedrock?'}]
        }
    ]
)
print(response)
```

gpt-oss-20b

OpenAI — gpt-oss-20b

Model Details

GPT OSS 20B is OpenAI's 20-billion parameter open-source model for efficient text generation and coding at lower compute cost. For more information about model development and performance, see the model/service card.

Model launch date: Aug 05, 2025

Quotas and Limits

Your AWS account has default quotas to maintain the performance of the service and to ensure appropriate usage of Amazon Bedrock. The default quotas assigned to an account might be updated depending on regional factors, payment history, fraudulent usage, and/or approval of a quota increase request. For more information, see the section called "Quotas" documentation and see the limits for the model.

Sample Code

Step 1 - AWS Account: If you have an AWS account already, skip this step. If you are new to AWS, sign up for an AWS account.

Step 2 - API key: Go to the Amazon Bedrock console and generate a long-term API key.

Step 3 - Get the SDK: To use this getting started guide, you must have Python already installed. Then install the relevant software depending on the APIs you are using.

For Responses or Chat Completions, choose the OpenAI SDK tab. For Invoke or Converse, choose the Boto3 tab.

OpenAI SDK

```
pip install boto3 openai
```

Boto3

```
pip install boto3
```

Step 4 - Set environment variables

Configure your environment to use the API key for authentication.

Choose the tab for your SDK and endpoint.

bedrock-runtime

```
OPENAI_API_KEY="<provide your Bedrock API key>"
OPENAI_BASE_URL="https://bedrock-runtime.<your-region>.amazonaws.com/openai/v1"
```

bedrock-mantle

```
OPENAI_API_KEY="<provide your Bedrock API key>"
OPENAI_BASE_URL="https://bedrock-mantle.<your-region>.api.aws/v1"
```

Boto3

```
AWS_BEARER_TOKEN_BEDROCK="<provide your Bedrock API key>"
```

Step 5 - Run your first inference request

Save the file as `bedrock-first-request.py`

bedrock-runtime: OpenAI SDK

Use the settings from Step 4 - Set environment variables. Choose the `bedrock-runtime` tab. This model supports the Chat Completions API, but not the Responses API, on this endpoint.

```
from openai import OpenAI

client = OpenAI()

response = client.chat.completions.create(
    model="openai.gpt-oss-20b-1:0",
    messages=[{"role": "user", "content": "Can you explain the features of Amazon
 Bedrock?"}]
)
print(response)
```

bedrock-mantle

Use the settings from Step 4 - Set environment variables. Choose the `bedrock-mantle` tab. The Chat tab uses the Chat Completions API.

Responses API

```
from openai import OpenAI

client = OpenAI()

response = client.responses.create(
    model="openai.gpt-oss-20b",
    input="Can you explain the features of Amazon Bedrock?"
)
print(response)
```

Chat

```
from openai import OpenAI

client = OpenAI()

response = client.chat.completions.create(
    model="openai.gpt-oss-20b",
    messages=[{"role": "user", "content": "Can you explain the features of Amazon
 Bedrock?"}]
)
print(response)
```

bedrock-runtime: Boto3

Use the Boto3 settings from Step 4 - Set environment variables. Choose the API for your request.

Invoke API

```
import json
import boto3

client = boto3.client('bedrock-runtime', region_name='us-east-1')
response = client.invoke_model(
    modelId='openai.gpt-oss-20b-1:0',
```

```
    body=json.dumps({
            'messages': [{ 'role': 'user', 'content': 'Can you explain the features
 of Amazon Bedrock?'}],
            'max_tokens': 1024
    })
)
print(json.loads(response['body'].read()))
```

Converse API

```
import boto3

client = boto3.client('bedrock-runtime', region_name='us-east-1')
response = client.converse(
    modelId='openai.gpt-oss-20b-1:0',
    messages=[
        {
            'role': 'user',
            'content': [{'text': 'Can you explain the features of Amazon Bedrock?'}]
        }
    ]
)
print(response)
```

Qwen

The following Qwen models are available in Amazon Bedrock:

Model	Description
the section called “Qwen3 Coder Next”	Qwen3 Coder Next is Qwen's coding model with improved code generation, debugging, and software engineering capabilities.
the section called “Qwen3 VL 235B A22B”	Qwen3 VL 235B A22B is Qwen's vision-language mixture-of-experts model that processes text and images for visual reasoning and document understanding.
the section called “Qwen3 Next 80B A3B”	Qwen3 Next 80B A3B is Qwen's efficient mixture-of-experts model with 80B total and 3B active parameters for fast, cost-effective inference.

Model	Description
the section called "Qwen3-Coder-30B-A3B-Instruct"	Qwen3 Coder 30B A3B is Qwen's compact coding mixture-of-experts model with 30B total and 3B active parameters for efficient code generation.
the section called "Qwen3 Coder 480B A35B Instruct"	Qwen3 Coder 480B A35B is Qwen's largest coding-specialized mixture-of-experts model with 480B total and 35B active parameters for software engineering tasks.
the section called "Qwen3 32B"	Qwen3 32B is Qwen's 32-billion parameter dense model with hybrid thinking modes for both fast responses and deep reasoning.
the section called "Qwen3 235B A22B 2507"	Qwen3 235B A22B is Qwen's 235-billion parameter mixture-of-experts model with 22 billion active parameters, supporting text and code generation with a 128K context window.

Qwen3 Coder Next

Qwen — Qwen3 Coder Next

Model Details

Qwen3 Coder Next is Qwen's coding model with improved code generation, debugging, and software engineering capabilities. For more information about model development and performance, see the model/service card.

Model launch date: Feb 04, 2026
EOL no sooner than: Feb 04, 2027
Legacy period: at least 6 months
Model lifecycle policy: Model lifecycle (For Models Launched Prior to Sept 7 2026)
Model EOL date: N/A
End User License Agreements and Terms of Use: View
Model lifecycle: Active
Context window: 256K tokens
Max output tokens: 16K

Input Modalities	Output Modalities	APIs supported	Endpoints supported
⊗ Audio	⊗ Embedding	⊗ Responses	✓ bedrock-runtime
⊗ Image	⊗ Image	✓ Chat Completions	✓ bedrock-mantle
⊗ Speech	⊗ Speech	✓ Invoke	
✓ Text	✓ Text	✓ Converse	
⊗ Video	⊗ Video		

Tip

Whenever possible, we recommend using the `bedrock-runtime` endpoint for new applications. See the section called "Inference endpoints" for details.

Capabilities and Features

Bedrock Features

Pricing

For pricing information, see the Amazon Bedrock Pricing page.

Programmatic Access

Use the following model IDs and endpoint URLs to access this model programmatically. For more information about the available APIs and endpoints, see APIs supported and Endpoints supported.

Endpoint	Model ID	In-Region endpoint URL	Geo inference ID	Global inference ID
bedrock-runtime	qwen.qwen3-coder-next	https://bedrock-runtime.{region}.amazonaws.com	Not supported	Not supported
bedrock-mantle	qwen.qwen3-coder-next	https://bedrock-mantle.{region}.api.aws/v1	Not supported	Not supported

For example, if region is us-east-1 (N. Virginia), then the bedrock-runtime endpoint URL will be "https://bedrock-runtime.us-east-1.amazonaws.com" and for bedrock-mantle will be "https://bedrock-mantle.us-east-1.api.aws/v1".

Service Tiers

Amazon Bedrock offers multiple service tiers to match your workload requirements. **Standard** provides pay-per-token access with no commitment (set `"service_tier": "default"` or omit

the field). **Priority** delivers the fastest response times for a price premium (set `"service_tier": "priority"`). **Flex** provides lower-cost access for flexible, non-time-sensitive workloads (set `"service_tier": "flex"`). **Reserved** provides dedicated throughput with a term commitment for predictable workloads; it is set at the account level rather than per request (contact your AWS account team to enable). For more information, see service tiers.

Standard	Priority	Flex	Reserved
✓	✗	✗	✗

Regional Availability

Regional availability at a glance

Amazon Bedrock offers three inference options: **In-Region** keeps requests within a single Region for strict compliance, **Geo Cross-Region** routes across Regions within a geography (such as US, EU, and APAC) while respecting data residency, and **Global Cross-Region** routes anywhere worldwide when there are no residency constraints. Refer to the the section called “Regional availability by models” page for more details.

Availability differs by endpoint.

Availability using the `bedrock-runtime` endpoint

Region	In-Region	Geo	Global
`us-east-1` (N. Virginia)	✓	✗	✗
`us-east-2` (Ohio)	✗	✗	✗

Quotas and Limits

Your AWS account has default quotas to maintain the performance of the service and to ensure appropriate usage of Amazon Bedrock. The default quotas assigned to an account might be updated depending on regional factors, payment history, fraudulent usage, and/or approval of a quota increase request. For more information, see the section called "Quotas" documentation and see the limits for the model.

Sample Code

Step 1 - AWS Account: If you have an AWS account already, skip this step. If you are new to AWS, sign up for an AWS account.

Step 2 - API key: Go to the Amazon Bedrock console and generate a long-term API key.

Step 3 - Get the SDK: To use this getting started guide, you must have Python already installed. Then install the relevant software depending on the APIs you are using.

Responses/Chat Completions API

```
pip install boto3 openai
```

Invoke/Converse API

```
pip install boto3
```

Step 4 - Set environment variables: Configure your environment to use the API key for authentication.

Responses/Chat Completions API

```
OPENAI_API_KEY="<provide your Bedrock API key>"
OPENAI_BASE_URL="https://bedrock-runtime.<your-region>.amazonaws.com/openai/v1"
```

Invoke/Converse API

```
AWS_BEARER_TOKEN_BEDROCK="<provide your Bedrock API key>"
```

Step 5 - Run your first inference request: Save the file as `bedrock-first-request.py`

Chat Completions API

```
from openai import OpenAI

client = OpenAI()

response = client.chat.completions.create(
    model="qwen.qwen3-coder-next",
    messages=[{"role": "user", "content": "Can you explain the features of Amazon
 Bedrock?"}]
    )
print(response)
```

Invoke API

```
import json
import boto3

client = boto3.client('bedrock-runtime', region_name='us-east-1')
response = client.invoke_model(
    modelId='qwen.qwen3-coder-next',
```

```
    body=json.dumps({
            'messages': [{ 'role': 'user', 'content': 'Can you explain the features
 of Amazon Bedrock?'}],
            'max_tokens': 1024
    })
)
print(json.loads(response['body'].read()))
```

Converse API

```
import boto3

client = boto3.client('bedrock-runtime', region_name='us-east-1')
response = client.converse(
    modelId='qwen.qwen3-coder-next',
    messages=[
        {
            'role': 'user',
            'content': [{'text': 'Can you explain the features of Amazon Bedrock?'}]
        }
    ]
)
print(response)
```

Qwen3 VL 235B A22B

Qwen — Qwen3 VL 235B A22B

Model Details

Qwen3 VL 235B A22B is Qwen's vision-language mixture-of-experts model that processes text and images for visual reasoning and document understanding. For more information about model development and performance, see the model/service card.

Model launch date: Sep 23, 2025
EOL no sooner than: Sep 23, 2026
Legacy period: at least 6 months
Model lifecycle policy: Model lifecycle (For Models Launched Prior to Sept 7 2026)

Model EOL date: N/A

End User License Agreements and Terms of Use: View

Model lifecycle: Active

Context window: 256K tokens

Max output tokens: 8K

Input Modalities	Output Modalities	APIs supported	Endpoints supported
⊗ Audio	⊗ Embedding	⊗ `Responses`	✓ `bedrock-runtime`

Quotas and Limits

Your AWS account has default quotas to maintain the performance of the service and to ensure appropriate usage of Amazon Bedrock. The default quotas assigned to an account might be updated depending on regional factors, payment history, fraudulent usage, and/or approval of a quota increase request. For more information, see the section called “Quotas” documentation and see the limits for the model.

Sample Code

Step 1 - AWS Account: If you have an AWS account already, skip this step. If you are new to AWS, sign up for an AWS account.

Step 2 - API key: Go to the Amazon Bedrock console and generate a long-term API key.

Step 3 - Get the SDK: To use this getting started guide, you must have Python already installed. Then install the relevant software depending on the APIs you are using.

Responses/Chat Completions API

```
pip install boto3 openai
```

Invoke/Converse API

```
pip install boto3
```

Step 4 - Set environment variables: Configure your environment to use the API key for authentication.

Responses/Chat Completions API

```
OPENAI_API_KEY="<provide your Bedrock API key>"
OPENAI_BASE_URL="https://bedrock-runtime.<your-region>.amazonaws.com/openai/v1"
```

Invoke/Converse API

```
AWS_BEARER_TOKEN_BEDROCK="<provide your Bedrock API key>"
```

Step 5 - Run your first inference request: Save the file as `bedrock-first-request.py`

Chat Completions API

```
from openai import OpenAI

client = OpenAI()
```

```
response = client.chat.completions.create(
    model="qwen.qwen3-vl-235b-a22b-instruct",
    messages=[{"role": "user", "content": "Can you explain the features of Amazon
 Bedrock?"}]
    )
print(response)
```

Invoke API

```
import json
import boto3

client = boto3.client('bedrock-runtime', region_name='us-east-1')
response = client.invoke_model(
    modelId='qwen.qwen3-vl-235b-a22b',
    body=json.dumps({
            'messages': [{ 'role': 'user', 'content': 'Can you explain the features
 of Amazon Bedrock?'}],
            'max_tokens': 1024
    })
)
print(json.loads(response['body'].read()))
```

Converse API

```
import boto3

client = boto3.client('bedrock-runtime', region_name='us-east-1')
response = client.converse(
    modelId='qwen.qwen3-vl-235b-a22b',
    messages=[
        {
            'role': 'user',
            'content': [{'text': 'Can you explain the features of Amazon Bedrock?'}]
        }
    ]
)
print(response)
```

Qwen3 Next 80B A3B

Qwen — Qwen3 Next 80B A3B

Quotas and Limits

Your AWS account has default quotas to maintain the performance of the service and to ensure appropriate usage of Amazon Bedrock. The default quotas assigned to an account might be updated depending on regional factors, payment history, fraudulent usage, and/or approval of a

quota increase request. For more information, see the section called "Quotas" documentation and see the limits for the model.

Sample Code

Step 1 - AWS Account: If you have an AWS account already, skip this step. If you are new to AWS, sign up for an AWS account.

Step 2 - API key: Go to the Amazon Bedrock console and generate a long-term API key.

Step 3 - Get the SDK: To use this getting started guide, you must have Python already installed. Then install the relevant software depending on the APIs you are using.

Chat Completions API

```
pip install boto3 openai
```

Invoke/Converse API

```
pip install boto3
```

Step 4 - Set environment variables: Configure your environment to use the API key for authentication.

Chat Completions API

```
OPENAI_API_KEY="<provide your Bedrock API key>"
OPENAI_BASE_URL="https://bedrock-runtime.<your-region>.amazonaws.com/openai/v1"
```

Invoke/Converse API

```
AWS_BEARER_TOKEN_BEDROCK="<provide your Bedrock API key>"
```

Step 5 - Run your first inference request: Save the file as `bedrock-first-request.py`

Chat Completions API

```
from openai import OpenAI
```

```
client = OpenAI()

response = client.chat.completions.create(
    model="qwen.qwen3-next-80b-a3b-instruct",
    messages=[{"role": "user", "content": "Can you explain the features of Amazon
 Bedrock?"}]
    )
print(response)
```

Invoke API

```
import json
import boto3

client = boto3.client('bedrock-runtime', region_name='us-east-1')
response = client.invoke_model(
    modelId='qwen.qwen3-next-80b-a3b',
    body=json.dumps({
            'messages': [{ 'role': 'user', 'content': 'Can you explain the features
 of Amazon Bedrock?'}],
            'max_tokens': 1024
    })
)
print(json.loads(response['body'].read()))
```

Converse API

```
import boto3

client = boto3.client('bedrock-runtime', region_name='us-east-1')
response = client.converse(
    modelId='qwen.qwen3-next-80b-a3b',
    messages=[
        {
            'role': 'user',
            'content': [{'text': 'Can you explain the features of Amazon Bedrock?'}]
        }
    ]
)
print(response)
```

Qwen3-Coder-30B-A3B-Instruct

Qwen — Qwen3-Coder-30B-A3B-Instruct

Model Details

Qwen3 Coder 30B A3B is Qwen's compact coding mixture-of-experts model with 30B total and 3B active parameters for efficient code generation. For more information about model development and performance, see the model/service card.

Model launch date: Jul 31, 2025
EOL no sooner than: Jul 31, 2026
Legacy period: at least 6 months
Model lifecycle policy: Model lifecycle (For Models Launched Prior to Sept 7 2026)
Model EOL date: March 30, 2027
End User License Agreements and Terms of Use: View
Model lifecycle: Legacy
Context window: 256K tokens
Max output tokens: 16K

Pricing

For pricing information, see the Amazon Bedrock Pricing page.

Programmatic Access

Use the following model IDs and endpoint URLs to access this model programmatically. For more information about the available APIs and endpoints, see APIs supported and Endpoints supported.

Endpoint	Model ID	In-Region endpoint URL	Geo inference ID	Global inference ID
bedrock-runtime	qwen.qwen3-coder-30b-a3b-v1:0	https://bedrock-runtime.{region}.amazonaws.com	Not supported	Not supported
bedrock-mantle	qwen.qwen3-coder-30b-a3b-instruct	https://bedrock-mantle.{region}.api.aws/v1	Not supported	Not supported

For example, if region is us-east-1 (N. Virginia), then the bedrock-runtime endpoint URL will be "https://bedrock-runtime.us-east-1.amazonaws.com" and for bedrock-mantle will be "https://bedrock-mantle.us-east-1.api.aws/v1".

Service Tiers

Amazon Bedrock offers multiple service tiers to match your workload requirements. **Standard** provides pay-per-token access with no commitment (set `"service_tier": "default"` or omit the field). **Priority** delivers the fastest response times for a price premium (set `"service_tier": "priority"`). **Flex** provides lower-cost access for flexible, non-time-sensitive workloads (set `"service_tier": "flex"`). **Reserved** provides dedicated throughput with a term commitment for predictable workloads; it is set at the account level rather than per request (contact your AWS account team to enable). For more information, see service tiers.

Standard	Priority	Flex	Reserved
✓	✓	✓	✗

Regional Availability

Regional availability at a glance

Amazon Bedrock offers three inference options: **In-Region** keeps requests within a single Region for strict compliance, **Geo Cross-Region** routes across Regions within a geography (such as US, EU,

and APAC) while respecting data residency, and **Global Cross-Region** routes anywhere worldwide when there are no residency constraints. Refer to the the section called “Regional availability by models” page for more details.

Availability differs by endpoint.

Availability using the `bedrock-runtime` endpoint

Region	In-Region	Geo	Global
`us-east-1` (N. Virginia)	✓	✗	✗
`us-east-2` (Ohio)	✓	✗	✗
`us-west-2` (Oregon)	✓	✗	✗
`eu-central-1` (Frankfurt)	✓	✗	✗
`eu-north-1` (Stockholm)	✓	✗	✗

Quotas and Limits

Your AWS account has default quotas to maintain the performance of the service and to ensure appropriate usage of Amazon Bedrock. The default quotas assigned to an account might be updated depending on regional factors, payment history, fraudulent usage, and/or approval of a

quota increase request. For more information, see the section called "Quotas" documentation and see the limits for the model.

Sample Code

Step 1 - AWS Account: If you have an AWS account already, skip this step. If you are new to AWS, sign up for an AWS account.

Step 2 - API key: Go to the Amazon Bedrock console and generate a long-term API key.

Step 3 - Get the SDK: To use this getting started guide, you must have Python already installed. Then install the relevant software depending on the APIs you are using.

Responses/Chat Completions API

```
pip install boto3 openai
```

Invoke/Converse API

```
pip install boto3
```

Step 4 - Set environment variables: Configure your environment to use the API key for authentication.

Responses/Chat Completions API

```
OPENAI_API_KEY="<provide your Bedrock API key>"
OPENAI_BASE_URL="https://bedrock-runtime.<your-region>.amazonaws.com/openai/v1"
```

Invoke/Converse API

```
AWS_BEARER_TOKEN_BEDROCK="<provide your Bedrock API key>"
```

Step 5 - Run your first inference request: Save the file as `bedrock-first-request.py`

Chat Completions API

```
from openai import OpenAI
```

```
client = OpenAI()

response = client.chat.completions.create(
    model="qwen.qwen3-coder-30b-a3b-instruct",
    messages=[{"role": "user", "content": "Can you explain the features of Amazon
 Bedrock?"}]
    )
print(response)
```

Invoke API

```
import json
import boto3

client = boto3.client('bedrock-runtime', region_name='us-east-1')
response = client.invoke_model(
    modelId='qwen.qwen3-coder-30b-a3b-v1:0',
    body=json.dumps({
            'messages': [{ 'role': 'user', 'content': 'Can you explain the features
 of Amazon Bedrock?'}],
            'max_tokens': 1024
    })
)
print(json.loads(response['body'].read()))
```

Converse API

```
import boto3

client = boto3.client('bedrock-runtime', region_name='us-east-1')
response = client.converse(
    modelId='qwen.qwen3-coder-30b-a3b-v1:0',
    messages=[
        {
            'role': 'user',
            'content': [{'text': 'Can you explain the features of Amazon Bedrock?'}]
        }
    ]
)
print(response)
```

Qwen3 Coder 480B A35B Instruct

Qwen — Qwen3 Coder 480B A35B Instruct

Model Details

Qwen3 Coder 480B A35B is Qwen's largest coding-specialized mixture-of-experts model with 480B total and 35B active parameters for software engineering tasks. For more information about model development and performance, see the model/service card.

Model launch date: Jul 23, 2025
EOL no sooner than: Jul 23, 2026
Legacy period: at least 6 months
Model lifecycle policy: Model lifecycle (For Models Launched Prior to Sept 7 2026)
Model EOL date: March 30, 2027
End User License Agreements and Terms of Use: View
Model lifecycle: Legacy
Context window: 256K tokens

Quotas and Limits

Your AWS account has default quotas to maintain the performance of the service and to ensure appropriate usage of Amazon Bedrock. The default quotas assigned to an account might be updated depending on regional factors, payment history, fraudulent usage, and/or approval of a quota increase request. For more information, see the section called “Quotas” documentation and see the limits for the model.

Sample Code

Step 1 - AWS Account: If you have an AWS account already, skip this step. If you are new to AWS, sign up for an AWS account.

Step 2 - API key: Go to the Amazon Bedrock console and generate a long-term API key.

Step 3 - Get the SDK: To use this getting started guide, you must have Python already installed. Then install the relevant software depending on the APIs you are using.

Chat Completions API

```
pip install boto3 openai
```

Invoke/Converse API

```
pip install boto3
```

Step 4 - Set environment variables: Configure your environment to use the API key for authentication.

Chat Completions API

```
OPENAI_API_KEY="<provide your Bedrock API key>"
OPENAI_BASE_URL="https://bedrock-runtime.<your-region>.amazonaws.com/openai/v1"
```

Invoke/Converse API

```
AWS_BEARER_TOKEN_BEDROCK="<provide your Bedrock API key>"
```

Step 5 - Run your first inference request: Save the file as `bedrock-first-request.py`

Chat Completions API

```
from openai import OpenAI

client = OpenAI()
```

```
response = client.chat.completions.create(
    model="qwen.qwen3-coder-480b-a35b-instruct",
    messages=[{"role": "user", "content": "Can you explain the features of Amazon
 Bedrock?"}]
    )
print(response)
```

Invoke API

```
import json
import boto3

client = boto3.client('bedrock-runtime', region_name='us-east-1')
response = client.invoke_model(
    modelId='qwen.qwen3-coder-480b-a35b-v1:0',
    body=json.dumps({
            'messages': [{ 'role': 'user', 'content': 'Can you explain the features
 of Amazon Bedrock?'}],
            'max_tokens': 1024
    })
)
print(json.loads(response['body'].read()))
```

Converse API

```
import boto3

client = boto3.client('bedrock-runtime', region_name='us-east-1')
response = client.converse(
    modelId='qwen.qwen3-coder-480b-a35b-v1:0',
    messages=[
        {
            'role': 'user',
            'content': [{'text': 'Can you explain the features of Amazon Bedrock?'}]
        }
    ]
)
print(response)
```

Qwen3 32B

Qwen — Qwen3 32B

Quotas and Limits

Your AWS account has default quotas to maintain the performance of the service and to ensure appropriate usage of Amazon Bedrock. The default quotas assigned to an account might be updated depending on regional factors, payment history, fraudulent usage, and/or approval of a

quota increase request. For more information, see the section called "Quotas" documentation and see the limits for the model.

Sample Code

Step 1 - AWS Account: If you have an AWS account already, skip this step. If you are new to AWS, sign up for an AWS account.

Step 2 - API key: Go to the Amazon Bedrock console and generate a long-term API key.

Step 3 - Get the SDK: To use this getting started guide, you must have Python already installed. Then install the relevant software depending on the APIs you are using.

Responses/Chat Completions API

```
pip install boto3 openai
```

Invoke/Converse API

```
pip install boto3
```

Step 4 - Set environment variables: Configure your environment to use the API key for authentication.

Responses/Chat Completions API

```
OPENAI_API_KEY="<provide your Bedrock API key>"
OPENAI_BASE_URL="https://bedrock-runtime.<your-region>.amazonaws.com/openai/v1"
```

Invoke/Converse API

```
AWS_BEARER_TOKEN_BEDROCK="<provide your Bedrock API key>"
```

Step 5 - Run your first inference request: Save the file as `bedrock-first-request.py`

Chat Completions API

```
from openai import OpenAI
```

```
client = OpenAI()

response = client.chat.completions.create(
    model="qwen.qwen3-32b",
    messages=[{"role": "user", "content": "Can you explain the features of Amazon
 Bedrock?"}]
    )
print(response)
```

Invoke API

```
import json
import boto3

client = boto3.client('bedrock-runtime', region_name='us-east-1')
response = client.invoke_model(
    modelId='qwen.qwen3-32b-v1:0',
    body=json.dumps({
            'messages': [{ 'role': 'user', 'content': 'Can you explain the features
 of Amazon Bedrock?'}],
            'max_tokens': 1024
    })
)
print(json.loads(response['body'].read()))
```

Converse API

```
import boto3

client = boto3.client('bedrock-runtime', region_name='us-east-1')
response = client.converse(
    modelId='qwen.qwen3-32b-v1:0',
    messages=[
        {
            'role': 'user',
            'content': [{'text': 'Can you explain the features of Amazon Bedrock?'}]
        }
    ]
)
print(response)
```

Sample Code

Step 1 - AWS Account: If you have an AWS account already, skip this step. If you are new to AWS, sign up for an AWS account.

Step 2 - API key: Go to the Amazon Bedrock console and generate a long-term API key.

Step 3 - Get the SDK: To use this getting started guide, you must have Python already installed. Then install the relevant software depending on the APIs you are using.

Chat Completions API

```
pip install boto3 openai
```

Invoke/Converse API

```
pip install boto3
```

Step 4 - Set environment variables: Configure your environment to use the API key for authentication.

Chat Completions API

```
OPENAI_API_KEY="<provide your Bedrock API key>"
OPENAI_BASE_URL="https://bedrock-runtime.<your-region>.amazonaws.com/openai/v1"
```

Invoke/Converse API

```
AWS_BEARER_TOKEN_BEDROCK="<provide your Bedrock API key>"
```

Step 5 - Run your first inference request: Save the file as `bedrock-first-request.py`

Chat Completions API

```
from openai import OpenAI

client = OpenAI()

response = client.chat.completions.create(
    model="qwen.qwen3-235b-a22b-2507",
    messages=[{"role": "user", "content": "Can you explain the features of Amazon
 Bedrock?"}]
    )
print(response)
```

Invoke API

```
import json
import boto3

client = boto3.client('bedrock-runtime', region_name='us-east-1')
response = client.invoke_model(
    modelId='qwen.qwen3-235b-a22b-2507-v1:0',
    body=json.dumps({
            'messages': [{ 'role': 'user', 'content': 'Can you explain the features
 of Amazon Bedrock?'}],
            'max_tokens': 1024
    })
)
print(json.loads(response['body'].read()))
```

Converse API

```
import boto3

client = boto3.client('bedrock-runtime', region_name='us-east-1')
response = client.converse(
    modelId='qwen.qwen3-235b-a22b-2507-v1:0',
    messages=[
        {
            'role': 'user',
            'content': [{'text': 'Can you explain the features of Amazon Bedrock?'}]
        }
    ]
)
```

```
print(response)
```

Stability AI

The following Stability AI models are available in Amazon Bedrock:

Model	Description
the section called "Stable Image Ultra 1.0"	Stable Image Ultra is Stability AI's highest-fidelity text-to-image model, producing photorealistic, large-scale output for professional and high-end creative work.
the section called "Stable Image Core 1.0"	Stable Image Core is Stability AI's fast, affordable text-to-image model for rapid, high-volume content generation.
the section called "Stable Diffusion 3.5 Large"	Stable Diffusion 3.5 Large is Stability AI's 8-billion-parameter model that supports 1 megapixel resolution output for text-to-image and image-to-image generation.
the section called "Stable Image Remove Background"	Stable Image Remove Background is Stability AI's model that accurately removes backgrounds from images, isolating the foreground subject.
the section called "Stable Image Search and Replace"	Stable Image Search and Replace is Stability AI's model that finds objects in images and replaces them with new content based on text prompts.
the section called "Stable Image Style Guide"	Stable Image Style Guide is Stability AI's model that generates images matching a reference style while following text prompt instructions.
the section called "Stable Image Style Transfer"	Stable Image Style Transfer is Stability AI's model that applies the artistic style of a reference image to a target image.

Model	Description
the section called “Stable Image Fast Upscale”	Stable Image Fast Upscale is Stability AI's model that quickly increases image resolution with minimal processing time.
the section called “Stable Image Search and Recolor”	Stable Image Search and Recolor is Stability AI's model that identifies objects in images and changes their colors based on text prompts.
the section called “Stable Image Conservative Upscale”	Stable Image Conservative Upscale is Stability AI's image upscaling model that increases resolution while preserving the original image's details and style.
the section called “Stable Image Erase Object”	Stable Image Erase Object is Stability AI's model that removes unwanted objects from images and fills the area with contextually appropriate content.
the section called “Stable Image Control Structure”	Stable Image Control Structure is Stability AI's model that generates images guided by structural inputs like depth maps and edge detection.
the section called “Stable Image Creative Upscale”	Stable Image Creative Upscale is Stability AI's model that upscales images while adding creative detail and enhancing visual quality.
the section called “Stable Image Control Sketch”	Stable Image Control Sketch is Stability AI's model that generates images guided by sketch inputs for controlled image creation.
the section called “Stable Image Outpaint”	Stable Image Outpaint is Stability AI's model that extends images beyond their original boundaries with contextually coherent content.
the section called “Stable Image Inpaint”	Stable Image Inpaint is Stability AI's model that fills in masked regions of images with contextually appropriate content based on text prompts.

Stable Image Ultra 1.0

Stability AI — Stable Image Ultra 1.0

Model Details

Stable Image Ultra is Stability AI's highest-fidelity text-to-image model, producing photorealistic, large-scale output for professional and high-end creative work. For more information about model development and performance, see the model/service card.

Legacy period: at least 6 months
Model lifecycle policy: Model lifecycle (For Models Launched Prior to Sept 7 2026)
Model EOL date: N/A

Tip

Whenever possible, we recommend using the `bedrock-runtime` endpoint for new applications. See the section called "Inference endpoints" for details.

Capabilities and Features

Bedrock Features

Features supported using `bedrock-runtime` endpoint

Supported	Not Supported
✓ Abuse detection ✓ Guardrails	✗ Intelligent prompt routing ✗ Response streaming ✗ Prompt optimization ✗ Count tokens ✗ Knowledge base ✗ Model evaluation ✗ Prompt management ✗ Flows ✗ Agents ✗ Watermarking

Pricing

For pricing information, see the Amazon Bedrock Pricing page.

Programmatic Access

Use the following model IDs and endpoint URLs to access this model programmatically. For more information about the available APIs and endpoints, see APIs supported and Endpoints supported.

Endpoint	Model ID	In-Region endpoint URL	Geo inference ID	Global inference ID
`bedrock-runtime`	`stability.stable-image-ultra-v1:1`	`https://bedrock-runtime.{region}.amazonaws.com`	Not supported	Not supported

For example, if region is us-west-2 (Oregon), then the bedrock-runtime endpoint URL will be "https://bedrock-runtime.us-west-2.amazonaws.com".

Service Tiers

Amazon Bedrock offers multiple service tiers to match your workload requirements. **Standard** provides pay-per-token access with no commitment (set `"service_tier": "default"` or omit the field). **Priority** delivers the fastest response times for a price premium (set `"service_tier": "priority"`). **Flex** provides lower-cost access for flexible, non-time-sensitive workloads (set `"service_tier": "flex"`). **Reserved** provides dedicated throughput with a term commitment for predictable workloads; it is set at the account level rather than per request (contact your AWS account team to enable). For more information, see service tiers.

Standard	Priority	Flex	Reserved
✓	✗	✗	✗

Regional Availability

Regional availability at a glance

Amazon Bedrock offers three inference options: **In-Region** keeps requests within a single Region for strict compliance, **Geo Cross-Region** routes across Regions within a geography (such as US, EU, and APAC) while respecting data residency, and **Global Cross-Region** routes anywhere worldwide when there are no residency constraints. Refer to the the section called “Regional availability by models” page for more details.

Region	In-Region	Geo	Global
`us-west-2` (Oregon)	✓	✗	✗

Quotas and Limits

Your AWS account has default quotas to maintain the performance of the service and to ensure appropriate usage of Amazon Bedrock. The default quotas assigned to an account might be updated depending on regional factors, payment history, fraudulent usage, and/or approval of a

quota increase request. For more information, see the section called "Quotas" documentation and see the limits for the model.

Sample Code

Step 1 - AWS Account: If you have an AWS account already, skip this step. If you are new to AWS, sign up for an AWS account.

Step 2 - API key: Go to the Amazon Bedrock console and generate a long-term API key.

Step 3 - Get the SDK: To use this getting started guide, you must have Python already installed. Then install the relevant software depending on the APIs you are using.

```
pip install boto3
```

Step 4 - Set environment variables: Configure your environment to use the API key for authentication.

```
AWS_BEARER_TOKEN_BEDROCK="<provide your Bedrock API key>"
```

Step 5 - Run your first inference request: Save the file as `bedrock-first-request.py`

Invoke API

```
import boto3
import json
import base64
import io
from PIL import Image

bedrock = boto3.client('bedrock-runtime', region_name='us-west-2')
response = bedrock.invoke_model(
    modelId='stability.stable-image-ultra-v1:1',
    body=json.dumps({
        'prompt': 'A car made out of vegetables.'
    })
)
output_body = json.loads(response["body"].read().decode("utf-8"))
base64_output_image = output_body["images"][0]
image_data = base64.b64decode(base64_output_image)
image = Image.open(io.BytesIO(image_data))
image.save("image.png")
```

Stable Image Core 1.0

Stability AI — Stable Image Core 1.0

Model Details

Stable Image Core is Stability AI's fast, affordable text-to-image model for rapid, high-volume content generation. For more information about model development and performance, see the model/service card.

Geo Inference ID: `us.stability.stable-image-search-replace-v1:0`

Source Region	Destination Regions
us-east-1 (N. Virginia)	us-east-1 (N. Virginia), us-east-2 (Ohio), us-west-2 (Oregon)
us-east-2 (Ohio)	us-east-1 (N. Virginia), us-east-2 (Ohio), us-west-2 (Oregon)
us-west-2 (Oregon)	us-east-1 (N. Virginia), us-east-2 (Ohio), us-west-2 (Oregon)

Quotas and Limits

Your AWS account has default quotas to maintain the performance of the service and to ensure appropriate usage of Amazon Bedrock. The default quotas assigned to an account might be updated depending on regional factors, payment history, fraudulent usage, and/or approval of a quota increase request. For more information, see the section called "Quotas" documentation and see the limits for the model.

Sample Code

Step 1 - AWS Account: If you have an AWS account already, skip this step. If you are new to AWS, sign up for an AWS account.

Step 2 - API key: Go to the Amazon Bedrock console and generate a long-term API key.

Step 3 - Get the SDK: To use this getting started guide, you must have Python already installed. Then install the relevant software depending on the APIs you are using.

```
pip install boto3
```

Step 4 - Set environment variables: Configure your environment to use the API key for authentication.

```
AWS_BEARER_TOKEN_BEDROCK="<provide your Bedrock API key>"
```

Step 5 - Run your first inference request: Save the file as `bedrock-first-request.py`

Invoke API

```
import json
import base64
import boto3

client = boto3.client('bedrock-runtime', region_name='us-east-1')
with open('input.png', 'rb') as f:
    image_base64 = base64.b64encode(f.read()).decode('utf-8')
params = {'image': image_base64, 'prompt': 'jacket', 'search_prompt': 'sweater'}
response = client.invoke_model(
    modelId='stability.stable-image-search-replace-v1:0',
    body=json.dumps(params)
)
response_body = json.loads(response['body'].read())
print(f'Image generated: {len(response_body["images"][0])} bytes (base64)')
```

Stable Image Style Guide

Stability AI — Stable Image Style Guide

Model Details

Stable Image Style Guide is Stability AI's model that generates images matching a reference style while following text prompt instructions. For more information about model development and performance, see the model/service card.

Model launch date: Oct 2024

EOL no sooner than: Oct 2025

Legacy period: at least 6 months

Model lifecycle policy: Model lifecycle (For Models Launched Prior to Sept 7 2026)

Model EOL date: N/A

End User License Agreements and Terms of Use: View

Model lifecycle: Active

Input Modalities	Output Modalities	APIs supported	Endpoints supported
⊗ Audio	⊗ Embedding	⊗ `Responses`	⊙ `bedrock-runtime`
⊙ Image	⊙ Image	⊗ `Chat Completions`	⊗ `bedrock-mantle`
⊗ Speech	⊗ Speech	⊙ `Invoke`	
⊙ Text	⊗ Text	⊗ `Converse`	
⊗ Video	⊗ Video		

Tip

Whenever possible, we recommend using the `bedrock-runtime` endpoint for new applications. See the section called "Inference endpoints" for details.

Capabilities and Features

Bedrock Features

Features supported using `bedrock-runtime` endpoint

Supported	Not Supported
✓ Abuse detection ✓ Guardrails	⊗ Intelligent prompt routing ⊗ Response streaming ⊗ Prompt optimization ⊗ Count tokens ⊗ Knowledge base ⊗ Model evaluation ⊗ Prompt management ⊗ Flows ⊗ Agents ⊗ Watermarking

Pricing

For pricing information, see the Amazon Bedrock Pricing page.

Programmatic Access

Use the following model IDs and endpoint URLs to access this model programmatically. For more information about the available APIs and endpoints, see APIs supported and Endpoints supported.

Endpoint	Model ID	In-Region endpoint URL	Geo inference ID	Global inference ID
bedrock-runtime	stability.stable-image-style-guide-v1:0	https://bedrock-runtime.{region}.amazonaws.com	us.stability.stable-image-style-guide-v1:0	Not supported

For example, if region is us-east-1 (N. Virginia), then the bedrock-runtime endpoint URL will be "https://bedrock-runtime.us-east-1.amazonaws.com" and for bedrock-mantle will be "https://bedrock-mantle.us-east-1.api.aws/v1".

Service Tiers

Amazon Bedrock offers multiple service tiers to match your workload requirements. **Standard** provides pay-per-token access with no commitment (set `"service_tier": "default"` or omit the field). **Priority** delivers the fastest response times for a price premium (set `"service_tier": "priority"`). **Flex** provides lower-cost access for flexible, non-time-sensitive workloads (set `"service_tier": "flex"`). **Reserved** provides dedicated throughput with a term commitment for predictable workloads; it is set at the account level rather than per request (contact your AWS account team to enable). For more information, see service tiers.

Standard	Priority	Flex	Reserved
✓	✗	✗	✗

Regional Availability

Regional availability at a glance

Amazon Bedrock offers three inference options: **In-Region** keeps requests within a single Region for strict compliance, **Geo Cross-Region** routes across Regions within a geography (such as US, EU, and APAC) while respecting data residency, and **Global Cross-Region** routes anywhere worldwide when there are no residency constraints. Refer to the the section called “Regional availability by models” page for more details.

Region	In-Region	Geo	Global

params = {'image': image_base64, 'prompt': 'high quality detailed image'}
response = client.invoke_model(
    modelId='stability.stable-conservative-upscale-v1:0',
    body=json.dumps(params)
)
response_body = json.loads(response['body'].read())
print(f'Image generated: {len(response_body["images"][0])} bytes (base64)')
```

Stable Image Erase Object

Stability AI — Stable Image Erase Object

Model Details

Stable Image Erase Object is Stability AI's model that removes unwanted objects from images and fills the area with contextually appropriate content. For more information about model development and performance, see the model/service card.

Model launch date: May 20, 2024

EOL no sooner than: May 20, 2025

Legacy period: at least 6 months

Model lifecycle policy: Model lifecycle (For Models Launched Prior to Sept 7 2026)

Model EOL date: N/A

End User License Agreements and Terms of Use: View

Model lifecycle: Active

Input Modalities	Output Modalities	APIs supported	Endpoints supported
⊗ Audio	⊗ Embedding	⊗ Responses	✓ bedrock-runtime
✓ Image	✓ Image	⊗ Chat Completions	⊗ bedrock-mantle
⊗ Speech	⊗ Speech	✓ Invoke	
✓ Text	⊗ Text	⊗ Converse	
⊗ Video	⊗ Video		

Tip

Whenever possible, we recommend using the `bedrock-runtime` endpoint for new applications. See the section called "Inference endpoints" for details.

Capabilities and Features

Bedrock Features

Features supported using `bedrock-runtime` endpoint

Supported	Not Supported
✓ Abuse detection ✓ Guardrails	⊗ Intelligent prompt routing ⊗ Response streaming ⊗ Prompt optimization ⊗ Count tokens ⊗ Knowledge base ⊗ Model evaluation ⊗ Prompt management ⊗ Flows

Supported	Not Supported
	⊗ Agents ⊗ Watermarking

Pricing

For pricing information, see the Amazon Bedrock Pricing page.

Programmatic Access

Use the following model IDs and endpoint URLs to access this model programmatically. For more information about the available APIs and endpoints, see APIs supported and Endpoints supported.

Endpoint	Model ID	In-Region endpoint URL	Geo inference ID	Global inference ID
bedrock-runtime	stability.stable-image-erase-object-v1:0	https://bedrock-runtime.{region}.amazonaws.com	us.stability.stable-image-erase-object-v1:0	Not supported

For example, if region is us-east-1 (N. Virginia), then the bedrock-runtime endpoint URL will be "https://bedrock-runtime.us-east-1.amazonaws.com" and for bedrock-mantle will be "https://bedrock-mantle.us-east-1.api.aws/v1".

Service Tiers

Amazon Bedrock offers multiple service tiers to match your workload requirements. **Standard** provides pay-per-token access with no commitment (set `"service_tier": "default"` or omit the field). **Priority** delivers the fastest response times for a price premium (set `"service_tier": "priority"`). **Flex** provides lower-cost access for flexible, non-time-sensitive workloads (set `"service_tier": "flex"`). **Reserved** provides dedicated throughput with a term commitment for predictable workloads; it is set at the account level rather than per request (contact your AWS account team to enable). For more information, see service tiers.

Standard	Priority	Flex	Reserved
✓	✗	✗	✗

Regional Availability

Regional availability at a glance

Amazon Bedrock offers three inference options: **In-Region** keeps requests within a single Region for strict compliance, **Geo Cross-Region** routes across Regions within a geography (such as US, EU, and APAC) while respecting data residency, and **Global Cross-Region** routes anywhere worldwide when there are no residency constraints. Refer to the the section called “Regional availability by models” page for more details.

Region	In-Region	Geo	Global
`us-east-1` (N. Virginia)	✗	✓	✗
`us-east-2` (Ohio)	✗	✓	✗
`us-west-2` (Oregon)	✗	✓	✗

Geo inference details

Geo: US

Geo Inference ID: `us.stability.stable-image-erase-object-v1:0`

Source Region	Destination Regions
us-east-1 (N. Virginia)	us-east-1 (N. Virginia), us-east-2 (Ohio), us-west-2 (Oregon)
us-east-2 (Ohio)	us-east-1 (N. Virginia), us-east-2 (Ohio), us-west-2 (Oregon)
us-west-2 (Oregon)	us-east-1 (N. Virginia), us-east-2 (Ohio), us-west-2 (Oregon)

Quotas and Limits

Your AWS account has default quotas to maintain the performance of the service and to ensure appropriate usage of Amazon Bedrock. The default quotas assigned to an account might be updated depending on regional factors, payment history, fraudulent usage, and/or approval of a quota increase request. For more information, see the section called "Quotas" documentation and see the limits for the model.

Sample Code

Step 1 - AWS Account: If you have an AWS account already, skip this step. If you are new to AWS, sign up for an AWS account.

Step 2 - API key: Go to the Amazon Bedrock console and generate a long-term API key.

Step 3 - Get the SDK: To use this getting started guide, you must have Python already installed. Then install the relevant software depending on the APIs you are using.

```
pip install boto3
```

Step 4 - Set environment variables: Configure your environment to use the API key for authentication.

```
AWS_BEARER_TOKEN_BEDROCK="<provide your Bedrock API key>"
```

Step 5 - Run your first inference request: Save the file as `bedrock-first-request.py`

Invoke API

```
import json
import base64
import boto3

client = boto3.client('bedrock-runtime', region_name='us-east-1')
with open('input.png', 'rb') as f:
    image_base64 = base64.b64encode(f.read()).decode('utf-8')
with open('mask.png', 'rb') as f:
    mask_base64 = base64.b64encode(f.read()).decode('utf-8')
params = {'image': image_base64, 'mask': mask_base64}
response = client.invoke_model(
```

```
    modelId='stability.stable-image-erase-object-v1:0',
    body=json.dumps(params)
)
response_body = json.loads(response['body'].read())
print(f'Image generated: {len(response_body["images"][0])} bytes (base64)')
```

Stable Image Control Structure

Stability AI — Stable Image Control Structure

Model Details

Stable Image Control Structure is Stability AI's model that generates images guided by structural inputs like depth maps and edge detection. For more information about model development and performance, see the model/service card.

Model launch date: Apr 30, 2024
EOL no sooner than: Apr 30, 2025
Legacy period: at least 6 months
Model lifecycle policy: Model lifecycle (For Models Launched Prior to Sept 7 2026)
Model EOL date: N/A
End User License Agreements and Terms of Use: View
Model lifecycle: Active

Input Modalities	Output Modalities	APIs supported	Endpoints supported

`us-east-1` (N. Virginia)	⊗	✓	⊗
`us-east-2` (Ohio)	⊗	✓	⊗
`us-west-2` (Oregon)	⊗	✓	⊗

Geo inference details

Geo: US

Geo Inference ID: `us.stability.stable-image-control-structure-v1:0`

Source Region	Destination Regions
us-east-1 (N. Virginia)	us-east-1 (N. Virginia), us-east-2 (Ohio), us-west-2 (Oregon)
us-east-2 (Ohio)	us-east-1 (N. Virginia), us-east-2 (Ohio), us-west-2 (Oregon)
us-west-2 (Oregon)	us-east-1 (N. Virginia), us-east-2 (Ohio), us-west-2 (Oregon)

Quotas and Limits

Your AWS account has default quotas to maintain the performance of the service and to ensure appropriate usage of Amazon Bedrock. The default quotas assigned to an account might be updated depending on regional factors, payment history, fraudulent usage, and/or approval of a quota increase request. For more information, see the section called "Quotas" documentation and see the limits for the model.

Sample Code

Step 1 - AWS Account: If you have an AWS account already, skip this step. If you are new to AWS, sign up for an AWS account.

Step 2 - API key: Go to the Amazon Bedrock console and generate a long-term API key.

Step 3 - Get the SDK: To use this getting started guide, you must have Python already installed. Then install the relevant software depending on the APIs you are using.

```
pip install boto3
```

Step 4 - Set environment variables: Configure your environment to use the API key for authentication.

```
AWS_BEARER_TOKEN_BEDROCK="<provide your Bedrock API key>"
```

Step 5 - Run your first inference request: Save the file as `bedrock-first-request.py`

Invoke API

```
import json
import base64
import boto3

client = boto3.client('bedrock-runtime', region_name='us-east-1')
with open('input.png', 'rb') as f:
    image_base64 = base64.b64encode(f.read()).decode('utf-8')
params = {'image': image_base64, 'prompt': 'surreal structure with motion generated
 sparks'}
response = client.invoke_model(
    modelId='stability.stable-image-control-structure-v1:0',
    body=json.dumps(params)
)
response_body = json.loads(response['body'].read())
print(f'Image generated: {len(response_body["images"][0])} bytes (base64)')
```

Stable Image Creative Upscale

Stability AI — Stable Image Creative Upscale

Model Details

Stable Image Creative Upscale is Stability AI's model that upscales images while adding creative detail and enhancing visual quality. For more information about model development and performance, see the model/service card.

Model launch date: Mar 21, 2024

EOL no sooner than: Mar 21, 2025

Legacy period: at least 6 months

Programmatic Access

Use the following model IDs and endpoint URLs to access this model programmatically. For more information about the available APIs and endpoints, see APIs supported and Endpoints supported.

Endpoint	Model ID	In-Region endpoint URL	Geo inference ID	Global inference ID
bedrock-runtime	stability.stable-image-inpaint-v1:0	https://bedrock-runtime.{region}.amazonaws.com	us.stability.stable-image-inpaint-v1:0	Not supported

For example, if region is us-east-1 (N. Virginia), then the bedrock-runtime endpoint URL will be "https://bedrock-runtime.us-east-1.amazonaws.com" and for bedrock-mantle will be "https://bedrock-mantle.us-east-1.api.aws/v1".

Service Tiers

Amazon Bedrock offers multiple service tiers to match your workload requirements. **Standard** provides pay-per-token access with no commitment (set `"service_tier": "default"` or omit the field). **Priority** delivers the fastest response times for a price premium (set `"service_tier": "priority"`). **Flex** provides lower-cost access for flexible, non-time-sensitive workloads (set `"service_tier": "flex"`). **Reserved** provides dedicated throughput with a term commitment for predictable workloads; it is set at the account level rather than per request (contact your AWS account team to enable). For more information, see service tiers.

Standard	Priority	Flex	Reserved
✓	✗	✗	✗

Regional Availability

Regional availability at a glance

Amazon Bedrock offers three inference options: **In-Region** keeps requests within a single Region for strict compliance, **Geo Cross-Region** routes across Regions within a geography (such as US, EU, and APAC) while respecting data residency, and **Global Cross-Region** routes anywhere worldwide when there are no residency constraints. Refer to the the section called “Regional availability by models” page for more details.

Region	In-Region	Geo	Global
us-east-1 (N. Virginia)	⊗	✓	⊗
us-east-2 (Ohio)	⊗	✓	⊗
us-west-2 (Oregon)	⊗	✓	⊗

Geo inference details

Geo: US

Geo Inference ID: `us.stability.stable-image-inpaint-v1:0`

Source Region	Destination Regions
us-east-1 (N. Virginia)	us-east-1 (N. Virginia), us-east-2 (Ohio), us-west-2 (Oregon)
us-east-2 (Ohio)	us-east-1 (N. Virginia), us-east-2 (Ohio), us-west-2 (Oregon)
us-west-2 (Oregon)	us-east-1 (N. Virginia), us-east-2 (Ohio), us-west-2 (Oregon)

Quotas and Limits

Your AWS account has default quotas to maintain the performance of the service and to ensure appropriate usage of Amazon Bedrock. The default quotas assigned to an account might be updated depending on regional factors, payment history, fraudulent usage, and/or approval of a quota increase request. For more information, see the section called "Quotas" documentation and see the limits for the model.

Sample Code

Step 1 - AWS Account: If you have an AWS account already, skip this step. If you are new to AWS, sign up for an AWS account.

Step 2 - API key: Go to the Amazon Bedrock console and generate a long-term API key.

Step 3 - Get the SDK: To use this getting started guide, you must have Python already installed. Then install the relevant software depending on the APIs you are using.

```
pip install boto3
```

Step 4 - Set environment variables: Configure your environment to use the API key for authentication.

```
AWS_BEARER_TOKEN_BEDROCK="<provide your Bedrock API key>"
```

Step 5 - Run your first inference request: Save the file as `bedrock-first-request.py`

Invoke API

```
import json
import base64
import boto3

client = boto3.client('bedrock-runtime', region_name='us-east-1')
with open('input.png', 'rb') as f:
    image_base64 = base64.b64encode(f.read()).decode('utf-8')
with open('mask.png', 'rb') as f:
    mask_base64 = base64.b64encode(f.read()).decode('utf-8')
params = {'image': image_base64, 'mask': mask_base64, 'prompt': 'a beautiful
 garden'}
response = client.invoke_model(
    modelId='stability.stable-image-inpaint-v1:0',
    body=json.dumps(params)
)
response_body = json.loads(response['body'].read())
print(f'Image generated: {len(response_body["images"][0])} bytes (base64)')
```

TwelveLabs

The following TwelveLabs models are available in Amazon Bedrock:

Model	Description
the section called “Pegasus v1.2”	Pegasus v1.2 is TwelveLabs' video-to-text generation model that produces detailed descriptions, summaries, and answers about video content.
the section called “Pegasus v1.5”	Pegasus v1.5 is TwelveLabs' video-to-text model, adding video segmentation and structured, timestamped metadata over v1.2.
the section called “Marengo Embed v2.7”	Marengo Embed v2.7 is TwelveLabs' video embedding model for multimodal video understanding, search, and classification.
the section called “Marengo Embed 3.0”	Marengo Embed 3.0 is TwelveLabs' video embedding model that generates vector representations of video content for search and retrieval.

Pegasus v1.2

TwelveLabs — Pegasus v1.2

Model Details

Pegasus v1.2 is TwelveLabs' video-to-text generation model that produces detailed descriptions, summaries, and answers about video content. For more information about model development and performance, see the model/service card.

Model launch date: Feb 11, 2025
EOL no sooner than: Feb 11, 2026
Legacy period: at least 6 months
Model lifecycle policy: Model lifecycle (For Models Launched Prior to Sept 7 2026)
Model EOL date: March 22, 2027
End User License Agreements and Terms of Use: View
Model lifecycle: Legacy
Marketplace product ID: `prod-635pcy5x5pc2a`

Input Modalities	Output Modalities	APIs supported	Endpoints supported
⊗ Audio	⊗ Embedding	⊗ Responses	⊙ bedrock-runtime
⊗ Image	⊗ Image	⊗ Chat Completions	⊗ bedrock-mantle
⊗ Speech	⊗ Speech	⊙ Invoke	
⊙ Text	⊙ Text	⊗ Converse	
⊙ Video	⊗ Video		

Tip

Whenever possible, we recommend using the `bedrock-runtime` endpoint for new applications. See the section called "Inference endpoints" for details.

Capabilities and Features

Bedrock Features

Features supported using `bedrock-runtime` endpoint

Supported	Not Supported
⊙ Response streaming ⊙ Guardrails	⊗ Intelligent prompt routing ⊗ Abuse detection ⊗ Prompt optimization ⊗ Count tokens ⊗ Knowledge base ⊗ Model evaluation ⊗ Prompt management ⊗ Flows

Supported	Not Supported
	⊗ Agents ⊗ Watermarking

Pricing

This model is a third-party model offered and billed through AWS Marketplace. Charges appear on your AWS bill and in AWS Cost Explorer under the model provider (not under Amazon Bedrock). For pricing, see the Amazon Bedrock Pricing page.

Programmatic Access

Use the following model IDs and endpoint URLs to access this model programmatically. For more information about the available APIs and endpoints, see APIs supported and Endpoints supported.

Endpoint	Model ID	In-Region endpoint URL	Geo inference ID	Global inference ID
bedrock-runtime	twelvelabs.pegasus-1-2-v1:0	https://bedrock-runtime.{region}.amazonaws.com	us.twelvelabs.pegasus-1-2-v1:0 eu.twelvelabs.pegasus-1-2-v1:0 apac.twelvelabs.pegasus-1-2-v1:0	global.twelvelabs.pegasus-1-2-v1:0

For example, if region is us-east-1 (N. Virginia), then the bedrock-runtime endpoint URL will be "https://bedrock-runtime.us-east-1.amazonaws.com" and for bedrock-mantle will be "https://bedrock-mantle.us-east-1.api.aws/v1".

Service Tiers

Amazon Bedrock offers multiple service tiers to match your workload requirements. **Standard** provides pay-per-token access with no commitment (set `"service_tier": "default"` or omit the field). **Priority** delivers the fastest response times for a price premium (set `"service_tier": "priority"`). **Flex** provides lower-cost access for flexible, non-time-sensitive workloads (set `"service_tier": "flex"`). **Reserved** provides dedicated throughput with a term commitment for predictable workloads; it is set at the account level rather than per request (contact your AWS account team to enable). For more information, see service tiers.

Global inference details

Global Inference ID	Americas	EMEA	Asia Pacific
global.twelvelabs.pegasus-1-2-v1:0	us-east-1 (N. Virginia) us-east-2 (Ohio) us-west-1 (N. California) us-west-2 (Oregon) ca-central-1 (Canada) ca-west-1 (Calgary) sa-east-1 (São Paulo) mx-central-1 (Mexico)	eu-central-1 (Frankfurt) eu-central-2 (Zurich) eu-north-1 (Stockholm) eu-south-1 (Milan) eu-south-2 (Spain) eu-west-1 (Ireland) eu-west-2 (London) eu-west-3 (Paris) il-central-1 (Tel Aviv) me-central-1 (UAE) me-south-1 (Bahrain) af-south-1 (Cape Town)	ap-east-2 (Taipei) ap-northeast-1 (Tokyo) ap-northeast-2 (Seoul) ap-northeast-3 (Osaka) ap-south-1 (Mumbai) ap-south-2 (Hyderabad) ap-southeast-1 (Singapore) ap-southeast-2 (Sydney) ap-southeast-3 (Jakarta) ap-southeast-4 (Melbourne) ap-southeast-5 (Malaysia) ap-southeast-7 (Thailand)

Quotas and Limits

Your AWS account has default quotas to maintain the performance of the service and to ensure appropriate usage of Amazon Bedrock. The default quotas assigned to an account might be updated depending on regional factors, payment history, fraudulent usage, and/or approval of a quota increase request. For more information, see the section called “Quotas” documentation and see the limits for the model.

Sample Code

Step 1 - AWS Account: If you have an AWS account already, skip this step. If you are new to AWS, sign up for an AWS account.

Step 2 - API key: Go to the Amazon Bedrock console and generate a long-term API key.

Step 3 - Get the SDK: To use this getting started guide, you must have Python already installed. Then install the relevant software depending on the APIs you are using.

```
pip install boto3
```

Step 4 - Set environment variables: Configure your environment to use the API key for authentication.

```
AWS_BEARER_TOKEN_BEDROCK="<provide your Bedrock API key>"
```

Step 5 - Run your first inference request: Save the file as `bedrock-first-request.py`

Invoke API

```
import json
import boto3

client = boto3.client('bedrock-runtime', region_name='us-east-1')
response = client.invoke_model(
    modelId='twelvelabs.pegasus-1-2-v1:0',
    body=json.dumps({
            'inputPrompt': 'Tell me about this video',
            'mediaSource': {
                's3Location': {
                    'uri': 's3://your-bucket/your-video.mp4',
                    'bucketOwner': '123456789012'
```

```
                }
            },
            'maxOutputTokens': 4096
    })
)
print(json.loads(response['body'].read()))
```

Pegasus v1.5

TwelveLabs — Pegasus v1.5

Model Details

Pegasus v1.5 is TwelveLabs' video-to-text generation model that produces summaries, detailed descriptions, and structured responses about video content. Building on Pegasus v1.2, it adds video segmentation to transform raw video into structured, timestamped metadata across an entire video. For more information about model development and performance, see the model/service card.

Model launch date: October 8, 2026
EOL no sooner than: Not Applicable. At least a 45-day EOL notice will be provided.
Legacy period: at least 45 days
Model lifecycle policy: Model lifecycle
Model EOL date: N/A
End User License Agreements and Terms of Use: View
Model lifecycle: Active
Context window: 261,120 tokens
Max output tokens: 98,304 tokens
Marketplace product ID: `prod-emhhqbi7fzsyo`

Input Modalities	Output Modalities	APIs supported	Endpoints supported
⊗ Audio	⊗ Embedding	⊗ `Responses`	⊙ `bedrock-runtime`

Input Modalities	Output Modalities	APIs supported	Endpoints supported
⊗ Image	⊗ Image	⊗ `Chat Completions`	⊗ `bedrock-mantle`
⊗ Speech	⊗ Speech	✓ `Invoke`	
✓ Text	✓ Text	⊗ `Converse`	
✓ Video	⊗ Video		

Tip

Whenever possible, we recommend using the `bedrock-runtime` endpoint for new applications. See the section called "Inference endpoints" for details.

Note

Pegasus v1.5 is available through cross-Region inference only. Requests must use the US geographic inference profile (`us.twelvelabs.pegasus-1-5-v1:0`) or the global inference profile (`global.twelvelabs.pegasus-1-5-v1:0`). In-Region on-demand inference is not supported.

Capabilities and Features

Bedrock Features

Features supported using `bedrock-runtime` endpoint

Supported	Not Supported
✓ Response streaming	⊗ Guardrails ⊗ Intelligent prompt routing ⊗ Abuse detection ⊗ Prompt optimization

Supported	Not Supported
	⊗ Count tokens ⊗ Knowledge base ⊗ Model evaluation ⊗ Prompt management ⊗ Flows ⊗ Agents ⊗ Watermarking

Pricing

This model is a third-party model offered and billed through AWS Marketplace. Charges appear on your AWS bill and in AWS Cost Explorer under the model provider (not under Amazon Bedrock). For pricing, see the Amazon Bedrock Pricing page.

Programmatic Access

Use the following model IDs and endpoint URLs to access this model programmatically. Pegasus v1.5 is available through cross-Region inference only, so you must use the geo or global inference ID rather than the base model ID. For more information about the available APIs and endpoints, see APIs supported and Endpoints supported.

For the full request parameters, response fields, and request and response examples, see the section called “TwelveLabs Pegasus 1.5”.

Endpoint	Model ID	In-Region endpoint URL	Geo inference ID	Global inference ID
`bedrock-runtime`	`twelvelabs.pegasus-1-5-v1:0`	N/A	`us.twelvelabs.pegasus-1-5-v1:0`	`global.twelvelabs.pegasus-1-5-v1:0`

For example, to use Global cross-Region inference from us-east-1 (N. Virginia), use the endpoint URL "https://bedrock-runtime.us-east-1.amazonaws.com" with the inference profile ID "global.twelvelabs.pegasus-1-5-v1:0".

Service Tiers

Amazon Bedrock offers multiple service tiers to match your workload requirements. **Standard** provides pay-per-token access with no commitment (set `"service_tier": "default"` or omit the field). **Priority** delivers the fastest response times for a price premium (set `"service_tier": "priority"`). **Flex** provides lower-cost access for flexible, non-time-sensitive workloads (set `"service_tier": "flex"`). **Reserved** provides dedicated throughput with a term commitment for predictable workloads; it is set at the account level rather than per request (contact your AWS account team to enable). For more information, see service tiers.

Standard	Priority	Flex	Reserved	Batch
✓	✗	✗	✗	✗

Regional Availability

Regional availability at a glance

Amazon Bedrock offers three inference options: **In-Region** keeps requests within a single Region for strict compliance, **Geo Cross-Region** routes across Regions within a geography (such as US, EU, and APAC) while respecting data residency, and **Global Cross-Region** routes anywhere worldwide when there are no residency constraints. Refer to the the section called “Regional availability by models” page for more details.

Pegasus v1.5 supports Geo Cross-Region inference from the US Regions and Global Cross-Region inference from the Regions listed in the following table. In-Region inference is not supported.

The Region you call is the source Region. The inference profile you use determines where the request can be served:

- The US geographic inference profile (`us.twelvelabs.pegasus-1-5-v1:0`) routes requests to us-east-1, us-east-2, and us-west-2.
- The global inference profile (`global.twelvelabs.pegasus-1-5-v1:0`) routes requests globally across all supported AWS Regions.

Region	In-Region	Geo	Global
us-east-1 (N. Virginia)	⊗	✓	✓
us-east-2 (Ohio)	⊗	✓	✓
us-west-1 (N. California)	⊗	✓	✓
us-west-2 (Oregon)	⊗	✓	✓
ca-central-1 (Canada)	⊗	⊗	✓
ca-west-1 (Calgary)	⊗	⊗	✓
eu-central-1 (Frankfurt)	⊗	⊗	✓
eu-central-2 (Zurich)	⊗	⊗	✓
eu-north-1 (Stockholm)	⊗	⊗	✓
eu-south-1 (Milan)	⊗	⊗	✓
eu-south-2 (Spain)	⊗	⊗	✓
eu-west-1 (Ireland)	⊗	⊗	✓
eu-west-2 (London)	⊗	⊗	✓
eu-west-3 (Paris)	⊗	⊗	✓
ap-east-2 (Taipei)	⊗	⊗	✓
ap-northeast-1 (Tokyo)	⊗	⊗	✓
ap-northeast-2 (Seoul)	⊗	⊗	✓
ap-northeast-3 (Osaka)	⊗	⊗	✓
ap-south-1 (Mumbai)	⊗	⊗	✓
ap-south-2 (Hyderabad)	⊗	⊗	✓

Region	In-Region	Geo	Global

ap-southeast-7 (Thailand)	⊗	⊗	⊘
il-central-1 (Tel Aviv)	⊗	⊗	⊘
af-south-1 (Cape Town)	⊗	⊗	⊘
mx-central-1 (Mexico)	⊗	⊗	⊘
sa-east-1 (São Paulo)	⊗	⊗	⊘

Quotas and Limits

Your AWS account has default quotas to maintain the performance of the service and to ensure appropriate usage of Amazon Bedrock. The default quotas assigned to an account might be updated depending on regional factors, payment history, fraudulent usage, and/or approval of a quota increase request. For more information, see the section called “Quotas” documentation and see the limits for the model.

Sample Code

Step 1 - AWS Account: If you have an AWS account already, skip this step. If you are new to AWS, sign up for an AWS account.

Step 2 - API key: Go to the Amazon Bedrock console and generate a long-term API key.

Step 3 - Get the SDK: To use this getting started guide, you must have Python already installed. Then install the relevant software depending on the APIs you are using.

```
pip install boto3
```

Step 4 - Set environment variables: Configure your environment to use the API key for authentication.

```
AWS_BEARER_TOKEN_BEDROCK="<provide your Bedrock API key>"
```

Step 5 - Run your first inference request: Save the file as `bedrock-first-request.py`

Invoke API

```
import json
import boto3

client = boto3.client('bedrock-runtime', region_name='us-east-1')
response = client.invoke_model(
    modelId='us.twelvelabs.pegasus-1-5-v1:0',
    body=json.dumps({
            'inputPrompt': 'Tell me about this video',
            'mediaSource': {
                's3Location': {
                    'uri': 's3://your-bucket/your-video.mp4',
                    'bucketOwner': '111122223333'
                }
            },
            'maxOutputTokens': 4096
    })
)
print(json.loads(response['body'].read()))
```

> **Note**
>
> Replace `s3Location.uri` with a bucket in the same AWS Region that you send the request to — `us-east-1` in this example. The bucket Region must match the request Region even though the model is accessed through a geo or global inference profile, and a bucket in any other Region fails with a `ValidationException`. For the full parameter reference, see the section called “TwelveLabs Pegasus 1.5”.

Marengo Embed v2.7

TwelveLabs — Marengo Embed v2.7

Model Details

Marengo Embed v2.7 is TwelveLabs' video embedding model for multimodal video understanding, search, and classification. For more information about model development and performance, see the model/service card.

Model launch date: Dec 4, 2024
EOL no sooner than: Dec 4, 2025
Legacy period: at least 6 months
Model lifecycle policy: Model lifecycle (For Models Launched Prior to Sept 7 2026)
Model EOL date: November 30, 2026
End User License Agreements and Terms of Use: View
Model lifecycle: Legacy
Marketplace product ID: `prod-o6xchhpirymvs`

Input Modalities	Output Modalities	APIs supported	Endpoints supported
⊗ Audio	⊙ Embedding	⊗ `Responses`	⊙ `bedrock-runtime`
⊙ Image	⊗ Image	⊗ `Chat Completions`	⊗ `bedrock-mantle`
⊙ Speech	⊗ Speech	⊗ `Invoke`	
⊙ Text	⊗ Text	⊗ `Converse`	
⊙ Video	⊗ Video	⊙ `StartAsyncInvoke`	

> **Tip**
>
> Whenever possible, we recommend using the `bedrock-runtime` endpoint for new applications. See the section called "Inference endpoints" for details.

Pricing

This model is a third-party model offered and billed through AWS Marketplace. Charges appear on your AWS bill and in AWS Cost Explorer under the model provider (not under Amazon Bedrock). For pricing, see the Amazon Bedrock Pricing page.

Programmatic Access

Use the following model IDs and endpoint URLs to access this model programmatically. For more information about the available APIs and endpoints, see APIs supported and Endpoints supported.

Endpoint	Model ID	In-Region endpoint URL	Geo inference ID	Global inference ID

`bedrock-runtime`	`twelvelabs.marengo-embed-2-7-v1:0`	`https://bedrock-runtime.{region}.amazonaws.com`	`us.twelvelabs.marengo-embed-2-7-v1:0`
			
			`eu.twelvelabs.marengo-embed-2-7-v1:0`
				Not supported

For example, if region is us-east-1 (N. Virginia), then the bedrock-runtime endpoint URL will be "https://bedrock-runtime.us-east-1.amazonaws.com" and for bedrock-mantle will be "https://bedrock-mantle.us-east-1.api.aws/v1".

> **Note**
>
> The model ID to use depends on the API. `StartAsyncInvoke` takes the base model ID, `twelvelabs.marengo-embed-2-7-v1:0`, as shown in the Sample Code section; passing

a Geo inference ID to `StartAsyncInvoke` returns a validation error. The Geo inference IDs apply to synchronous `InvokeModel` requests, which don't accept the base model ID for this model. The **In-Region** and **Geo** columns in the Regional Availability section describe synchronous on-demand inference.

Service Tiers

Amazon Bedrock offers multiple service tiers to match your workload requirements. **Standard** provides pay-per-token access with no commitment (set `"service_tier": "default"` or omit the field). **Priority** delivers the fastest response times for a price premium (set `"service_tier": "priority"`). **Flex** provides lower-cost access for flexible, non-time-sensitive workloads (set `"service_tier": "flex"`). **Reserved** provides dedicated throughput with a term commitment for predictable workloads; it is set at the account level rather than per request (contact your AWS account team to enable). For more information, see service tiers.

Standard	Priority	Flex	Reserved
✓	✗	✗	✗

Regional Availability

Regional availability at a glance

Amazon Bedrock offers three inference options: **In-Region** keeps requests within a single Region for strict compliance, **Geo Cross-Region** routes across Regions within a geography (such as US, EU, and APAC) while respecting data residency, and **Global Cross-Region** routes anywhere worldwide when there are no residency constraints. Refer to the the section called “Regional availability by models” page for more details.

Region	In-Region	Geo	Global
`us-east-1` (N. Virginia)	✗	✓	✗
`eu-west-1` (Ireland)	✗	✓	✗

Geo inference details

Geo: US

Geo Inference ID: `us.twelvelabs.marengo-embed-2-7-v1:0`

Source Region	Destination Regions
us-east-1 (N. Virginia)	us-east-1 (N. Virginia), us-east-2 (Ohio), us-west-1 (N. California), us-west-2 (Oregon)

Geo: EU

Geo Inference ID: `eu.twelvelabs.marengo-embed-2-7-v1:0`

Source Region	Destination Regions
eu-west-1 (Ireland)	eu-central-1 (Frankfurt), eu-north-1 (Stockholm), eu-south-1 (Milan), eu-south-2 (Spain), eu-west-1 (Ireland), eu-west-3 (Paris)

Quotas and Limits

Your AWS account has default quotas to maintain the performance of the service and to ensure appropriate usage of Amazon Bedrock. The default quotas assigned to an account might be updated depending on regional factors, payment history, fraudulent usage, and/or approval of a quota increase request. For more information, see the section called “Quotas” documentation and see the limits for the model.

Sample Code

Step 1 - AWS Account: If you have an AWS account already, skip this step. If you are new to AWS, sign up for an AWS account.

Step 2 - API key: Go to the Amazon Bedrock console and generate a long-term API key.

Step 3 - Get the SDK:

```
pip install boto3
```

Step 4 - Set environment variables:

```
AWS_BEARER_TOKEN_BEDROCK="<provide your Bedrock API key>"
```

Step 5 - Run your first inference request: This model uses `StartAsyncInvoke`. Save the file as `bedrock-first-request.py`

```
import boto3

client = boto3.client('bedrock-runtime', region_name='us-east-1')
response = client.start_async_invoke(
    modelId='twelvelabs.marengo-embed-2-7-v1:0',
    modelInput={},
    outputDataConfig={'s3OutputDataConfig': {'s3Uri': 's3://your-bucket/output/'}}
)
print(response)
```

Marengo Embed 3.0

TwelveLabs — Marengo Embed 3.0

Model Details

Marengo Embed 3.0 is TwelveLabs' video embedding model that generates vector representations of video content for search and retrieval. For more information about model development and performance, see the model/service card.

Model launch date: Oct 29, 2025

EOL no sooner than: Oct 29, 2026

Legacy period: at least 6 months

Model lifecycle policy: Model lifecycle (For Models Launched Prior to Sept 7 2026)

Model EOL date: March 22, 2027 (ap-northeast-2 only)

End User License Agreements and Terms of Use: View

Model lifecycle: Legacy in ap-northeast-2; Active in other Regions

Marketplace product ID: `prod-ibqpnh3htjd4s`

Input Modalities	Output Modalities	APIs supported	Endpoints supported
⊗ Audio	✓ Embedding	⊗ Responses	✓ bedrock-runtime
✓ Image	⊗ Image	⊗ Chat Completions	⊗ bedrock-mantle
✓ Speech	⊗ Speech	✓ Invoke	
✓ Text	⊗ Text	⊗ Converse	
✓ Video	⊗ Video	✓ StartAsyncInvoke	

Tip

Whenever possible, we recommend using the `bedrock-runtime` endpoint for new applications. See the section called "Inference endpoints" for details.

Capabilities and Features

Bedrock Features

Features supported using `bedrock-runtime` endpoint

Supported	Not Supported
✓ Abuse detection	⊗ Intelligent prompt routing ⊗ Response streaming ⊗ Guardrails ⊗ Prompt optimization ⊗ Count tokens ⊗ Knowledge base ⊗ Model evaluation ⊗ Prompt management

Supported	Not Supported
	⊗ Flows ⊗ Agents

Pricing

This model is a third-party model offered and billed through AWS Marketplace. Charges appear on your AWS bill and in AWS Cost Explorer under the model provider (not under Amazon Bedrock). For pricing, see the Amazon Bedrock Pricing page.

Programmatic Access

Use the following model IDs and endpoint URLs to access this model programmatically. For more information about the available APIs and endpoints, see APIs supported and Endpoints supported.

Endpoint	Model ID	In-Region endpoint URL	Geo inference ID	Global inference ID
bedrock-runtime	twelvelabs.marengo-embed-3-0-v1:0	https://bedrock-runtime.{region}.amazonaws.com	us.twelvelabs.marengo-embed-3-0-v1:0 eu.twelvelabs.marengo-embed-3-0-v1:0	Not supported

For example, if region is us-east-1 (N. Virginia), then the bedrock-runtime endpoint URL will be "https://bedrock-runtime.us-east-1.amazonaws.com" and for bedrock-mantle will be "https://bedrock-mantle.us-east-1.api.aws/v1".

Service Tiers

Amazon Bedrock offers multiple service tiers to match your workload requirements. **Standard** provides pay-per-token access with no commitment (set `"service_tier": "default"` or omit the field). **Priority** delivers the fastest response times for a price premium (set `"service_tier":`

"priority"). **Flex** provides lower-cost access for flexible, non-time-sensitive workloads (set "service_tier": "flex"). **Reserved** provides dedicated throughput with a term commitment for predictable workloads; it is set at the account level rather than per request (contact your AWS account team to enable). For more information, see service tiers.

Standard	Priority	Flex	Reserved
✓	✗	✗	✗

Regional Availability

Regional availability at a glance

Amazon Bedrock offers three inference options: **In-Region** keeps requests within a single Region for strict compliance, **Geo Cross-Region** routes across Regions within a geography (such as US, EU, and APAC) while respecting data residency, and **Global Cross-Region** routes anywhere worldwide when there are no residency constraints. Refer to the the section called "Regional availability by models" page for more details.

Region	In-Region	Geo	Global
us-east-1 (N. Virginia)	✓	✓	✗

    modelId='twelvelabs.marengo-embed-3-0-v1:0',
    modelInput={},
    outputDataConfig={'s3OutputDataConfig': {'s3Uri': 's3://your-bucket/output/'}}
)
print(response)
```

Writer

The following Writer models are available in Amazon Bedrock:

Model	Description
the section called “Palmyra Vision 7B”	Palmyra Vision 7B is Writer's advanced multimodal language model for visual analysis, excelling at image understanding, handwritten text extraction, and chart interpretation.
the section called “Palmyra X5”	Palmyra X5 is Writer's enterprise model with improved reasoning, coding, and agentic capabilities for complex business workflows.
the section called “Palmyra X4”	Palmyra X4 is Writer's enterprise LLM optimized for business writing, content generation, and knowledge work with strong instruction following.

Palmyra Vision 7B

Writer — Palmyra Vision 7B

Model Details

Palmyra Vision 7B is Writer's advanced multimodal language model, designed to interpret and generate text from images and video, providing robust visual analysis capabilities for enterprise needs. It excels at extracting handwritten text, interpreting complex charts and graphs, image-based compliance checks, and product description generation. For more information about model development and performance, see the model/service card.

Model launch date: Mar 26, 2026

Quotas and Limits

Your AWS account has default quotas to maintain the performance of the service and to ensure appropriate usage of Amazon Bedrock. The default quotas assigned to an account might be updated depending on regional factors, payment history, fraudulent usage, and/or approval of a

quota increase request. For more information, see the section called "Quotas" documentation and see the limits for the model.

Sample Code

Step 1 - AWS Account: If you have an AWS account already, skip this step. If you are new to AWS, sign up for an AWS account.

Step 2 - API key: Go to the Amazon Bedrock console and generate a long-term API key.

Step 3 - Get the SDK: To use this getting started guide, you must have Python already installed. Then install the relevant software depending on the APIs you are using.

Chat Completions API

```
pip install boto3 openai
```

Invoke/Converse API

```
pip install boto3
```

Step 4 - Set environment variables: Configure your environment to use the API key for authentication.

Chat Completions API

```
OPENAI_API_KEY="<provide your Bedrock API key>"
OPENAI_BASE_URL="https://bedrock-runtime.<your-region>.amazonaws.com/openai/v1"
```

Invoke/Converse API

```
AWS_BEARER_TOKEN_BEDROCK="<provide your Bedrock API key>"
```

Step 5 - Run your first inference request: Save the file as `bedrock-first-request.py`

Chat Completions API

```
from openai import OpenAI
```

```
client = OpenAI()

response = client.chat.completions.create(
    model="writer.palmyra-vision-7b",
    messages=[{"role": "user", "content": "Can you explain the features of Amazon
 Bedrock?"}]
    )
print(response)
```

Invoke API

```
import json
import boto3

client = boto3.client('bedrock-runtime', region_name='us-east-1')
response = client.invoke_model(
    modelId='writer.palmyra-vision-7b',
    body=json.dumps({
            'messages': [{ 'role': 'user', 'content': 'Can you explain the features
 of Amazon Bedrock?'}],
            'max_tokens': 1024
    })
)
print(json.loads(response['body'].read()))
```

Converse API

```
import boto3

client = boto3.client('bedrock-runtime', region_name='us-east-1')
response = client.converse(
    modelId='writer.palmyra-vision-7b',
    messages=[
        {
            'role': 'user',
            'content': [{'text': 'Can you explain the features of Amazon Bedrock?'}]
        }
    ]
)
print(response)
```

Palmyra X5

Writer — Palmyra X5

Model Details

Palmyra X5 is Writer's enterprise model with improved reasoning, coding, and agentic capabilities for complex business workflows. For more information about model development and performance, see the model/service card.

Model launch date: Jan 21, 2026
EOL no sooner than: Jan 21, 2027

        }
    ]
)
print(response)
```

xAI

The following xAI models are available in Amazon Bedrock:

Model	Description
the section called “Grok 4.7”	Grok 4.7 is xAI's frontier model for coding, long-running agents, and knowledge work.
the section called “Grok 4.6”	Grok 4.6 is xAI's frontier model built for coding, agentic tasks, and knowledge work.
the section called “Grok 4.3”	Grok 4.3 is xAI's latest model with low hallucination rate and strong tool calling capabilities, well suited to enterprise workloads such as customer support and financial document Q&A.

Grok 4.7

xAI — Grok 4.7

Model Details

Grok 4.7 is [illegible]ntier m[illegible]for coding, agentic tasks, and knowledge work, with support for text and image in[illegible]ds on previous generations of Grok with a focus on long-running agents and mor[illegible]s interac[illegible]k. It offers a 524,288-token context window shared between in[illegible]utput, [illegible]onfigu[illegible]soning efforts (low, medium, high, xhigh).

M[illegible]n dat[illegible]026
EOL no sooner than: September [illegible]
Legacy period: at least 6 months
Model lifecycle policy: Model lifecycle
Model EOL date: N/A
End User License Agreements and Terms of Use: View
Model lifecycle: Active
Context window: 524,288 tokens, shared between input and output
Max output tokens: 524,288 minus input tokens
Reasoning: Supported (configurable: low, medium, high, xhigh)

Input Modalities	Output Modalities	APIs supported	Endpoints supported
⊗ Audio	⊗ Embedding	⊙ Responses	⊙ bedrock-runtime
⊙ Image	⊗ Image	⊙ Chat Completions	⊗ bedrock-mantle
⊗ Speech	⊗ Speech	⊙ Converse	
⊙ Text	⊙ Text	⊙ Invoke	
⊗ Video	⊗ Video		

Capabilities and Features

Bedrock Features

Features supported using `bedrock-runtime` endpoint

Supported	Not Supported
✓ Projects (default project only) ✓ Invocation logs ✓ Response streaming ✓ Application inference profiles (`Invoke` and Converse APIs only; not supported with Responses or Chat Completions APIs) ✓ Implicit Prompt Caching ✓ Reasoning ✓ Structured outputs ✓ Guardrails ✓ Client-side tool calling ✓ Flows ✓ Prompt management ✓ Prompt optimization (base model ID `xai.grok-4.7` only) ✓ Model evaluation (base model ID `xai.grok-4.7` only; inference parameters are not supported)	✗ Server-side tool use ✗ Intelligent prompt routing ✗ Count tokens ✗ Explicit Prompt Caching ✗ Watermarking

Pricing

The following table shows on-demand pricing for Grok 4.7 by inference option.

Inference option	Input	Output	Cache read
Geo CRIS	$2.20	$6.60	$0.55
Global CRIS	$2.00	$6.00	$0.50

AWS GovCloud (US)

Inference option	Input	Output	Cache read
Geo CRIS	$2.64	$7.92	$0.66

All prices are per 1 million tokens. Pricing shown is for the Standard tier.

Priority and Flex tier support: In addition to Standard, Grok 4.7 supports the Priority and Flex service tiers on the `Responses`, `Chat Completions`, and `Invoke` APIs. The Converse API supports the Standard tier only for this model; requesting `priority` or `flex` through Converse returns a validation error. Priority is billed at **1.75 times** the Standard per-token rate (a 75% premium) and Flex at **0.5 times** the Standard rate (a 50% discount). Apply these multipliers to the Standard rates shown above. For details on each service tier, see service tiers.

Programmatic Access

Use the following model IDs and endpoint URLs to access this model programmatically. For more information about the available APIs and endpoints, see APIs supported and Endpoints supported.

Endpoint	Model ID	In-Region endpoint URL	Geo inference ID	Global inference ID
`bedrock-runtime`	`xai.grok-4.7`	Not supported	`us.xai.grok-4.7`	`global.xai.grok-4.7`

On `bedrock-runtime`, the base URL is "https://bedrock-runtime.{region}.amazonaws.com/openai/v1" and requests must name the geographic cross-Region inference ID `us.xai.grok-4.7` or the Global cross-Region inference ID `global.xai.grok-4.7` as the model.

Service Tiers

Amazon Bedrock offers multiple service tiers to match your workload requirements. **Standard** provides pay-per-token access with no commitment (set `"service_tier": "default"` or omit the field). **Priority** delivers faster, prioritized processing for a price premium (set

`"service_tier": "priority"`). **Flex** provides lower-cost access for flexible, non-time-sensitive workloads (set `"service_tier": "flex"`). For this model, Priority and Flex are available on the `Responses`, `Chat Completions`, and `Invoke` APIs only — the Converse API supports Standard only. For more information, see service tiers.

Standard	Priority	Flex	Reserved
✓	✓	✓	✗

Regional Availability

Regional availability at a glance

Amazon Bedrock offers three inference options: **In-Region** keeps requests within a single Region for strict compliance, **Geo Cross-Region** routes across Regions within a geography (such as US, EU, and APAC) while respecting data residency, and **Global Cross-Region** routes anywhere worldwide when there are no residency constraints. Refer to the the section called "Regional availability by models" page for more details.

Grok 4.7 is available on the `bedrock-runtime` endpoint using Geo (US) and Global cross-Region inference. The following table shows availability by Region.

Region	In-Region	Geo	Global
`us-east-1` (N. Virginia)	✗	✓	✓
`us-east-2` (Ohio)	✗	✓	✓
`us-west-1` (N. California)	✗	✓	✓

Geo inference details

The destination Regions available to a geographic inference profile depend on the source Region. To retrieve the current routing configuration, call GetInferenceProfile from the source Region.

Geo: US

Geo inference ID: `us.xai.grok-4.7`

Source Region	Destination Regions
us-east-1 (N. Virginia)	us-east-1 (N. Virginia), us-east-2 (Ohio), us-west-2 (Oregon)
us-east-2 (Ohio)	us-east-1 (N. Virginia), us-east-2 (Ohio), us-west-2 (Oregon)
us-west-1 (N. California)	us-east-1 (N. Virginia), us-east-2 (Ohio), us-west-1 (N. California), us-west-2 (Oregon)
us-west-2 (Oregon)	us-east-1 (N. Virginia), us-east-2 (Ohio), us-west-2 (Oregon)
ca-central-1 (Canada)	ca-central-1 (Canada), us-east-1 (N. Virginia), us-east-2 (Ohio), us-west-2 (Oregon)
ca-west-1 (Calgary)	ca-west-1 (Calgary), us-east-1 (N. Virginia), us-east-2 (Ohio), us-west-2 (Oregon)

Quotas and Limits

Your AWS account has default quotas to maintain the performance of the service and to ensure appropriate usage of Amazon Bedrock. The default quotas assigned to an account might be updated depending on regional factors, payment history, fraudulent usage, and/or approval of a quota increase request. For more information, see the section called "Quotas" documentation and see the limits for the model.

Sample Code

Step 1 - AWS Account: If you have an AWS account already, skip this step. If you are new to AWS, sign up for an AWS account.

Step 2 - API key: Go to the Amazon Bedrock console and generate a long-term API key.

> **Using OpenAI-compatible SDKs with xAI models**
>
> Grok 4.7 is an xAI model. Amazon Bedrock serves its Responses and Chat Completions APIs through OpenAI-compatible endpoints, so those examples use the OpenAI Python SDK as the client. Configure the SDK with your Amazon Bedrock API key and an Amazon Bedrock base URL as shown below. The requests invoke the xAI model on Amazon Bedrock and are not sent to OpenAI.

Step 3 - Get the SDK: To use this getting started guide, you must have Python already installed. Then install the relevant software depending on the APIs you are using.

Responses API / Chat Completions API

```
pip install openai
```

Converse API

```
pip install boto3
```

Step 4 - Set environment variables: Configure your environment to use the API key for authentication.

bedrock-runtime

```
OPENAI_API_KEY="<provide your Bedrock API key>"
OPENAI_BASE_URL="https://bedrock-runtime.us-east-1.amazonaws.com/openai/v1"
```

Cross-Region inference profile required

On `bedrock-runtime`, name a cross-Region inference profile as the model — `us.xai.grok-4.7` or `global.xai.grok-4.7`. This model is not available for in-Region inference on that endpoint. Your IAM identity also needs `bedrock:InvokeModel` on your account's default project (`arn:aws:bedrock:{region}:{account-id}:project/default`) in addition to the inference profile.

Step 5 - Run your first inference request: Save the file as `bedrock-first-request.py`

Responses API (bedrock-runtime)

```
from openai import OpenAI

client = OpenAI()

response = client.responses.create(
    model="us.xai.grok-4.7",
    input="Can you explain the features of Amazon Bedrock?"
)
print(response)
```

Chat Completions API (bedrock-runtime)

```
from openai import OpenAI

client = OpenAI()

response = client.chat.completions.create(
    model="us.xai.grok-4.7",
    messages=[
        {"role": "user", "content": "Can you explain the features of Amazon
 Bedrock?"}
    ]
```

```
)
print(response)
```

Converse API (bedrock-runtime)

```
import boto3

client = boto3.client("bedrock-runtime", region_name="us-east-1")

response = client.converse(
    modelId="us.xai.grok-4.7",
    messages=[
        {"role": "user", "content": [{"text": "Can you explain the features of
 Amazon Bedrock?"}]}
    ]
)
print(response)
```

Usage Considerations and Limitations

- **Reasoning effort** — Reasoning is always active by default. You can configure effort through the `reasoning` parameter: `"low"`, `"medium"`, `"high"` (default), or `"xhigh"`. Reasoning content is encrypted and can be returned by passing `include: ["reasoning.encrypted_content"]` in the Responses API request. You can send the encrypted content back in subsequent turns to provide reasoning context for multi-turn conversations. The Chat Completions API does not return reasoning tokens.

```
response = client.responses.create(
    model="us.xai.grok-4.7",
    reasoning={"effort": "high"},
    include=["reasoning.encrypted_content"],
    input="Explain quantum entanglement simply."
)
print(response.output_text)
```

Grok 4.6

xAI — Grok 4.6

Model Details

Grok 4.6 is xAI's frontier model for coding, agentic tasks, and knowledge work. It builds on previous generations with a particular focus on long-running agents and more ambitious interactive workflows. 500K context window and configurable reasoning efforts (low, medium, high, xhigh).

Model launch date: [illegible]
EOL no sooner than: August 18, 2027
Legacy period: at least 6 months
Model lifecycle policy: Model lifecycle (For Models Launched Prior to Sept 7 2026)
Model EOL date: N/A
End User License Agreements and Terms of Use: View
Model lifecycle: Active
Context window: 500K tokens
Reasoning: Supported (configurable: low, medium, high, xhigh)

Input Modalities	Output Modalities	APIs supported	Endpoints supported

Capabilities and Features

Bedrock Features

Features supported using `bedrock-runtime` endpoint

Supported	Not Supported
✓ Projects (default project only) ✓ Invocation logs ✓ Response streaming ✓ Application inference profiles (`Invoke` and Converse APIs only; not supported with Responses or Chat Completions APIs) ✓ Implicit Prompt Caching ✓ Reasoning ✓ Guardrails	✗ Server-side tool use ✗ Intelligent prompt routing ✗ Count tokens ✗ Structured outputs ✗ Watermarking

Features supported using `bedrock-mantle` endpoint

Supported	Not Supported
✓ Client-side tool calling ✓ Reasoning ✓ Projects ✓ Abuse detection ✓ Response streaming ✓ Structured outputs ✓ Implicit Prompt Caching	✗ Application inference profiles (Responses and Chat Completions APIs only) ✗ Watermarking

Pricing

Inference option	Input	Output	Cache read
In-Region	$2.20	$6.60	$0.55

Inference option	Input	Output	Cache read
Geo CRIS	$2.20	$6.60	$0.55
Global CRIS	$2.00	$6.00	$0.50

All prices are per 1 million tokens. Pricing shown is for the Standard tier.

Priority and Flex tier support: In addition to Standard, Grok 4.6 supports the Priority and Flex service tiers. Priority is billed at **1.75x** the Standard per-token rate (a 75% premium) and Flex at **0.5x** the Standard rate (a 50% discount); apply these multipliers to the Standard rates shown above. For details on each service tier, see service tiers.

Programmatic Access

Use the following model IDs and endpoint URLs to access this model programmatically. For more information about the available APIs and endpoints, see APIs supported and Endpoints supported.

Endpoint	Model ID	In-Region endpoint URL	Geo inference ID	Global inference ID
`bedrock-mantle`	`xai.grok-4.6`	`https://bedrock-mantle.{region}.api.aws/openai/v1`	Not supported	Not supported
`bedrock-runtime`	`xai.grok-4.6`	Not supported	`us.xai.grok-4.6`	`global.xai.grok-4.6`

For example, if region is us-west-2 (Oregon), then the bedrock-mantle endpoint URL will be "https://bedrock-mantle.us-west-2.api.aws/openai/v1". On `bedrock-runtime`, the base URL is "https://bedrock-runtime.{region}.amazonaws.com/openai/v1" and requests must name the geographic cross-Region inference ID `us.xai.grok-4.6` or `global.xai.grok-4.6` as the model.

Service Tiers

Amazon Bedrock offers multiple service tiers to match your workload requirements. **Standard** provides pay-per-token access with no commitment (set `"service_tier": "default"` or omit the field). **Priority** delivers faster, prioritized processing for a price premium (set `"service_tier": "priority"`). **Flex** provides lower-cost access for flexible, non-time-sensitive workloads (set `"service_tier": "flex"`). For more information, see service tiers.

Geo inference details

The destination Regions available to a geographic inference profile depend on the source Region. To retrieve the current routing configuration, call GetInferenceProfile from the source Region.

Geo: US

Geo inference ID: `us.xai.grok-4.6`

Source Region	Destination Regions
us-east-1 (N. Virginia)	us-east-1 (N. Virginia), us-east-2 (Ohio), us-west-2 (Oregon)
us-east-2 (Ohio)	us-east-1 (N. Virginia), us-east-2 (Ohio), us-west-2 (Oregon)
us-west-1 (N. California)	us-east-1 (N. Virginia), us-east-2 (Ohio), us-west-1 (N. California), us-west-2 (Oregon)
us-west-2 (Oregon)	us-east-1 (N. Virginia), us-east-2 (Ohio), us-west-2 (Oregon)
ca-central-1 (Canada)	ca-central-1 (Canada), us-east-1 (N. Virginia), us-east-2 (Ohio), us-west-2 (Oregon)
ca-west-1 (Calgary)	ca-west-1 (Calgary), us-east-1 (N. Virginia), us-east-2 (Ohio), us-west-2 (Oregon)

Quotas and Limits

Your AWS account has default quotas to maintain the performance of the service and to ensure appropriate usage of Amazon Bedrock. The default quotas assigned to an account might be updated depending on regional factors, payment history, fraudulent usage, and/or approval of a quota increase request. For more information, see the section called "Quotas" documentation and see the limits for the model.

Sample Code

Step 1 - AWS Account: If you have an AWS account already, skip this step. If you are new to AWS, sign up for an AWS account.

Step 2 - API key: Go to the Amazon Bedrock console and generate a long-term API key.

> **Note**
>
> Grok 4.6 is an xAI model. Amazon Bedrock serves its Responses and Chat Completions APIs through OpenAI-compatible endpoints, so those examples use the OpenAI Python SDK as

the client. Configure the SDK with your Amazon Bedrock API key and an Amazon Bedrock base URL as shown below; the requests invoke the xAI model on Amazon Bedrock and are not sent to OpenAI.

Step 3 - Get the SDK: To use this getting started guide, you must have Python already installed. Then install the relevant software depending on the APIs you are using.

Responses API / Chat Completions API

```
pip install openai
```

Converse API

```
pip install boto3
```

Step 4 - Set environment variables: Configure your environment to use the API key for authentication.

bedrock-mantle

```
OPENAI_API_KEY="<provide your Bedrock API key>"
OPENAI_BASE_URL="https://bedrock-mantle.us-west-2.api.aws/openai/v1"
```

bedrock-runtime

```
OPENAI_API_KEY="<provide your Bedrock API key>"
OPENAI_BASE_URL="https://bedrock-runtime.us-east-1.amazonaws.com/openai/v1"
```

Note

On `bedrock-runtime`, name a cross-Region inference profile as the model — `us.xai.grok-4.6` or `global.xai.grok-4.6`. This model is not available for in-Region inference on that endpoint. Your IAM identity also needs `bedrock:InvokeModel` on your account's default project (`arn:aws:bedrock:{region}:{account-id}:project/default`) in addition to the inference profile.

Step 5 - Run your first inference request: Save the file as `bedrock-first-request.py`

Responses API (bedrock-mantle)

```
from openai import OpenAI

client = OpenAI()

response = client.responses.create(
    model="xai.grok-4.6",
    input="Can you explain the features of Amazon Bedrock?"
)
print(response)
```

Responses API (bedrock-runtime)

```
from openai import OpenAI

client = OpenAI()

response = client.responses.create(
    model="us.xai.grok-4.6",
    input="Can you explain the features of Amazon Bedrock?"
)
print(response)
```

Chat Completions API (bedrock-mantle)

```
from openai import OpenAI

client = OpenAI()

response = client.chat.completions.create(
    model="xai.grok-4.6",
    messages=[
        {"role": "user", "content": "Can you explain the features of Amazon
 Bedrock?"}
    ]
)
print(response)
```

Chat Completions API (bedrock-runtime)

```
from openai import OpenAI

client = OpenAI()

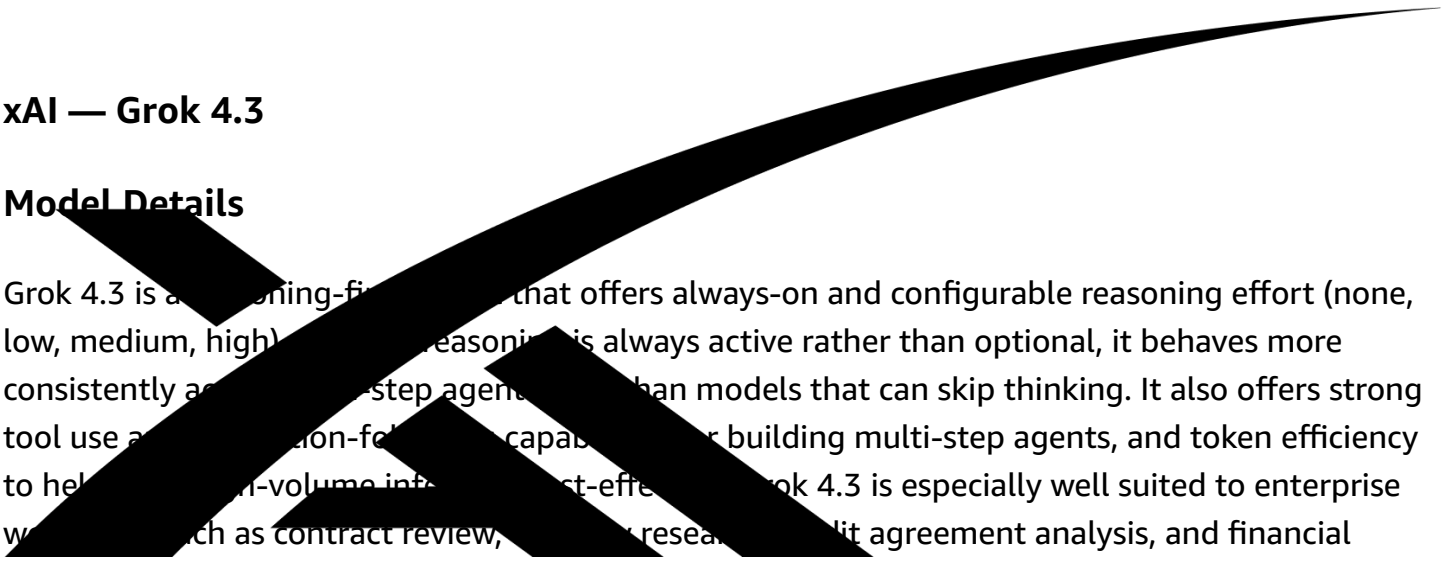
response = client.chat.completions.create(
    model="us.xai.grok-4.6",
    messages=[
        {"role": "user", "content": "Can you explain the features of Amazon
 Bedrock?"}
    ]
)
print(response)
```

Converse API (bedrock-runtime)

```
import boto3

client = boto3.client("bedrock-runtime", region_name="us-east-1")

response = client.converse(
    modelId="us.xai.grok-4.6",
    messages=[
        {"role": "user", "content": [{"text": "Can you explain the features of
 Amazon Bedrock?"}]}
    ]
)
print(response)
```



Usage Considerations and Limitations

Keep the following considerations and limitations in mind when you use Grok 4.6:

- **Reasoning effort** — Reasoning is always active by default. You can configure effort through the `reasoning` parameter: `"low"` (default), `"medium"`, `"high"`, or `"xhigh"`. Reasoning content is encrypted and can be returned by passing `include: ["reasoning.encrypted_content"]` in the Responses API request. You can send the encrypted content back in subsequent turns to provide reasoning context for multi-turn conversations. The Chat Completions API does not return reasoning tokens.

```
response = client.responses.create(
    model="us.xai.grok-4.6",
    reasoning={"effort": "high"},
    include=["reasoning.encrypted_content"],
    input="Explain quantum entanglement simply."
)
print(response.output_text)
```

Grok 4.3

xAI — Grok 4.3

Model Details

Grok 4.3 is a [illegible]ning-fi[illegible] that offers always-on and configurable reasoning effort (none, low, medium, high) [illegible]easoni[illegible]s always active rather than optional, it behaves more consistently a[illegible]-step agent[illegible]han models that can skip thinking. It also offers strong tool use a[illegible]ion-fo[illegible] capab[illegible]r building multi-step agents, and token efficiency to hel[illegible]n-volume int[illegible]st-effe[illegible]ok 4.3 is especially well suited to enterprise w[illegible]ch as contract review, [illegible] resea[illegible]lit agreement analysis, and financial document Q&A, while delivering consistent, high-quality results across conversational AI, search, chat, and multi-turn workflows. Grok 4.3 runs on Mantle, a new inference engine in Amazon Bedrock designed for price performance, with support for tool calling, structured output, and response streaming.

Model launch date: June 15, 2026
EOL no sooner than: June 15, 2027
Legacy period: at least 6 months
Model lifecycle policy: Model lifecycle (For Models Launched Prior to Sept 7 2026)
Model EOL date: N/A
End User License Agreements and Terms of Use: View
Model lifecycle: Active
Context window: 1M tokens
Reasoning: Supported (configurable: none, low, medium, high)

Input Modalities	Output Modalities	APIs supported	Endpoints supported
⊗ Audio	⊗ Embedding	✓ `Chat Completions`	⊗ `bedrock-runtime`
✓ Image	⊗ Image	✓ `Responses`	✓ `bedrock-mantle`
⊗ Speech	⊗ Speech	⊗ `Invoke`	
✓ Text	✓ Text	⊗ `Converse`	
⊗ Video	⊗ Video		

On `bedrock-mantle`, this model is served at `/openai/v1/responses`, not the default `/v1/responses`.

Bedrock Features

Features supported using `bedrock-mantle` endpoint

Supported	Not Supported
✓ Client-side tool calling ✓ Reasoning ✓ Projects ✓ Abuse detection ✓ Response streaming ✓ Structured outputs	⊗ Watermarking

Pricing

Inference option	Input	Output	Cache read
In-Region	$1.25	$2.50	$0.20

AWS GovCloud (US-West)

Inference option	Input	Output	Cache read
In-Region	$1.50	$3.00	$0.24

All prices are per 1 million tokens. Pricing shown is for the Standard tier. Grok 4.3 supports In-Region inference only.

Priority and Flex tier support: In addition to Standard, Grok 4.3 supports the Priority and Flex service tiers. Priority is billed at **1.75x** the Standard per-token rate (a 75% premium) and Flex at **0.5x** the Standard rate (a 50% discount); apply these multipliers to the Standard rates shown above. For details on each service tier, see service tiers.

Programmatic Access

Use the following model IDs and endpoint URLs to access this model programmatically. For more information about the available APIs and endpoints, see APIs supported and Endpoints supported.

Endpoint	Model ID	In-Region endpoint URL	Geo inference ID	Global inference ID
`bedrock-mantle`	`xai.grok-4.3`	`https://bedrock-mantle.{region}.api.aws/openai/v1`	Not supported	Not supported

For example, if region is us-west-2 (Oregon), then the bedrock-mantle endpoint URL will be "https://bedrock-mantle.us-west-2.api.aws/openai/v1".

Service Tiers

Amazon Bedrock offers multiple service tiers to match your workload requirements. **Standard** provides pay-per-token access with no commitment (set `"service_tier": "default"` or omit the field). **Priority** delivers the fastest response times for a price premium (set `"service_tier": "priority"`). **Flex** provides lower-cost access for flexible, non-time-sensitive workloads (set `"service_tier": "flex"`). **Reserved** provides dedicated throughput with a term commitment for predictable workloads; it is set at the account level rather than per request (contact your AWS account team to enable). For more information, see service tiers.

Standard	Priority	Flex	Reserved

Quotas and Limits

Your AWS account has default quotas to maintain the performance of the service and to ensure appropriate usage of Amazon Bedrock. The default quotas assigned to an account might be

updated depending on regional factors, payment history, fraudulent usage, and/or approval of a quota increase request. For more information, see the section called “Quotas” documentation and see the limits for the model.

When consuming on-demand throughput on the `bedrock-mantle` endpoint, available throughput scales over time. Not all requests within your quota are guaranteed to succeed during periods of high demand, so ramping gradually is important. For this model, default limits aren't surfaced directly through Service Quotas, so we recommend following the ramp as your guide.

Sample Code

Step 1 - AWS Account: If you have an AWS account already, skip this step. If you are new to AWS, sign up for an AWS account.

Step 2 - API key: Go to the Amazon Bedrock console and generate a long-term API key.

Step 3 - Get the SDK: To use this getting started guide, you must have Python already installed. Then install the relevant software depending on the APIs you are using.

Chat Completions API

```
pip install openai
```

Responses API

```
pip install openai
```

Step 4 - Set environment variables: Configure your environment to use the API key for authentication.

Chat Completions API

```
OPENAI_API_KEY="<provide your Bedrock API key>"
OPENAI_BASE_URL="https://bedrock-mantle.us-west-2.api.aws/openai/v1"
```

Responses API

```
OPENAI_API_KEY="<provide your Bedrock API key>"
OPENAI_BASE_URL="https://bedrock-mantle.us-west-2.api.aws/openai/v1"
```

Step 5 - Run your first inference request: Save the file as `bedrock-first-request.py`

Chat Completions API

```
from openai import OpenAI

client = OpenAI()

response = client.chat.completions.create(
    model="xai.grok-4.3",
    messages=[
        {"role": "user", "content": "Can you explain the features of Amazon
 Bedrock?"}
    ]
)
print(response)
```

Responses API

```
from openai import OpenAI

client = OpenAI()

response = client.responses.create(
    model="xai.grok-4.3",
    input="Can you explain the features of Amazon Bedrock?"
)
print(response)
```

Usage Considerations and Limitations

- **Reasoning effort** — Reasoning is always active by default. You can configure effort through the `reasoning` parameter: `{"effort": "none"}` (disables reasoning), `"low"` (default), `"medium"`, or `"high"`. Reasoning content is encrypted and can be returned by passing `include: ["reasoning.encrypted_content"]` in the Responses API request. You can send the encrypted content back in subsequent turns to provide reasoning context for multi-turn conversations. The Chat Completions API does not return reasoning tokens.

```
response = client.responses.create(
    model="xai.grok-4.3",
```

```
    reasoning={"effort": "high"},
    include=["reasoning.encrypted_content"],
    input="Explain quantum entanglement simply."
)
print(response.output_text)
```

- **Default parameters** — Grok 4.3 uses defaults that differ from the standard OpenAI API specification: `temperature` defaults to `0.7` (not 1), `top_p` defaults to `0.95` (not 1), and `max_completion_tokens` defaults to `131072`. Adjust these values explicitly if your application requires different behavior.

Z.AI

The following Z.AI models are available in Amazon Bedrock:

Model	Description
the section called "GLM 4.7"	GLM 4.7 is Z.AI's large language model with strong multilingual capabilities and solid performance on reasoning, coding, and knowledge benchmarks.
the section called "GLM 4.7 Flash"	GLM 4.7 Flash is Z.AI's lightweight model optimized for fast inference and low-latency tasks while maintaining strong general capabilities.
the section called "GLM 5"	GLM 5 is Z.AI's frontier-class general-purpose model with 744B parameters and 40B active, optimized for complex systems engineering and long-horizon agentic tasks.
the section called "GLM 5.3"	GLM 5.3 is Z.AI's flagship open weight model for agentic coding and long-horizon engineering work, with a 1M-token context window and selectable reasoning effort levels.

GLM 4.7

Z.AI — GLM 4.7

Model Details

GLM 4.7 is Z.AI's large language model with strong multilingual capabilities and solid performance on reasoning, coding, and knowledge benchmarks. For more information about model development and performance, see the model/service card.

Model launch date: Dec 22, 2025
EOL no sooner than: Dec 22, 2026
Legacy period: at least 6 months
Model lifecycle policy: Model lifecycle (For Models Launched Prior to Sept 7 2026)
Model EOL date: March 30, 2027
End User License Agreements and Terms of Use: View
Model lifecycle: Legacy
Context window: 203K tokens
Max output tokens: 128K

Input Modalities	Output Modalities	APIs supported	Endpoints supported

Pricing

For pricing information, see the Amazon Bedrock Pricing page.

Programmatic Access

Use the following model IDs and endpoint URLs to access this model programmatically. For more information about the available APIs and endpoints, see APIs supported and Endpoints supported.

Endpoint	Model ID	In-Region endpoint URL	Geo inference ID	Global inference ID
bedrock-runtime	zai.glm-4.7	https://bedrock-runtime.{region}.amazonaws.com	Not supported	Not supported
bedrock-mantle	zai.glm-4.7	https://bedrock-mantle.{region}.api.aws/v1	Not supported	Not supported

For example, if region is us-east-1 (N. Virginia), then the bedrock-runtime endpoint URL will be "https://bedrock-runtime.us-east-1.amazonaws.com" and for bedrock-mantle will be "https://bedrock-mantle.us-east-1.api.aws/v1".

Service Tiers

Amazon Bedrock offers multiple service tiers to match your workload requirements. **Standard** provides pay-per-token access with no commitment (set `"service_tier": "default"` or omit the field). **Priority** delivers the fastest response times for a price premium (set `"service_tier": "priority"`). **Flex** provides lower-cost access for flexible, non-time-sensitive workloads (set `"service_tier": "flex"`). **Reserved** provides dedicated throughput with a term commitment for predictable workloads; it is set at the account level rather than per request (contact your AWS account team to enable). For more information, see service tiers.

Standard	Priority	Flex	Reserved
✓	✓	✓	✗

Regional Availability

Regional availability at a glance

Amazon Bedrock offers three inference options: **In-Region** keeps requests within a single Region for strict compliance, **Geo Cross-Region** routes across Regions within a geography (such as US, EU,

and APAC) while respecting data residency, and **Global Cross-Region** routes anywhere worldwide when there are no residency constraints. Refer to the the section called "Regional availability by models" page for more details.

Region	In-Region	Geo	Global
us-east-1 (N. Virginia)	✓	✗	✗
us-east-2 (Ohio)	✓	✗	✗
us-west-2 (Oregon)	✓	✗	✗
eu-north-1 (Stockholm)	✓	✗	✗
eu-west-2 (London)	✓	✗	✗
ap-northeast-1 (Tokyo)	✓	✗	✗
ap-south-1 (Mumbai)	✓	✗	✗
ap-southeast-2 (Sydney)	✓	✗	✗
ap-southeast-3 (Jakarta)	✓	✗	✗
sa-east-1 (São Paulo)	✓	✗	✗
ap-southeast-4 (Melbourne)	✓	✗	✗
ap-northeast-2 (Seoul)	✓	✗	✗
ap-southeast-1 (Singapore)	✓	✗	✗

Quotas and Limits

Your AWS account has default quotas to maintain the performance of the service and to ensure appropriate usage of Amazon Bedrock. The default quotas assigned to an account might be updated depending on regional factors, payment history, fraudulent usage, and/or approval of a quota increase request. For more information, see the section called "Quotas" documentation and see the limits for the model.

Sample Code

Step 1 - AWS Account: If you have an AWS account already, skip this step. If you are new to AWS, sign up for an AWS account.

Step 2 - API key: Go to the Amazon Bedrock console and generate a long-term API key.

Step 3 - Get the SDK: To use this getting started guide, you must have Python already installed. Then install the relevant software depending on the APIs you are using.

Chat Completions API

```
pip install boto3 openai
```

Invoke/Converse API

```
pip install boto3
```

Step 4 - Set environment variables: Configure your environment to use the API key for authentication.

Chat Completions API

```
OPENAI_API_KEY="<provide your Bedrock API key>"
OPENAI_BASE_URL="https://bedrock-runtime.<your-region>.amazonaws.com/openai/v1"
```

Invoke/Converse API

```
AWS_BEARER_TOKEN_BEDROCK="<provide your Bedrock API key>"
```

Step 5 - Run your first inference request: Save the file as `bedrock-first-request.py`

Chat Completions API

```
from openai import OpenAI

client = OpenAI()
```

```
response = client.chat.completions.create(
    model="zai.glm-4.7",
    messages=[{"role": "user", "content": "Can you explain the features of Amazon
 Bedrock?"}]
    )
print(response)
```

Invoke API

```
import json
import boto3

client = boto3.client('bedrock-runtime', region_name='us-east-1')
response = client.invoke_model(
    modelId='zai.glm-4.7',
    body=json.dumps({
            'messages': [{ 'role': 'user', 'content': 'Can you explain the features
 of Amazon Bedrock?'}],
            'max_tokens': 1024
    })
)
print(json.loads(response['body'].read()))
```

Converse API

```
import boto3

client = boto3.client('bedrock-runtime', region_name='us-east-1')
response = client.converse(
    modelId='zai.glm-4.7',
    messages=[
        {
            'role': 'user',
            'content': [{'text': 'Can you explain the features of Amazon Bedrock?'}]
        }
    ]
)
print(response)
```

GLM 4.7 Flash

Z.AI — GLM 4.7 Flash

Model Details

GLM 4.7 Flash is Z.AI's lightweight model optimized for fast inference and low-latency tasks while maintaining strong general capabilities. For more information about model development and performance, see the model/service card.

Model launch date: Jan 19, 2026
EOL no sooner than: Jan 19, 2027

print(response)
```

GLM 5

Z.AI — GLM 5

Model Details

GLM 5 is a frontier-class, general-purpose large language model optimized for complex systems engineering and long-horizon agentic tasks. It builds on the GLM 4.5 agent-centric lineage and is designed to support multi-step reasoning, math (including AIME-style benchmarks), advanced coding, and tool-augmented workflows, with long context support suitable for sophisticated agents and enterprise applications. For more information about model development and performance, see the model card.

Model launch date: Feb 11, 2026

        }
    ]
)
```

```
print(response)
```

GLM 5.3

Z.AI — GLM 5.3

Model Details

GLM 5.3 is Z.AI's flagship open weight text generation model for complex software engineering and agentic tasks. It uses a Mixture-of-Experts architecture with 753B total parameters (744B excluding the multi-token-prediction layer) and approximately 40B active per token, and is built on the same base model as GLM 5.2 with improvements driven by scaled post-training. The model provides a 1M-token context window with up to 128K output tokens, and supports selectable reasoning effort levels so you can trade latency and token consumption against task performance. Typical uses include agentic coding and autonomous software engineering, terminal and CLI task execution, repository-scale code generation and refactoring, long-horizon multi-step engineering tasks spanning many tool calls, infrastructure diagnosis, and long-context analysis of large codebases. It supports function calling, structured JSON output, and response streaming including streamed reasoning content. For more information about model development and performance, see the model card.

> **Note**
>
> Access to this model is limited to eligible customers. For more information, contact your AWS account team.

Model launch date: October 5, 2026
EOL no sooner than: Not Applicable, at least 45 day EOL Notice will be provided
Legacy period: at least 45 days
Model lifecycle policy: Bedrock Model Lifecycle
Model EOL date: N/A
Model lifecycle: Active
Context window: 1M tokens
Max output tokens: 128K

Reasoning: Supported (effort configurable: low, medium, high, xhigh, max; default max)
End User License Agreements and Terms of Use: View

Input Modalities	Output Modalities	APIs supported	Endpoints supported
⊗ Audio	⊗ Embedding	✓ `Responses`	✓ `bedrock-runtime`
⊗ Image	⊗ Image	✓ `Chat Completions`	⊗ `bedrock-mantle`
⊗ Speech	⊗ Speech	✓ `Converse`	
✓ Text	✓ Text	✓ `Invoke`	
⊗ Video	⊗ Video		

> **Note**
>
> GLM 5.3 is available through cross-Region inference only. Requests must use the US geographic inference profile (`us.zai.glm-5.3`) or the global inference profile (`global.zai.glm-5.3`). In-Region on-demand inference is not supported.

Capabilities and Features

Bedrock Features

Features supported using `bedrock-runtime` endpoint

Supported	Not Supported
✓ Response streaming ✓ Implicit Prompt Caching (Responses and Chat Completions APIs)	⊗ Intelligent prompt routing ⊗ Abuse detection ⊗ Prompt optimization ⊗ Count tokens

Supported	Not Supported
Explicit Prompt Caching (Responses and Chat Completions APIs) Guardrails Model evaluation Prompt management Flows Agents Structured outputs Client-side tool calling Reasoning (effort configurable; see Reasoning effort below) Application inference profiles	Knowledge base Server-side tool use Watermarking

Explicit prompt caching using `bedrock-runtime` endpoint

For more information, see Prompt caching for faster model inference.

Explicit Prompt Caching supported	Min tokens per cache checkpoint	Cache retention (TTL)
Yes	1,024	At least 30 minutes

> **Note**
>
> By default, GLM 5.3 supports implicit (automatic) prompt caching. Configuring explicit cache controls can improve your cache hit rate, and therefore reduce latency and cost, so we recommend using explicit prompt caching. See the prompt caching guide for more details.

Reasoning effort

Reasoning is always active for GLM 5.3. You can trade latency and token consumption against task performance by setting the reasoning effort. The supported values are `low`, `medium`, `high`,

`xhigh`, and `max`. If you don't set a value, the model uses `max`. The values none and `minimal` are not supported for this model, and a request that sets either one fails with a validation error.

Set the effort with the parameter for the API that you call:

- Responses API — `reasoning.effort`
- Chat Completions API — `reasoning_effort`
- Converse API — `reasoning_effort` in `additionalModelRequestFields`
- InvokeModel API — `reasoning_effort` in the request body

Pricing

For pricing information, see the Amazon Bedrock Pricing page.

Programmatic Access

Use the following model IDs and endpoint URLs to access this model programmatically. GLM 5.3 is available through cross-Region inference only, so you must use the geo or global inference ID rather than the base model ID. For more information about the available APIs and endpoints, see APIs supported and Endpoints supported.

Endpoint	Model ID	In-Region endpoint URL	Geo inference ID	Global inference ID
`bedrock-runtime`	`zai.glm-5.3`	Not supported	`us.zai.glm-5.3`	`global.zai.glm-5.3`

On `bedrock-runtime`, the base URL is "https://bedrock-runtime.{region}.amazonaws.com" and requests must name a cross-Region inference ID — `us.zai.glm-5.3` or `global.zai.glm-5.3` — as the model. The base model ID is not available for in-Region inference.

Service Tiers

Amazon Bedrock offers multiple service tiers to match your workload requirements. **Standard** provides pay-per-token access with no commitment (set `"service_tier": "default"` or omit the field). **Priority** delivers the fastest response times for a price premium (set `"service_tier":`

`"priority"`). **Flex** provides lower-cost access for flexible, non-time-sensitive workloads (set `"service_tier": "flex"`). **Reserved** provides dedicated throughput with a term commitment for predictable workloads; it is set at the account level rather than per request (contact your AWS account team to enable). For more information, see service tiers.

Standard	Priority	Flex	Reserved
✓	✓	✓	✗

Regional Availability

Regional availability at a glance

Amazon Bedrock offers three inference options: **In-Region** keeps requests within a single Region for strict compliance, **Geo Cross-Region** routes across Regions within a geography (such as US, EU, and APAC) while respecting data residency, and **Global Cross-Region** routes anywhere worldwide when there are no residency constraints. Refer to the the section called “Regional availability by models” page for more details.

GLM 5.3 supports Geo Cross-Region inference from the US Regions and Global Cross-Region inference from the Regions listed in the following table. In-Region inference is not supported.

Region	In-Region	Geo	Global
`us-east-1` (N. Virginia)	✗	✓	✓
`us-east-2` (Ohio)	✗	✓	✓
`us-west-1` (N. California)	✗	✓	✓

Quotas and Limits

Your AWS account has default quotas to maintain the performance of the service and to ensure appropriate usage of Amazon Bedrock. The default quotas assigned to an account might be updated depending on regional factors, payment history, fraudulent usage, and/or approval of a quota increase request. For more information, see the section called "Quotas" documentation and see the limits for the model.

The burndown rate for Z.AI GLM 5.3 on the `bedrock-runtime` endpoint is 10x for output tokens (1 output token consumes 10 tokens from your quotas).

Sample Code

Step 1 - AWS Account: If you have an AWS account already, skip this step. If you are new to AWS, sign up for an AWS account.

Step 2 - API key: Go to the Amazon Bedrock console and generate a long-term API key.

Step 3 - Get the SDK: To use this getting started guide, you must have Python already installed. Then install the relevant software depending on the APIs you are using.

Chat Completions API

```
pip install boto3 openai
```

Invoke/Converse API

```
pip install boto3
```

Step 4 - Set environment variables: Configure your environment to use the API key for authentication.

Chat Completions API

```
OPENAI_API_KEY="<provide your Bedrock API key>"
OPENAI_BASE_URL="https://bedrock-runtime.<your-region>.amazonaws.com/openai/v1"
```

Invoke/Converse API

```
AWS_BEARER_TOKEN_BEDROCK="<provide your Bedrock API key>"
```

Step 5 - Run your first inference request: Save the file as `bedrock-first-request.py`

Chat Completions API

```
from openai import OpenAI

client = OpenAI()

response = client.chat.completions.create(
    model="us.zai.glm-5.3",
    messages=[{"role": "user", "content": "Can you explain the features of Amazon
 Bedrock?"}]
    )
print(response)
```

Invoke API

```
import json
import boto3

client = boto3.client('bedrock-runtime', region_name='us-east-1')
response = client.invoke_model(
    modelId='us.zai.glm-5.3',
    body=json.dumps({
            'messages': [{ 'role': 'user', 'content': 'Can you explain the features
 of Amazon Bedrock?'}],
            'reasoning_effort': 'max',
            'max_tokens': 1024
    })
)
print(json.loads(response['body'].read()))
```

Converse API

```
import boto3

client = boto3.client('bedrock-runtime', region_name='us-east-1')
response = client.converse(
    modelId='us.zai.glm-5.3',
    messages=[
        {
            'role': 'user',
            'content': [{'text': 'Can you explain the features of Amazon Bedrock?'}]
        }
    ]
)
print(response)
```

Model availability & compatibility

Amazon Bedrock supports a wide catalog of foundation models from leading providers. This chapter explains where each model is available, which APIs and endpoints support it, how to access it, and how to manage models throughout their lifecycle. For an overview of all available models with their capabilities and pricing, see *Models at a glance*.

> **Tip**
>
> For new applications, we recommend the `bedrock-runtime` endpoint. See the section called "Inference endpoints" for details.

In this chapter

- the section called "API compatibility" – Which APIs (InvokeModel, Converse, Chat Completions, Responses, Messages) each model supports.
- the section called "Endpoint availability" – Which endpoints (`bedrock-runtime`, `bedrock-mantle`) each model is hosted on.
- the section called "Regional availability by models" – AWS Regions and cross-Region inference profiles each model is available in.
- the section called "Regional availability by endpoints" – AWS Regions where each Amazon Bedrock endpoint (`bedrock-runtime`, `bedrock-mantle`) is available.
- the section called "Get list of models" – Programmatically list and discover available models on each endpoint.
- the section called "Model lifecycle" – Model versioning, deprecation timelines, and migration guidance.
- the section called "Request access to models" – Request and manage access to models in your account.
- the section called "Subscribe from Marketplace" – Use IAM product ID condition keys to control which models users can invoke.

Choosing a model

When picking a model, consider:

- **Capabilities** – modalities (text, image, embeddings), context window, and tool use support.
- **Endpoint and API** – whether the model is on `bedrock-runtime`, `bedrock-mantle`, or both, and which APIs it supports. See the section called “Inference endpoints”.
- **Region** – whether the model is available in the AWS Regions you operate in, or through a cross-Region inference profile.
- **Cost and throughput** – on-demand pricing vs. the section called “Provisioned Throughput”.

API compatibility

Amazon Bedrock supports four families of runtime APIs, each designed for different integration patterns and use cases.

Invoke family: `InvokeModel` handles synchronous, single-response calls. `InvokeModelWithResponseStream` returns responses as a real-time stream. `InvokeModelWithBidirectionalStream` enables full-duplex streaming for interactive applications. `AsyncInvoke` submits long-running requests asynchronously, storing output to Amazon S3.

Converse family: `Converse` provides a unified, model-agnostic interface for synchronous multi-turn conversations. `ConverseStream` delivers the same experience with streaming output.

OpenAI-compatible family: `ChatCompletions` implements the OpenAI Chat Completions interface, enabling existing OpenAI-based integrations to run on Bedrock with minimal changes. `Responses` API implements the OpenAI Responses interface, supporting stateful, agentic interactions with built-in tool use and conversation history management.

Messages family: `Messages` implements the Anthropic Messages interface, enabling existing Anthropic SDK-based integrations to run on Bedrock with minimal changes.

We will now look at the list of APIs supported by each model.

OpenAI

Use the `bedrock-runtime` endpoint for new applications. API support can differ between `bedrock-runtime` and `bedrock-mantle`, so this table summarizes a model's capabilities across endpoints and doesn't imply that each supported API is available on both endpoints. Check the endpoint-specific API tables on each model card before choosing a model. For example, GPT OSS models support Chat Completions, Converse, and Invoke on `bedrock-runtime`, but the Responses API for those models is available only on `bedrock-mantle`.

Note

* **Streaming Support:** Models marked with an asterisk (*) also support `InvokeModelWithResponseStream`, which returns responses as a real-time stream.

Models supporting StartAsyncInvoke

StartAsyncInvoke is an Amazon Bedrock Runtime API that allows callers to submit a model invocation request and immediately receive back an invocationArn without waiting for the model to finish processing. The job runs in the background, and the output is written to a caller-specified

S3 bucket once complete. Callers can then poll job status using the companion GetAsyncInvoke and ListAsyncInvokes APIs. The pattern is purpose-built for workloads involving large or latency-insensitive inputs, particularly video, audio, and bulk embedding generation, where holding an open synchronous connection would be impractical.

In terms of which models support it, the following models support StartAsyncInvoke:

- **TwelveLabs Marengo Embed 2.7** (twelvelabs.marengo-embed-2-7-v1:0) — required for video and audio input; InvokeModel only handles text and image
- **TwelveLabs Marengo Embed 3.0** (twelvelabs.marengo-embed-3-0-v1:0) — same pattern; async required for video/audio at scale
- **Amazon Nova Reel** (amazon.nova-reel-v1:0 and v1:1) — video generation is exclusively async; output lands in S3
- **Luma AI Ray2** (luma.ray-v2:0) — video generation is exclusively async; output lands in S3
- **Amazon Nova Multimodal Embeddings** (amazon.nova-2-multimodal-embeddings-v1:0) — async is required for video inputs larger than 25MB base64-encoded; sync is available for text, image, and document inputs

InvokeModelWithBidirectionalStream

`InvokeModelWithBidirectionalStream` is an Amazon Bedrock Runtime API that establishes a persistent, full-duplex channel between the caller and the model, allowing audio data to flow in both directions simultaneously and continuously. Unlike the standard `InvokeModel` or even `InvokeModelWithResponseStream` APIs, which follow a request-then-response pattern, this API keeps the connection open for the duration of a session so that the model can process incoming audio as it arrives and stream generated speech back in near real-time, without waiting for a complete utterance to finish. The interaction is structured around three phases: session initialization (where the client sends configuration events to set up the stream), audio streaming (where captured audio is encoded and sent as a continuous event stream), and response streaming (where the model simultaneously returns text transcriptions of user speech and synthesized audio output). `InvokeModelWithBidirectionalStream` cannot be used with Amazon Bedrock API keys and requires standard AWS credential-based authentication, reflecting its more complex session lifecycle compared to other Bedrock Runtime operations.

The following models support this API:

- **Amazon Nova 2 Sonic**: `amazon.nova-2-sonic-v1:0` uses it as its sole invocation path, since the speech-to-speech architecture fundamentally requires a live bidirectional channel that neither `InvokeModel` nor `Converse` can provide.

Endpoint availability

Amazon Bedrock supports two endpoints: bedrock-runtime and bedrock-mantle. For new applications, we recommend the `bedrock-runtime` endpoint. Please refer to the the section called "Inference endpoints" to learn more about how to choose between the two endpoints.

Endpoint	Supported APIs	Description
`bedrock-runtime.{region}.amazonaws.com` (recommended)	InvokeModel / Converse / Chat Completions / Responses API / Messages API	Region-specific endpoints for making inference requests for models hosted in Amazon Bedrock using the InvokeModel/ Converse/Chat Completions/Responses/Messages APIs. For more information, see Amazon Bedrock Runtime API operations.
`bedrock-mantle.{region}.api.aws`	Responses API / Chat Completions API / Messages API	Region-specific endpoints for making inference requests for models hosted in Amazon Bedrock using the OpenAI-compatible endpoints and the Anthropic Messages API.

The following tables show which Amazon Bedrock endpoints support each model, organized by provider. Endpoint support does not mean that a model is available through that endpoint in every AWS Region where the endpoint is available. For model availability by Region, see the section called "Regional availability by models".

Regional availability by models

Amazon Bedrock gives you three options so you can match the routing behavior of your inference calls to the scale, compliance, and cost requirements of your workload.

Process to enabling Bedrock models in GovCloud

Accessing Bedrock foundation models in AWS GovCloud (US) requires initiating the access request through the standard AWS account linked to your GovCloud account. You must first agree to the model's End User License Agreement (EULA) in a standard region (`us-east-1` or `us-west-2`), then enable the model in your GovCloud account. You can do this in two ways:

- **Console:** Sign in to your linked standard AWS account, open the Amazon Bedrock Chat/Text playground, choose the model, and run a prompt to establish the EULA.
- **AWS CLI:** Run `aws bedrock list-foundation-models` to get the model ID, then `aws bedrock list-foundation-model-agreement-offers --model-id <model-id>` to get the offer token, and finally `aws bedrock create-foundation-model-agreement --model-id <model-id> --offer-token <offerToken>`.

After completing either method, go to your GovCloud account and enable the model via the Model Access page. It may take a few minutes for entitlements to propagate. For the full walkthrough, see Process to enabling Bedrock models in GovCloud.

- **In-Region:** Your requests never leave the AWS Region you specify. Use this when regulations require strict single-Region data processing.
- **Geographic (Geo):** Bedrock routes your request to a Region within a defined geography (US, Canada, EU, Asia Pacific, Japan, Australia, or India), keeping data within that geography. Use this when you have data residency requirements tied to a geography rather than a single Region. Some Regions belong to more than one geography: from Asia Pacific (Sydney), for example, you can use either the `au` prefix, which routes only among Australian Regions, or the `apac` prefix, which can route to any supported Asia Pacific Region, so choose the prefix that matches your data residency requirement.
- **Global:** Bedrock routes your request to a supported commercial Region worldwide. For some models, global cross-Region inference is priced lower per token than geographic cross-Region inference. Use this when you have no data residency constraints.

Inference options at a glance

	In-Region	Geographic (Geo) Cross-Region	Global Cross-Region
How it works	Request is processed entirely within the single AWS Region you specify	Bedrock routes the request to a Region within a defined geography (US, CA, EU, APAC, JP, AU, IN)	Bedrock routes the request to any supported commercial Region worldwide
Data residency	Strictly within one Region	Within geographic boundaries (e.g., all EU Regions); prompts and outputs may move within the geography but not outside it	No geographic restricti ons; data may be processed in any commercial Region
Request routing	Processed in the Region you specify; subject to per-Region service quotas	Routed to a Region within the geography	Routed to a supported commercial Region worldwide

	In-Region	Geographic (Geo) Cross-Region	Global Cross-Region
Pricing	Standard on-demand pricing for that Region	Priced at source Region rates; no surcharge for cross-Region routing	Priced at source Region rates; no surcharge for cross-Region routing. For some models, the per-token price is lower than geographic cross-Region inference
modelId format	Direct model ID: `anthropic.claude-3-5-sonnet-20241022-v2:0`	Geography prefix + model ID: `us.anthropic.claude-3-5-sonnet-20241022-v2:0`	Global prefix + model ID: `global.anthropic.claude-3-5-sonnet-20241022-v2:0`
Best for	Strict single-Region compliance; Provisioned Throughput workloads	Data residency regulations scoped to a geography (e.g., GDPR in EU, data sovereignty requirements)	Cost efficiency with no data residency constraints

Now, let us look at Regional availability across all the models supported by Amazon Bedrock.

Inference profiles with limited model selection

Amazon Bedrock offers a range of inference options, including in-Region inference, geographic cross-Region inference, and global cross-Region inference, to help customers meet different performance, cost, and compliance needs. For example, in-Region inference is designed primarily for customers with data residency requirements, and keeps inference processing within a specific Region. The following table lists the inference profiles that are designated as inference profiles with limited model selection. Compared with other inference profiles, they are expected to offer a

narrower selection of models, new models or model versions might not be released for them, and quota increase requests might take longer to process.

Review the following considerations as you take dependencies on an inference profile with limited model selection.

Current inference profiles with limited model selection

Region name	Region code	Inference option
Canada (Central)	`ca-central-1`	Canada cross-Region inference
Canada West (Calgary)	`ca-west-1`	Canada cross-Region inference
Asia Pacific (Seoul)	`ap-northeast-2`	In-Region inference
Asia Pacific (Singapore)	`ap-southeast-1`	In-Region inference
Europe (London)	`eu-west-2`	In-Region inference
Europe (Zurich)	`eu-central-2`	In-Region inference
South America (São Paulo)	`sa-east-1`	In-Region inference

The designation applies only to the inference options listed in this table. Other cross-Region inference profiles that you invoke from these Regions keep their standard model selection. These include global cross-Region inference and geographic cross-Region inference profiles that route requests outside these Regions.

Considerations

Model availability expectations

- New models, and new versions of existing models, might not be released for inference profiles with limited model selection, or might be released much later than for other inference profiles.
- When a model reaches end of life, a successor model might not be released for an inference profile with limited model selection.

Model lifecycle

- Models offered through inference profiles with limited model selection continue to follow the standard Amazon Bedrock model lifecycle, including advance notice of Legacy and End-of-Life dates.
- When a model reaches its End-of-Life date, it's no longer available through the inference profile. A replacement model might not be offered through the same inference profile for you to migrate to. Plan your workloads around published End-of-Life dates, including how you'll migrate to another inference profile if needed.

Choosing an inference profile with limited model selection

In-Region and geographic inference profiles are best suited for workloads whose compliance, regulatory, or contractual obligations require inference to be processed within a specific Region or geography. However, some of these inference profiles might be subject to the limitations described on this page.

If you use these inference profiles, we recommend that you do the following:

- **Plan for model lifecycle events.** Treat each model's End-of-Life date as a planning milestone. Don't expect a successor model to become available through the same inference profile.
- **Reassess your requirements periodically.** If your data residency requirements change, evaluate other inference profiles. For workloads that don't require inference to be processed within a specific Region or geography, global cross-Region inference and other geographic cross-Region inference profiles, such as US and EU cross-Region inference, route requests across a broader set of AWS Regions.
- **Engage your AWS account team early.** Talk to your account team if your workload has long-term model or version requirements.

Regional availability by endpoints

The following tables show which AWS Regions support each Amazon Bedrock inference endpoint, organized by geography. The `bedrock-runtime` endpoint is available in every AWS Region where Amazon Bedrock is offered. The `bedrock-mantle` endpoint is available in a subset of those Regions. To choose between endpoints, see the section called “Inference endpoints”; for model-level Regional availability, see the section called “Regional availability by models”.

Get list of models

Amazon Bedrock provides separate model discovery experiences for its inference endpoints. For new applications, use `bedrock-runtime`. For an overview of the endpoints, see the section called "Inference endpoints".

- **`bedrock-runtime` (recommended)** – Use the AWS-native ListFoundationModels API to discover foundation models and ListInferenceProfiles to discover inference profiles. The OpenAI-compatible `GET /openai/v1/models` operation and `client.models.list()` aren't available on `bedrock-runtime`. Check each model card for endpoint-specific API support and the exact model or system inference profile ID to use.

  > **Note**
  >
  > The response also returns model IDs that aren't in the base model ID or base model IDs for Provisioned Throughput charts. These model IDs are deprecated or for backwards compatibility.

- **`bedrock-mantle` (compatibility)** – Use the OpenAI-compatible `/models` endpoint (for example, `client.models.list()` with the OpenAI SDK) to list the models available on `bedrock-mantle`.

Choose a tab to see code examples in an interface or language.

Discover models and inference profiles for `bedrock-runtime`

AWS CLI

List the Amazon Bedrock foundation models.

```
aws bedrock list-foundation-models
```

List the inference profiles available to your account.

```
aws bedrock list-inference-profiles
```

Get information about Anthropic Claude v2.

```
aws bedrock get-foundation-model --model-identifier anthropic.claude-
sonnet-4-20250514-v1:0
```

Python

List the Amazon Bedrock foundation models.

```
import boto3
bedrock = boto3.client(service_name='bedrock')

bedrock.list_foundation_models()
```

List the inference profiles available to your account.

```
import boto3
bedrock = boto3.client(service_name='bedrock')

bedrock.list_inference_profiles()
```

Get information about Anthropic Claude v2.

```
import boto3
bedrock = boto3.client(service_name='bedrock')

bedrock.get_foundation_model(modelIdentifier='anthropic.claude-sonnet-4-20250514-
v1:0')
```

curl

List the Amazon Bedrock foundation models. Requires AWS credentials in the environment (`AWS_ACCESS_KEY_ID`, `AWS_SECRET_ACCESS_KEY`, and optionally `AWS_SESSION_TOKEN`) and curl 7.75.0 or later for `--aws-sigv4` support.

```
curl -X GET "https://bedrock.us-east-1.amazonaws.com/foundation-models" \
    --aws-sigv4 "aws:amz:us-east-1:bedrock" \
    --user "$AWS_ACCESS_KEY_ID:$AWS_SECRET_ACCESS_KEY"
```

Get information about Anthropic Claude v2.

```
curl -X GET "https://bedrock.us-east-1.amazonaws.com/foundation-model/
anthropic.claude-sonnet-4-20250514-v1:0" \
    --aws-sigv4 "aws:amz:us-east-1:bedrock" \
    --user "$AWS_ACCESS_KEY_ID:$AWS_SECRET_ACCESS_KEY"
```

List models on `bedrock-mantle`

Note

The Anthropic SDK's `AnthropicBedrockMantle` client doesn't provide a model-listing resource. To list models on `bedrock-mantle`, use the OpenAI SDK or curl to call the OpenAI-compatible `/v1/models` endpoint.
Model discovery is always on `/v1/models`, including for models whose inference APIs use a different base path. Some models, such as the proprietary OpenAI GPT models and the Google Gemma models, are served for inference under `/openai/v1` rather than `/v1`, but they are still listed by `/v1/models`. A request to `/openai/v1/models` returns `404`.

OpenAI SDK (Python)

```
# List all available models using the OpenAI SDK
# Requires OPENAI_API_KEY and OPENAI_BASE_URL environment variables

from openai import OpenAI

client = OpenAI()
```

```
models = client.models.list()

for model in models.data:
    print(model.id)
```

curl

```
# List all available models
# Requires OPENAI_API_KEY and OPENAI_BASE_URL environment variables

curl -X GET $OPENAI_BASE_URL/models \
   -H "Authorization: Bearer $OPENAI_API_KEY"
```

Model lifecycle

This page describes the model lifecycle policy for models launched on Amazon Bedrock on or after September 7, 2026. For models launched before this date, see the section called "Model lifecycle (Legacy)".

Every model on Amazon Bedrock has one of three states: **Active**, **Legacy**, or **End-of-Life (EOL)**. You can see the status of a model in the console, and when you make a GetFoundationModel or ListFoundationModels call, the state is shown in the `modelLifecycle` field in the response.

Before using a model, review the model card for its EOL policy, including how much notice you will receive before the model is deprecated. Where applicable, model cards show two things:

1. An **EOL no sooner than** date: the model will not reach EOL before this date.
2. The **Legacy period**: the notice period before EOL. There are two Legacy periods: 6 months and 45 days. Most models have a 6-month Legacy period.

GPT-6.1 Sol follows the OpenAI first-party model's lifecycle and end-of-life terms. This includes the deprecation notice period and exceptions for safety or compliance. This model has no separate Bedrock minimum-availability date. See the section called "GPT-6.1 Sol" and OpenAI model deprecation notice periods.

When a model enters its Legacy period, the EOL date of the model is added to the model card.

> **Note**
>
> Model lifecycle dates are specific to Amazon Bedrock and may differ from dates published by model providers (such as Anthropic or Cohere). For Amazon Bedrock usage, only the dates on the model card apply.

Active

Active — The model provider is actively working on this version. In most cases, model providers sunset a model after newer versions become available. For a list of currently active models and their supported regions, see Regional availability. For model specific details, see Model cards.

Legacy and end-of-life (EOL) models

Legacy — The model is scheduled for retirement. At the beginning of the Legacy period, we notify you of the EOL date for the model. You can keep using the model, but you should migrate to an Active model before the EOL date. Once the Legacy period begins, new customers can't adopt the model, and existing customers may lose access after 15 days of inactivity. You can't create a new Provisioned Throughput for models in the Legacy state.

EOL — After the EOL date, the model is removed from all AWS Regions and requests made to it will fail, unless there is a private arrangement between you and the provider for continued access. Migrate to an Active model before the EOL date; migration will not happen automatically.

Customized Models and Lifecycle Behavior

When a foundation model transitions to the Legacy state, customization capabilities become restricted. If you previously fine-tuned or customized the model before it entered the Legacy state, you may:

- Create a new custom model deployment for on-demand inference.
- Continue using any existing on-demand deployments or any existing Provisioned Throughput (PT) endpoints, provided they were created before the model entered Legacy state.

However, after the model is in Legacy state, you cannot create new fine-tuning jobs on that model. You cannot create new Provisioned Throughput (PT) endpoints. New customers cannot start using the Legacy model and existing customers may lose access after 15 days of inactivity.

Because Legacy models are scheduled for retirement, customers are strongly encouraged to begin transitioning workloads and customized deployments to an Active model as soon as the Legacy announcement is made, and complete migration before the model's End-of-Life (EOL) date.

Model lifecycle (Legacy)

> **Important**
>
> This page applies to all models launched on Amazon Bedrock before September 7, 2026. For models launched on or after September 7, 2026, see the section called “Model lifecycle”.

Amazon Bedrock is continuously working to bring the latest versions of foundation models that have better capabilities, accuracy, and safety. As we launch new model versions, you can test them with the Amazon Bedrock console or API, and migrate your applications to benefit from the latest model versions.

A model offered on Amazon Bedrock can be in one of these states: **Active**, **Legacy**, or **End-of-Life (EOL)**. You can see the status of offered models in the console and in the tables below. Additionally, when you make a GetFoundationModel or ListFoundationModels call, the state of the model will be shown in the `modelLifecycle` field in the response. Once a model launches on Amazon Bedrock, it will remain on Amazon Bedrock for at least 12 months before the EOL date.

> **Note**
>
> Model lifecycle dates on this page are specific to Amazon Bedrock and may differ from dates published by model providers (such as Anthropic or Cohere). For Amazon Bedrock usage, only the dates on this page apply.

Active versions

Active — The model provider is actively working on this version. In most cases, model providers sunset a model after newer versions become available. For a list of currently active models and their supported regions, see Regional availability. For model specific details, see Model cards.

Legacy and end-of-life (EOL) models

Legacy — We will notify you when a model provider moves a model to the Legacy state. **A model will be in the Legacy state for at least 6 months before the EOL date**. While you can continue to use a Legacy model during this period, you should plan to transition to an Active model before the EOL date. New customers can't use Legacy models and existing customers may lose access to Legacy models after 15 days of inactivity.

For models with EOL dates after February 1, 2026: After a minimum of 3 months in the Legacy state, a model will enter the public extended access portion of the Legacy period. During this public extended access period, active users of a Legacy model can continue to use it until the EOL date (for a minimum of 3 months), but you should expect higher pricing, which will be set by the model provider. When the model first enters the Legacy state, we will notify you of the provider's chosen date to transition a model to public extended access (which will be at least 3 months from notification) and pricing changes (if any). We will also notify you before any further pricing changes during the public extended access period.

You can't create a new Provisioned Throughput for models in the Legacy state.

EOL — After the EOL date, a model will be marked EOL in the console and in the following table. On, or soon after the EOL date, the model is no longer available for use in all AWS Regions and requests made to this version will fail, unless there is a private arrangement between you and the provider for continued access. You will need to migrate to the latest model by updating your application code before the EOL date. Migration will not happen automatically.

Model lifecycle state can differ by AWS Region. The **Regions** column in the following tables lists only the Regions covered by a model's announced EOL date. A model can remain Active in other Regions, and the absence of a Region from a row doesn't mean the model will stay available there indefinitely. To check the current state for the Region you use, call ListFoundationModels or GetFoundationModel in that Region and read the `modelLifecycle` field.

Models with a scheduled EOL date

The following models are in the Legacy state with an announced EOL date. Migrate to an Active model before the EOL date.

Model provider	Model name	Model ID	Regions	Legacy date	EOL date	Public extended access start date

The public extended access date indicates when a Legacy model enters the public extended access portion of the Legacy period. During this phase, pricing may increase as set by the model provider. The model remains available until its EOL date.

Customized Models and Lifecycle Behavior

When a foundation model transitions to the Legacy state, customization capabilities become restricted. If you previously fine-tuned or customized the model before it entered the Legacy state, you may:

- Create a new custom model deployment for on-demand inference.
- Continue using any existing on-demand deployments or any existing Provisioned Throughput (PT) endpoints, provided they were created before the model entered Legacy state.

However, after the model is in Legacy state, you cannot create new fine-tuning jobs on that model. You cannot create new Provisioned Throughput (PT) endpoints. New customers cannot start using the legacy model and existing customers may lose access after 15 days of inactivity.

Because Legacy models are scheduled for retirement, customers are strongly encouraged to begin transitioning workloads and customized deployments to an Active model as soon as the Legacy announcement is made, and complete migration before the model's End-of-Life (EOL) date.

Request access to models

Access to many Amazon Bedrock foundation models is enabled by default with the correct AWS Marketplace permissions. To get started, simply select a model from the model catalog in the Amazon Bedrock console and open it in the playground or invoke the model using the InvokeModel or Converse API operations. For information about the different models supported in Amazon Bedrock, see Amazon Bedrock foundation model information. For information about model pricing, see Amazon Bedrock Pricing.

Default model access applies in all commercial AWS Regions where the model is supported. For programmatic access to third-party models, see Manage model access using SDK and CLI.

Additional account-level access

Some models require additional account-level access. Completing model activation requirements, such as AWS Marketplace subscription and provider prerequisites, doesn't grant this additional access. Access is determined separately for each AWS account, so accounts in the same AWS Organization can have different access. If you complete the activation requirements and verify that the model is supported in the AWS Region but still receive an `AccessDeniedException`, contact AWS Sales for additional access options.

Understanding automatic model access

When you invoke a third-party model for the first time in your account, Amazon Bedrock automatically initiates the subscription process in the background. During this setup period (up to 15 minutes), your API calls may succeed temporarily while the subscription is being finalized. If any prerequisites are missing, the subscription attempt fails and subsequent API calls will return `AccessDeniedException`. After granting the necessary permissions, it may take up to 2 minutes for the subscription to complete. During this time, API calls may continue to return `AccessDeniedException`. Once the subscription is complete, subsequent invocations can proceed if your account has access to the model. To avoid subscription failures, verify all prerequisites before invoking models in production.

Prerequisites for successful model access:

1. **AWS Marketplace permissions**: Your IAM role must have `aws-marketplace:Subscribe`, `aws-marketplace:Unsubscribe`, and `aws-marketplace:ViewSubscriptions` permissions. See the section called "Grant permissions to request access to foundation models with a product ID" for details.
2. **Anthropic models**: For Anthropic models earlier than Claude Opus 4.7, you must complete the First Time Use (FTU) form before invoking the model. This requirement does not apply to Anthropic models accessed through the `bedrock-mantle` endpoint. For more information, see the section called "Step 2: [Anthropic models only] Put use case for first-time user".
3. **Valid payment method**: Your AWS account must have a valid payment method configured for AWS Marketplace purchases.

Where the first invocation has to come from: The invocation that initiates the subscription is authorized like any other `bedrock:InvokeModel` request, against the policies that apply to the principal making it. If those policies restrict `bedrock:InvokeModel` with condition keys, the invocation has to be made by a principal, and from a request context, that satisfies them. Otherwise it fails with `AccessDeniedException` and the subscription isn't initiated. For example, if the permission is scoped with an `IpAddress` condition on `aws:SourceIp`, make the first invocation from a host whose address the condition permits.
The address that a host reports for itself isn't always the address that AWS records as `aws:SourceIp`, and it can differ between requests from the same host. To find the value that your condition has to permit, read the `sourceIPAddress` field of the CloudTrail event for the invocation, as described in the section called "Monitor APIs". Also note that `aws:SourceIp` isn't present in the request context when the request is made through a VPC endpoint, and that network context is redacted when an AWS service calls Amazon Bedrock on your behalf. In both cases an `IpAddress` condition on that key can't be satisfied. For more information, see AWS global condition context keys in the *IAM User Guide*.

Note

Anthropic requires first-time customers to submit use case details before invoking a model earlier than Claude Opus 4.7, once per account or once at the organization's

management account. This requirement does not apply to Anthropic models accessed through the `bedrock-mantle` endpoint. You can submit use case details by selecting an Anthropic model from the model catalog in the Amazon Bedrock console or calling the `PutUseCaseForModelAccess` API command. In most cases, access to the model is granted as soon as use case details are successfully submitted. Submission doesn't always complete immediately, however. The model agreement can enter a pending state, during which invoking the model continues to return `AccessDeniedException` even though your submission succeeded. AWS sends you an email when the agreement finishes being set up. To check the state of your submission rather than waiting, call `GetFoundationModelAvailability` and read the `agreementAvailability` status, as described in the section called "Step 4: Get foundation model availability". The form submission at the root account will be inherited by other accounts in the same AWS Organization.

The use case form requires a description of your intended use and a website URL. If you are an individual developer or student without a company website, you can provide a personal portfolio, GitHub profile, or project URL that describes your use case.

Note

For 3P models, by invoking/using the model for the first time you are agreeing to the applicable End User License Agreement. For more information, see AWS Service Terms and Serverless Third-Party Model License Agreements.

Organizations that need to review and agree to EULA before allowing model usage should:

1. Initially block model access using Service Control Policies (SCP) or IAM policies
2. Review the EULA terms
3. Enable model access through SCP/IAM policies only if you agree to the EULA terms

Topics

- Request access to models using the console
- Grant IAM permissions to request access to Amazon Bedrock foundation models with a product ID
- Manage model access using SDK and CLI
- Access Amazon Bedrock foundation models in AWS GovCloud (US)

Request access to models using the console

If you are signed in to the AWS Management Console, you can complete the model access requirements without using the AWS CLI or an SDK. Open the Amazon Bedrock console and use the following paths.

- **Most models** – Choose **Model catalog** in the navigation pane, choose a model, and then open it in the playground. Amazon Bedrock starts the subscription for you on the first invocation, so there is no access request to submit. Your identity still needs the AWS Marketplace permissions described in Grant IAM permissions to request access to Amazon Bedrock foundation models with a product ID.
- **Anthropic models** – For models earlier than Claude Opus 4.7, submit your first-time use case details before you invoke the model. Choose an Anthropic model from **Model catalog** and open it in the playground, or go to the Anthropic providers page, and then complete the form. If the management account for your organization has already submitted these details, you can use Anthropic models right away.
- **AWS Marketplace permissions** – Attach the policy described in Grant IAM permissions to request access to Amazon Bedrock foundation models with a product ID in the IAM console.

> **Note**
>
> The **Model access** page under **Bedrock configurations** applies to AWS GovCloud (US). In commercial AWS Regions, access to most models is enabled on first use and there is no access request to submit on that page. For the GovCloud procedure, see Access Amazon Bedrock foundation models in AWS GovCloud (US).

Grant IAM permissions to request access to Amazon Bedrock foundation models with a product ID

You can manage model access permissions by creating custom IAM policies. To modify access to Amazon Bedrock foundation models, you first need to attach an identity-based IAM policy with the following AWS Marketplace actions to the IAM role that allows access to Amazon Bedrock.

When you first invoke an Amazon Bedrock serverless model served from AWS Marketplace in an account, Bedrock attempts to automatically enable the model for your account. For this auto-enablement to work, AWS Marketplace permissions are required.

If you can't assume AWS Marketplace permission, someone with AWS Marketplace permissions must enable the model for the account as a one-time step (either manually or through auto-enablement). After the model is enabled, you can invoke the model without needing AWS Marketplace permissions. Users don't need AWS Marketplace subscription permissions to invoke models after they've been enabled. These permissions are only required the first time a model is being used in an account.

Access to Amazon Bedrock serverless foundation models with a product ID is controlled by the following IAM actions:

IAM action	Description	Applies to which models
aws-marketplace:Subscribe	Allows an IAM entity to subscribe to AWS Marketplace products, including Amazon Bedrock foundation models.	Only Amazon Bedrock serverless models that have a product ID in AWS Marketplace.
aws-marketplace:Unsubscribe	Allows an IAM identity to unsubscribe from AWS Marketplace products, including Amazon Bedrock foundation models.	Only Amazon Bedrock serverless models that have a product ID in AWS Marketplace.
aws-marketplace:ViewSubscriptions	Allows an IAM identity to return a list of AWS Marketplace products, including Amazon Bedrock foundation models.	Only Amazon Bedrock serverless models that have a product ID in AWS Marketplace.

Note

For the `aws-marketplace:Subscribe` action only, you can use the `aws-marketplace:ProductId` condition key to restrict subscription to specific models.

For an IAM identity to request access to models with a product ID

The identity must have a policy attached that allows `aws-marketplace:Subscribe`.

Note

If an identity has already subscribed to a model in one AWS Region, the model becomes available for the identity to request access in all AWS Regions in which the model is available, even if `aws-marketplace:Subscribe` is denied for other Regions.

For information on creating the policy, see Quickstart.

For the `aws-marketplace:Subscribe` action only, you can use the `aws-marketplace:ProductId` condition key to restrict subscription to specific models.

Note

Models from the following providers aren't sold through AWS Marketplace and don't have product keys, so you can't scope the `aws-marketplace` actions to them:

- Amazon
- DeepSeek
- Google
- Meta
- MiniMax
- Mistral AI
- Moonshot AI
- NVIDIA
- Qwen
- xAI
- Z.AI

Some providers sell only part of their model catalog through AWS Marketplace. The following models don't have product keys even though other models from the same provider do:

- OpenAI open-weight models: gpt-oss-120b, gpt-oss-20b, gpt-oss-safeguard-120b, and gpt-oss-safeguard-20b. These models are available to all Amazon Bedrock users and don't require a AWS Marketplace subscription.

- Writer Palmyra Vision 7B.

This list covers providers whose models have no product key at all. It isn't a complete list of models without a documented product ID. To check a specific model, see the **Marketplace product ID** field on its model card in models at a glance. If a model's card doesn't show that field, scope your policy by model ID instead.
You can, however, prevent the usage of these models by denying Amazon Bedrock actions and specifying these model IDs in the `Resource` field. For an example, see Prevent an identity from using a model after access has already been granted.

Select a section to see IAM policy examples for a specific use case:

Topics

- Prevent an identity from requesting access to a model with a product ID
- Prevent an identity from using a model after access has already been granted

Prevent an identity from requesting access to a model with a product ID

To prevent an IAM entity from requesting access to a specific model that has a product ID, attach an IAM policy to the user that denies the `aws-marketplace:Subscribe` action and scope the `Condition` field to the product ID of the model.

For example, you can attach the following policy to an identity to prevent it from subscribing to the Anthropic Claude 3.5 Sonnet model:

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Effect": "Deny",
            "Action": [
                "aws-marketplace:Subscribe"
            ],
            "Resource": "*",
            "Condition": {
```

```
                "ForAnyValue:StringEquals": {
                    "aws-marketplace:ProductId": [
                        "prod-m5ilt4siql27k"
                    ]
                }
            }
        }
    ]
}
```

Note

Denying `aws-marketplace:Subscribe` alone will **not** block the first model invocation, because Amazon Bedrock **auto-initiates** the subscription in the background.
To **block model access from the start**, apply **Deny policies on `bedrock:InvokeModel`** at the **Organization (SCP) or Account (IAM) level**.

Note

With this policy, the IAM entity will have access to any newly added models by default. If the identity has already subscribed to the model in at least one Region, this policy doesn't prevent access in other Regions. Instead, you can prevent its usage by seeing the example in Prevent an identity from using a model after access has already been granted.

Prevent an identity from using a model after access has already been granted

If an IAM identity has already been granted access to a model, you can prevent usage of the model by denying all Amazon Bedrock actions and scoping the `Resource` field to the ARN of the foundation model.

For example, you can attach the following policy to an identity to prevent it from using the Anthropic Claude 3.5 Sonnet model in all AWS Regions:

JSON

```
{
```

```
    "Version":"2012-10-17",
    "Statement": [
        {
            "Effect": "Deny",
            "Action": [
                "bedrock:*"
            ],
            "Resource": [
                "arn:aws:bedrock:*::foundation-model/anthropic.claude-3-5-
sonnet-20240620-v1:0"
            ]
        }
    ]
}
```

Manage model access using SDK and CLI

Model access can be managed using SDK in addition to invoking the model. Below steps can be used to create/delete model access as well as check if access already exists or not. Note this is applicable only for third-party models.

> **Important**
>
> By invoking or using a third-party model, you are implicitly agreeing to the applicable End User License Agreement (EULA). For more information, see Serverless Third-Party Model License Agreements.

Follow these steps to manage model access programmatically:

- Prerequisites
- Step 1: List foundation model agreement offers
- Step 2: [Anthropic models only] Put use case for first-time user
- Step 3: Create foundation model agreement
- Step 4: Get foundation model availability
- [Optional] Step 5: Delete foundation model agreement

Prerequisites

- Attach the AmazonBedrockFullAccess policy to the IAM user/role used for the SDK/CLI.
- Bedrock SDK Setup: Set up the AWS SDK for Amazon Bedrock

  Note: Below instructions use python3 for the examples
- If you are using the AWS CLI, these commands require AWS CLI version 2.27.42 or later. Run `aws --version` to check your version and update if needed.
- Note the modelId of the model for which the access needs to be managed.

Step 1: List foundation model agreement offers

Use this API to get the agreement offers for a particular model. This will provide the offerToken used to create model access in next steps.

Documentation

- API: ListFoundationModelAgreementOffers
- CLI Documentation: list-foundation-model-agreement-offers

AWS CLI

```
aws bedrock list-foundation-model-agreement-offers --model-id <ModelId>
```

Python

```
# Placeholder for modelId
model_id = "<enter model id here>"
# Placeholder for offerId
offer_id = "<enter offer id here>"
try:
    # offerType= "ALL" means both public and private offers, if offerType isn't
 defined, the default would be "PUBLIC"
    model_agreement_offers_response =
 bedrock_client.list_foundation_model_agreement_offers(modelId=model_id,offerType="ALL")
    print(model_agreement_offers_response)
except ClientError as e:
    print(f"Failed to list foundation model offers for modelId: {model_id} due to
 the following error: {e}")
```

Step 2: [Anthropic models only] Put use case for first-time user

Used to put the first-time user use-case form required for some Anthropic models. This is a prerequisite for gaining access to those models in the account. This API is only required one time per account or per AWS organization across all commercial regions, with the exception of opt-in regions where this form needs to be filled again. This requirement does not apply to Anthropic models accessed through the `bedrock-mantle` endpoint.

> **Note**
>
> Starting with Claude Opus 4.7, Anthropic models don't require the FTU form. It's still required for earlier models, including Claude Sonnet 4.6, Claude Opus 4.6, Claude Haiku 4.5, and the Claude 3.x models.

Documentation

- API: PutUseCaseForModelAccess
- CLI Documentation: put-use-case-for-model-access

AWS CLI

```
aws bedrock put-use-case-for-model-access \
  --form-data <Base64EncodedFormData>
```

Python

```
# Placeholder for form data, replace the names
COMPANY_NAME = "<enter company name here>"
COMPANY_WEBSITE = "<enter company website here>"
INTENDED_USERS = "1" #for external users
INDUSTRY_OPTION = "<enter industry option here>"
OTHER_INDUSTRY_OPTION = "<enter other industry option here>"
USE_CASES = "<enter use cases here>"
form_data = {
    "companyName": COMPANY_NAME,
    "companyWebsite": COMPANY_WEBSITE,
    "intendedUsers": INTENDED_USERS,
    "industryOption": INDUSTRY_OPTION,
    "otherIndustryOption": OTHER_INDUSTRY_OPTION,
```

```
    "useCases": USE_CASES
}
form_data_json = json.dumps(form_data)
model_access_response =
 bedrock_client.put_use_case_for_model_access(formData=form_data_json)
```

For CLI, the form data is base64 encoded json of the form below.

```
{
    "companyName": COMPANY_NAME,
    "companyWebsite": COMPANY_WEBSITE,
    "intendedUsers": INTENDED_USERS,
    "industryOption": INDUSTRY_OPTION,
    "otherIndustryOption": OTHER_INDUSTRY_OPTION,
    "useCases": USE_CASES
}
```

- COMPANY_NAME: String with maximum length of 128
- COMPANY_WEBSITE: String with a maximum length of 128
- INTENDED USERS: Either 0, 1 or 2. 0: Internal, 1: External, 2: Internal_and_External
- INDUSTRY_OPTION: String with maximum length of 128
- OTHER_INDUSTRY_OPTION: String with maximum length of 128
- USE_CASES: String with maximum length of 8192

Step 3: Create foundation model agreement

Used to create agreement (access) for the foundation model. Use the offer token and modelId from above.

Documentation

- API: CreateFoundationModelAgreement
- CLI Documentation: create-foundation-model-agreement

AWS CLI

```
aws bedrock create-foundation-model-agreement \
```

```
  --model-id <ModelId> \
  --offer-token <OfferToken>
```

Python

```
offer_token= ''

for agreement_offer in model_agreement_offers_response['offers']:
    if  agreement_offer['offerId'] == offer_id:

            offer_token = agreement_offer['offerToken']
            print(f"offer token found. Offer token is {offer_token}")
            break

if(not offer_token):
    print(f"Offer token for  modelId: {model_id} is not found")

foundation_model_agreement_reponse =
 bedrock_client.create_foundation_model_agreement(offerToken= offer_token , modelId=
 model_id)
```

Step 4: Get foundation model availability

Used to check if the foundation model currently has access or not. Use the modelId from above.

Documentation

- API: GetFoundationModelAvailability
- CLI Documentation: get-foundation-model-availability

AWS CLI

```
aws bedrock get-foundation-model-availability \
  --model-id <ModelId>
```

Python

```
model_availability_response =
 bedrock_client.get_foundation_model_availability(modelId=model_id)
```

Expected response

`agreementAvailability` returns a `status` of `AVAILABLE` if access exists, `PENDING` if the agreement is still being set up, `NOT_AVAILABLE` if access doesn't exist, or `ERROR` if the agreement couldn't be completed. When the status is `ERROR`, the `errorMessage` field describes the problem. A status of `PENDING` can occur after you submit Anthropic use case details; invoking the model returns `AccessDeniedException` until the status becomes `AVAILABLE`.

```
{
  "modelId": "anthropic.claude-sonnet-4-20250514-v1:0",
  "agreementAvailability": {
    "status": "AVAILABLE"
  },
  "authorizationStatus": "AUTHORIZED",
  "entitlementAvailability": "AVAILABLE",
  "regionAvailability": "AVAILABLE"
}
```

[Optional] Step 5: Delete foundation model agreement

Used to delete foundation model agreement (access). Use the modelId from above.

> **Note**
>
> Deleting model access is not enough for blocking access in the future since invoking the model will create the access again. To make sure access is not created again, apply restrictive deny IAM policies for the model.

Documentation

- API: DeleteFoundationModelAgreement
- CLI Documentation: delete-foundation-model-agreement

AWS CLI

```
aws bedrock delete-foundation-model-agreement \
  --model-id <ModelId>
```

Python

```
delete_foundation_model_agreement_reponse =
 bedrock_client.delete_foundation_model_agreement(modelId= model_id)
```

Access Amazon Bedrock foundation models in AWS GovCloud (US)

AWS GovCloud (US) accounts are linked on a one-to-one basis with standard AWS commercial accounts. This linked commercial account is used for billing, service access, support purposes, and access to Amazon Bedrock Model Marketplace. For more information about the relationship between GovCloud and commercial accounts, see Standard account linking in AWS GovCloud (US).

For third-party models, model access needs to be enabled in both the linked AWS commercial account in addition the AWS GovCloud account. For models provided by Amazon Bedrock, model access only needs to be enabled in the GovCloud account. This is a manual process.

Enabling model access for AWS GovCloud in linked AWS commercial account (only for third-party models)

Model access can be enabled in an AWS commercial account using 2 ways:

1. Invoke the required model for AWS commercial account in `us-east-1` or `us-west-2` region.
2. Programmatically enable access to the model using SDK/CLI for AWS commercial account in `us-east-1` or `us-west-2` region. This can be done by following the steps described in the previous sections.

> **Note**
>
> After you enable access in the linked AWS commercial account, it can take a few minutes for the model entitlement to propagate to the associated AWS GovCloud (US) account.

Enabling model access for AWS GovCloud account

In AWS GovCloud (US), you use the **Model access** page in the Amazon Bedrock console in the `us-gov-west-1` region to enable foundation models as described below:

1. Make sure you have permissions to request model access to request access, or modify access, to Amazon Bedrock foundation models. It is recommended to attach the AmazonBedrockFullAccess policy to the user/role being used.
2. Sign into the Amazon Bedrock console in the `us-gov-west-1` region at https://console.aws.amazon.com/bedrock/.
3. In the left navigation pane, under **Bedrock configurations**, choose **Model access**.
4. On the **Model access** page, choose **Modify model access**.
5. Select the models that you want the account to have access to and unselect the models that you don't want the account to have access to. You have the following options:
    1. Be sure to review the **End User License Agreement (EULA)** for terms and conditions of using a model before requesting access to it.
    2. Select the check box next to an individual model to check or uncheck it.
    3. Select the top check box to check or uncheck all models.
    4. Select how the models are grouped and then check or uncheck all the models in a group by selecting the check box next to the group. For example, you can choose to **Group by provider** and then select the check box next to **Cohere** to check or uncheck all Cohere models.
6. Choose **Next**.
7. If you add access to Anthropic models, you must describe your use case details. Choose **Submit use case details**, fill out the form, and then select **Submit form**. Notification of access is granted or denied based on your answers when completing the form for the provider.
8. Review the access changes you're making, and then read the **Terms**.
9. If you agree with the terms, choose **Submit**. The changes can take several minutes to be reflected in the console.
10. If your request is successful, the **Access status** changes to **Access granted** or **Available to request**.

Use product ID condition keys to control access

The `aws-marketplace:ProductId` condition key can be used to control the ability to subscribe to Amazon Bedrock serverless models that have a product ID in AWS Marketplace. To learn how to use the product ID condition key, see the examples in Grant IAM permissions to request access to Amazon Bedrock foundation models with a product ID.

Note

Models from the following providers aren't sold through AWS Marketplace and don't have product keys, so you can't scope the `aws-marketplace` actions to them:

- Amazon
- DeepSeek
- Google
- Meta
- MiniMax
- Mistral AI
- Moonshot AI
- NVIDIA
- Qwen
- xAI
- Z.AI

Some providers sell only part of their model catalog through AWS Marketplace. The following models don't have product keys even though other models from the same provider do:

- OpenAI open-weight models: gpt-oss-120b, gpt-oss-20b, gpt-oss-safeguard-120b, and gpt-oss-safeguard-20b. These models are available to all Amazon Bedrock users and don't require a AWS Marketplace subscription.
- Writer Palmyra Vision 7B.

This list covers providers whose models have no product key at all. It isn't a complete list of models without a documented product ID. To check a specific model, see the **Marketplace product ID** field on its model card in models at a glance. If a model's card doesn't show that field, scope your policy by model ID instead.
You can, however, prevent the usage of these models by denying Amazon Bedrock actions and specifying these model IDs in the `Resource` field. For an example, see Prevent an identity from using a model after access has already been granted.

Please refer to models at a glance to see product IDs for individual models. The following table shows product IDs for additional models, including older models that do not have a model card:

Model	Product ID
AI21 Labs Jurassic-2 Mid	1d288c71-65f9-489a-a3e2-9c7f4f6e6a85
AI21 Labs Jurassic-2 Ultra	cc0bdd50-279a-40d8-829c-4009b77a1fcc
AI21 Jamba-Instruct	prod-dr2vpvd4k73aq
Anthropic Claude	c468b48a-84df-43a4-8c46-8870630108a7
Anthropic Claude Instant	b0eb9475-3a2c-43d1-94d3-56756fd43737
Anthropic Claude 3 Sonnet	prod-6dw3qvchef7zy
Anthropic Claude 3.5 Sonnet	prod-m5ilt4siql27k
Anthropic Claude 3.5 Sonnet v2	prod-cx7ovbu5wex7g
Anthropic Claude 3.7 Sonnet	prod-4dlfvry4v5hbi
Anthropic Claude 3 Opus	prod-fm3feywmwerog
Anthropic Claude Opus 4	prod-azycxvnd5mhqi
Cohere Command	a61c46fe-1747-41aa-9af0-2e0ae8a9ce05
Cohere Command Light	216b69fd-07d5-4c7b-866b-936456d68311
Stable Image Core 1.0	prod-eacdrmv7zfc5e
Stable Image Ultra 1.0	prod-7boen2z2wnxrg
Stability 3.5 Large 1.0	prodview-ajc3gw4mjy7my

For examples of how to manage model access with IAM policies, see Identity-based policy examples for Amazon Bedrock.

Build

This section covers how to interact with Amazon Bedrock programmatically. For new applications, we recommend the `bedrock-runtime` endpoint. Pick an API, and start making inference requests.

Quick start

Your situation	Recommended path
Want a unified AWS-native interface across all models	Use the `bedrock-runtime` endpoint with the Converse API
Need direct model control or non-text modalities	Use the `bedrock-runtime` endpoint with the Invoke API
Migrating from OpenAI APIs	Use the `bedrock-runtime` endpoint with the Responses API or Chat Completions API — same OpenAI shape, plus Amazon Bedrock features such as Guardrails and cross-Region inference .
Migrating from Anthropic APIs	Use the `bedrock-runtime` endpoint with the Messages API

Topics

- Inference endpoints supported by Amazon Bedrock
- APIs supported by Amazon Bedrock
- Making inference requests
- Use a tool to complete an Amazon Bedrock model response
- Web Search
- Projects (OpenAI-compatible)
- Workspaces (Anthropic-compatible)
- API keys

Inference endpoints supported by Amazon Bedrock

An endpoint is the URL that your application uses to send inference requests to Amazon Bedrock. Amazon Bedrock provides two inference endpoints. The endpoint you choose determines which APIs and features are available.

For most new applications, use the `bedrock-runtime` endpoint. Use `bedrock-mantle` when you specifically need capabilities that are currently available only there, such as server-side and pre-configured tools (including web search), background inference, Projects, or Workspaces. To see which endpoint each model supports, see the section called "Endpoint availability". The following table compares the two endpoints.

Endpoint	Supported APIs	Description
`bedrock-runtime.{region}.amazonaws.com` (recommended)	InvokeModel / Converse / Chat Completions / Responses API / Messages API	Region-specific endpoints for making inference requests for models hosted in Amazon Bedrock using the InvokeModel/ Converse/Chat Completions/Responses/ Messages APIs. For more information about the Bedrock-native operations, see Amazon Bedrock Runtime API operations. The OpenAI-compatible APIs are called on the `/openai/v1` paths of this endpoint rather than through the AWS SDKs.
`bedrock-mantle.{region}.api.aws`	Responses API / Chat Completions API / Messages API	Region-specific endpoints for making inference requests for models hosted in Amazon Bedrock using the OpenAI-compatible endpoints and the Anthropic Messages API.

Note

Both endpoints use the same underlying Mantle inference engine. The `bedrock-mantle` name identifies an endpoint surface, not a different inference engine.

Existing applications that use `bedrock-mantle` continue to be fully supported and do not need to change. Both endpoints let you bring an existing OpenAI SDK codebase to Amazon Bedrock by changing only the base URL and API key, and both support the OpenAI-compatible Responses and Chat Completions APIs and the Anthropic Messages API.

API support

API	`bedrock-runtime`	`bedrock-mantle`
InvokeModel	✓	✗
Converse / ConverseStream	✓	✗
Chat Completions (OpenAI-compatible)	✓	✓
Responses API (OpenAI-compatible)	✓	✓
Messages API (Anthropic-native)	✓	✓

Note

The Messages API is available on both endpoints. Structured outputs (the `output_config.format` parameter) is supported for Anthropic Claude models on both the `bedrock-runtime` and `bedrock-mantle` endpoints. For Claude-specific guidance, see the section called "Structured Outputs".

Note

The Responses API is also available on both endpoints without identical feature support. On `bedrock-runtime`:

- **Requests are always synchronous.** `background=true` is rejected with a 400 error. The `store` parameter is unaffected and keeps its default of `true`, so stored, multi-turn conversations work normally.
- **Server-side tool use and pre-configured tools are not available**, including web search. Client-side tool use works on both endpoints.

- **Only the default project is supported.** See the section called "Projects".
- **A stored response belongs to the AWS Region that served it.** Retrieving, cancelling, or deleting it, and continuing the conversation with `previous_response_id`, are all handled by that Region.

Inference capabilities

Capability	`bedrock-runtime`	`bedrock-mantle`
Cross-region inference (geographic and global profiles)	✓	✗
Stateful conversation management	✓	✓
Asynchronous (long-running) inference	✗	✓
Client-side tool use	✓	✓
Server-side tool use	✗	✓
Pre-configured ready-to-use tools	✗	✓
Projects	Default project only	✓
Workspaces	✗	✓

Authentication does not grant access by itself. Whether you use SigV4 or a Bedrock API key, the associated IAM principal must have permission for the required action. For complete policy requirements and examples, see Prerequisites for running model inference.

Operational

Item	`bedrock-runtime`	`bedrock-mantle`
AWS SigV4 authentication	✓	✓

Item	bedrock-runtime	bedrock-mantle
Bedrock API key (also works with OpenAI SDK)	✓	✓
IAM authorization for inference	bedrock:InvokeModel on the inference target and, for the Responses API, the default project; bedrock:InvokeModelWithResponseStream for streaming	bedrock-mantle:CreateInference
Usage attribution	IAM principal, per-request metadata tagging, application inference profiles	Projects, Workspaces

Note

On bedrock-runtime, the Responses API attributes usage by IAM principal only. Per-request metadata tagging and application inference profiles are not available on it — a request that names an application inference profile as its inference target is rejected with a 400 error. This does not affect cross-Region inference: the system-defined geographic and global inference profiles work normally.

Bedrock feature availability

Feature	`bedrock-runtime`	`bedrock-mantle`
Guardrails	✓	✗
Prompt caching	✓	✓
Intelligent prompt routing	✓	✗

> **Note**
>
> Prompt caching support on `bedrock-mantle` depends on the specific model — see each model card under *Models at a glance* for details.

Throughput and quota approach

Each endpoint uses a different approach to managing throughput.

- **`bedrock-runtime`** – In many traditional multi-tenant services, the architecture is designed around per-account quotas to manage fair-share access to shared resources. This is the approach used with `bedrock-runtime`. Each model has fixed throughput quotas (RPM and TPM) that you can request increases for. For details, see the section called "bedrock-runtime quotas".
- **`bedrock-mantle`** – This endpoint is architected with advanced scheduling and work-queueing mechanisms that deliver fair-share distribution while supporting higher initial throughput limits. This design also allows `bedrock-mantle` to host a broad set of models and deliver the full breadth of capabilities available across the model catalog. In most cases, requests are served immediately. In some cases, a request may be briefly queued while in-flight workloads complete and throughput becomes available. For details, see the section called "bedrock-mantle quotas" and the section called "Best practices".

Pricing

Per-token pricing for the same model is identical on `bedrock-runtime` and `bedrock-mantle`. Choose an endpoint based on the APIs and capabilities you need, not cost. For current pricing, see Amazon Bedrock pricing.

When to choose each endpoint

Start with `bedrock-runtime` when you want to:

- Call the OpenAI-compatible Responses or Chat Completions APIs, or the Anthropic Messages API.
- Use the Bedrock-native InvokeModel or Converse APIs.
- Use Amazon Bedrock features that are available only on this endpoint, such as Guardrails and intelligent prompt routing.
- Use cross-Region inference to route requests across a geography or globally.

Use `bedrock-mantle` when you want to:

- Build agentic workflows with server-side tool use or pre-configured tools, including web search.
- Run asynchronous or long-running inference workloads, including Responses requests with `background=true`.
- Create the section called "Projects" or the section called "Workspaces" to isolate workloads and track cost and usage at the application level.
- Use a model that is available only on `bedrock-mantle`. See the section called "Endpoint availability".

Both endpoints can be used together from the same application — choose per use case.

> **Reduce data egress costs with VPC interface endpoints**
>
> If you are calling Amazon Bedrock from within a VPC, consider using VPC interface endpoints (AWS PrivateLink) to keep traffic within the AWS network and avoid data egress charges associated with NAT gateways or internet gateways.

APIs supported by Amazon Bedrock

Inference APIs supported

Amazon Bedrock provides five main API patterns to perform inference. For new applications, we recommend the `bedrock-runtime` endpoint. The APIs are grouped by the service endpoint they use.

`bedrock-runtime` endpoint (recommended)

The `bedrock-runtime.{region}.amazonaws.com` endpoint supports the following APIs:

API method	Use-case best suited for	Key feature
Converse	Multi-turn chat / standardizing	The Converse API provides a unified interface for interacting with all models in Amazon Bedrock.
Invoke	Single transactions / Large payloads	The Invoke API provides direct access to models with more control over the request and response format.
Responses	OpenAI-compatible, stateful conversations	Use the Responses API for OpenAI-compatible stateful, multi-turn conversations with Amazon Bedrock features such as Guardrails and cross-Region inference. On `bedrock-runtime`, requests are always synchronous, and server-side tools are not available — see the section called "Inference endpoints" for the full comparison.
Chat Completions	OpenAI-compatible, stateless multi-turn chat	Use the Chat Completions API for OpenAI-compatible stateless chat interactions.
Messages API	Anthropic-native interface	Use the Messages API through InvokeModel for direct access to Anthropic models using the native request format.

`bedrock-mantle` endpoint

The `bedrock-mantle.{region}.api.aws` endpoint supports the following APIs:

API method	Use-case best suited for	Key feature
Responses API	Stateful conversations with server-side tools	Use the Responses API on `bedrock-mantle` for agentic applications that require built-in server-side tool use (search, code interpreter), multimodal inputs, and asynchronous inference.
Messages API	Anthropic-native interface	Use the Messages API for direct access to Anthropic models using the Anthropic-native request and response format.
Chat Completions	Stateless multi-turn chat	Use the Chat Completions API for lightweight, stateless, text-focused tasks where you need full control over chat history management and lower latency.

Read more about the APIs supported by Amazon Bedrock.

Deciding between APIs

The API you use depends on your use-case.

Use Case	Recommended API
Migrating from OpenAI API-compatible endpoint	Use the OpenAI-compatible Responses API or Chat Completions API on the `bedrock-runtime` endpoint — same OpenAI shape, plus Amazon Bedrock features such as Guardrails and cross-Region inference. According to OpenAI, the recommended API long-term is the Responses API.
Using models not compatible with OpenAI-compatible endpoint	Use native Amazon Bedrock APIs: Converse and Invoke. For more information, see the section called “Invoke API”.

Use Case	Recommended API
Consistent interface across all models	Converse API - Works with all models that support messages. Write code once and use it with different models. For example code, see the section called "Converse API examples".
Direct model access with full control	Invoke API - Provides direct access to models with more control over request and response format. Use for generating text, images, and embeddings. For example code, see the section called "Invoke model code examples".
New to Amazon Bedrock	We recommend using the `bedrock-runtime` endpoint with the Messages API, Chat Completions API, or Responses API for an OpenAI- or Anthropic-compatible interface.

Models supported by each API and endpoint

First, browse our models to decide on the model you want to use. Once you decide on the model you want to use, you can see the APIs it supports and choose an endpoint. We recommend the `bedrock-runtime` endpoint, which supports the Invoke, Converse, Responses, Chat Completions, and Messages APIs. The `bedrock-mantle` endpoint is also fully supported and offers the Responses, Chat Completions, and Messages APIs. Because the Responses, Chat Completions, and Messages APIs are available on both endpoints but do not have identical feature support on each, see the section called "Inference endpoints" before you choose.

Making inference requests

Inference is the process of generating an output from an input provided to a model. Before you can send an inference request to Amazon Bedrock, you need to allow your role to perform the model invocation API actions. This depends on the endpoint you are using. For new applications, we recommend the `bedrock-runtime` endpoint.

`bedrock-runtime` endpoint (recommended)

If your role has the AmazonBedrockFullAccess AWS managed policy attached, you can skip this section. Otherwise, attach the following permissions to allow inference through the `bedrock-runtime` endpoint (Converse, Invoke, Chat Completions, and Responses APIs):

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "ModelInvocationPermissions",
            "Effect": "Allow",
            "Action": [
                "bedrock:InvokeModel",
                "bedrock:InvokeModelWithResponseStream",
                "bedrock:GetInvoke",
                "bedrock:CancelInvoke",
                "bedrock:DeleteInvoke",
                "bedrock:GetInferenceProfile",
                "bedrock:ListInferenceProfiles",
                "bedrock:RenderPrompt",
                "bedrock:GetCustomModel",
                "bedrock:ListCustomModels",
                "bedrock:GetImportedModel",
                "bedrock:ListImportedModels",
                "bedrock:GetProvisionedModelThroughput",
                "bedrock:ListProvisionedModelThroughputs",
                "bedrock:GetGuardrail",
                "bedrock:ListGuardrails",
                "bedrock:ApplyGuardrail"
            ],
            "Resource": "*"
        }
    ]
}
```

`bedrock-mantle` endpoint

If your role has the `AmazonBedrockMantleInferenceAccess` AWS managed policy attached, you can skip this section. Otherwise, attach the following permissions to allow inference through the `bedrock-mantle` endpoint (Responses API, Chat Completions, Messages API):

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "MantleInferencePermissions",
            "Effect": "Allow",
            "Action": [
```

```
                "bedrock-mantle:CreateInference",
                "bedrock-mantle:GetProject",
                "bedrock-mantle:ListProjects",
                "bedrock-mantle:ListTagsForResources"
            ],
            "Resource": "*"
        }
    ]
}
```

Important

If you scope your policy to specific resources instead of using `"Resource": "*"`, the Responses API on the `bedrock-runtime` endpoint needs two resources rather than one. In addition to the inference target, creating a response requires `bedrock:InvokeModel` on your account's default project, and retrieving, canceling, or deleting a stored response requires `bedrock:GetInvoke`, `bedrock:CancelInvoke`, or `bedrock:DeleteInvoke` on that same project. The following policy grants the minimum:

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "CreateResponses",
            "Effect": "Allow",
            "Action": [
                "bedrock:InvokeModel",
                "bedrock:InvokeModelWithResponseStream"
            ],
            "Resource": [
                "arn:aws:bedrock:*::foundation-model/openai.*",
                "arn:aws:bedrock:*:111122223333:inference-profile/*.openai.*",
                "arn:aws:bedrock:*:111122223333:project/default"
            ]
        },
        {
            "Sid": "ManageStoredResponses",
            "Effect": "Allow",
            "Action": [
                "bedrock:GetInvoke",
                "bedrock:CancelInvoke",
                "bedrock:DeleteInvoke"
```

```
            ],
            "Resource": "arn:aws:bedrock:*:111122223333:project/default"
        }
    ]
}
```

The Converse, Invoke, and Chat Completions APIs don't require a project resource. For more information about the default project, see the section called “Projects”.

For a detailed breakdown of each permission, see Prerequisites for running model inference.

Topics

- Inference using Invoke API
- Inference using Converse API
- Responses API
- Chat Completions API
- Inference using Anthropic Messages API
- Influence response generation with inference parameters
- Get validated JSON results from models
- Enhance model responses with model reasoning
- Optimize model inference for latency
- Supported Regions and models for running model inference

Inference using Invoke API

The Invoke API is available on the `bedrock-runtime` endpoint only. Amazon Bedrock offers the following API operations for carrying out model inference with the Invoke API:

- InvokeModel – Submit a prompt and generate a response. The request body is model-specific. To generate streaming responses, use InvokeModelWithResponseStream.
- StartAsyncInvoke – Submit a prompt and generate a response asynchronously that can be retrieved later. Used to generate videos.
- InvokeModelWithBidirectionalStream –

> **Note**
>
> Restrictions apply to the following operations: `InvokeModel`, `InvokeModelWithResponseStream`, `Converse`, and `ConverseStream`. See API restrictions for details.

For model inference, you need to determine the following parameters:

- Model ID – The ID or Amazon Resource Name (ARN) of the model or inference profile to use in the `modelId` field for inference. The following table describes how to find IDs for different types of resources:

Model type	Description	Find ID in console	Find ID in API	Relevant documentation
Base model	A foundation model from a provider.	Choose **Base models** from the left navigation pane, search for a model, and look for the **Model ID**.	Send a GetFoundationModel or ListFoundationModels request and find the `modelId` in the response.	See a list of IDs at Supported foundation models in Amazon Bedrock.
Inference profile	Increases throughput by allowing invocation of a model in multiple regions.	Choose **Cross-Region inference** from the left navigation pane and look for an **Inference profile ID**.	Send a GetInferenceProfile or ListInferenceProfiles request and find the `inferenceProfileId` in the response.	Choose the model on the models at a glance page and review its *Regional availability* section for inference profile IDs.

Model type	Description	Find ID in console	Find ID in API	Relevant documentation
Prompt	A prompt that was constructed using Prompt management.	Choose **Prompt management** from the left navigation pane, select a prompt in the **Prompts** section, and look for the **Prompt ARN**.	Send a GetPrompt or ListPrompts request and find the `promptArn` in the response.	Learn about creating a prompt in Prompt management at Construct and store reusable prompts with Prompt management in Amazon Bedrock.
Provisioned Throughput	Provides a higher level of throughput for a model at a fixed cost.	Choose **Provisioned Throughput** from the left navigation pane, select a Provisioned Throughput, and look for the ARN.	Send a GetProvisionedModelThroughput or ListProvisionedModelThroughputs request and find the `provisionedModelArn` in the response.	Learn how to purchase a Provisioned Throughput for a model at Increase model invocation capacity with Provisioned Throughput in Amazon Bedrock.

Model type	Description	Find ID in console	Find ID in API	Relevant documentation
Custom model	A model whose parameters are shifted from a foundation model based on training data.	After purchasing Provisioned Throughput for a custom model, follow the steps to find the ID for the Provisioned Throughput.	After purchasing Provisioned Throughput for a custom model, follow the steps to find the ID for the Provisioned Throughput.	Learn how to customize a model at Customize your model to improve its performance for your use case. After customization, you must purchase Provisioned Throughput for it and use the ID of the Provisioned Throughput.

- Request body – Contains the inference parameters for a model and other configurations. Each base model has its own inference parameters. The inference parameters for a custom or provisioned model depends on the base model from which it was created. For more information, see Inference request parameters and response fields for foundation models.

Submit a single prompt with InvokeModel

You run inference on a single prompt by using the InvokeModel and InvokeModelWithResponseStream API operations and specifying a model. Amazon Bedrock models differ in whether they accept text, image, or video inputs and whether they can produce outputs of text, image, or embeddings. Some models can return the response in a stream. To check model support for input, output, and streaming support, do one of the following:

- Check the value in the **Input modalities**, **Output modalities**, or **Streaming supported** columns for a model at Supported foundation models in Amazon Bedrock.
- Send a GetFoundationModel request with the model ID and check the values in the `inputModalities`, `outputModalities`, and `responseStreamingSupported` field.

Run model inference on a prompt by sending an InvokeModel or InvokeModelWithResponseStream request with an Amazon Bedrock runtime endpoint.

> **Note**
>
> Restrictions apply to the following operations: `InvokeModel`, `InvokeModelWithResponseStream`, `Converse`, and `ConverseStream`. See API restrictions for details.

The following fields are required:

Field	Use case
modelId	To specify the model, inference profile, or prompt from Prompt management to use. To learn how to find this value, see Inference using Invoke API.
body	To specify the inference parameters for a model. To see inference parameters for different models, see Inference request parameters and response fields for foundation models. If you specify a prompt from Prompt management in the `modelId` field, omit this field (if you include it, it will be ignored).

The following fields are optional:

Field	Use case
accept	To specify the media type for the request body. For more information, see **Media Types** on the Swagger website.

Field	Use case
contentType	To specify the media type for the response body. For more information, see **Media Types** on the Swagger website.
performanceConfigLatency	To specify whether to optimize a model for latency. For more information, see Optimize model inference for latency.
guardrailIdentifier	To specify a guardrail to apply to the prompt and response. For more information, see Test your guardrail.
guardrailVersion	To specify a guardrail to apply to the prompt and response. For more information, see Test your guardrail.
trace	To specify whether to return the trace for the guardrail you specify. For more information, see Test your guardrail.
serviceTier	To specify the service tier for a request. For more information, see Service tiers for optimizing performance and cost.

Invoke model code examples

This topic provides some basic examples for running inference using a single prompt with the InvokeModel API. For more examples with different models, visit the following resources:

- Pick an example under the Code examples for Amazon Bedrock Runtime using AWS SDKs topic.
- Visit the inference parameter reference for the desired model at Inference request parameters and response fields for foundation models.

The following examples assume that you've set up programmatic access such that you automatically authenticate to the AWS CLI and the AWS SDK for Python (Boto3) in a default AWS

Region when you run these examples. For information on setting up programmating access, see Get started with the API.

> **Note**
>
> Review the following points before trying out the examples:
>
> - You should test these examples in US East (N. Virginia) (us-east-1), which supports all the models used in the examples.
> - The body parameter can be large, so for some CLI examples, you'll be asked to create a JSON file and provide that file into the `--body` argument instead of specifying it in the command line.
> - For the image and video examples, you'll be asked to use your own image and video. The examples assume that your image file is named *`image.png`* and that your video file is named *`video.mp4`*.
> - You might have to convert images or videos into a base64-encoded string or upload them to an Amazon S3 location. In the examples, you'll have to replace the placeholders with the actual base64-encoded string or S3 location.

Generate text with a text prompt

The following examples generate a text response to a text prompt using the Amazon Titan Text Premier model. Choose the tab for your preferred method, and then follow the steps:

CLI

Run the following command in a terminal and find the generated response in a file called *`invoke-model-output.txt`*.

```
aws bedrock-runtime invoke-model \
    --model-id amazon.titan-text-premier-v1:0 \
    --body '{
        "inputText": "Describe the purpose of a 'hello world' program in one line.",
        "textGenerationConfig": {
            "maxTokenCount": 512,
            "temperature": 0.5
        }
    }' \
    --cli-binary-format raw-in-base64-out \
```

```
    invoke-model-output.txt
```

Python

Run the following Python code example to generate a text response:

```
# Use the native inference API to send a text message to Amazon Titan Text.

import boto3
import json

from botocore.exceptions import ClientError

# Create a Bedrock Runtime client in the AWS Region of your choice.
client = boto3.client("bedrock-runtime", region_name="us-east-1")

# Set the model ID, e.g., Titan Text Premier.
model_id = "amazon.titan-text-premier-v1:0"

# Define the prompt for the model.
prompt = "Describe the purpose of a 'hello world' program in one line."

# Format the request payload using the model's native structure.
native_request = {
    "inputText": prompt,
    "textGenerationConfig": {
        "maxTokenCount": 512,
        "temperature": 0.5,
    },
}

# Convert the native request to JSON.
request = json.dumps(native_request)

try:
    # Invoke the model with the request.
    response = client.invoke_model(modelId=model_id, body=request)

except (ClientError, Exception) as e:
    print(f"ERROR: Can't invoke '{model_id}'. Reason: {e}")
    exit(1)

# Decode the response body.
model_response = json.loads(response["body"].read())
```

```
# Extract and print the response text.
response_text = model_response["results"][0]["outputText"]
print(response_text)
```

Generate text with a text prompt using service tier

The following examples generate a text response to a text prompt using the OpenAI GPT model with a service tier to prioritize the request. Choose the tab for your preferred method, and then follow the steps:

CLI

Run the following command in a terminal and validate the service tier in the response.

```
aws bedrock-runtime invoke-model \
    --model-id openai.gpt-oss-120b-1:0 \
    --body '{
        "messages": [
            {
                "role": "user",
                "content": "Describe the purpose of a '\''hello world'\'' program in
 one line."
            }
        ],
        "max_tokens": 512,
        "temperature": 0.7
    }' \
    --content-type application/json \
    --accept application/json \
    --service-tier priority \
    --cli-binary-format raw-in-base64-out
```

Python

Run the following Python code example to generate a text response with service tier:

```
import boto3
import json

# Create a Bedrock Runtime client
```

```
bedrock_runtime = boto3.client(
    service_name="bedrock-runtime",
    region_name="us-east-1"
)

# Define the model ID and request body
model_id = "openai.gpt-oss-120b-1:0"
body = json.dumps({
    "messages": [
        {
            "role": "user",
            "content": "Describe the purpose of a 'hello world' program in one
 line."
        }
    ],
    "max_tokens": 512,
    "temperature": 0.7
})

# Make the request with service tier
response = bedrock_runtime.invoke_model(
    modelId=model_id,
    body=body,
    contentType="application/json",
    accept="application/json",
    serviceTier="priority"
)

# Parse and print the response
response_body = json.loads(response["body"])
print(response_body)
```

Generate an image with a text prompt

The following code examples generate an image using a text prompt with the Stable Diffusion XL 1.0 model. Choose the tab for your preferred method, and then follow the steps:

CLI

Run the following command in a terminal and find the generated response in a file called *invoke-model-output.txt*. The bytes that represent the image can be found in the `base64` field in the response:

```
aws bedrock-runtime invoke-model \
    --model-id stability.stable-image-core-v1:1 \
    --body '{
        "prompt": "A stylized picture of a cute old steampunk robot.",
        "seed": 0
    }' \
    --cli-binary-format raw-in-base64-out \
    invoke-model-output.txt
```

Python

Run the following Python code example to generate an image and find the resulting *stability_1.png* image file in a folder called *output*.

```
# Use the native inference API to create an image with Amazon Titan Image Generator

import base64
import boto3
import json
import os
import random

# Create a Bedrock Runtime client in the AWS Region of your choice.
client = boto3.client("bedrock-runtime", region_name="us-east-1")

# Set the model ID, e.g., Titan Image Generator G1.
model_id = "amazon.titan-image-generator-v2:0"

# Define the image generation prompt for the model.
prompt = "A stylized picture of a cute old steampunk robot."

# Generate a random seed.
seed = random.randint(0, 2147483647)

# Format the request payload using the model's native structure.
native_request = {
    "taskType": "TEXT_IMAGE",
    "textToImageParams": {"text": prompt},
    "imageGenerationConfig": {
        "numberOfImages": 1,
        "quality": "standard",
        "cfgScale": 8.0,
        "height": 512,
```

```
        "width": 512,
        "seed": seed,
    },
}

# Convert the native request to JSON.
request = json.dumps(native_request)

# Invoke the model with the request.
response = client.invoke_model(modelId=model_id, body=request)

# Decode the response body.
model_response = json.loads(response["body"].read())

# Extract the image data.
base64_image_data = model_response["images"][0]

# Save the generated image to a local folder.
i, output_dir = 1, "output"
if not os.path.exists(output_dir):
    os.makedirs(output_dir)
while os.path.exists(os.path.join(output_dir, f"titan_{i}.png")):
    i += 1

image_data = base64.b64decode(base64_image_data)

image_path = os.path.join(output_dir, f"titan_{i}.png")
with open(image_path, "wb") as file:
    file.write(image_data)

print(f"The generated image has been saved to {image_path}")
```

Generate embeddings from text

The following examples use the Amazon Titan Text Embeddings V2 model to generate binary embeddings for a text input. Choose the tab for your preferred method, and then follow the steps:

CLI

Run the following command in a terminal and find the generated response in a file called *invoke-model-output.txt*. The resulting embeddings are in the `binary` field.

```
aws bedrock-runtime invoke-model \
    --model-id amazon.titan-embed-text-v2:0 \
    --body '{
        "inputText": "What are the different services that you offer?",
        "embeddingTypes": ["binary"]
    }' \
    --cli-binary-format raw-in-base64-out \
    invoke-model-output.txt
```

Python

Run the following Python code example to generate embeddings for the provided text:

```
# Copyright Amazon.com, Inc. or its affiliates. All Rights Reserved.
# SPDX-License-Identifier: Apache-2.0
"""
Shows how to generate an embedding with the Amazon Titan Text Embeddings V2 Model
"""

import json
import logging
import boto3

from botocore.exceptions import ClientError

logger = logging.getLogger(__name__)
logging.basicConfig(level=logging.INFO)

def generate_embedding(model_id, body):
    """
    Generate an embedding with the vector representation of a text input using
 Amazon Titan Text Embeddings G1 on demand.
    Args:

 V2 model {model_id}.")

if __name__ == "__main__":
    main()
```

Generate embeddings from an image

The following examples use the Amazon Titan Multimodal Embeddings G1 model to generate embeddings for an image input. Choose the tab for your preferred method, and then follow the steps:

CLI

Open a terminal and do the following:

1. Convert an image titled *image.png* in your current folder into a base64-encoded string and write it to a file titled *image.txt* by running the following command:

```
base64 -i image.png -o image.txt
```

2. Create a JSON file called *image-input-embeddings-output.json* and paste the following JSON, replacing *${image-base64}* with the contents of the *image.txt* file (make sure there is no new line at the end of the string):

```
{
    "inputImage": "${image-base64}",
    "embeddingConfig": {
        "outputEmbeddingLength": 256
    }
}
```

3. Run the following command, specifying the *image-input-embeddings-output.json* file as the body.

```
aws bedrock-runtime invoke-model \
    --model-id amazon.titan-embed-image-v1 \
    --body file://image-input-embeddings-output.json \
    --cli-binary-format raw-in-base64-out \
    invoke-model-output.txt
```

4. Find the resulting embeddings in the *invoke-model-output.txt* file.

Python

In the following Python script, replace */path/to/image* with the path to an actual image. Then run the script to generate embeddings:

```
# Copyright Amazon.com, Inc. or its affiliates. All Rights Reserved.
# SPDX-License-Identifier: Apache-2.0
"""
Shows how to generate embeddings from an image with the Amazon Titan Multimodal
 Embeddings G1 model (on demand).

```

Generate a text response to an image with an accompanying text prompt

Choose the tab for your preferred method, and then follow the steps:

CLI

The following example uses the Anthropic Claude 3 Haiku model to generate a response, given an image and a text prompt that asks the contents of the image. Open a terminal and do the following:

1. Convert an image titled *image.png* in your current folder into a base64-encoded string and write it to a file titled *image.txt* by running the following command:

```
base64 -i image.png -o image.txt
```

2. Create a JSON file called *image-text-input.json* and paste the following JSON, replacing *${image-base64}* with the contents of the *image.txt* file (make sure there is no new line at the end of the string):

```
{
    "anthropic_version": "bedrock-2023-05-31",
    "max_tokens": 1000,
    "messages": [
        {
            "role": "user",
            "content": [
                {
                    "type": "image",
                    "source": {
                        "type": "base64",
                        "media_type": "image/png",
                        "data": "${image-base64}"
                    }
                },
                {
                    "type": "text",
                    "text": "What's in this image?"
                }
            ]
        }
    ]
}
```

3. Run the following command to generate a text output, based on the image and the accompanying text prompt, to a file called *invoke-model-output.txt*:

```
aws bedrock-runtime invoke-model \
    --model-id anthropic.claude-3-haiku-20240307-v1:0 \
    --body file://image-text-input.json \
    --cli-binary-format raw-in-base64-out \
    invoke-model-output.txt
```

4. Find the output in the *invoke-model-output.txt* file in the current folder.

Python

In the following python script, replace */path/to/image.png* with the actual path to the image before running the script:

Generate a text response to a video uploaded to Amazon S3 with an accompanying text prompt

The following examples show how to generate a response with the Amazon Nova Lite model, given a video you upload to an S3 bucket and an accompanying text prompt.

Prerequisite: Upload a video titled *video.mp4* to an Amazon S3 bucket in your account by following the steps at Uploading objects in the Amazon Simple Storage Service User Guide. Take note of the S3 URI of the video.

Choose the tab for your preferred method, and then follow the steps:

CLI

Open a terminal and run the following command, replacing *s3://amzn-s3-demo-bucket/video.mp4* with the actual S3 location of your video:

```
aws bedrock-runtime invoke-model \
    --model-id amazon.nova-lite-v1:0 \
    --body '{
        "messages": [
            {
                "role": "user",
                "content": [
                    {
                        "video": {
                            "format": "mp4",
                            "source": {
                                "s3Location": {
                                    "uri": "s3://amzn-s3-demo-bucket/video.mp4"
                                }
                            }
                        }
                    },
                    {
                        "text": "What happens in this video?"
                    }
                ]
            }
        ]
    }' \
    --cli-binary-format raw-in-base64-out \
    invoke-model-output.txt
```

Find the output in the *invoke-model-output.txt* file in the current folder.

Python

In the following Python script, replace *s3://amzn-s3-demo-bucket/video.mp4* with the actual S3 location of your video. Then run the script:

Generate a text response to a video converted to a base64-encoded string with an accompanying text prompt

The following examples show how to generate a response with the Amazon Nova Lite model, given a video converted to a base64-encoded string and an accompanying text prompt. Choose the tab for your preferred method, and then follow the steps:

CLI

Do the following:

1. Convert a video titled *video.mp4* in your current folder into base64 by running the following command:

```
base64 -i video.mp4 -o video.txt
```

2. Create a JSON file called *video-text-input.json* and paste the following JSON, replacing *${video-base64}* with the contents of the `video.txt` file (make sure there is no new line at the end):

```
{
    "messages": [
        {
            "role": "user",
            "content": [
                {
                    "video": {
                        "format": "mp4",
                        "source": {
                            "bytes": ${video-base64}
                        }
                    }
                },
                {
                    "text": "What happens in this video?"
                }
```

```
            ]
        }
    ]
}
```

3. Run the following command to generate a text output based on the video and the accompanying text prompt to a file called *invoke-model-output.txt*:

```
aws bedrock-runtime invoke-model \
    --model-id amazon.nova-lite-v1:0 \
    --body file://video-text-input.json \
    --cli-binary-format raw-in-base64-out \
    invoke-model-output.txt
```

4. Find the output in the *invoke-model-output.txt* file in the current folder.

Python

In the following Python script, replace */path/to/video.mp4* with the actual path to the video. Then run the script:

if __name__ == "__main__":
    main()
```

Invoke model with streaming code example

> **Note**
>
> The AWS CLI does not support streaming.

The following example shows how to use the InvokeModelWithResponseStream API to generate streaming text with Python using the prompt *write an essay for living on mars in 1000 words*.

```
import boto3
import json

brt = boto3.client(service_name='bedrock-runtime')

body = json.dumps({
    'prompt': '\n\nHuman: write an essay for living on mars in 1000 words\n
\nAssistant:',
    'max_tokens_to_sample': 4000
})

response = brt.invoke_model_with_response_stream(
    modelId='anthropic.claude-v2',
    body=body
)

stream = response.get('body')
if stream:
    for event in stream:
        chunk = event.get('chunk')
        if chunk:
            print(json.loads(chunk.get('bytes').decode()))
```

Inference using Converse API

The Converse API is available on the `bedrock-runtime` endpoint only.

You can use the Amazon Bedrock Converse API to create conversational applications that send and receive messages to and from an Amazon Bedrock model. For example, you can create a chat bot that maintains a conversation over many turns and uses a persona or tone customization that is unique to your needs, such as a helpful technical support assistant.

To use the Converse API, you use the Converse or ConverseStream (for streaming responses) operations to send messages to a model. It is possible to use the existing base inference operations (InvokeModel or InvokeModelWithResponseStream) for conversation applications. However, the Converse API provides a consistent API that works with all Amazon Bedrock models that support messages. This means you can write code once and use it with different models. Should a

model have unique inference parameters, the Converse API also allows you to pass those unique parameters in a model specific structure.

You can use the Converse API to implement tool use and guardrails in your applications.

> **Note**
>
> - With Mistral AI and Meta models, the Converse API embeds your input in a model-specific prompt template that enables conversations.
> - Restrictions apply to the following operations: `InvokeModel`, `InvokeModelWithResponseStream`, `Converse`, and `ConverseStream`. See API restrictions for details.

For code examples, see the following:

- Python examples for this topic – Converse API examples
- Various languages and models – Code examples for Amazon Bedrock Runtime using AWS SDKs
- Java tutorial – A Java developer's guide to Bedrock's new Converse API
- JavaScript tutorial – A developer's guide to Bedrock's new Converse API

Using the Converse API

To use the Converse API, you call the `Converse` or `ConverseStream` operations to send messages to a model. To call `Converse`, you require permission for the `bedrock:InvokeModel` operation. To call `ConverseStream`, you require permission for the `bedrock:InvokeModelWithResponseStream` operation.

Request

When you make a Converse request with an Amazon Bedrock runtime endpoint, you can include the following fields:

- **modelId** – A required parameter in the header that lets you specify the resource to use for inference.
- The following fields let you customize the prompt:
  - **messages** – Use to specify the content and role of the prompts.

- **system** – Use to specify system prompts, which define instructions or context for the model.
- **inferenceConfig** – Use to specify inference parameters that are common to all models. Inference parameters influence the generation of the response.
- **additionalModelRequestFields** – Use to specify inference parameters that are specific to the model that you run inference with.
- **promptVariables** – (If you use a prompt from Prompt management) Use this field to define the variables in the prompt to fill in and the values with which to fill them.

- The following fields let you customize how the response is returned:
  - **guardrailConfig** – Use this field to include a guardrail to apply to the entire prompt.
  - **toolConfig** – Use this field to include a tool to help a model generate responses.
  - **additionalModelResponseFieldPaths** – Use this field to specify fields to return as a JSON pointer object.
  - **serviceTier** – Use this field to specify the service tier for a particular request
- **requestMetadata** – Use this field to include metadata that can be filtered on when using invocation logs.

> **Note**
>
> The following restrictions apply when you use a Prompt management prompt with `Converse` or `ConverseStream`:
>
> - You can't include the `additionalModelRequestFields`, `inferenceConfig`, `system`, or `toolConfig` fields.
> - If you include the `messages` field, the messages are appended after the messages defined in the prompt.
> - If you include the `guardrailConfig` field, the guardrail is applied to the entire prompt. If you include `guardContent` blocks in the ContentBlock field, the guardrail will only be applied to those blocks.

Expand a section to learn more about a field in the `Converse` request body:

messages

The `messages` field is an array of Message objects, each of which defines a message between the user and the model. A `Message` object contains the following fields:

- **role** – Defines whether the message is from the `user` (the prompt sent to the model) or `assistant` (the model response).
- **content** – Defines the content in the prompt.

> **Note**
>
> Amazon Bedrock doesn't store any text, images, or documents that you provide as content. The data is only used to generate the response.

You can maintain conversation context by including all the messages in the conversation in subsequent `Converse` requests and using the `role` field to specify whether the message is from the user or the model.

The `content` field maps to an array of ContentBlock objects. Within each ContentBlock, you can specify one of the following fields (to see what models support what blocks, see models at a glance):

text

The `text` field maps to a string specifying the prompt. The `text` field is interpreted alongside other fields that are specified in the same ContentBlock.

The following shows a Message object with a `content` array containing only a text ContentBlock:

```
{
    "role": "user",
    "content": [
        {
            "text": "string"
        }
    ]
}
```

image

The `image` field maps to an ImageBlock. Pass the raw bytes, encoded in base64, for an image in the `bytes` field. If you use an AWS SDK, you don't need to encode the bytes in base64.

If you exclude the `text` field, the model describes the image.

The following shows an example Message object with a `content` array containing only an image ContentBlock:

```
{
    "role": "user",
    "content": [
        {
            "image": {
                "format": "png",
                "source": {
                    "bytes": "image in bytes"
                }
            }
        }
    ]
}
```

If you are using an Amazon Nova model, you can also specify an Amazon S3 URI instead of passing the bytes directly in the request body. Other models accept only the `bytes` field and reject an Amazon S3 URI with a validation error. The following shows a sample `Message` object with a content array containing the source passed through an Amazon S3 URI.

```
{
    "role": "user",
    "content": [
        {
            "image": {
                "format": "png",
                "source": {
                    "s3Location": {
                        "uri": "s3://amzn-s3-demo-bucket/myImage",
                        "bucketOwner": "111122223333"
                    }
                }
            }
```

```
        }
    ]
}
```

document

The document field maps to an DocumentBlock. If you include a DocumentBlock, check that your request conforms to the following restrictions:

- You must specify the format field. Amazon Bedrock doesn't infer the document format from the name field or from the file extension in an s3Location URI. If you omit format, the request fails with a ValidationException and the message Document format is required. The same requirement applies to a document that you return in a toolResult field.

  The one exception is a document that has citations enabled and that supplies its content inline in the content field of source. For that document, format is optional and defaults to txt.
- In the content field of the Message object, you must also include a text field with a prompt related to the document.
- Pass the raw bytes, encoded in base64, for the document in the bytes field. If you use an AWS SDK, you don't need to encode the document bytes in base64.
- The name field can only contain the following characters:
  - Alphanumeric characters
  - Whitespace characters (no more than one in a row)
  - Hyphens
  - Parentheses
  - Square brackets

  Note

  The name field is vulnerable to prompt injections, because the model might inadvertently interpret it as instructions. Therefore, we recommend that you specify a neutral name.

When using a document you can enable the `citations` tag, which will provide document specific citations in the response of the API call. See the DocumentBlock API for more details.

When `citations` is enabled, the following additional restrictions apply:

- The `format` field can only be `txt` or `pdf`. Any other value fails with a `ValidationException`.
- You can't use `s3Location` as the document source. Pass the document in the `bytes` or `content` field instead.

The following shows a sample Message object with a `content` array containing only a document ContentBlock and a required accompanying text ContentBlock.

```
{
    "role": "user",
    "content": [
        {
            "text": "string"
        },
        {
            "document": {
                "format": "pdf",
                "name": "MyDocument",
                "source": {
                    "bytes": "document in bytes"
                }
            }
        }
    ]
}
```

If you are using an Amazon Nova model, you can also specify an Amazon S3 URI instead of passing the bytes directly in the request body. Other models accept only the `bytes` field and reject an Amazon S3 URI with a validation error. The following shows a sample `Message` object with a content array containing the source passed through an Amazon S3 URI.

```
{
    "role": "user",
    "content": [
        {
```

```
            "text": "string"
        },
        {
            "document": {
                "format": "pdf",
                "name": "MyDocument",
                "source": {
                    "s3Location": {
                      "uri": "s3://amzn-s3-demo-bucket/myDocument",
                      "bucketOwner": "111122223333"
                    }
                }
            }
        }
    ]
}
```

video

The `video` field maps to a VideoBlock object. Pass the raw bytes in the `bytes` field, encoded in base64. If you use the AWS SDK, you don't need to encode the bytes in base64.

If you don't include the `text` field, the model will describe the video.

The following shows a sample Message object with a `content` array containing only a video ContentBlock.

```
{
    "role": "user",
    "content": [
        {
            "video": {
                "format": "mp4",
                "source": {
                    "bytes": "video in bytes"
                }
            }
        }
    ]
}
```

If you are using an Amazon Nova model, you can also specify an Amazon S3 URI instead of passing the bytes directly in the request body. Other models accept only the `bytes` field and

reject an Amazon S3 URI with a validation error. The following shows a sample `Message` object with a content array containing the source passed through an Amazon S3 URI.

```
{
    "role": "user",
    "content": [
        {
            "video": {
                "format": "mp4",
                "source": {
                    "s3Location": {
                        "uri": "s3://amzn-s3-demo-bucket/myVideo",
                        "bucketOwner": "111122223333"
                    }
                }
            }
        }
    ]
}
```

> **Note**
>
> The assumed role must have the `s3:GetObject` permission to the Amazon S3 URI. The `bucketOwner` field is optional but must be specified if the account making the request does not own the bucket the Amazon S3 URI is found in. For more information, see Configure access to Amazon S3 buckets.

cachePoint

You can add cache checkpoints as a block in a message alongside an accompanying prompt by using `cachePoint` fields to use prompt caching. Prompt caching is a feature that lets you begin caching the context of conversations to achieve cost and latency savings. For more information, see Prompt caching for faster model inference.

The following shows a sample Message object with a `content` array containing a document ContentBlock and a required accompanying text ContentBlock, as well as a **cachePoint** that adds both the document and text contents to the cache.

```
{
    "role": "user",
```

```
    "content": [
        {
            "text": "string"
        },
        {
            "document": {
                "format": "pdf",
                "name": "string",
                "source": {
                    "bytes": "document in bytes"
                }
            }
        },
        {
            "cachePoint": {
                "type": "default"
            }
        }
    ]
}
```

guardContent

The `guardContent` field maps to a GuardrailConverseContentBlock object. You can use this field to target an input to be evaluated by the guardrail defined in the `guardrailConfig` field. If you don't specify this field, the guardrail evaluates all messages in the request body. You can pass the following types of content in a `GuardBlock`:

- **text** – The following shows an example Message object with a `content` array containing only a text GuardrailConverseContentBlock:

```
{
    "role": "user",
    "content": [
        {
            "text": "Tell me what stocks to buy.",
            "qualifiers": [
                "guard_content"
            ]
        }
    ]
}
```

You define the text to be evaluated and include any qualifiers to use for contextual grounding.

- **image** – The following shows a Message object with a `content` array containing only an image GuardrailConverseContentBlock:

```
{
    "role": "user",
    "content": [
        {
            "format": "png",
            "source": {
                "bytes": "image in bytes"
            }
        }
    ]
}
```

You specify the format of the image and define the image in bytes.

For more information about using guardrails, see Detect and filter harmful content by using Amazon Bedrock Guardrails.

reasoningContent

The `reasoningContent` field maps to a ReasoningContentBlock. This block contains content regarding the reasoning that was carried out by the model to generate the response in the accompanying `ContentBlock`.

The following shows a `Message` object with a `content` array containing only a `ReasoningContentBlock` and an accompanying text `ContentBlock`.

```
{
    "role": "user",
    "content": [
        {
            "text": "string"
        },
        {
            "reasoningContent": {
                "reasoningText": {
```

```
                    "text": "string",
                    "signature": "string"
                }
                "redactedContent": "base64-encoded binary data object"
            }
        }
    ]
}
```

The `ReasoningContentBlock` contains the reasoning used to generate the accompanying content in the `reasoningText` field, in addition to any content in the reasoning that was encrypted by the model provider for trust and safety reasons in the `redactedContent` field.

Within the `reasoningText` field, the `text` fields describes the reasoning. The `signature` field is a hash of all the messages in the conversation and is a safeguard against tampering of the reasoning used by the model. You must include the signature and all previous messages in subsequent `Converse` requests. If any of the messages are changed, the response throws an error.

toolUse

Contains information about a tool for the model to use. For more information, see Use a tool to complete an Amazon Bedrock model response.

toolResult

Contains information about the result from the model using a tool. For more information, see Use a tool to complete an Amazon Bedrock model response.

In the following `messages` example, the user asks for a list of three pop songs, and the model generates a list of songs.

```
[
    {
        "role": "user",
        "content": [
            {
                "text": "Create a list of 3 pop songs."
            }
        ]
    },
```

```
    {
        "role": "assistant",
        "content": [
            {
                "text": "Here is a list of 3 pop songs by artists from the United
 Kingdom:\n\n1. \"As It Was\" by Harry Styles\n2. \"Easy On Me\" by Adele\n3. \"Unholy
\" by Sam Smith and Kim Petras"
            }
        ]
    }
]
```

system

A system prompt is a type of prompt that provides instructions or context to the model about the task it should perform, or the persona it should adopt during the conversation. You can specify a list of system prompts for the request in the `system` (SystemContentBlock) field, as shown in the following example.

```
[
    {
        "text": "You are an app that creates play lists for a radio station that plays
 rock and pop music. Only return song names and the artist. "
    }
]
```

inferenceConfig

The Converse API supports a base set of inference parameters that you set in the `inferenceConfig` field (InferenceConfiguration). The base set of inference parameters are:

- **maxTokens** – The maximum number of tokens to allow in the generated response.
- **stopSequences** – A list of stop sequences. A stop sequence is a sequence of characters that causes the model to stop generating the response.
- **temperature** – The likelihood of the model selecting higher-probability options while generating a response.
- **topP** – The percentage of most-likely candidates that the model considers for the next token.

For more information, see Influence response generation with inference parameters.

The following example JSON sets the `temperature` inference parameter.

```
{"temperature": 0.5}
```

additionalModelRequestFields

If the model you are using has additional inference parameters, you can set those parameters by specifying them as JSON in the `additionalModelRequestFields` field. The following example JSON shows how to set `top_k`, which is available in Anthropic Claude models, but isn't a base inference parameter in the messages API.

```
{"top_k": 200}
```

promptVariables

If you specify a prompt from Prompt management in the `modelId` as the resource to run inference on, use this field to fill in the prompt variables with actual values. The `promptVariables` field maps to a JSON object with keys that correspond to variables defined in the prompts and values to replace the variables with.

For example, let's say that you have a prompt that says **`Make me a {{genre}} playlist consisting of the following number of songs: {{number}}.`**. The prompt's ID is `PROMPT12345` and its version is 1. You could send the following `Converse` request to replace the variables:

```
POST /model/arn:aws:bedrock:us-east-1:111122223333:prompt/PROMPT12345:1/converse
 HTTP/1.1
Content-type: application/json

{
   "promptVariables": {
      "genre": {
         "text": "pop"
      },
      "number": {
         "text": "3"
      }
   }
}
```

guardrailConfig

You can apply a guardrail that you created with Amazon Bedrock Guardrails by including this field. To apply the guardrail to a specific message in the conversation, include the message in a GuardrailConverseContentBlock. If you don't include any `GuardrailConverseContentBlocks` in the request body, the guardrail is applied to all the messages in the `messages` field. For an example, see Include a guardrail with the Converse API.

toolConfig

This field lets you define a tool for the model to use to help it generate a response. For more information, see Use a tool to complete an Amazon Bedrock model response.

additionalModelResponseFieldPaths

Each model that Amazon Bedrock supports has its own native response shape with provider-specific fields (for example, Anthropic Claude returns a `stop_sequence` field; Cohere returns `is_finished`; and so on). To give you a uniform response across models, Converse and ConverseStream drop most model-native fields by default and return a normalized envelope with `output`, `stopReason`, `usage`, and `metrics`.

If your application needs one or more of those model-native fields, list their JSON Pointer paths in `additionalModelResponseFieldPaths`. Converse and ConverseStream then include those fields in the `additionalModelResponseFields` field of the response.

The following example asks Converse to also return Anthropic Claude's `stop_sequence` field, which contains the value of the stop sequence that ended generation:

```
[ "/stop_sequence" ]
```

Each path is a JSON Pointer (RFC 6901) into the model's native response. Empty pointers and malformed pointers return a `400` error. If a pointer is valid but the requested path doesn't exist in the model's response, it is silently ignored.

> **Note**
>
> This field controls which model-native *response fields* are surfaced through Converse. It does not control text-output formatting. Some models — particularly reasoning models such as DeepSeek-R1, Claude 3.7 Sonnet with extended thinking, and Amazon Nova reasoning models — can include reasoning content or model-specific tokens in their text

output. For how to work with reasoning content, see Enhance model responses with model reasoning.

requestMetadata

The `requestMetadata` field maps to a JSON object of key-value tags that are recorded with the request in your model invocation logs. You can use request metadata to filter and aggregate logs by team, application, environment, or any other dimension that varies per call.

The same capability is available on InvokeModel and InvokeModelWithResponseStream through the `X-Amzn-Bedrock-Request-Metadata` HTTP header. For details on supported APIs, limits, and how request metadata appears in invocation logs, see the section called "Per-request metadata tagging".

serviceTier

This field maps to a JSON object. You can specify the service tier for a particular request.

The following example shows the `serviceTier` structure:

```
"serviceTier": {
  "type": "reserved" | "priority" | "default" | "flex"
}
```

For detailed information about service tiers, including pricing and performance characteristics, see Service tiers for optimizing performance and cost.

You can also optionally add cache checkpoints to the `system` or `tools` fields to use prompt caching, depending on which model you're using. For more information, see Prompt caching for faster model inference.

Response

The response you get from the Converse API depends on which operation you call, `Converse` or `ConverseStream`.

Converse response

In the response from `Converse`, the `output` field (ConverseOutput) contains the message (Message) that the model generates. The message content is in the `content` (ContentBlock) field and the role (`user` or `assistant`) that the message corresponds to is in the `role` field.

If you used prompt caching, then in the usage field, `cacheReadInputTokens` and `cacheWriteInputTokens` tell you how many total tokens were read from the cache and written to the cache, respectively.

If you used service tiers, then in the response field, `service tier` would tell you which service tier was used for the request.

The `metrics` field (ConverseMetrics) includes metrics for the call. To determine why the model stopped generating content, check the `stopReason` field. You can get information about the tokens passed to the model in the request, and the tokens generated in the response, by checking the `usage` field (TokenUsage). If you specified additional response fields in the request, the API returns them as JSON in the `additionalModelResponseFields` field.

The following example shows the response from `Converse` when you pass the prompt discussed in Request.

```
{
    "output": {
        "message": {
            "role": "assistant",
            "content": [
                {
                    "text": "Here is a list of 3 pop songs by artists from the United
 Kingdom:\n\n1. \"Wannabe\" by Spice Girls\n2. \"Bitter Sweet Symphony\" by The Verve
 \n3. \"Don't Look Back in Anger\" by Oasis"
                }
            ]
        }
    },
    "stopReason": "end_turn",
    "usage": {
        "inputTokens": 125,
        "outputTokens": 60,
        "totalTokens": 185
    },
    "metrics": {
        "latencyMs": 1175
    }
}
```

ConverseStream response

If you call `ConverseStream` to stream the response from a model, the stream is returned in the `stream` response field. The stream emits the following events. The diagram below shows the order in which the events are received; the content block events repeat once per content block, grouped by `contentBlockIndex`.

```
messageStart                          (once per response)
    |
    v
+-- for each content block (indexed by contentBlockIndex) --+
|                                                           |
|   contentBlockStart    (tool use only)                    |
|   contentBlockDelta    (one or more; text / reasoning /   |
|                         tool use partial JSON)            |
|   contentBlockStop                                        |
|                                                           |
+-----------------------------------------------------------+
    |
    v
messageStop                           (once per response;
    |                                  carries stopReason)
    v
metadata                              (once per response;
                                       usage + metrics)
```

1. `messageStart` (MessageStartEvent). The start event for a message. Includes the role for the message.
2. `contentBlockStart` (ContentBlockStartEvent). A Content block start event. Tool use only.
3. `contentBlockDelta` (ContentBlockDeltaEvent). A Content block delta event. Includes one of the following:
   - `text` – The partial text that the model generates.
   - `reasoningContent` – The partial reasoning carried out by the model to generate the response. You must submit the returned `signature`, in addition to all previous messages in subsequent `Converse` requests. If any of the messages are changed, the response throws an error.
   - `toolUse` – The partial input JSON object for tool use.
4. `contentBlockStop` (ContentBlockStopEvent). A Content block stop event.

5. `messageStop` (MessageStopEvent). The stop event for the message. Includes the reason why the model stopped generating output.
6. `metadata` (ConverseStreamMetadataEvent). Metadata for the request. The metadata includes the token usage in `usage` (TokenUsage) and metrics for the call in `metrics` (ConverseStreamMetadataEvent).

ConverseStream streams a complete content block as a `ContentBlockStartEvent` event, one or more `ContentBlockDeltaEvent` events, and a `ContentBlockStopEvent` event. Use the `contentBlockIndex` field as an index to correlate the events that make up a content block.

The following example is a partial response from `ConverseStream`.

```
{'messageStart': {'role': 'assistant'}}
{'contentBlockDelta': {'delta': {'text': ''}, 'contentBlockIndex': 0}}
{'contentBlockDelta': {'delta': {'text': ' Title'}, 'contentBlockIndex': 0}}
{'contentBlockDelta': {'delta': {'text': ':'}, 'contentBlockIndex': 0}}
.
.
.
{'contentBlockDelta': {'delta': {'text': ' The'}, 'contentBlockIndex': 0}}
{'messageStop': {'stopReason': 'max_tokens'}}
{'metadata': {'usage': {'inputTokens': 47, 'outputTokens': 20, 'totalTokens': 67},
 'metrics': {'latencyMs': 100.0}}}
```

Converse API examples

The following examples show you how to use the `Converse` and `ConverseStream` operations.

Text

This example shows how to call the `Converse` operation with the *Anthropic Claude 3 Sonnet* model. The example shows how to send the input text, inference parameters, and additional parameters that are unique to the model. The code starts a conversation by asking the model to create a list of songs. It then continues the conversation by asking that the songs are by artists from the United Kingdom.

Responses API

Amazon Bedrock provides the OpenAI Responses API on both the `bedrock-runtime` and `bedrock-mantle` endpoints. Use `bedrock-runtime` for new applications. Use `bedrock-mantle` only when a model or capability that you require isn't available on `bedrock-runtime`.

Endpoint	Base URL	When to use
`bedrock-runtime` (recommended)	`https://bedrock-runtime.{region}.amazonaws.com/openai/v1`	New applications and migrations when the required model and Responses API features are supported.
`bedrock-mantle` (compatibility)	`https://bedrock-mantle.{region}.api.aws/v1`	Existing applications and workloads that require Mantle-only support, such as Responses API access to GPT OSS models, background inference, or server-side tools.

Note

On `bedrock-mantle`, the path prefix varies by model. Most models are served under `/v1`, as shown in the preceding table, but some are served under `/openai/v1` instead. A request that uses the wrong prefix for a model is rejected with `model `<model-id>`

`isn't supported on this route`. To confirm the base URL for a specific model, see the **Programmatic Access** table on its card in *Models at a glance*.

The two endpoints don't have identical feature support. Requests on `bedrock-runtime` are always synchronous, server-side tools aren't available, and only the default project is supported. For the full comparison, see the section called "Inference endpoints", and for the details of each difference, see Using the Responses API on the bedrock-runtime endpoint.

Important

When using the OpenAI SDK with Amazon Bedrock, you must point it to the Amazon Bedrock endpoint, not the OpenAI endpoint. Set the following environment variables, choosing the base URL for the endpoint you want:

```
# bedrock-runtime (recommended)
OPENAI_BASE_URL="https://bedrock-runtime.<your-region>.amazonaws.com/openai/v1"

# bedrock-mantle
OPENAI_BASE_URL="https://bedrock-mantle.<your-region>.api.aws/v1"

OPENAI_API_KEY="<your Bedrock API key>"
```

Do not use your OpenAI API key or the OpenAI base URL (`https://api.openai.com/v1`). Those connect to OpenAI directly, not to Amazon Bedrock. To create a Amazon Bedrock API key, see the section called "API keys".

Key benefits include:

- **Asynchronous inference** – Support for long-running inference workloads through the Responses API. Available on `bedrock-mantle` only.
- **Stateful conversation management** – Automatically rebuild context without manually passing conversation history with each request
- **Simplified tool use** – Streamlined integration for agentic workflows
- **Flexible response modes** – Support for both streaming and non-streaming responses
- **Easy migration** – Compatible with existing OpenAI SDK codebases

Each endpoint is governed by its own set of quotas. For Responses traffic on `bedrock-runtime`, the model's tokens-per-minute and tokens-per-day quotas apply, and they're shared with the other inference APIs on that endpoint — see Quotas for the bedrock-runtime endpoint. For `bedrock-mantle`, see Quotas for the bedrock-mantle endpoint.

Supported Regions and Endpoints

On the `bedrock-runtime` endpoint, the Responses API is available in every AWS Region where that endpoint is available, including the AWS GovCloud (US) Regions. For the list, see the section called "Regional availability by endpoints". Which models support the API on each endpoint is listed in the section called "Endpoint availability".

The `bedrock-mantle` endpoint is available in a subset of those AWS Regions. For the Regions that support each endpoint, see the section called "Regional availability by endpoints". For the base URL to use with a Region, see the section called "Inference endpoints".

Prerequisites

Before using OpenAI APIs, make sure you have the following:

- **Authentication** – You can authenticate using:
  - Amazon Bedrock API key (required for OpenAI SDK)
  - AWS credentials (supported for HTTP requests)
- **OpenAI SDK** (optional) – Install the OpenAI Python SDK if using SDK-based requests.
- **Environment variables** – Set the following environment variables:
  - `OPENAI_API_KEY` – Set to your Amazon Bedrock API key
  - `OPENAI_BASE_URL` – Set to the Amazon Bedrock endpoint for your region (for example, `https://bedrock-runtime.us-east-1.amazonaws.com/openai/v1` or `https://bedrock-mantle.us-east-1.api.aws/v1`)
- **Permissions** – The actions you need depend on the endpoint. On `bedrock-mantle`, inference authorizes `bedrock-mantle:CreateInference`. On `bedrock-runtime`, it authorizes `bedrock:InvokeModel` on both the inference target and your account's default project, and managing stored responses authorizes `bedrock:GetInvoke`, `bedrock:CancelInvoke`, and `bedrock:DeleteInvoke` on that project. For policy examples, see Prerequisites for running model inference.

Choose a model

Model and API support differs between endpoints. For `bedrock-runtime`, choose a model whose model card lists the Responses API as supported on that endpoint. Requests for the closed-weight OpenAI GPT models must name a system-defined inference profile, such as `us.openai.gpt-5.6-sol` or `global.openai.gpt-5.6-sol`, rather than the foundation model ID.

> **Important**
>
> `bedrock-runtime` doesn't implement the OpenAI-compatible `GET /models` operation, so `client.models.list()` and `GET /openai/v1/models` don't work on that endpoint. Use the Amazon Bedrock control-plane ListFoundationModels and ListInferenceProfiles operations, and see the model cards in *Models at a glance* for endpoint-specific API support and inference profile IDs. For examples, see the section called "Get list of models".

> **Note**
>
> GPT OSS models support Chat Completions, Converse, and Invoke on `bedrock-runtime`, but they don't support the Responses API there. To use both Responses and Chat Completions entirely on `bedrock-runtime`, choose a model that lists both APIs as supported on that endpoint. To use the Responses API with GPT OSS, use `bedrock-mantle`.

List models on bedrock-mantle

The OpenAI-compatible Models API is available on `bedrock-mantle`. For complete API details, see the OpenAI Models documentation. To list models on that endpoint, choose the tab for your preferred method, and then follow the steps:

OpenAI SDK (Python)

```
# List all available models using the OpenAI SDK
# Requires OPENAI_API_KEY and OPENAI_BASE_URL environment variables

from openai import OpenAI
```

```
client = OpenAI()

models = client.models.list()

for model in models.data:
    print(model.id)
```

HTTP request

Make a GET request to `/v1/models`:

```
# List all available models
# Requires OPENAI_API_KEY and OPENAI_BASE_URL environment variables

curl -X GET $OPENAI_BASE_URL/models \
   -H "Authorization: Bearer $OPENAI_API_KEY"
```

Migrate from bedrock-mantle to bedrock-runtime

Before moving a Responses API workload, confirm that its model and required features are supported on `bedrock-runtime`. Then make the following changes:

Setting	bedrock-mantle	bedrock-runtime
Base URL	`https://bedrock-mantle.{region}.api.aws/v1`	`https://bedrock-runtime.{region}.amazonaws.com/openai/v1`
Model value	Model ID, such as `openai.gpt-5.6-sol`	Runtime model or system inference profile ID, such as `global.openai.gpt-5.6-sol`
Model discovery	`GET /models` or `client.models.list()`	`ListFoundationModels`, `ListInferenceProfiles`, and model cards
Project	Default or customer-created project	Default project only

Test requests that use background processing, server-side tools, application inference profiles, or model inheritance through `previous_response_id`, because those behaviors differ on `bedrock-runtime`. For the complete list, see the section called “On bedrock-runtime”.

Responses API

The Responses API provides stateful conversation management with support for streaming and multi-turn interactions. The `bedrock-mantle` endpoint also supports background processing. For complete API details, see the OpenAI Responses documentation.

> **Note**
>
> Not all models support the Responses API on both endpoints. Check the endpoint-specific API table on the model card before choosing a model. The compatibility table in the section called “API compatibility” summarizes model capabilities across endpoints, but doesn't imply that an API is available on every endpoint.

How the Responses API stores conversation state

The Responses API can use stored state to enable multi-turn conversations and let you reference previous turns through the `previous_response_id` parameter. Storage is enabled by default but can be disabled per request through the `store` parameter. Stored responses are scoped by Project. A response from one Project cannot be used as the previous response or read in a second Project. For more information about Projects, see the section called “Projects”.

- When `store` is `true` (the default), Amazon Bedrock retains the response, including the input and output, for 30 days. During this window you can chain follow-up requests by passing `previous_response_id` and retrieve the response with `GET /v1/responses/{id}` on `bedrock-mantle`, or `GET /openai/v1/responses/{id}` on `bedrock-runtime`. After 30 days, the response is automatically deleted and is no longer retrievable.
- When `store` is `false`, Amazon Bedrock does not retain any data from the request or response. The `previous_response_id` parameter cannot be used to continue the conversation.

The default value is `true` to match the OpenAI Responses API specification. Customers who do not want Amazon Bedrock to retain conversation data should explicitly set `store` to `false` on every request, or set the account's data retention mode to none, which rejects an explicit `store=true` outright. For more information, see the section called “Data retention”.

Stored data is encrypted at rest and scoped to the calling AWS account's Project resource. The data is stored solely to service your requests and is not used or retained for any other purpose. On `bedrock-mantle`, it is kept in the AWS Region the request was sent to. On `bedrock-runtime`, a request that uses cross-Region inference can be processed in another AWS Region, and the response is stored in the Region that processed it — so a request that uses a global inference profile can store data in any commercial Region that profile routes to. If you have data residency requirements, use a geographic inference profile rather than a global one.

Basic request

To create a response, choose an example for your endpoint. The `bedrock-runtime` examples use a global system inference profile. Use a geographic profile instead if you have data residency requirements.

bedrock-runtime: OpenAI SDK (Python)

```
from openai import OpenAI

client = OpenAI()

response = client.responses.create(
    model="global.openai.gpt-5.6-sol",
    input="Can you explain the features of Amazon Bedrock?"
)
print(response)
```

bedrock-runtime: HTTP request

Make a POST request to `/openai/v1/responses`:

```
curl -X POST "$OPENAI_BASE_URL/responses" \
   -H "Content-Type: application/json" \
   -H "Authorization: Bearer $OPENAI_API_KEY" \
   -d '{
    "model": "global.openai.gpt-5.6-sol",
    "input": "Can you explain the features of Amazon Bedrock?"
}'
```

bedrock-mantle: OpenAI SDK (Python)

```
# Create a basic response using the OpenAI SDK
```

```
# Requires OPENAI_API_KEY and OPENAI_BASE_URL environment variables

from openai import OpenAI

client = OpenAI()

response = client.responses.create(
    model="openai.gpt-oss-120b",
    input=[
        {"role": "user", "content": "Hello! How can you help me today?"}
    ]
)

print(response)
```

bedrock-mantle: HTTP request

Make a POST request to `/v1/responses`:

```
# Create a basic response
# Requires OPENAI_API_KEY and OPENAI_BASE_URL environment variables

curl -X POST $OPENAI_BASE_URL/responses \
   -H "Content-Type: application/json" \
   -H "Authorization: Bearer $OPENAI_API_KEY" \
   -d '{
    "model": "openai.gpt-oss-120b",
    "input": [
        {"role": "user", "content": "Hello! How can you help me today?"}
    ]
}'
```

Stream responses

To receive response events incrementally, choose an example for your endpoint.

bedrock-runtime: OpenAI SDK (Python)

```
from openai import OpenAI

client = OpenAI()
```

```
stream = client.responses.create(
    model="global.openai.gpt-5.6-sol",
    input="Tell me a story",
    stream=True
)

for event in stream:
    print(event)
```

bedrock-runtime: HTTP request

Make a POST request to `/openai/v1/responses` with `stream` set to `true`:

```
curl -X POST "$OPENAI_BASE_URL/responses" \
   -H "Content-Type: application/json" \
   -H "Authorization: Bearer $OPENAI_API_KEY" \
   -d '{
    "model": "global.openai.gpt-5.6-sol",
    "input": "Tell me a story",
    "stream": true
}'
```

bedrock-mantle: OpenAI SDK (Python)

```
# Stream response events incrementally using the OpenAI SDK
# Requires OPENAI_API_KEY and OPENAI_BASE_URL environment variables

from openai import OpenAI

client = OpenAI()

stream = client.responses.create(
    model="openai.gpt-oss-120b",
    input=[{"role": "user", "content": "Tell me a story"}],
    stream=True
)

for event in stream:
    print(event)
```

bedrock-mantle: HTTP request

Make a POST request to `/v1/responses` with `stream` set to `true`:

```
# Stream response events incrementally
# Requires OPENAI_API_KEY and OPENAI_BASE_URL environment variables

curl -X POST $OPENAI_BASE_URL/responses \
   -H "Content-Type: application/json" \
   -H "Authorization: Bearer $OPENAI_API_KEY" \
   -d '{
    "model": "openai.gpt-oss-120b",
    "input": [
        {"role": "user", "content": "Tell me a story"}
    ],
    "stream": true
}'
```

Using the Responses API on the bedrock-runtime endpoint

The Responses API on `bedrock-runtime` uses the same request and response format as on `bedrock-mantle`, so the OpenAI SDK works against either one. What changes is the base URL, the model IDs, the permissions, and a small number of behaviors described in this section.

Base URL and paths

Set your base URL to `https://bedrock-runtime.region.amazonaws.com/openai/v1`. The API is served on the following paths:

- `POST /openai/v1/responses` – create a response.
- `GET /openai/v1/responses/{id}` – retrieve a stored response.
- `POST /openai/v1/responses/{id}/cancel` – cancel a response that is still in progress.
- `DELETE /openai/v1/responses/{id}` – delete a stored response.

Model IDs

Name a cross-Region inference profile as the model, not a foundation model ID. The OpenAI GPT models use the `us.` and `global.` profiles in the commercial Regions and the `us-gov.` profiles in the AWS GovCloud (US) Regions — for example, `us.openai.gpt-5.6-sol`. In-Region inference isn't available for these models on this endpoint. For the profile ID of each model, see its model card in *Models at a glance*, and for how routing works, see the section called "Cross-Region inference".

Permissions

Creating a response authorizes two resources: `bedrock:InvokeModel` (or `bedrock:InvokeModelWithResponseStream`) on the inference target, as any inference request does, and `bedrock:InvokeModel` on your account's default project. Retrieving, canceling, and deleting a stored response authorize `bedrock:GetInvoke`, `bedrock:CancelInvoke`, and `bedrock:DeleteInvoke` respectively, each on the project. Individual response IDs are not IAM resources.

Two condition keys let a policy on either resource constrain the other. The inference-target authorization carries `bedrock:ProjectArn`, and the project authorization carries `bedrock:ModelArn`, valued at the inference profile or foundation model your request named — never the destination models that a cross-Region profile routes to. For policy examples, see Prerequisites for running model inference.

Behavior differences

- **Requests are always synchronous.** `background=true` is rejected with a 400 error. The `store` parameter is unaffected and keeps its default of `true`, so stored, multi-turn conversations work normally.
- **`model` is required on every request**, including one that supplies `previous_response_id`. This differs from the OpenAI Responses API specification and from `bedrock-mantle`, where the model can be omitted and inherited from the previous response. The model is part of what the request is authorized against, so it has to be named in the request itself.
- **Server-side tool use and pre-configured tools aren't available**, including web search. Client-side tool use works on both endpoints.
- **Only the default project is supported.** The `OpenAI-Project` header is accepted only as `default` or as your own default project ARN; any other value is rejected. See the section called "Projects".
- **Application inference profiles aren't supported.** A request that names one as its inference target is rejected with a 400 error. System, geographic, and global inference profiles work normally.
- **Guardrails are supported.** Set the `X-Amzn-Bedrock-GuardrailIdentifier` and `X-Amzn-Bedrock-GuardrailVersion` request headers. With the OpenAI SDK, pass these values through `extra_headers`. For more information, see Test your guardrail.
- **A stored response belongs to the AWS Region that served it.** Retrieving, canceling, or deleting it, and continuing the conversation with `previous_response_id`, are all handled by that

Region. A response ID that can't be found — because it never existed, belongs to another account, or was never stored — returns the same 404 error in every case.

Monitoring and cost

Because every request is synchronous, CloudWatch metrics and model invocation logging work for the Responses API the same way they do for the other inference APIs on this endpoint, including for streaming requests. Usage is attributed to the inference target, exactly as it is for Converse and InvokeModel — the default project is never the billing anchor. See *Track usage and costs*.

Chat Completions API

The OpenAI Chat Completions API generates conversational responses using Amazon Bedrock models. Use the `bedrock-runtime` endpoint for new applications. Use `bedrock-mantle` only when a model or capability that you require isn't available on `bedrock-runtime`. For complete API details, see the OpenAI Chat Completions documentation.

Endpoint	Base URL	Authentication
`bedrock-runtime` (recommended)	`https://bedrock-runtime.{region}.amazonaws.com/openai/v1/chat/completions`	AWS credentials (SigV4) or Amazon Bedrock API key
`bedrock-mantle` (compatibility)	`https://bedrock-mantle.{region}.api.aws/v1/chat/completions`	Amazon Bedrock API key or AWS credentials

Note

On `bedrock-mantle`, the path prefix varies by model. Most models are served under `/v1`, as shown in the preceding table, but some are served under `/openai/v1` instead. A request that uses the wrong prefix for a model is rejected with `model `<model-id>` isn't supported on this route`. To confirm the base URL for a specific model, see the **Programmatic Access** table on its card in *Models at a glance*.

Each endpoint has its own per-model token quotas. For details on the quotas applied to traffic on each endpoint, see Quotas for the bedrock-runtime endpoint and Quotas for the bedrock-mantle endpoint.

Chat Completions with the bedrock-runtime endpoint

The `bedrock-runtime` endpoint supports AWS SigV4 authentication and Amazon Bedrock API key authentication.

Choose a model

Important

`bedrock-runtime` doesn't implement the OpenAI-compatible `GET /models` operation, so `client.models.list()` and `GET /openai/v1/models` don't work on this endpoint. Use ListFoundationModels, ListInferenceProfiles, and the endpoint-specific tables in *Models at a glance*. For examples, see the section called "Get list of models".

Note

The following examples use `openai.gpt-oss-120b-1:0`. GPT OSS models support Chat Completions on `bedrock-runtime`, but don't support the Responses API there. To use both OpenAI-compatible APIs on `bedrock-runtime`, choose a model whose model card lists both APIs as supported.

Create a chat completion

To create a chat completion, choose the tab for your preferred method, and then follow the steps:

OpenAI SDK (Python)

Configure the OpenAI client to point to the `bedrock-runtime` endpoint:

```
from openai import OpenAI
import os

client = OpenAI(
```

```
    base_url="https://bedrock-runtime.us-east-1.amazonaws.com/openai/v1",
    api_key=os.environ.get("OPENAI_API_KEY")
)

response = client.chat.completions.create(
    model="openai.gpt-oss-120b-1:0",
    messages=[{"role": "user", "content": "Hello"}]
)
print(response.choices[0].message.content)
```

HTTP request (API key)

```
curl -X POST "https://bedrock-runtime.us-east-1.amazonaws.com/openai/v1/chat/
completions" \
  -H "Content-Type: application/json" \
  -H "Authorization: Bearer $OPENAI_API_KEY" \
  -d '{
    "model": "openai.gpt-oss-120b-1:0",
    "messages": [{"role": "user", "content": "Hello"}]
  }'
```

HTTP request (SigV4)

```
curl -X POST "https://bedrock-runtime.us-east-1.amazonaws.com/openai/v1/chat/
completions" \
  -H "Content-Type: application/json" \
  --aws-sigv4 "aws:amz:us-east-1:bedrock" \
  --user "$AWS_ACCESS_KEY_ID:$AWS_SECRET_ACCESS_KEY" \
  -d '{
    "model": "openai.gpt-oss-120b-1:0",
    "messages": [{"role": "user", "content": "Hello"}]
  }'
```

Chat Completions with the bedrock-mantle endpoint

Use `bedrock-mantle` as a compatibility option when a model or feature that you require isn't available on `bedrock-runtime`. The endpoint supports Amazon Bedrock API key authentication, AWS credentials, and the OpenAI SDK.

The examples in this section read the `OPENAI_BASE_URL` and `OPENAI_API_KEY` environment variables. Set them to the `bedrock-mantle` base URL and your Amazon Bedrock API key:

```
OPENAI_BASE_URL="https://bedrock-mantle.<your-region>.api.aws/v1"
OPENAI_API_KEY="<provide your Bedrock API key>"
```

Important

Point `OPENAI_BASE_URL` at `bedrock-mantle` for these examples. Model cards set it to the `bedrock-runtime` base URL (`https://bedrock-runtime.{region}.amazonaws.com/openai/v1`), and `bedrock-runtime` doesn't implement the Models API, so listing models against that base URL returns `404 UnknownOperationException`.

List available models

The OpenAI-compatible Models API is available only on `bedrock-mantle`. To list models available on this endpoint, choose the tab for your preferred method, and then follow the steps:

OpenAI SDK (Python)

```
# List all available models using the OpenAI SDK
# Requires OPENAI_API_KEY and OPENAI_BASE_URL environment variables

from openai import OpenAI

client = OpenAI()

models = client.models.list()

for model in models.data:
    print(model.id)
```

HTTP request

```
# List all available models
# Requires OPENAI_API_KEY and OPENAI_BASE_URL environment variables

curl -X GET $OPENAI_BASE_URL/models \
   -H "Authorization: Bearer $OPENAI_API_KEY"
```

Create a chat completion

Choose the tab for your preferred method, and then follow the steps:

OpenAI SDK (Python)

Configure the OpenAI client using environment variables:

```
# Create a chat completion using the OpenAI SDK
# Requires OPENAI_API_KEY and OPENAI_BASE_URL environment variables

from openai import OpenAI

client = OpenAI()

completion = client.chat.completions.create(
    model="openai.gpt-oss-120b",
    messages=[
        {"role": "system", "content": "You are a helpful assistant."},
        {"role": "user", "content": "Hello!"}
    ]
)

print(completion.choices[0].message)
```

HTTP request

Make a POST request to `/v1/chat/completions`:

```
# Create a chat completion
# Requires OPENAI_API_KEY and OPENAI_BASE_URL environment variables

curl -X POST $OPENAI_BASE_URL/chat/completions \
   -H "Content-Type: application/json" \
   -H "Authorization: Bearer $OPENAI_API_KEY" \
   -d '{
    "model": "openai.gpt-oss-120b",
    "messages": [
        {"role": "system", "content": "You are a helpful assistant."},
        {"role": "user", "content": "Hello!"}
    ]
}'
```

Streaming

To receive responses incrementally, choose the tab for your preferred method, and then follow the steps:

OpenAI SDK (Python)

```
# Stream chat completion responses incrementally using the OpenAI SDK
# Requires OPENAI_API_KEY and OPENAI_BASE_URL environment variables

from openai import OpenAI

client = OpenAI()

stream = client.chat.completions.create(
    model="openai.gpt-oss-120b",
    messages=[{"role": "user", "content": "Tell me a story"}],
    stream=True
)

for chunk in stream:
    if chunk.choices[0].delta.content is not None:
        print(chunk.choices[0].delta.content, end="")
```

HTTP request

Make a POST request to `/v1/chat/completions` with `stream` set to `true`:

```
# Stream chat completion responses incrementally
# Requires OPENAI_API_KEY and OPENAI_BASE_URL environment variables

curl -X POST $OPENAI_BASE_URL/chat/completions \
   -H "Content-Type: application/json" \
   -H "Authorization: Bearer $OPENAI_API_KEY" \
   -d '{
    "model": "openai.gpt-oss-120b",
    "messages": [
        {"role": "user", "content": "Tell me a story"}
    ],
    "stream": true
}'
```

Include a guardrail in a chat completion

To include safeguards in model input and responses, apply a guardrail when running model invocation by including the following extra parameters as fields in the request body:

- `extra_headers` – Maps to an object containing the following fields, which specify extra headers in the request:
  - `X-Amzn-Bedrock-GuardrailIdentifier` (required) – The ID of the guardrail.
  - `X-Amzn-Bedrock-GuardrailVersion` (required) – The version of the guardrail.
  - `X-Amzn-Bedrock-Trace` (optional) – Whether or not to enable the guardrail trace.
- `extra_body` – Maps to an object. In that object, you can include the `amazon-bedrock-guardrailConfig` field, which maps to an object containing the following fields:
  - `tagSuffix` (optional) – Include this field for input tagging.

For more information about these parameters in Amazon Bedrock Guardrails, see Test your guardrail.

To see examples of using guardrails with OpenAI chat completions, choose the tab for your preferred method, and then follow the steps:

OpenAI SDK (Python)

```
import openai
from openai import OpenAIError

# Endpoint for Amazon Bedrock Runtime
bedrock_endpoint = "https://bedrock-runtime.us-west-2.amazonaws.com/openai/v1"

# Model ID
model_id = "openai.gpt-oss-20b-1:0"

# Replace with actual values
bedrock_api_key = "$AWS_BEARER_TOKEN_BEDROCK"
guardrail_id = "GR12345"
guardrail_version = "DRAFT"

client = openai.OpenAI(
    api_key=bedrock_api_key,
    base_url=bedrock_endpoint,
)
```

```
try:
    response = client.chat.completions.create(
        model=model_id,
        # Specify guardrail information in the header
        extra_headers={
            "X-Amzn-Bedrock-GuardrailIdentifier": guardrail_id,
            "X-Amzn-Bedrock-GuardrailVersion": guardrail_version,
            "X-Amzn-Bedrock-Trace": "ENABLED",
        },
        # Additional guardrail information can be specified in the body
        extra_body={
            "amazon-bedrock-guardrailConfig": {
                "tagSuffix": "xyz"  # Used for input tagging
            }
        },
        messages=[
            {
                "role": "system",
                "content": "You are a helpful assistant."
            },
            {
                "role": "assistant",
                "content": "Hello! How can I help you today?"
            },
            {
                "role": "user",
                "content": "What is the weather like today?"
            }
        ]
    )

    request_id = response._request_id
    print(f"Request ID: {request_id}")
    print(response)

except OpenAIError as e:
    print(f"An error occurred: {e}")
    if hasattr(e, 'response') and e.response is not None:
        request_id = e.response.headers.get("x-request-id")
        print(f"Request ID: {request_id}")
```

OpenAI SDK (Java)

```
import com.openai.client.OpenAIClient;
import com.openai.client.okhttp.OpenAIOkHttpClient;
import com.openai.core.http.HttpResponseFor;
import com.openai.models.chat.completions.ChatCompletion;
import com.openai.models.chat.completions.ChatCompletionCreateParams;

// Endpoint for Amazon Bedrock Runtime
String bedrockEndpoint = "http://bedrock-runtime.us-west-2.amazonaws.com/openai/v1"

// Model ID
String modelId = "openai.gpt-oss-20b-1:0"

// Replace with actual values
String bedrockApiKey = "$AWS_BEARER_TOKEN_BEDROCK"
String guardrailId = "GR12345"
String guardrailVersion = "DRAFT"

OpenAIClient client = OpenAIOkHttpClient.builder()
        .apiKey(bedrockApiKey)
        .baseUrl(bedrockEndpoint)
        .build()

ChatCompletionCreateParams request = ChatCompletionCreateParams.builder()
        .addUserMessage("What is the temperature in Seattle?")
        .model(modelId)
        // Specify additional headers for the guardrail
        .putAdditionalHeader("X-Amzn-Bedrock-GuardrailIdentifier", guardrailId)
        .putAdditionalHeader("X-Amzn-Bedrock-GuardrailVersion", guardrailVersion)
        // Specify additional body parameters for the guardrail
        .putAdditionalBodyProperty(
                "amazon-bedrock-guardrailConfig",
                JsonValue.from(Map.of("tagSuffix", JsonValue.of("xyz"))) // Allows
 input tagging
        )
        .build();

HttpResponseFor<ChatCompletion> rawChatCompletionResponse =
        client.chat().completions().withRawResponse().create(request);

final ChatCompletion chatCompletion = rawChatCompletionResponse.parse();
```

```
System.out.println(chatCompletion);
```

Inference using Anthropic Messages API

The Anthropic Messages API provides native access to Claude models using the Anthropic request and response format. You can use the Messages API on both the `bedrock-runtime` and `bedrock-mantle` endpoints. For new applications, we recommend the `bedrock-runtime` endpoint.

Endpoint	Base URL	Use case
`bedrock-runtime`	`https://bedrock-runtime.{region}.amazonaws.com/anthropic`	Recommended for new applications. Uses AWS SDK integrations, IAM authentication, and invocation logging.
`bedrock-mantle`	`https://bedrock-mantle.{region}.api.aws/anthropic/v1/messages`	Supports Amazon Bedrock API key authentication and the section called "Workspaces".

Supported Regions

The Messages API is available on the `bedrock-runtime` endpoint in all Regions where Claude models are available. See the section called "Regional availability by models" for details. On the `bedrock-mantle` endpoint, it is available in all Regions that support `bedrock-mantle` (see the section called "Supported Regions and Endpoints").

Prerequisites

Before using the Messages API, make sure you have the following:

- **Model access** – Request access to Claude models in the Amazon Bedrock console. See the section called "Request access to models".
- **Authentication** – Depends on the endpoint:
  - `bedrock-runtime` – Use AWS SigV4 credentials through the AWS SDK (boto3, etc.), a Amazon Bedrock API key (see the section called "API keys"), or a short-term Bedrock bearer token generated from AWS credentials with the aws-bedrock-token-generator library.

- `bedrock-mantle` – Use a Amazon Bedrock API key (see the section called "API keys") or AWS SigV4 credentials.
- **Anthropic version header** – All requests require an API version:
  - `bedrock-runtime`: Set `"anthropic_version": "bedrock-2023-05-31"` in the request body when calling `InvokeModel`. The Anthropic SDK adds the required header automatically when using `base_url=https://bedrock-runtime.{region}.amazonaws.com/anthropic`.
  - `bedrock-mantle`: Set `anthropic-version: 2023-06-01` as an HTTP header.

Basic request

To send a basic message to a Claude model, choose the tab for your preferred method, and then follow the steps:

> **Note**
>
> The AWS CLI doesn't provide a native command for the `bedrock-mantle` Messages API. Use the Anthropic SDK or an HTTP client such as curl.

bedrock-runtime (Python, Anthropic SDK)

Use the Anthropic SDK against the `bedrock-runtime` endpoint's `/anthropic` route with a short-term Bedrock bearer token generated by aws-bedrock-token-generator:

```
from anthropic import Anthropic
from aws_bedrock_token_generator import provide_token

token = provide_token(region="us-east-1")

client = Anthropic(
    base_url="https://bedrock-runtime.us-east-1.amazonaws.com/anthropic",
    api_key=token,
)

response = client.messages.create(
    model="global.anthropic.claude-sonnet-5",
    max_tokens=1024,
    messages=[
```

```
        {"role": "user", "content": "Explain quantum computing in one sentence."}
    ]
)
print(response.content[0].text)
```

bedrock-runtime (Python, boto3)

```
import boto3
import json

client = boto3.client("bedrock-runtime", region_name="us-east-1")

response = client.invoke_model(
    modelId="anthropic.claude-sonnet-5",
    body=json.dumps({
        "anthropic_version": "bedrock-2023-05-31",
        "max_tokens": 1024,
        "messages": [
            {"role": "user", "content": "Explain quantum computing in one
 sentence."}
        ]
    })
)

result = json.loads(response["body"].read())
print(result["content"][0]["text"])
```

bedrock-runtime (AWS CLI)

Use the AWS CLI to invoke the model:

```
aws bedrock-runtime invoke-model \
  --model-id anthropic.claude-sonnet-5 \
  --body '{
    "anthropic_version": "bedrock-2023-05-31",
    "max_tokens": 1024,
    "messages": [
        {"role": "user", "content": "Explain quantum computing in one sentence."}
    ]
  }' \
  --cli-binary-format raw-in-base64-out \
  output.json
```

bedrock-runtime (curl)

You can call `bedrock-runtime` directly with curl by signing the request with AWS SigV4. The example below uses curl's built-in `--aws-sigv4` flag (available in curl 7.75.0 and later):

```
curl -X POST \
  "https://bedrock-runtime.us-east-1.amazonaws.com/model/anthropic.claude-sonnet-5/
invoke" \
  -H "Content-Type: application/json" \
  --aws-sigv4 "aws:amz:us-east-1:bedrock" \
  --user "$AWS_ACCESS_KEY_ID:$AWS_SECRET_ACCESS_KEY" \
  -d '{
    "anthropic_version": "bedrock-2023-05-31",
    "max_tokens": 1024,
    "messages": [
        {"role": "user", "content": "Explain quantum computing in one sentence."}
    ]
  }'
```

Note

If you are using temporary credentials from AWS STS (for example, an assumed role), also pass the session token by adding `-H "X-Amz-Security-Token: $AWS_SESSION_TOKEN"` to the request. For most use cases we recommend the AWS SDKs or CLI, which handle request signing and credential refresh automatically.

bedrock-runtime (curl, API key)

You can also call `bedrock-runtime` with a Amazon Bedrock API key using the Anthropic-native `/anthropic/v1/messages` route, just like `bedrock-mantle`:

```
curl -X POST https://bedrock-runtime.us-east-1.amazonaws.com/anthropic/v1/messages \
  -H "x-api-key: $AWS_BEARER_TOKEN_BEDROCK" \
  -H "anthropic-version: 2023-06-01" \
  -H "Content-Type: application/json" \
  -d '{
    "model": "us.anthropic.claude-sonnet-5",
    "max_tokens": 1024,
    "messages": [
        {"role": "user", "content": "Explain quantum computing in one sentence."}
```

```
    ]
  }'
```

bedrock-mantle (Python, Anthropic SDK)

Install the Anthropic SDK and set BEDROCK_API_KEY to your Amazon Bedrock API key.

```
import os
from anthropic import Anthropic

client = Anthropic(
    base_url="https://bedrock-mantle.us-east-1.api.aws/anthropic",
    api_key=os.environ["BEDROCK_API_KEY"],
)

response = client.messages.create(
    model="anthropic.claude-sonnet-5",
    max_tokens=1024,
    messages=[
        {"role": "user", "content": "Explain quantum computing in one sentence."}
    ],
)
print(response.content[0].text)
```

bedrock-mantle (curl)

```
curl -X POST https://bedrock-mantle.us-east-1.api.aws/anthropic/v1/messages \
  -H "x-api-key: $BEDROCK_API_KEY" \
  -H "anthropic-version: 2023-06-01" \
  -H "Content-Type: application/json" \
  -d '{
    "model": "anthropic.claude-sonnet-5",
    "max_tokens": 1024,
    "messages": [
        {"role": "user", "content": "Explain quantum computing in one sentence."}
    ]
  }'
```

Stream responses

To receive response tokens incrementally as they are generated, choose the tab for your preferred method, and then follow the steps:

bedrock-runtime (Python, Anthropic SDK)

```
from anthropic import Anthropic
from aws_bedrock_token_generator import provide_token

token = provide_token(region="us-east-1")

client = Anthropic(
    base_url="https://bedrock-runtime.us-east-1.amazonaws.com/anthropic",
    api_key=token,
)

with client.messages.stream(
    model="global.anthropic.claude-sonnet-5",
    max_tokens=1024,
    messages=[
        {"role": "user", "content": "Write a short poem about cloud computing."}
    ],
) as stream:
    for text in stream.text_stream:
        print(text, end="", flush=True)
```

bedrock-runtime (Python, boto3)

```
import boto3
import json

client = boto3.client("bedrock-runtime", region_name="us-east-1")

response = client.invoke_model_with_response_stream(
    modelId="anthropic.claude-sonnet-5",
    body=json.dumps({
        "anthropic_version": "bedrock-2023-05-31",
        "max_tokens": 1024,
        "messages": [
            {"role": "user", "content": "Write a short poem about cloud computing."}
        ]
    })
)

for event in response["body"]:
    chunk = json.loads(event["chunk"]["bytes"])
    if chunk["type"] == "content_block_delta":
```

```
        print(chunk["delta"]["text"], end="")
```

bedrock-runtime (curl, API key)

```
curl -X POST https://bedrock-runtime.us-east-1.amazonaws.com/anthropic/v1/messages \
  -H "x-api-key: $AWS_BEARER_TOKEN_BEDROCK" \
  -H "anthropic-version: 2023-06-01" \
  -H "Content-Type: application/json" \
  -d '{
    "model": "us.anthropic.claude-sonnet-5",
    "max_tokens": 1024,
    "stream": true,
    "messages": [
        {"role": "user", "content": "Write a short poem about cloud computing."}
    ]
  }'
```

bedrock-mantle (Python, Anthropic SDK)

```
import os
from anthropic import Anthropic

client = Anthropic(
    base_url="https://bedrock-mantle.us-east-1.api.aws/anthropic",
    api_key=os.environ["BEDROCK_API_KEY"],
)

with client.messages.stream(
    model="anthropic.claude-sonnet-5",
    max_tokens=1024,
    messages=[
        {"role": "user", "content": "Write a short poem about cloud computing."}
    ],
) as stream:
    for text in stream.text_stream:
        print(text, end="", flush=True)
```

bedrock-mantle (curl)

```
curl -X POST https://bedrock-mantle.us-east-1.api.aws/anthropic/v1/messages \
  -H "x-api-key: $BEDROCK_API_KEY" \
  -H "anthropic-version: 2023-06-01" \
```

```
-H "Content-Type: application/json" \
-d '{
  "model": "anthropic.claude-sonnet-5",
  "max_tokens": 1024,
  "stream": true,
  "messages": [
      {"role": "user", "content": "Write a short poem about cloud computing."}
  ]
}'
```

Extended thinking

See also

- Thinking encryption – encrypted-thinking and redaction behavior specific to Claude 3.7 Sonnet.
- Differences in thinking across model versions – differences in how Claude 3.7 Sonnet and Claude 4 models return thinking output.

Extended thinking gives Claude enhanced reasoning capabilities for complex tasks, while providing varying levels of transparency into its step-by-step thought process before it delivers its final answer. Whenever you enable Claude's thinking mode, you will need to set a budget for the maximum number of tokens that Claude can use for its internal reasoning process.

The supported models are as follows:

Model	Model ID
Claude Opus 4.5	`anthropic.claude-opus-4-5-20251101-v1:0`
Claude Opus 4	`anthropic.claude-opus-4-20250514-v1:0`
Claude Sonnet 4	`anthropic.claude-sonnet-4-20250514-v1:0`

Model	Model ID
Claude Sonnet 4.5	`anthropic.claude-sonnet-4-5-20250929-v1:0`
Claude Sonnet 4.6	`anthropic.claude-sonnet-4-6`
Claude Opus 4.6	`anthropic.claude-opus-4-6-v1`
Claude Haiku 4.5	`anthropic.claude-haiku-4-5-20251001-v1:0`
Claude 3.7 Sonnet	`anthropic.claude-3-7-sonnet-20250219-v1:0`

Note

Claude Fable 5.2, Claude Mythos 5.2, Claude Fable 5.1, Claude Mythos 5.1, Claude Mythos 5, and Claude Fable 5 do not support extended thinking. Requests with `thinking.type: "enabled"` or `thinking.type: "disabled"` will return a 400 error. These models use adaptive thinking exclusively. See Adaptive thinking for details.

Migration from extended thinking:

- Replace `{"type": "enabled", "budget_tokens": N}` with `{"type": "adaptive"}` and use `output_config.effort` to control thinking depth.
- Remove `{"type": "disabled"}` — omitting the thinking parameter entirely gives you adaptive thinking by default.

Note

API behavior differs between Claude 3.7 and Claude 4 models. For more information, see Differences in thinking across model versions.

Best practices and considerations for extended thinking

Usage guidelines

- **Task selection**: Use extended thinking for particularly complex tasks that benefit from step-by-step reasoning like math, coding, and analysis.
- **Context handling**: You do not need to remove previous thinking blocks yourself. The Anthropic API automatically ignores thinking blocks from previous turns and they are not included when calculating context usage.
- **Prompt engineering**: Review Anthropic's extended thinking prompting tips if you want to maximize Claude's thinking capabilities.

Performance considerations

- **Response times**: Be prepared for potentially longer response times due to the additional processing required for the reasoning process. Factor in that generating thinking blocks might increase the overall response time.
- **Streaming requirements**: Streaming is required when `max_tokens` is greater than 21,333. When streaming, be prepared to handle both `thinking` and `text` content blocks as they arrive.

Feature compatibility

- Thinking isn't compatible with `temperature`, `top_p`, or `top_k` modifications or forced tool use.
- You cannot pre-fill responses when thinking is enabled.

- Changes to the thinking budget invalidate cached prompt prefixes that include messages. However, cached system prompts and tool definitions will continue to work when thinking parameters change.

Working with thinking budgets

- **Budget optimizations**: The minimum budget is 1,024 tokens. Anthropic suggests starting at the minimum and increasing the thinking budget incrementally to find the optimal range for your use case. Larger token counts might allow for more comprehensive and nuanced reasoning, but there can also be diminishing returns depending on the task. The thinking budget is a target rather than a strict limit - actual token usage may vary based on the task.
- **Minimum and optimal settings**: The minimum budget is 1,024 tokens. We suggest starting at the minimum and increasing the thinking budget incrementally to find the optimal range for Claude to perform well for your use case. Higher token counts might allow you to achieve more comprehensive and nuanced reasoning, but there might also be diminishing returns depending on the task. The thinking budget is a target rather than a strict limit - actual token usage can vary based on the task.
- **Experimentation**: The model might perform differently at different max thinking budget settings. Increasing the max thinking budget can make the model think better or harder, at the tradeoff of increased latency. For critical tasks, consider testing different budget settings to find the optimal balance between quality and performance.
- **Large budgets**: For thinking budgets above 32K, we recommend using batch processing to avoid networking issues. Requests pushing the model to think above 32K tokens causes long running requests that might result in system timeouts and open connection limits. Please note that `max_tokens` limits vary among Claude models. For more information, see Max tokens and context window size with extended thinking.
- **Token usage tracking**: Monitor thinking token usage to optimize costs and performance.

How extended thinking works

When extended thinking is turned on, Claude creates `thinking` content blocks where it outputs its internal reasoning. Claude incorporates insights from this reasoning before crafting a final response. The API response will include `thinking` content blocks, followed by `text` content blocks.

Here's an example of the default response format:

```
{
  "content": [
    {
      "type": "thinking",
      "thinking": "Let me analyze this step by step...",
      "signature": "WaUjzkypQ2mUEVM36O2TxuC06KN8xyfbJwyem2dw3URve/op91XWHOEBLLqIOMfFG/
UvLEczmEsUjavL...."
    },
    {
      "type": "text",
      "text": "Based on my analysis..."
    }
  ]
}
```

For more information about the response format of extended thinking, see Anthropic's Messages API Request and Response.

How to use extended thinking

To turn on extended thinking, add a `thinking` object, with the `thinking` parameter set to enabled and the `budget_tokens` set to a specified token budget for extended thinking.

The `budget_tokens` parameter determines the maximum number of tokens Claude is allowed to use for its internal reasoning process. In Claude 4 models, this limit applies to full thinking tokens, and not to the summarized output. Larger budgets can improve response quality by enabling more thorough analysis for complex problems, although Claude might not use the entire budget allocated, especially at ranges above 32K.

The value of `budget_tokens` must be set to a value less than `max_tokens`. However, when using Interleaved thinking (beta) with tools, you can exceed this limit because the token limit becomes your entire context window (200K tokens).

Summarized thinking

With extended thinking enabled, the Messages API for Claude 4 models returns a summary of Claude's full thinking process. Summarized thinking provides the full intelligence benefits of extended thinking, while preventing misuse.

Here are some important considerations for summarized thinking:

- You're charged for the full thinking tokens generated by the original request, not the summary tokens.
- The billed output token count will not match the count of tokens you see in the response.
- The prompt provided to the summarizer model is subject to change.
- The first few lines of thinking output are more verbose, providing detailed reasoning that's particularly helpful for prompt engineering purposes.

> **Note**
>
> Claude 3.7 Sonnet still returns the full thinking output.

Streaming thinking

You can stream extended thinking responses using server-sent events (SSE). When streaming is enabled for extended thinking, you receive thinking content through `thinking_delta` events. Streamed events are not guaranteed to return at a constant rate. There can be delays between streaming events. For more documentation on streaming through the Messages API, see Streaming messages.

Here's how to handle streaming with thinking using **InvokeModelWithResponseStream**:

```
{
    "anthropic_version": "bedrock-2023-05-31",
    "max_tokens": 10000,
    "thinking": {
        "type": "enabled",
        "budget_tokens": 4000
    },
    "messages": [
        {
            "role": "user",
            "content": "What is 27 * 453?"
        }
    ]
}
```

Response:

```
event: message_start
data: {"type": "message_start", "message": {"id": "msg_01...", "type": "message",
 "role": "assistant", "content": [], "model": "claude-3-7-sonnet-20250219",
 "stop_reason": null, "stop_sequence": null}}

event: content_block_start
data: {"type": "content_block_start", "index": 0, "content_block": {"type": "thinking",
 "thinking": ""}}

event: content_block_delta
data: {"type": "content_block_delta", "index": 0, "delta": {"type": "thinking_delta",
 "thinking": "Let me solve this step by step:\n\n1. First break down 27 * 453"}}

event: content_block_delta
data: {"type": "content_block_delta", "index": 0, "delta": {"type": "thinking_delta",
 "thinking": "\n2. 453 = 400 + 50 + 3"}}

// Additional thinking deltas...

event: content_block_delta
data: {"type": "content_block_delta", "index": 0, "delta": {"type": "signature_delta",
 "signature": "EqQBCgIYAhIM1gbcDa9GJwZA2b3hGgxBdjrkzLoky3dl1pkiMOYds..."}}

event: content_block_stop
data: {"type": "content_block_stop", "index": 0}

event: content_block_start
data: {"type": "content_block_start", "index": 1, "content_block": {"type": "text",
 "text": ""}}

event: content_block_delta
data: {"type": "content_block_delta", "index": 1, "delta": {"type": "text_delta",
 "text": "27 * 453 = 12,231"}}

// Additional text deltas...

event: content_block_stop
data: {"type": "content_block_stop", "index": 1}

event: message_delta
data: {"type": "message_delta", "delta": {"stop_reason": "end_turn", "stop_sequence":
 null}}
```

```
event: message_stop
data: {"type": "message_stop"}
```

About streaming behavior with thinking

When using streaming with thinking enabled, you might notice that text sometimes arrives in larger chunks alternating with smaller, token-by-token delivery. This is expected behavior, especially for thinking content. The streaming system needs to process content in batches for optimal performance, which can result in this delivery pattern.

Extended thinking with tool use

Extended thinking can be used alongside Anthropic Claude tool use allowing Claude to reason through tool selection and results processing. When using extended thinking with tool use, be aware of the following limitations:

- **Tool choice limitation**: Tool use with thinking only supports `tool_choice: auto` (default) or `tool_choice: none`. It does not support forced tool use (any or specifying a specific tool).
- **Preserving thinking blocks**: During tool use, you must pass thinking blocks back to the API for the last assistant message. Include the complete unmodified block back to the API to maintain reasoning continuity.

Here is how context window management works with tools:

```
{
    "anthropic_version": "bedrock-2023-05-31",
    "max_tokens": 10000,
    "thinking": {
        "type": "enabled",
        "budget_tokens": 4000
    },
  "tools": [
  {
    "name": "get_weather",
    "description": "Get current weather for a location",
    "input_schema": {
      "type": "object",
      "properties": {
        "location": {
```

```
          "type": "string"
        }
      },
      "required": [
        "location"
      ]
    }
  }
],
    "messages": [
        {
            "role": "user",
            "content": "What's the weather in Paris?"
        }
    ]
}
```

The first response is the following:

```
{
    "content": [
        {
            "type": "thinking",
            "thinking": "The user wants to know the current weather in Paris. I have
 access to a function `get_weather`...",
            "signature": "BDaL4VrbR2Oj0hO4XpJxT28J5TILnCrrUXoKiiNBZW9P
+nr8XSj1zuZzAl4egiCCpQNvfyUuFFJP5CncdYZEQPPmLxYsNrcs...."
        },
        {
            "type": "text",
            "text": "I can help you get the current weather information for Paris. Let
 me check that for you"
        },
        {
            "type": "tool_use",
            "id": "toolu_01CswdEQBMshySk6Y9DFKrfq",
            "name": "get_weather",
            "input": {
                "location": "Paris"
            }
        }
    ]
}
```

Continuing the conversation with tool use will generate another response. Notice that the `thinking_block` is passed in as well as the `tool_use_block`. If this is not passed in, an error occurs.

```
{
  "anthropic_version": "bedrock-2023-05-31",
  "max_tokens": 10000,
  "thinking": {
    "type": "enabled",
    "budget_tokens": 4000
  },
  "tools": [
    {
      "name": "get_weather",
      "description": "Get current weather for a location",
      "input_schema": {
        "type": "object",
        "properties": {
          "location": {
            "type": "string"
          }
        },
        "required": [
          "location"
        ]
      }
    }
  ],
      "messages": [
        {
          "role": "user",
          "content": "What's the weather in Paris?"
        },
        {
          "role": "assistant",
          "content": [
            {
              "type": "thinking",
              "thinking": "The user wants to know the current weather in Paris. I have
 access to a function `get_weather`…",
              "signature": "BDaL4VrbR2Oj0hO4XpJxT28J5TILnCrrUXoKiiNBZW9P
+nr8XSj1zuZzAl4egiCCpQNvfyUuFFJP5CncdYZEQPPmLxY",
            },
```

```
            {
              "type": "tool_use",
              "id": "toolu_01CswdEQBMshySk6Y9DFKrfq",
              "name": "get_weather",
              "input": {
                "location": "Paris"
              }
            }
          ]
        },
        {
          "role": "user",
          "content": [
            {
              "type": "tool_result",
              "tool_use_id": "toolu_01CswdEQBMshySk6Y9DFKrfq",
              "content": "Current temperature: 88°F"
            }
          ]
        }
      ]
    }
```

The API response will now only include text

```
{
  "content": [
    {
      "type": "text",
      "text": "Currently in Paris, the temperature is 88°F (31°C)"
    }
  ]
}
```

Preserve thinking blocks

During tool use, you must pass thinking blocks back to the API, and you must include the complete unmodified block back to the API. This is critical for maintaining the model's reasoning flow and conversation integrity.

Tip

While you can omit `thinking` blocks from prior `assistant` role turns, we suggest always passing back all thinking blocks to the API for any multi-turn conversation. The API will do the following:

- Automatically filter the provided thinking blocks
- Use the relevant thinking blocks necessary to preserve the model's reasoning
- Only bill for the input tokens for the blocks shown to Claude

When Claude invokes tools, it is pausing its construction of a response to await external information. When tool results are returned, Claude will continue building that existing response. This necessitates preserving thinking blocks during tool use, for the following reasons:

- **Reasoning continuity**: The thinking blocks capture Claude's step-by-step reasoning that led to tool requests. When you post tool results, including the original thinking ensures Claude can continue its reasoning from where it left off.
- **Context maintenance**: While tool results appear as user messages in the API structure, they're part of a continuous reasoning flow. Preserving thinking blocks maintains this conceptual flow across multiple API calls.

Important

When providing thinking blocks, the entire sequence of consecutive thinking blocks must match the outputs generated by the model during the original request; you cannot rearrange or modify the sequence of these blocks.

Interleaved thinking (beta)

Warning

Interleaved thinking is made available to you as a 'Beta Service' as defined in the AWS Service Terms. It is subject to your Agreement with AWS and the AWS Service Terms, and the applicable model EULA.

Claude 4 models support interleaved thinking, a feature that enables Claude to think between tool calls and run more sophisticated reasoning after receiving tool results. This allows for more complex agentic interactions where Claude can do the following:

- Reason about the results of a tool call before deciding what to do next
- Chain multiple tool calls with reasoning steps in between
- Make more nuanced decisions based on intermediate results

To enable interleaved thinking, add the beta header `interleaved-thinking-2025-05-14` to your API request.

> **Note**
>
> With interleaved thinking, the `budget_tokens` can exceed the `max_tokens` parameter because it represents the total budget across all thinking blocks within one assistant turn.

Thinking block clearing (beta)

> **Warning**
>
> Thinking block clearing is made available as a "Beta Service" as defined in the AWS Service Terms.

> **Note**
>
> This feature is currently supported on Claude Sonnet 4/4.5, Claude Haiku 4.5, and Claude Opus 4/4.1/4.5.

Thinking block clearing is an Anthropic Claude model capability (in beta). With this feature, Claude can automatically clear older thinking blocks from previous turns. To use Thinking block clearing, you need to add `context-management-2025-06-27` to the list of beta headers on the anthropic_beta request parameter. You will also need to specify the use of `clear_thinking_20251015` and choose from the following configuration options.

These are the available controls for the `clear_thinking_20251015` context management strategy. All are optional or have defaults:

Configuration Option	Description
`keep` default: 1 thinking turn	Defines how many recent assistant turns with thinking blocks to preserve. Use `{"type": "thinking_turns", "value": N}` where N must be > 0 to keep the last N turns, or `{"type": "all"}` to keep all thinking blocks.

Request

Extended thinking with prompt caching

Prompt caching with thinking has several important considerations:

Thinking block context removal

- Thinking blocks from previous turns are removed from context, which can affect cache breakpoints.
- When continuing conversations with tool use, thinking blocks are cached and count as input tokens when read from cache. This creates a tradeoff where thinking blocks don't consume context window space visually, but they will still count towards your input token usage when cached.
- If thinking becomes disabled, requests will fail if you pass thinking content in the current tool use turn. In other contexts, thinking content passed to the API is simply ignored.

Cache invalidation patterns

- Changes to thinking parameters (such as enabling, disabling, or altering the budget allocation) invalidate message cache breakpoints.
- Interleaved thinking (beta) amplifies cache invalidation, as thinking blocks can occur between multiple tool calls.
- System prompts and tools remain cached despite thinking parameter changes or block removal.

> **Note**
>
> While thinking blocks are removed for caching and context calculations, they must be preserved when continuing conversations with tool use, especially with interleaved thinking.

Understanding thinking block caching behavior

When using extended thinking with tool use, thinking blocks exhibit specific caching behavior that affects token counting. The following sequence demonstrates how this works.

1. Caching only occurs when you make a subsequent request that includes tool results.

2. When the subsequent request is made, the previous conversation history (including thinking blocks) can be cached.
3. These cached thinking blocks count as input tokens in your usage metrics when they are read from the cache.
4. When a non-tool-result user block is included, all previous thinking blocks are ignored and stripped from context.

Here is a detailed example flow:

Request 1:

```
User: "What's the weather in Paris?"
```

Response 1:

```
[thinking_block 1] + [tool_use block 1]
```

Request 2:

```
User: "What's the weather in Paris?",
Assistant: [thinking_block_1] + [tool_use block 1],
User: [tool_result_1, cache=True]
```

Response 2:

```
[thinking_block 2] + [text block 2]
```

Request 2 writes a cache of the request content (not the response). The cache includes the original user message, the first thinking block, tool use block, and the tool result.

Request 3:

```
User: ["What's the weather in Paris?"],
Assistant: [thinking_block_1] + [tool_use block 1],
User: [tool_result_1, cache=True],
Assistant: [thinking_block_2] + [text block 2],
User: [Text response, cache=True]
```

Because a non-tool-result user block was included, all previous thinking blocks are ignored. This request will be processed the same as the following request:

Request 3 Alternate:

```
User: ["What's the weather in Paris?"]
Assistant: [tool_use block 1]
User: [tool_result_1, cache=True]
Assistant: [text block 2]
User: [Text response, cache=True]
```

This behavior is consistent whether using regular thinking or interleaved thinking.

Max tokens and context window size with extended thinking

In older Claude models (before Claude 3.7 Sonnet), if the sum of prompt tokens and max_tokens exceeded the model's context window, the system would automatically adjust max_tokens to fit within the context limit. This meant you could set a large max_tokens value and the system would silently reduce it as needed. With Claude 3.7 and 4 models, `max_tokens` (which includes your thinking budget when thinking is enabled) is enforced as a strict limit. The system now returns a validation error if prompt tokens + max_tokens exceeds the context window size.

The context window with extended thinking

When calculating context window usage with thinking enabled, there are some considerations to be aware of:

- Thinking blocks from previous turns are removed and not counted towards your context window.
- Current turn thinking counts towards your `max_tokens` limit for that turn.

The effective context window is calculated as: context window = (current input tokens - previous thinking tokens) + (thinking tokens + encrypted thinking tokens + text output tokens).

Managing tokens with extended thinking and tool use

When using extended thinking with tool use, thinking blocks must be explicitly preserved and returned with the tool results. The effective context window calculation for extended thinking with tool use becomes the following:

```
context window = (current input tokens + previous thinking tokens + tool
use tokens) + (thinking tokens + encrypted thinking tokens + text output
tokens)
```

Managing tokens with extended thinking

Given the context window and `max_tokens` behavior with extended thinking Claude 3.7 and 4 models, you might need to perform one of the following actions:

- More actively monitor and manage your token usage.
- Adjust `max_tokens` values as your prompt length changes.
- Be aware that previous thinking blocks don't accumulate in your context window. This change has been made to provide more predictable and transparent behavior, especially as maximum token limits have increased significantly.

Extended thinking token cost considerations

The thinking process incurs charges for the following:

- Tokens used during thinking (output tokens)
- Thinking blocks from the last assistant turn included in subsequent requests (input tokens)
- Standard text output tokens

> **Tip**
>
> When extended thinking is enabled, a specialized 28 or 29 token system prompt is automatically included to support this feature.

The `budget_tokens` parameter determines the maximum number of tokens Claude is allowed to use for its internal reasoning process. Larger budgets can improve response quality by enabling more thorough analysis for complex problems, although Claude may not use the entire budget allocated, especially at ranges above 32K.

With interleaved thinking, the `budget_tokens` can exceed the `max_tokens` parameter as it represents the total budget across all thinking blocks within one assistant turn.

When using summarized thinking, keep the following information in mind:

- **Input tokens**: Tokens in your original request
- **Output tokens (billed)**: The original thinking tokens that Claude generated internally
- **Output tokens (visible)**: The summarized thinking tokens you see in the response
- **No charge**: Tokens used to generate the summary
- The `summary_status` field can indicate if token limits affected summarization
- The billed output token count will not match the visible token count in the response. You are billed for the full thinking process, not the summary you see.

Adaptive thinking

Adaptive thinking lets Claude dynamically decide when and how much to think based on the complexity of each request, instead of requiring a fixed thinking token budget. Adaptive thinking reliably drives better performance than extended thinking with a fixed `budget_tokens`. No beta header is required.

The following models support adaptive thinking. Each model's card describes its thinking defaults, whether thinking can be turned off, and its supported effort levels under **Reasoning**. For a side-by-side comparison, see Thinking configuration by model.

Model	Model ID
the section called “Claude Fable 5.2”	`anthropic.claude-fable-5-2`

the section called “Claude Sonnet 4.6”	`anthropic.claude-sonnet-4-6`

Important

Adaptive thinking is on by default on Claude 5 and later models. A request that omits the `thinking` field runs with adaptive thinking. On Claude Opus 4.8 and earlier models, the same request runs without thinking, so an application migrated from an earlier model without changes will produce thinking output — and be billed for those thinking tokens as output tokens — even though the request body did not change.

Omitting the `thinking` field doesn't turn thinking off, and neither does a zero or reduced `budget_tokens` (`"enabled"` returns a 400 error on these models). To turn thinking off where the model allows it, send `"thinking": {"type": "disabled"}`, or `"between_tools"` on Claude Sonnet 5.5. Some models can't turn thinking off; see Thinking configuration by model.

Because `max_tokens` is a hard limit on total output — thinking plus response text — revisit `max_tokens` for workloads that previously ran without thinking. If you were using disabled thinking on Claude Sonnet 4.6, consider adaptive thinking with a lower `output_config.effort` level on Claude Sonnet 5 instead of disabling it.

Thinking configuration by model

The following table shows how each model handles each `thinking.type` value. A 400 error means the request is rejected with a `ValidationException`.

Model	No thinking field	"adaptive"	"enabled" with budget_tokens	"between_tools"	"disabled"
Claude Opus 5.5	Adaptive	Adaptive	400 error	400 error	400 error
Claude Sonnet 5.5	Adaptive	Adaptive	400 error	Up-front thinking off at `high` effort or below	400 error
Claude Haiku 5.5	Adaptive	Adaptive	400 error	400 error	Thinking off at `high` effort or below
Claude Fable 5.2, Claude Mythos 5.2, Claude Fable 5.1, Claude Mythos 5.1, Claude Fable 5, Claude Mythos 5	Adaptive	Adaptive	400 error	400 error	400 error
Claude Opus 5	Adaptive	Adaptive	400 error	400 error	Thinking off at `high` effort or below
Claude Sonnet 5	Adaptive	Adaptive	400 error	400 error	Thinking off
Claude Opus 4.8, Claude Opus 4.7	Thinking off	Adaptive	400 error	400 error	Thinking off

Model	No thinking field	"adaptive"	"enabled" with budget_tokens	"between_tools"	"disabled"
Claude Opus 4.6, Claude Sonnet 4.6	Thinking off	Adaptive	Extended thinking (deprecated)	400 error	Thinking off

"At high effort or below" means that combining that thinking type with xhigh or max effort returns a 400 error: `output_config.effort 'xhigh' is not supported when thinking is disabled on this model`. On those models, use adaptive thinking with a lower effort level instead of turning thinking off.

`thinking.type: "enabled"` and budget_tokens are deprecated on Claude Opus 4.6 and Claude Sonnet 4.6 and will be removed in a future model release. Older models (Claude Sonnet 4.5, Claude Opus 4.5, and earlier) don't support adaptive thinking and require `thinking.type: "enabled"` with budget_tokens.

How adaptive thinking works

In adaptive mode, Claude evaluates the complexity of each request and decides whether and how much to think. A simple question might get a direct answer with no thinking block, while a multi-step problem triggers deeper reasoning. The same conversation can contain turns with and without thinking, so don't build application logic that assumes every assistant turn starts with a thinking block. Higher effort levels make thinking more likely and deeper, but no effort level guarantees a thinking block on every request. In a tool-use loop, follow-up requests that only process tool results can skip thinking at any effort level.

Adaptive thinking also automatically enables Interleaved thinking (beta). This means Claude can think between tool calls, making it especially effective for agentic workflows.

Set `thinking.type` to `"adaptive"` in your API request:

CLI

```
aws bedrock-runtime invoke-model \
```

```
--model-id "global.anthropic.claude-opus-5-5" \
--body '{
"anthropic_version": "bedrock-2023-05-31",
"max_tokens": 16000,
"thinking": {
"type": "adaptive",
"display": "summarized"
},
"messages": [
{
"role": "user",
"content": "Three players A, B, C play a game. Each has a jar with 100 balls
 numbered 1-100. Simultaneously, each draws one ball. A beats B if As number > Bs
 number (mod 100, treating 100 as 0 for comparison). Similarly for B vs C and C
 vs A. The overall winner is determined by majority of pairwise wins (ties broken
 randomly). Is there a mixed strategy Nash equilibrium where each player draws
 uniformly? If not, characterize the equilibrium."
}
]
}' \
--cli-binary-format raw-in-base64-out \
output.json && cat output.json | jq '.content[] | {type, thinking: .thinking[0:200],
 text}'
```

Python

```
import boto3
import json

bedrock_runtime = boto3.client(
    service_name='bedrock-runtime',
    region_name='us-east-1'
)

response = bedrock_runtime.invoke_model(
    modelId="global.anthropic.claude-opus-5-5",
    body=json.dumps({
        "anthropic_version": "bedrock-2023-05-31",
        "max_tokens": 16000,
        "thinking": {
            "type": "adaptive",
            "display": "summarized"
        },
```

```
        "messages": [{
            "role": "user",
            "content": "Explain why the sum of two even numbers is always even."
        }]
    })
)

response_body = json.loads(response["body"].read())

for block in response_body["content"]:
    if block["type"] == "thinking":
        print(f"\nThinking: {block['thinking']}")
    elif block["type"] == "text":
        print(f"\nResponse: {block['text']}")
```

TypeScript

```
import { BedrockRuntimeClient, InvokeModelCommand } from "@aws-sdk/client-bedrock-
runtime";

async function main() {
    const client = new BedrockRuntimeClient({});

    const command = new InvokeModelCommand({
        modelId: "global.anthropic.claude-opus-5-5",
        body: JSON.stringify({
            anthropic_version: "bedrock-2023-05-31",
            max_tokens: 16000,
            thinking: {
                type: "adaptive",
                display: "summarized"
            },
            messages: [{
                role: "user",
                content: "Explain why the sum of two even numbers is always even."
            }]
        })
    });

    const response = await client.send(command);
    const responseBody = JSON.parse(new TextDecoder().decode(response.body));

    for (const block of responseBody.content) {
```

```
        if (block.type === "thinking") {
            console.log(`\nThinking: ${block.thinking}`);
        } else if (block.type === "text") {
            console.log(`\nResponse: ${block.text}`);
        }
    }
}

main().catch(console.error);
```

On Claude 5 and later models, `display` defaults to `omitted`, so these examples set `"display": "summarized"` to return readable thinking text. For more information, see Controlling thinking visibility with the display parameter.

Adaptive thinking with the effort parameter

You can combine adaptive thinking with the effort parameter to guide how much thinking Claude does. The effort level acts as soft guidance for Claude's thinking allocation:

Effort level	Thinking behavior
`max`	Claude thinks the most readily and at the greatest depth, with no constraint on thinking length. Supported on Claude Opus 5.5, Claude Sonnet 5.5, Claude Haiku 5.5, Claude Fable 5.2, Claude Mythos 5.2, Claude Fable 5.1, Claude Mythos 5.1, Claude Fable 5, Claude Mythos 5, Claude Opus 5, Claude Sonnet 5, Claude Opus 4.8, Claude Opus 4.7, Claude Opus 4.6, and Claude Sonnet 4.6. Requests using `max` on unsupported models return an error.
`xhigh`	Claude thinks more readily and at greater depth than at `high`, suited to long-running agentic work. Supported on Claude Opus 5.5, Claude Sonnet 5.5, Claude Haiku 5.5, Claude Fable 5.2, Claude Mythos 5.2, Claude Fable 5.1, Claude Mythos 5.1, Claude Fable 5, Claude Mythos 5, Claude Opus 5, Claude Sonnet 5, Claude Opus 4.8, and Claude Opus 4.7.

Effort level	Thinking behavior
`high` (default on most models)	Claude thinks on most requests that benefit from it. Provides deep reasoning on complex tasks.
`medium` (default on Claude Opus 5.5 and Claude Haiku 5.5)	Claude uses moderate thinking. May skip thinking for simple queries.
`low`	Claude minimizes thinking. Skips thinking for simple tasks where speed matters most.

Setting `effort` to the model's default produces the same behavior as omitting it. Because Claude Opus 5.5 defaults to `medium`, a request that omits `effort` runs one level lower on Claude Opus 5.5 than on Claude Opus 5.

Important

The `effort` parameter must be placed inside a separate `output_config` object in your request body — not inside the `thinking` object. Placing `effort` inside `thinking` returns a 400 error: `thinking.adaptive.effort: Extra inputs are not permitted`.

The following example shows how to set the effort level when using the InvokeModel API:

```
{
    "anthropic_version": "bedrock-2023-05-31",
    "max_tokens": 16000,
    "thinking": {
        "type": "adaptive"
    },
    "output_config": {
        "effort": "high"
    },
    "messages": [{
        "role": "user",
        "content": "Your prompt here"
    }]
}
```

Turning off up-front thinking on Claude Sonnet 5.5

Claude Sonnet 5.5 rejects `"thinking": {"type": "disabled"}` with a 400 error. To turn off the thinking that Claude Sonnet 5.5 does before it responds, set `thinking.type` to `"between_tools"`. This is the lowest thinking setting on Claude Sonnet 5.5. The model doesn't think before responding, but it still returns short progress updates between tool calls.

```
{
    "anthropic_version": "bedrock-2023-05-31",
    "max_tokens": 4096,
    "thinking": {"type": "between_tools"},
    "output_config": {"effort": "medium"},
    "messages": [{"role": "user", "content": "Your prompt here"}]
}
```

- `between_tools` works at `low`, `medium`, and `high` effort. At `xhigh` or `max`, the request returns a 400 error.
- `between_tools` accepts no other fields. Setting `display` alongside it returns a 400 error.
- Other models return `"thinking.type.between_tools" is not supported for this model`.

Controlling thinking visibility with the display parameter

When you use adaptive thinking, the `display` field controls whether Claude returns the text of its reasoning. Set it inside the `thinking` object, alongside `"type": "adaptive"`:

Display value	Behavior
`omitted` (default on Claude 5 and later models)	The response still contains a thinking block, but its `thinking` text is empty. The block carries a signature, so you can pass it back unchanged in multi-turn conversations.
`summarized`	The thinking block contains a summary of Claude's reasoning as text. This is the default on Claude Opus 4.6, Claude Sonnet 4.6, and earlier models.
`updates` (beta)	Thinking blocks are returned with empty `thinking` text, as with `omitted`, and the short progress updates that some

Display value	Behavior
	models write between tool calls are returned as readable text. Requires the `thinking-display-updates-2026-08-18` value in `anthropic_beta` .

`summarized` and `omitted` are generally available and don't require a beta header. Without the beta value, `updates` or any other value returns a `400` error: `thinking.adaptive.display: Input should be 'summarized', 'omitted'`. `display` isn't valid with `thinking.type: "disabled"` or `"between_tools"`. You're billed for the full thinking tokens regardless of the `display` value.

> **Note**
>
> Setting `summarized` doesn't guarantee that reasoning text is returned. Some models accept the parameter but return no thinking text, and some don't return a thinking block at all. Read the `thinking` field of the response rather than assuming that a request accepted with `summarized` produced reasoning text.

The following example requests summarized reasoning when using the InvokeModel API:

```
{
    "anthropic_version": "bedrock-2023-05-31",
    "max_tokens": 16000,
    "thinking": {
        "type": "adaptive",
        "display": "summarized"
    },
    "messages": [{
        "role": "user",
        "content": "Your prompt here"
    }]
}
```

Thinking token usage

Thinking tokens are billed as output tokens. To see how many output tokens were spent on thinking, read `usage.output_tokens_details.thinking_tokens` in the response. This

value counts the full reasoning that the model generated, not the summarized text returned in the response, and is always less than or equal to `output_tokens`. It is `0` when the model skipped thinking. When streaming, the breakdown appears only in the final `message_delta` event.

```
"usage": {
    "input_tokens": 52,
    "output_tokens": 498,
    "output_tokens_details": {
        "thinking_tokens": 312
    }
}
```

`output_tokens` remains the total used for billing. Because thinking counts toward `max_tokens`, set `max_tokens` high enough for both the reasoning and the answer. If responses stop with `stop_reason: "max_tokens"`, raise `max_tokens` or lower the effort level.

Using adaptive thinking with the Converse API

When using the Converse API, pass the `thinking` and `effort` parameters inside `additionalModelRequestFields`. The following example shows adaptive thinking with the default effort level:

```
import boto3, json

bedrock_runtime = boto3.client(service_name='bedrock-runtime', region_name='us-east-1')

response = bedrock_runtime.converse(
    modelId="global.anthropic.claude-opus-5-5",
    messages=[{
        "role": "user",
        "content": [{"text": "Explain why the sum of two even numbers is always
 even."}]
    }],
    additionalModelRequestFields={
        "thinking": {
            "type": "adaptive"
        }
    }
)

print(json.dumps(response["output"], indent=2, default=str))
```

To specify an effort level, add the `effort` field inside a separate `output_config` object in `additionalModelRequestFields`:

```
response = bedrock_runtime.converse(
    modelId="global.anthropic.claude-opus-5-5",
    messages=[{
        "role": "user",
        "content": [{"text": "What is 2 + 2?"}]
    }],
    additionalModelRequestFields={
        "thinking": {
            "type": "adaptive"
        },
        "output_config": {
            "effort": "low"
        }
    }
)
```

Setting effort per turn (beta)

This feature is a Beta Service as defined in the AWS Service Terms. On Claude Haiku 5.5, Claude Sonnet 5.5, Claude Opus 5.5, Claude Fable 5.2, Claude Mythos 5.2, Claude Fable 5.1, and Claude Mythos 5.1, you can change the effort level partway through a conversation instead of setting it once for the whole request. Insert a system message that carries an `output_config.effort` value at any point in the `messages` array. The new effort level applies to the turns that follow it. The request returns 200 with no change to the response shape.

To use per-turn effort, include one of the following `anthropic_beta` values: `mid-conversation-output-config-2026-07-01`, `mid-conversation-effort-2026-08-01`, `per-turn-control-2026-07-01`, or `per-message-effort-2026-07-01`.

```
{
    "anthropic_version": "bedrock-2023-05-31",
    "anthropic_beta": ["mid-conversation-effort-2026-08-01"],
    "max_tokens": 16000,
    "output_config": {"effort": "high"},
    "messages": [
        {"role": "user", "content": "First question"},
        {"role": "assistant", "content": "First answer"},
        {"role": "system", "content": [], "output_config": {"effort": "low"}},
        {"role": "user", "content": "A simpler follow-up question"}
```

```
    ]
}
```

> **Note**
>
> Without one of the listed beta values — or on a model that does not support per-turn effort — a request that includes `output_config` on a system message returns `400 messages.N.output_config: Extra inputs are not permitted`. A per-turn `task_budget` is not supported and also returns a 400.
> Claude Opus 5, Claude Sonnet 5, and Claude Opus 4.8 don't support per-turn effort and return the same error even with a beta value. On Claude Sonnet 5.5 with `thinking.type: "between_tools"` and on Claude Haiku 5.5 with `thinking.type: "disabled"`, effort can't change mid-conversation; use adaptive thinking to vary effort per turn.

Prompt caching

Consecutive requests that keep the same thinking configuration preserve prompt cache breakpoints. Switching between thinking modes (for example, from `adaptive` to `disabled`) invalidates the cache, including breakpoints on the system prompt and tool definitions, so the next request writes the cache again. Pick a thinking mode for each conversation and keep it.

To change effort for later turns of a conversation, use Setting effort per turn (beta) on models that support it.

Tuning thinking behavior

If Claude is thinking more or less often than you'd like, lower or raise the effort level first. You can also add guidance to your system prompt:

```
Extended thinking adds latency and should only be used when it
will meaningfully improve answer quality — typically for problems
that require multi-step reasoning. When in doubt, respond directly.
```

> **Note**
>
> On Claude Sonnet 5.5 and Claude Haiku 5.5, prompt guidance to think less doesn't reliably reduce thinking. Lower the effort level instead.

> **Warning**
>
> Steering Claude to think less often may reduce quality on tasks that benefit from reasoning. Measure the impact on your specific workloads before deploying prompt-based tuning to production. Consider testing with lower effort levels first.

Connector text summarization (beta)

On Claude Fable 5, text that the model emits between tool calls (sometimes called "connector text" — for example, "Let me check that file next...") is summarized server-side and returned as a thinking block rather than a plain text content block. The thinking block uses the same shape as any other thinking block (empty text with a signature under the default `omitted` display, described in Controlling thinking visibility with the display parameter).

Customer impact:

- **Response shape:** Tool-use responses from Claude Fable 5 may contain additional thinking blocks where previous models emitted plain text between `tool_use` blocks. There is no new content block type. Final assistant answers (after all tool use is complete) are unaffected and remain plain text.
- **Multi-turn handling:** Pass these thinking blocks back unchanged in multi-turn conversations — the same handling as protected thinking (signature validated on passback; silently stripped if sent to a different model).
- **Scope:** Connector summarization applies only after a `tool_result` exists in the conversation. Narration before the first tool call in a fresh conversation remains plain text. Short text segments may pass through as plain text without summarization.

This feature is enabled server-side for Claude Fable 5. There is no customer opt-in or opt-out.

Preserved thinking

Overview

On Claude Fable 5.2, Claude Mythos 5.2, Claude Fable 5.1, Claude Opus 5.5, Claude Sonnet 5.5, and Claude Haiku 5.5, each thinking block is tied to the model and the conversation that produced it. On Claude Mythos 5.1, thinking blocks are tied to the model only; the conversation prefix isn't checked. The API checks that the system prompt, the tool list, and all messages before the block

are unchanged when you replay that block in a later request. This protects the integrity of Claude's reasoning: reasoning produced under one set of instructions cannot be replayed under a different set.

If your harness sends conversation history back exactly as it received it, nothing changes for you. If you edit history between requests — injecting per-turn reminders, summarizing older turns, or rebuilding the system prompt — the API rejects the request by default.

What is checked on replay

Check	Description
Model	The model reading the block is allowed to read the producer's thinking. A model cannot read another model's thinking unless the two are explicitly compatible. This check applies on any thinking-capable model. A block that fails this check is always dropped as `model_binding_mismatch`, and the request still succeeds. For which models read each other's blocks, see Model compatibility.
Conversation prefix	The top-level system prompt, tools, and all message content before the block are unchanged from the request that produced it. Claude Fable 5.2, Claude Mythos 5.2, Claude Fable 5.1, Claude Opus 5.5, Claude Sonnet 5.5, and Claude Haiku 5.5 run this check. By default, a failed check returns a 400 error. Claude Mythos 5.1 doesn't run this check: a block replayed after the prefix changed reaches the model, and `prefix_mismatch_behavior` has no effect.
Organization	The thinking block was produced by the same AWS account, or an account in the same customer group. A block replayed from a different account — or one minted in a Claude app (claude.ai or Claude Code) — is removed before the model runs; the request still succeeds. Applies on Claude Fable 5.2, Claude Mythos 5.2, Claude Sonnet 5.5, and Claude Haiku 5.5.

> **Note**
>
> A thinking block whose signature has been altered or cannot be decrypted always returns a 400, regardless of these checks or the beta value.

Model compatibility

When you switch models partway through a conversation, the model check decides whether earlier thinking blocks reach the new model. Blocks that the new model can't read are dropped for that request; the API doesn't edit your `messages`, so the blocks are used again if you switch back to a model that can read them.

Thinking blocks produced by	Read by	Dropped as `model_binding_mismatch` on

The block_binding request object (beta)

Add `block_binding` to the `thinking` object and include the beta value in `anthropic_beta` to control what happens when a prefix mismatch is detected:

```
{
    "anthropic_version": "bedrock-2023-05-31",
    "anthropic_beta": ["thinking-binding-controls-2026-08-01"],
    "max_tokens": 16000,
    "thinking": {
        "type": "adaptive",
        "block_binding": {
            "prefix_mismatch_behavior": "drop_block"
        }
    },
    "messages": [{ "role": "user", "content": "Your prompt here" }]
}
```

`block_binding` accepts one field, `prefix_mismatch_behavior`, which controls what the API does with a thinking block that fails the conversation prefix check. `mismatch_behavior` is accepted as a deprecated alias for this field. Setting both `prefix_mismatch_behavior` and `mismatch_behavior` in the same request returns a `400 invalid_request_error`:

`cannot set both block_binding.prefix_mismatch_behavior and block_binding.mismatch_behavior; send only prefix_mismatch_behavior`. Sent without the beta value, `block_binding` returns `400 thinking.adaptive.block_binding: Extra inputs are not permitted`. Malformed values also return a 400 naming the field. On Claude Sonnet 5.5 and Claude Haiku 5.5, `block_binding` works only with `thinking.type: "adaptive"`.

Controlling mismatch behavior

Value	Behavior on a failed check
`"error"` (default)	Request fails with `400 invalid_request_error` naming the failed block. Not retryable; returned before any streaming events.
`"drop_block"`	Request succeeds with 200. The failing block is removed before the model, along with every later thinking block in the conversation, and each removed block is listed in `input_transformations`. Dropping blocks restarts the prompt cache from the first dropped block and can increase output tokens, so treat `drop_block` as a temporary fix while you remove the edit that causes the mismatch.

Neither value changes the model check, which always drops.

The input_transformations response array

When the beta value is sent, the response may include a top-level `input_transformations` array describing any blocks that were removed:

```
{
    "type": "message", "role": "assistant", "content": [ ... ],
    "stop_reason": "end_turn",
    "usage": {"input_tokens": 18234, "output_tokens": 911},
    "input_transformations": [
        {"type": "thinking_dropped", "path": "messages.3.content.0", "reason":
 "prefix_binding_mismatch"}
    ]
}
```

This is a top-level array (a sibling of `usage`), present only with the beta value; `[]` when no blocks were removed and absent otherwise. Each entry contains a `path` identifying the removed block and a `reason`: `model_binding_mismatch` (created by a different model), `prefix_binding_mismatch` (the conversation prefix changed), `organization_binding_mismatch` (created by another account or customer group), or `end_user_binding_mismatch` (created in a Claude app). In streaming responses, the array appears within the message object inside the `message_start` event. Removed blocks do not count toward `input_tokens`.

Organization-locked thinking

On Claude Fable 5.2, Claude Mythos 5.2, Claude Sonnet 5.5, and Claude Haiku 5.5, each thinking block is also bound to the AWS account (or customer group) that produced it, in addition to the model and conversation-prefix checks. A block replayed from a different account, or one minted in a Claude app (claude.ai or Claude Code), is dropped before the model runs; the request still succeeds and the model does not see that earlier reasoning.

By default the drop is silent. With the `thinking-binding-controls-2026-08-01` beta, each dropped block is listed in the top-level `input_transformations` array:

```
{
    "input_transformations": [
        {"type": "thinking_dropped", "path": "messages.1.content.0", "reason":
 "organization_binding_mismatch"}
    ]
}
```

Replaying thinking blocks within the same AWS account (or customer group) is unaffected. Without the `thinking-binding-controls-2026-08-01` beta, the response does not include an `input_transformations` field. In the same-account case with the beta, the field is present as an empty array (`[]`).

This binding applies on Claude Fable 5.2, Claude Mythos 5.2, Claude Sonnet 5.5, and Claude Haiku 5.5; earlier models are unaffected.

Error responses

When `prefix_mismatch_behavior` is `"error"`, a prefix mismatch returns:

```
{
```

```
    "type": "error",
    "error": {
        "type": "invalid_request_error",
        "message": "messages.3.content.0: Invalid `signature` in `thinking`
 block. The block is bound to a different conversation. Remove the block, or set
 `thinking.block_binding.prefix_mismatch_behavior` to \"drop_block\". The `system`
 prompt differs from the one this block was created with."
    }
}
```

The last sentence names what changed. For example, when the `system` prompt changed, it reads `The `system` prompt differs from the one this block was created with.` When message content before the block changed, it reads `Content before this block differs from when it was created, first at `messages.0.content.0`.`, with the path of the first changed content block. If the request doesn't include the `thinking-binding-controls-2026-08-01` beta value, the message also includes the sentence `That setting requires the `thinking-binding-controls-2026-08-01` value in the `anthropic-beta` header.` before the last sentence.

This error is permanent for that request — an automatic retry loop will not clear it. When you catch it, either strip all thinking blocks from history and retry, or retry with `prefix_mismatch_behavior: "drop_block"` and the beta header.

Guidance for multi-turn and agentic applications

- Replay assistant turns exactly as they were returned, including thinking blocks with empty `thinking` text, and keep the system prompt and tools stable within a conversation. A serializer that skips empty thinking blocks silently removes the model's earlier reasoning.
- Changes that invalidate later thinking blocks include editing earlier messages, changing `system` or `tools`, re-rendering an earlier message with different values (such as the current date), and changing earlier tool results or images. For an image or document referenced by URL, the check covers the fetched content, so a URL whose content changes between turns also invalidates later thinking.
- Changes that are safe include appending messages and changing `output_config.effort`, `max_tokens`, `tool_choice`, `metadata`, or `cache_control`. Server-side compaction doesn't count as an edit.
- Removing thinking blocks from the start or end of the history, or removing all of them, is valid. Removing a thinking block from the middle invalidates every later thinking block.

- Avoid one-off content injected into earlier turns (for example, a transient system message or reminder text appended to the last user turn). These change the conversation prefix and invalidate later thinking blocks. Use mid-conversation system messages instead.
- If your application rewrites conversation history, drop thinking blocks from the rewritten point onward, or set `prefix_mismatch_behavior` to `"drop_block"`.
- When using the Converse API with a model that supports it, pass the beta value and `thinking.block_binding` through `additionalModelRequestFields`.
- If you build a library, proxy, or gateway, pass the caller's `anthropic_beta` values and `thinking.block_binding` through unchanged, return `input_transformations` to the caller, and leave `role: "system"` messages where the caller put them.
- Log `input_transformations` in production. Any `prefix_binding_mismatch` entry means something before that block changed. Ignore entries with types or reasons you don't recognize.

Compaction

Tip

Server-side compaction is recommended for managing context in long-running conversations and agentic workflows as it handles context management automatically with minimal integration work.

Note

Compaction is available in beta through two independent mechanisms, each with its own beta header:

- `compact-2026-01-12` — threshold-triggered auto-summarization, configured through `context_management.edits` (the `compact_20260112` strategy). This mechanism is described below.
- `compact-2026-09-04` — a newer mechanism driven by a top-level `compaction` parameter (an explicit compaction request plus signed-block adoption). See the section called “Compaction with the compaction parameter (compact-2026-09-04 beta)”.

Include the beta header that matches the mechanism you use. Neither mechanism is supported by the Converse API; both work with InvokeModel.

Compaction extends the effective context length for long-running conversations and tasks by automatically summarizing older context when approaching the context window limit. This is ideal for:

- Chat-based, multi-turn conversations where you want users to use one chat for a long period of time
- Task-oriented prompts that require a lot of follow-up work (often tool use) that may exceed the model's context window

The `compact-2026-01-12` mechanism is supported on the following models:

Model	Model ID
Claude Fable 5.2	`anthropic.claude-fable-5-2`
Claude Mythos 5.2	`anthropic.claude-mythos-5-2`
Claude Haiku 5.5	`anthropic.claude-haiku-5-5`
Claude Sonnet 5.5	`anthropic.claude-sonnet-5-5`
Claude Opus 5.5	`anthropic.claude-opus-5-5`
Claude Fable 5.1	`anthropic.claude-fable-5-1`
Claude Mythos 5.1	`anthropic.claude-mythos-5-1`
Claude Opus 5	`anthropic.claude-opus-5`
Claude Sonnet 5	`anthropic.claude-sonnet-5`
Claude Fable 5	`anthropic.claude-fable-5`
Claude Opus 4.8	`anthropic.claude-opus-4-8`

Model	Model ID
Claude Opus 4.7	`anthropic.claude-opus-4-7`
Claude Sonnet 4.6	`anthropic.claude-sonnet-4-6`
Claude Opus 4.6	`anthropic.claude-opus-4-6-v1`

Note

The top-level `input_tokens` and `output_tokens` in the `usage` field do not include compaction iteration usage, and reflect the sum of all non-compaction iterations. To calculate the total tokens consumed and billed for a request, sum across all entries in the `usage.iterations` array.
If you previously relied on `usage.input_tokens` and `usage.output_tokens` for cost tracking or auditing, you will need to update your tracking logic to aggregate across `usage.iterations` when compaction is enabled. The `iterations` array is only present when a new compaction is triggered during the request. Re-applying a previous `compaction` block incurs no additional compaction cost, and the top-level usage fields remain accurate in that case.

How compaction works

When compaction is enabled, Claude automatically summarizes your conversation when it approaches the configured token threshold. The API:

1. Detects when input tokens exceed your specified trigger threshold.
2. Generates a summary of the current conversation.
3. Creates a `compaction` block containing the summary.
4. Continues the response with the compacted context.

On subsequent requests, append the response to your messages. The API automatically drops all message blocks before the `compaction` block, continuing the conversation from the summary.

Basic usage

Enable compaction by adding the `compact_20260112` strategy to `context_management.edits` in your Messages API request.

CLI

```
aws bedrock-runtime invoke-model \
    --model-id "us.anthropic.claude-opus-4-6-v1" \
    --body '{
        "anthropic_version": "bedrock-2023-05-31",
        "anthropic_beta": ["compact-2026-01-12"],
        "max_tokens": 4096,
        "messages": [
            {
                "role": "user",
                "content": "Help me build a website"
            }
        ],
        "context_management": {
            "edits": [
                {
                    "type": "compact_20260112"
                }
            ]
        }
    }' \
    --cli-binary-format raw-in-base64-out \
    /tmp/response.json

echo "Response:"
cat /tmp/response.json | jq '.content[] | {type, text: .text[0:500]}'
```

Python

```
import boto3
import json

bedrock_runtime = boto3.client(service_name='bedrock-runtime')

messages = [{"role": "user", "content": "Help me build a website"}]

response = bedrock_runtime.invoke_model(
```

```
    modelId="us.anthropic.claude-opus-4-6-v1",
    body=json.dumps({
        "anthropic_version": "bedrock-2023-05-31",
        "anthropic_beta": ["compact-2026-01-12"],
        "max_tokens": 4096,
        "messages": messages,
        "context_management": {
            "edits": [
                {
                    "type": "compact_20260112"
                }
            ]
        }
    })
)

response_body = json.loads(response["body"].read())

# Append the response (including any compaction block) to continue the conversation
messages.append({"role": "assistant", "content": response_body["content"]})

for block in response_body["content"]:
    if block.get("type") == "compaction":
        print(f"[COMPACTION]: {block['content'][:200]}...")
    elif block.get("type") == "text":
        print(f"[RESPONSE]: {block['text']}")
```

TypeScript

```
import { BedrockRuntimeClient, InvokeModelCommand } from "@aws-sdk/client-bedrock-
runtime";

async function main() {
    const client = new BedrockRuntimeClient({});

    const messages: Array<{role: string, content: string | object[]}> = [
        { role: "user", content: "Help me build a website" }
    ];

    const command = new InvokeModelCommand({
        modelId: "us.anthropic.claude-opus-4-6-v1",
        body: JSON.stringify({
            anthropic_version: "bedrock-2023-05-31",
```

```
            anthropic_beta: ["compact-2026-01-12"],
            max_tokens: 4096,
            messages,
            context_management: {
                edits: [
                    {
                        type: "compact_20260112"
                    }
                ]
            }
        })
    });

    const response = await client.send(command);
    const responseBody = JSON.parse(new TextDecoder().decode(response.body));

    // Append response to continue conversation
    messages.push({ role: "assistant", content: responseBody.content });

    for (const block of responseBody.content) {
        if (block.type === "compaction") {
            console.log(`[COMPACTION]: ${block.content.substring(0, 200)}...`);
        } else if (block.type === "text") {
            console.log(`[RESPONSE]: ${block.text}`);
        }
    }
}

main().catch(console.error);
```

Parameters

Parameter	Type	Default	Description
`type`	string	Required	Must be `"compact_20260112"`
`trigger`	object	150,000 tokens	When to trigger compaction. Must be at least 50,000 tokens.

Parameter	Type	Default	Description
`pause_after_compaction`	boolean	`false`	Whether to pause after generating the compaction summary
`instructions`	string	`null`	Custom summarization prompt. Completely replaces the default prompt when provided.

Trigger configuration

Configure when compaction triggers using the `trigger` parameter:

```
import boto3
import json

bedrock_runtime = boto3.client(service_name='bedrock-runtime')

response = bedrock_runtime.invoke_model(
    modelId="us.anthropic.claude-opus-4-6-v1",
    body=json.dumps({
        "anthropic_version": "bedrock-2023-05-31",
        "anthropic_beta": ["compact-2026-01-12"],
        "max_tokens": 4096,
        "messages": [{"role": "user", "content": "Help me build a website"}],
        "context_management": {
            "edits": [
                {
                    "type": "compact_20260112",
                    "trigger": {
                        "type": "input_tokens",
                        "value": 100000
                    }
                }
            ]
        }
    })
)

response_body = json.loads(response["body"].read())
```

```
print(response_body["content"][-1]["text"])
```

Custom summarization instructions

By default, compaction uses the following summarization prompt:

```
You have written a partial transcript for the initial task above. Please write a
 summary of the transcript. The purpose of this summary is to provide continuity so you
 can continue to make progress towards solving the task in a future context, where the
 raw history above may not be accessible and will be replaced with this summary. Write
 down anything that would be helpful, including the state, next steps, learnings etc.
 You must wrap your summary in a <summary></summary> block.
```

You can provide custom instructions through the `instructions` parameter to replace this prompt entirely. Custom instructions don't supplement the default; they completely replace it:

```
import boto3
import json

bedrock_runtime = boto3.client(service_name='bedrock-runtime')

response = bedrock_runtime.invoke_model(
    modelId="us.anthropic.claude-opus-4-6-v1",
    body=json.dumps({
        "anthropic_version": "bedrock-2023-05-31",
        "anthropic_beta": ["compact-2026-01-12"],
        "max_tokens": 4096,
        "messages": [{"role": "user", "content": "Help me build a website"}],
        "context_management": {
            "edits": [
                {
                    "type": "compact_20260112",
                    "instructions": "Focus on preserving code snippets, variable names,
 and technical decisions."
                }
            ]
        }
    })
)

response_body = json.loads(response["body"].read())
print(response_body["content"][-1]["text"])
```

Pausing after compaction

Use `pause_after_compaction` to pause the API after generating the compaction summary. This allows you to add additional content blocks (such as preserving recent messages or specific instruction-oriented messages) before the API continues with the response.

When enabled, the API returns a message with the `compaction` stop reason after generating the compaction block:

```
import boto3
import json

bedrock_runtime = boto3.client(service_name='bedrock-runtime')

messages = [{"role": "user", "content": "Help me build a website"}]

response = bedrock_runtime.invoke_model(
    modelId="us.anthropic.claude-opus-4-6-v1",
    body=json.dumps({
        "anthropic_version": "bedrock-2023-05-31",
        "anthropic_beta": ["compact-2026-01-12"],
        "max_tokens": 4096,
        "messages": messages,
        "context_management": {
            "edits": [
                {
                    "type": "compact_20260112",
                    "pause_after_compaction": True
                }
            ]
        }
    })
)

response_body = json.loads(response["body"].read())

# Check if compaction triggered a pause
if response_body.get("stop_reason") == "compaction":
    # Response contains only the compaction block
    messages.append({"role": "assistant", "content": response_body["content"]})

    # Continue the request
    response = bedrock_runtime.invoke_model(
```

```
        modelId="us.anthropic.claude-opus-4-6-v1",
        body=json.dumps({
            "anthropic_version": "bedrock-2023-05-31",
            "anthropic_beta": ["compact-2026-01-12"],
            "max_tokens": 4096,
            "messages": messages,
            "context_management": {
                "edits": [{"type": "compact_20260112"}]
            }
        })
    )
    response_body = json.loads(response["body"].read())

print(response_body["content"][-1]["text"])
```

Working with compaction blocks

When compaction is triggered, the API returns a `compaction` block at the start of the assistant response.

A long-running conversation may result in multiple compactions. The last compaction block reflects the final state of the prompt, replacing content before it with the generated summary.

```
{
  "content": [
    {
      "type": "compaction",
      "content": "Summary of the conversation: The user requested help building a web
 scraper..."
    },
    {
      "type": "text",
      "text": "Based on our conversation so far..."
    }
  ]
}
```

Streaming

When streaming responses with compaction enabled, you'll receive a `content_block_start` event when compaction begins. The compaction block streams differently from text blocks. You'll

receive a `content_block_start` event, followed by a single `content_block_delta` with the complete summary content (no intermediate streaming), and then a `content_block_stop` event.

Prompt caching

You may add a `cache_control` breakpoint on compaction blocks, which caches the full system prompt along with the summarized content. The original compacted content is ignored. Note that when compaction is triggered, it can result in a cache miss on the subsequent request.

```
{
    "role": "assistant",
    "content": [
        {
            "type": "compaction",
            "content": "[summary text]",
            "cache_control": {"type": "ephemeral"}
        },
        {
            "type": "text",
            "text": "Based on our conversation..."
        }
    ]
}
```

Understanding usage

Compaction requires an additional sampling step, which contributes to rate limits and billing. The API returns detailed usage information in the response:

```
{
  "usage": {
    "input_tokens": 45000,
    "output_tokens": 1234,
    "iterations": [
      {
        "type": "compaction",
        "input_tokens": 180000,
        "output_tokens": 3500
      },
      {
        "type": "message",
        "input_tokens": 23000,
```

```
        "output_tokens": 1000
      }
    ]
  }
}
```

The `iterations` array shows usage for each sampling iteration. When compaction occurs, you'll see a `compaction` iteration followed by the main `message` iteration. The final iteration's token counts reflect the effective context size after compaction.

Compaction with the compaction parameter (compact-2026-09-04 beta)

> **Note**
>
> This section documents a different, newer compaction mechanism from the `compact-2026-01-12` beta described earlier on this page. The `compact-2026-01-12` beta drives compaction through `context_management.edits` with the `compact_20260112` strategy. The `compact-2026-09-04` beta described in this section instead uses a top-level `compaction` parameter. The two mechanisms are independent. Include the beta flag that matches the mechanism you use.

A request that sends the top-level `compaction` parameter is a compaction request. The server summarizes the messages with one inference call on the requested model, and returns the summary as a single signed `compaction` content block, alone, with `stop_reason: "compaction"`. A later request adopts the block by sending it first in `messages`, in place of the messages it summarizes, and the later request is served as an ordinary turn. The server keeps no state between requests.

This mechanism requires the beta flag `compact-2026-09-04` in `anthropic_beta`, both on the compaction request and on every later request that carries the returned block. It is supported on `bedrock-runtime` through InvokeModel, InvokeModelWithResponseStream, and CountTokens. It is not supported by the Converse API.

Model support for this mechanism differs from the `compact-2026-01-12` beta, and the table earlier on this page applies only to that older beta. To find out whether a model supports compaction and which beta value it takes, see the **Compaction** section of that model's card in Models at a glance. Sending the `compaction` parameter to a model that doesn't support this beta returns `400` with the message `compaction: Extra inputs are not permitted`.

Compaction with the `compaction` parameter is a beta capability available on models whose policy supports the `compact_20260904` strategy (for example, Claude Opus 5.5 and Claude Haiku 5.5). To check whether a specific model supports it, see the **Capabilities and Features** table in that model's model card (see *Models at a glance*).

Request shape

The `compaction` parameter is an object of the form `{"type": "summarize", "instructions"?: string}`. The `instructions` member is optional. The following example sends a compaction request with the beta flag, a few messages, and custom instructions.

```
{
  "anthropic_version": "bedrock-2023-05-31",
  "anthropic_beta": ["compact-2026-09-04"],
  "max_tokens": 4096,
  "messages": [
    {"role": "user", "content": "Help me build a web scraper in Python."},
    {"role": "assistant", "content": "Sure. Let's start with the requests and
 BeautifulSoup libraries..."},
    {"role": "user", "content": "Now add retry logic and rate limiting."}
  ],
  "compaction": {
    "type": "summarize",
    "instructions": "Preserve code snippets, library choices, and any decisions about
 retries and rate limiting."
  }
}
```

Response and adoption

The response `content` holds a single signed `compaction` block, and `stop_reason` is `"compaction"`. The top-level `usage` counts are zeroed, and the tokens for the summarization call appear under `usage.iterations` as a `compaction` entry.

```
{
  "content": [
    {
      "type": "compaction",
      "content": "<summary>The user is building a Python web scraper...</summary>",
      "signature": "<opaque>"
    }
```

```
  ],
  "stop_reason": "compaction",
  "usage": {
    "input_tokens": 0,
    "output_tokens": 0,
    "iterations": [
      {
        "type": "compaction",
        "input_tokens": 180000,
        "output_tokens": 3500
      }
    ]
  }
}
```

To continue the conversation, the adopting request sends the returned `compaction` block back byte-for-byte as the first block of its first user or assistant message, followed by the turns kept or added since compaction. The adopting request does not include the `compaction` parameter. It is served as an ordinary turn.

Custom summarization instructions

Use `compaction.instructions` to replace the server summarization prompt. Instructions can be at most 16,384 characters, and a blank value is treated as absent. Before the summarization call, a server-side classifier screens the instructions. The following table lists the outcomes.

Scenario	Behavior
No instructions, or instructions pass the classifier	200 response, a signed `compaction` block, and `stop_reason` is `"compaction"`.
Instructions flagged by the classifier	200 response, empty `content`, `stop_reason` is `"refusal"`, and `stop_details` is `null`. No summarization call is made.
Classifier unreachable or timed out	529 response with the message `the compaction instructions could not be checked; retry the request`. Screening fails closed.

Scenario	Behavior
No summary produced (output cut off, context exceeded, or model refusal)	200 response, empty `content`, and the `stop_reason` from the summarization call itself.

Tool changes across a compaction

When the compaction request also carries the `inline-tools-2026-09-15` or `mid-conversation-tool-changes-2026-07-01` beta flag, and the summarized messages held `tool_addition` or `tool_removal` blocks, the returned `compaction` block has a third member, `tool_changes`. This member is an array of those blocks that gives the net tool changes across the summarized range, with `cache_control` stripped. The `tool_changes` member is covered by the signature. It is absent when there were no tool changes, and it is never an empty array.

Send `tool_changes` back with the block unmodified. On adoption, the server re-applies its entries at the block's position, so the tools available after the block match those that were available before compaction.

Streaming

When you stream a compaction request, the `compaction` block arrives whole in one `content_block_start` and `content_block_stop` pair, with no deltas.

Parameters you cannot combine with compaction

A compaction request returns a 400 error when it also sends any of the following:

- `context_management`
- `stop_sequences`
- `output_config.format`
- A forced `tool_choice`
- `output_config.task_budget.remaining`
- `max_tokens: 0`

Error responses

Match these conditions on the message text of the response.

Condition	Response
The `compaction` parameter is sent without the beta flag	400 with the message `compaction: Extra inputs are not permitted .`
The adopted block was altered	400 with the message `compaction block content does not match its signature` or `invalid signature in compaction block .`
Instructions are sent while custom instructions are disabled	400 with the message `compaction.instructions is not available on this platform`.
A transient signing failure	529 with the message `the compaction summary could not be signed; retry the request`.

Fallback credit for refused requests (beta)

Prompt caches are per model. When a Claude model refuses a request and you retry the same conversation on a different model, the conversation prefix that was already cached for the first model is written into the new model's cache in full, at cache-write rates. Fallback credit removes this extra cost. The refusal carries a one-time credit token. When you include the token on the retry, the retry is billed as though the conversation had been on the fallback model from the start: the overlapping prefix is billed as cache-read tokens instead of cache-write tokens.

To use fallback credit, include the beta flag `fallback-credit-2026-07-01` on both the original request and the retry. The earlier flag `fallback-credit-2026-06-01` is still accepted and returns the same refusal fields. On Amazon Bedrock, a retry redeemed under `fallback-credit-2026-06-01` doesn't report `usage.fallback_credit`. Use `fallback-credit-2026-07-01` for new code. The `server-side-fallback-2026-07-01` flag is not supported on Amazon Bedrock and returns a `400` error.

Supported models

The following models issue a fallback credit token when they refuse a request. The retry must use one of the listed fallback models for that source model. You can use the base model ID or a cross-Region inference profile ID (for example, `global.anthropic.claude-opus-5-5`) for either request.

Source model (issues the token)	Model ID	Valid fallback models (redeem the token)
Claude Fable 5.2	`anthropic.claude-fable-5-2`	Claude Opus 5 (`anthropic.claude-opus-5`), Claude Opus 4.8 (`anthropic.claude-opus-4-8`)
Claude Fable 5	`anthropic.claude-fable-5`	Claude Opus 5 (`anthropic.claude-opus-5`), Claude Opus 4.8 (`anthropic.claude-opus-4-8`)
Claude Fable 5.1	`anthropic.claude-fable-5-1`	Claude Opus 5 (`anthropic.claude-opus-5`), Claude Opus 4.8 (`anthropic.claude-opus-4-8`)
Claude Opus 5.5	`anthropic.claude-opus-5-5`	Claude Opus 5 (`anthropic.claude-opus-5`), Claude Opus 4.8 (`anthropic.claude-opus-4-8`)
Claude Opus 5	`anthropic.claude-opus-5`	Claude Opus 4.8 (`anthropic.claude-opus-4-8`)
Claude Sonnet 5.5	`anthropic.claude-sonnet-5-5`	Claude Sonnet 5 (`anthropic.claude-sonnet-5`)

Refusals from other models, including Claude Haiku 5.5, don't carry a fallback credit token. A retry after one of those refusals pays the full cost of writing the fallback model's prompt cache.

A refusal from a source model doesn't always carry a token. When no credit is available for the refusal, `fallback_credit_token` and `fallback_has_prefill_claim` are both `null`. Check for a token before you build a redeeming retry.

Supported endpoints

Fallback credit works on both of the following endpoints. Where you pass the beta flag depends on the endpoint.

Endpoint	How to pass the beta flag
bedrock-runtime (InvokeModel , InvokeModelWithResponseStream)	In the anthropic_beta array of the request body.
bedrock-runtime (/anthropic/v1/messages)	In the anthropic-beta HTTP header, or the betas parameter of the Anthropic SDK.
bedrock-mantle (/anthropic/v1/messages)	In the anthropic-beta HTTP header, or the betas parameter of the Anthropic SDK.
bedrock-runtime (Converse)	In the anthropic_beta array of additionalModelRequestFields .

Fallback credit is available on each endpoint that the source model supports.

With Converse, a refusal returns stopReason: "content_filtered". To get the token, add "/stop_details" to additionalModelResponseFieldPaths, and pass fallback_credit_token on the retry in additionalModelRequestFields. Converse doesn't report usage.fallback_credit. To confirm that the credit applied, check that cacheReadInputTokens covers the conversation prefix and cacheWriteInputTokens doesn't.

Redeem the token on the same endpoint that issued it. A token minted on bedrock-mantle can only be redeemed on bedrock-mantle, and a token minted on bedrock-runtime can only be redeemed on bedrock-runtime. A token sent to the other endpoint is rejected with a request body ... does not match error.

How it works

Step 1: Receive a fallback credit token on refusal

When a request to a supported source model returns stop_reason: "refusal" and the beta flag is present, the stop_details object includes two fields:

- fallback_credit_token – An opaque string that represents the credit.

- `fallback_has_prefill_claim` – A boolean that tells you which retry body shape to use. For more information, see the section called “Redemption rules”.

```
{
  "id": "msg_bdrk_...",
  "type": "message",
  "role": "assistant",
  "model": "anthropic.claude-opus-5-5",
  "content": [],
  "stop_reason": "refusal",
  "stop_details": {
    "type": "refusal",
    "category": "cyber",
    "explanation": "This request triggered restrictions on violative cyber content and
 was blocked under Anthropic's Usage Policy.",
    "fallback_credit_token": "<opaque token>",
    "fallback_has_prefill_claim": false
  },
  "usage": {
    "input_tokens": 12,
    "cache_creation_input_tokens": 0,
    "cache_read_input_tokens": 42029,
    "output_tokens": 1
  }
}
```

Both fields are `null` when no credit is available for the refusal, for example when no cache was read on the refused request, the model isn't a supported source model, or the beta flag is absent. Server-side minting failures produce `null`, never an error. In streaming mode, the fields are delivered in the `stop_details` of the final `message_delta` event.

Because a token requires a cache read, a refusal on the first request of a conversation, which only writes the cache, doesn't carry a token. A later refused request that reads the cached prefix does.

> **Note**
>
> On Amazon Bedrock, `fallback_has_prefill_claim` can be absent even when a token is present. If it's absent, treat the retry shape as unknown rather than as `false`: try the continuation shape first, and fall back to the unchanged body if the retry is rejected. For more information, see the section called “Error handling”.

Step 2: Redeem the token on a retry request

Start from the refused request body. Change `model` (or the model ID in the request path) to a valid fallback model, keep the same beta flag, and add the token as the top-level `fallback_credit_token` parameter. Send the retry within 5 minutes of the refusal.

The following example shows a retry body for `InvokeModel` with the model ID `global.anthropic.claude-opus-5`:

```
{
  "anthropic_version": "bedrock-2023-05-31",
  "anthropic_beta": ["fallback-credit-2026-07-01"],
  "max_tokens": 4096,
  "system": "...",
  "messages": [...],
  "tools": [...],
  "fallback_credit_token": "<token from the refusal's stop_details>"
}
```

The following example shows the same retry on `bedrock-mantle`:

```
curl -X POST "https://bedrock-mantle.$BEDROCK_REGION.api.aws/anthropic/v1/messages" \
  -H "x-api-key: $BEDROCK_API_KEY" \
  -H "anthropic-version: 2023-06-01" \
  -H "anthropic-beta: fallback-credit-2026-07-01" \
  -H "Content-Type: application/json" \
  -d '{
    "model": "anthropic.claude-opus-5",
    "max_tokens": 4096,
    "system": "...",
    "messages": [...],
    "tools": [...],
    "fallback_credit_token": "<token from the refusal's stop_details>"
  }'
```

Redemption rules

Rule	Requirement
Time window	The token expires 5 minutes after the refusal. After that, send the retry without it.

Rule	Requirement
Caller binding	The token can only be redeemed by the same caller identity that received the refusal, on the same endpoint. Tokens are stateless; there is no API to inspect or revoke them.
Target model	The retry must use a valid fallback model for the refused model. See the section called “Supported models”.
Fields that must match	`system`, `messages`, `tools`, `tool_choice` , `thinking`, and `cache_control` , plus `output_config` , `mcp_servers` , `context_management` , and `container` if you use them. Send them as-is. Don't strip `thinking` or `redacted_thinking` blocks from earlier turns.
Fields that can change	`model`, `max_tokens` , `stop_sequences` , `stream`, `metadata`, and `service_tier` .
Beta flags	Send the same beta flags on the retry as on the refused request. A flag that is present on only one of the two requests causes a `request body ... does not match` error, even if the bodies are identical. Don't add or drop flags based on the target model. On models that include the 1M token context window by default, such as Claude Fable 5.2, Claude Fable 5.1, Claude Fable 5, Claude Opus 5.5, Claude Opus 5, and Claude Opus 4.8, the `context-1m-2025-08-07` flag has no effect. Omit it on both requests.

Rule	Requirement
Retry shape	Choose the retry body based on `fallback_has_prefill_claim` : • `true` – The refused request body, unchanged, plus one appended `assistant` message whose `content` echoes the refused response's `content`. The fallback model continues the response from where the refused model stopped. Strip trailing whitespace from a final `text` block, and omit any client `tool_use` block that has no matching `tool_result` . • `false` – The refused request body, unchanged. The fallback model regenerates the response.

Error handling

With the beta flag present, a redemption validation failure returns a `400` error. Failure conditions include:

- Malformed or unrecognizable token
- Token older than 5 minutes
- Request body or beta flags don't match the refused request
- Target model isn't a valid fallback model for the refused model
- Token has already been redeemed

When a retry is rejected, step down through progressively simpler retries:

1. If the continuation retry (with the appended `assistant` message) is rejected, resend the refused request body unchanged, still with the token.
2. If the unchanged body is also rejected with an error that names `fallback_credit_token`, retry without the token. The credit is forfeited, but the retry goes through.

If the error message says `redemption temporarily unavailable`, the rejection is transient. Retry the same request with the same token within the 5-minute window instead of stepping down.

> **Important**
>
> If the refused request ran server tools, a retry without the token runs those tools again and bills them again. In that case, surface the error to your caller instead of silently retrying without the token.

Without the beta flag, `fallback_credit_token` is rejected as an unknown field (`400`). The parameter is also rejected on `CountTokens` requests.

Billing impact

When a token is redeemed, the credit is applied by repricing the retry's token usage. There is no separate credit or refund line item. Compared with the same retry without a token, the retry's `usage` reports fewer `cache_creation_input_tokens` and more `cache_read_input_tokens` by the same amount. Your bill, cost and usage reports, and the `CacheWriteInputTokenCount` and `CacheReadInputTokenCount` metrics in CloudWatch reflect the repriced counts.

The following example shows the retry's usage for a conversation with a 42,000-token cached prefix that was refused by Claude Opus 5.5 and retried on Claude Opus 5:

Retry	usage.fallback_credit	cache_creation_input_tokens	cache_read_input_tokens
Without `fallback_credit_token`	–	42,029	0
With `fallback_credit_token`	`{"status": {"type": "redeemed"}}`	0	42,033

A successfully redeemed retry also reports the redemption in `usage.fallback_credit`:

```
"usage": {
  "input_tokens": 45,
  "cache_creation_input_tokens": 0,
  "cache_read_input_tokens": 42033,
  "fallback_credit": {
    "status": {"type": "redeemed"}
  },
  "output_tokens": 512
}
```

If a redeemed retry shows no shift, the token was honored but there was nothing to reprice, for example because the fallback model's cache was already warm.

Fallback credit reduces only the cost of the retry. The refused request itself is billed by its `stop_details.category`: before any output, `bio`, `frontier_llm`, and `reasoning_extraction` refusals are billed, and `cyber`, `general_harms`, and `null` refusals aren't. Amazon Bedrock always bills a mid-stream refusal. For details, see Billing notes.

A `reasoning_extraction` refusal has no recommended fallback model. Change the prompt instead of retrying on another model.

Limitations

- Refusals in batch inference jobs don't issue tokens. A token passed in a batch inference record is accepted but ignored.
- Amazon Bedrock doesn't expose the `allowed_fallback_models` list. Use the table in the section called “Supported models”.
- Server-side fallback (the `fallbacks` parameter and the `server-side-fallback-2026-07-01` flag) isn't supported on Amazon Bedrock. You build the retry yourself. Because of this, `stop_details.recommended_model` doesn't appear in Amazon Bedrock responses.
- If the request used `output_config.format` or a `tool_choice` that forces tool use, and the refusal arrived after server tools had run, the token can't be redeemed by either retry shape. Retry without the token.

Example workflow

1. Send a request to Claude Opus 5.5 with `"anthropic_beta": ["fallback-credit-2026-07-01"]` and a cached prompt prefix.

2. Receive a refusal with a `fallback_credit_token` in `stop_details`.
3. Within 5 minutes, retry on Claude Opus 5 with the same body and beta flags, plus the `fallback_credit_token`.
4. Check the retry's `usage`: the overlapping prefix is billed as cache-read tokens instead of cache-write tokens.

The following Python example implements this workflow with `InvokeModel`, including the retry steps described in the section called “Error handling”.

```
import json
import time

import boto3
from botocore.exceptions import ClientError

client = boto3.client("bedrock-runtime", region_name="us-east-1")

SOURCE_MODEL = "global.anthropic.claude-opus-5-5"
FALLBACK_MODEL = "global.anthropic.claude-opus-5"

request = {
    "anthropic_version": "bedrock-2023-05-31",
    "anthropic_beta": ["fallback-credit-2026-07-01"],
    "max_tokens": 1024,
    "system": [
        {
            "type": "text",
            "text": "<long system prompt>",
            "cache_control": {"type": "ephemeral"},
        }
    ],
    "messages": [{"role": "user", "content": "Hello, Claude"}],
}

def invoke(model_id, body):
    response = client.invoke_model(modelId=model_id, body=json.dumps(body))
    return json.loads(response["body"].read())

def invoke_with_transient_retry(model_id, body, tries=3):
```

```
    # "redemption temporarily unavailable" is transient: resend the same body,
    # with the same token, within the 5-minute window.
    for attempt in range(tries):
        try:
            return invoke(model_id, body)
        except ClientError as error:
            transient = "redemption temporarily unavailable" in error.response["Error"]
["Message"]
            if not transient or attempt == tries - 1:
                raise
            time.sleep(2 ** attempt)

def can_step_down(error, forfeit_next):
    message = error.response["Error"]["Message"]
    if error.response["Error"]["Code"] != "ValidationException":
        return False
    if "redemption temporarily unavailable" in message:
        return False  # Still transient after retries: surface it, keep the token
    # Drop the token only when the error names it.
    return not forfeit_next or "fallback_credit_token" in message

result = invoke(SOURCE_MODEL, request)
details = result.get("stop_details") or {}
token = details.get("fallback_credit_token")

if result["stop_reason"] == "refusal" and token:
    exact_body = {**request, "fallback_credit_token": token}
    attempts = []

    # Prefer the continuation shape unless the claim is explicitly false.
    if details.get("fallback_has_prefill_claim") is not False and result["content"]:
        # Omit client tool_use blocks: they have no matching tool_result.
        echoed = [block for block in result["content"] if block["type"] != "tool_use"]
        if echoed and echoed[-1]["type"] == "text":
            echoed[-1]["text"] = echoed[-1]["text"].rstrip()
        attempts.append(
            {**exact_body, "messages": [*request["messages"], {"role": "assistant",
 "content": echoed}]}
        )

    attempts.append(exact_body)  # Unchanged body, still with the token
    attempts.append(request)     # Last resort: forfeit the credit
```

```
    for body in attempts:
        try:
            result = invoke_with_transient_retry(FALLBACK_MODEL, body)
            break
        except ClientError as error:
            forfeit_next = attempts.index(body) == len(attempts) - 2
            if body is request or not can_step_down(error, forfeit_next):
                raise

print(json.dumps({"stop_reason": result["stop_reason"], "usage": result["usage"]},
 indent=2))
```

If the token is `null`, expired, or rejected, retry without it. The credit is a cost optimization; the retry doesn't need it to succeed.

Mid-conversation system messages

You can append `{"role": "system", ...}` messages to the `messages` array. This adds or updates system instructions partway through a conversation without invalidating the cached prefix.

Previously, system instructions could only be supplied through the top-level `system` parameter. This makes it possible to update instructions without resetting prior context.

This is useful in agentic workflows where the model needs to adapt as a task progresses. Examples include introducing a new constraint mid-task, refreshing authoritative context, or changing tool guidance for later turns.

Supported models

Mid-conversation system messages are supported on Claude Opus 4.8 and the Claude 5 family (for example, Claude Opus 5, Claude Opus 5.5, Claude Sonnet 5, Claude Fable 5, Claude Fable 5.1, and Claude Fable 5.2). Sending text system messages does not require a beta header. Including `tool_addition` or `tool_removal` blocks in system-role content requires the mid-conversation tool-changes beta (see the section called “Mid-conversation tool changes (Beta)”). Requests that include `role: "system"` in `messages[]` on unsupported models return a `400 invalid_request_error`.

Message fields

Field	Type	Description
`role`	String	Required. Must be `system`
`content`	String or list of content blocks	Required. Use a plain string or content blocks, the same as a user or assistant message.
`cache_control`	Object	Optional. Same semantics as the top-level system parameter.

Placement rules

A `{"role": "system"}` message in `messages` has the following placement constraints:

- Cannot be the first entry in `messages`. Use the top-level `system` field for instructions that apply from the very start.
- Must immediately follow a user message or an assistant message that ends in a server tool result.
- Must either be the last entry in `messages` or be followed by an assistant turn.

Requests that violate these placement rules return a `400 invalid_request_error`.

Content rules

System-role message content supports text blocks. You can also include `tool_addition` and `tool_removal` blocks when using the mid-conversation tool-changes beta (see the section called "Mid-conversation tool changes (Beta)"). Images, documents, and citations are not supported. A system message can also be directive-only, with an empty `content` list and an `output_config` field (see the section called "Directive-only system messages").

Set `content` to either a plain string or content blocks. The instruction applies from that point in the conversation onward. Use the top-level `system` field for instructions that should apply to the entire conversation, and use mid-conversation system messages for instructions that become relevant later.

Directive-only system messages

A system-role message can carry a directive instead of instructional text. In this form, `content` is an empty list (`[]`) and the message carries an `output_config` field — for example, to change the thinking effort level for the turns that follow. This requires one of the per-turn control beta values; see the section called “Setting effort per turn (beta)”.

```
{
    "role": "system",
    "content": [],
    "output_config": {"effort": "low"}
}
```

Without a supporting beta value, or on a model that does not support per-turn directives, a system message that includes `output_config` returns `400 messages.N.output_config: Extra inputs are not permitted`.

Prompt caching

Mid-conversation system messages are designed to work with prompt caching. Cache the stable prefix as usual by placing `cache_control` on the last block that remains unchanged across requests. Then append the system message after that breakpoint. Because the new instruction appears after the cached prefix, it does not change the prefix hash, and the cache can still hit.

Once a mid-conversation system message becomes part of the stable history, it can itself be read from cache on subsequent turns. Avoid editing or removing a previously sent mid-conversation system message, because changing earlier messages invalidates the cache from that point forward.

For more information about prompt caching, see Prompt caching for faster model inference.

Response behavior

The response shape is unchanged. System-role messages do not appear in the response content array. The model processes the system instructions but does not echo them back in its response.

Code example

The following Python example demonstrates how to use mid-conversation system prompts with Amazon Bedrock:

```
import boto3
```

```
import json

client = boto3.client("bedrock-runtime", region_name="us-east-1")

response = client.invoke_model(
    modelId="us.anthropic.claude-opus-4-8",
    body=json.dumps({
        "anthropic_version": "bedrock-2023-05-31",
        "max_tokens": 1024,
        "system": "You are a helpful travel planning assistant.",
        "messages": [
            {"role": "user", "content": "Help me plan a week in Paris."},
            {"role": "assistant", "content": "I'd love to help! What kind of experience
 are you looking for?"},
            {"role": "user", "content": "I want to see the major sights. What should I
 do on day one?"},
            {"role": "system", "content": "The user has a budget of $150/day.
 Only suggest options that fit within this budget. Prioritize free attractions and
 affordable dining."}
        ]
    })
)

result = json.loads(response["body"].read())
print(result["content"][0]["text"])
```

Supported features

In addition to the Extended thinking, Adaptive thinking, Structured outputs, Compaction, Fallback credit for refused requests (beta), and Mid-conversation system messages sections above, the Messages API supports the following features with Claude models:

- **System prompts** – Set model behavior with a `system` parameter.
- **Multi-turn conversations** – Pass alternating `user` and `assistant` messages.
- **Tool use** – Define tools the model can call. See the section called “Tool use”.
- **Vision** – Send images in the `content` array alongside text.
- **Prompt caching** – Cache frequently used context to reduce latency and cost.

For the full Messages API request and response field reference, see the section called “Request and Response”.

Count tokens

To count the number of input tokens that a request would consume before sending it for inference, use the Anthropic `count_tokens` path on the `bedrock-mantle` endpoint. This is the only token-counting path supported for Claude models that are not available on `bedrock-runtime` with a Region-specific endpoint, including Claude models that launch with cross-Region inference (CRIS) only. For details and an example, see the section called “Count tokens with bedrock-mantle”.

Influence response generation with inference parameters

When running model inference, you can adjust inference parameters to influence the model response. Inference parameters can change the pool of possible outputs that the model considers during generation, or they can limit the final response.

Inference parameter default values and ranges depend on the model. To learn about inference parameters for different models, see Inference request parameters and response fields for foundation models.

The following categories of parameters are commonly found across different models:

Topics

- Randomness and diversity
- Length

Randomness and diversity

For any given sequence, a model determines a probability distribution of options for the next token in the sequence. To generate each token in an output, the model samples from this distribution. Randomness and diversity refer to the amount of variation in a model's response. You can control these factors by limiting or adjusting the distribution. Foundation models typically support the following parameters to control randomness and diversity in the response.

- **Temperature**– Affects the shape of the probability distribution for the predicted output and influences the likelihood of the model selecting lower-probability outputs.
  - Choose a lower value to influence the model to select higher-probability outputs.
  - Choose a higher value to influence the model to select lower-probability outputs.

In technical terms, the temperature modulates the probability mass function for the next token. A lower temperature steepens the function and leads to more deterministic responses, and a higher temperature flattens the function and leads to more random responses.

- **Top K** – The number of most-likely candidates that the model considers for the next token.
  - Choose a lower value to consider fewer candidate tokens, regardless of how the probability is distributed across them.
  - Choose a higher value to consider more candidate tokens, which allows less likely outputs.

  For example, if you choose a value of 50 for Top K, the model selects from 50 of the most probable tokens that could be next in the sequence.
- **Top P** – The percentage of most-likely candidates that the model considers for the next token.
  - Choose a lower value to consider a smaller share of the cumulative probability distribution. The number of candidate tokens that share covers varies from one token to the next.
  - Choose a higher value to consider a larger share of the distribution, which allows less likely outputs.

  In technical terms, the model computes the cumulative probability distribution for the set of responses and considers only the top P% of the distribution.

  For example, if you choose a value of 0.8 for Top P, the model selects from the top 80% of the probability distribution of tokens that could be next in the sequence.

The following table summarizes the effects of these parameters.

Parameter	Effect of lower value	Effect of higher value
Temperature	Increase likelihood of higher-probability tokens Decrease likelihood of lower-probability tokens	Increase likelihood of lower-probability tokens Decrease likelihood of higher-probability tokens
Top K	Consider fewer candidate tokens, cutting the least likely ones from a fixed-size pool	Consider more candidate tokens, allowing lower-pro bability tokens

Parameter	Effect of lower value	Effect of higher value
Top P	Consider a smaller share of the cumulative probability distribution, so the pool size varies per token	Consider a larger share of the distribution, allowing lower-probability tokens

As an example to understand these parameters, consider the example prompt **`I hear the hoof beats of "`**. Let's say that the model determines the following three words to be candidates for the next token. The model also assigns a probability for each word.

```
{
    "horses": 0.7,
    "zebras": 0.2,
    "unicorns": 0.1
}
```

- If you set a high **temperature**, the probability distribution is flattened and the probabilities become less different, which would increase the probability of choosing "unicorns" and decrease the probability of choosing "horses".
- If you set **Top K** as 2, the model only considers the top 2 most likely candidates: "horses" and "zebras."
- If you set **Top P** as 0.7, the model only considers "horses" because it is the only candidate that lies in the top 70% of the probability distribution. If you set **Top P** as 0.9, the model considers "horses" and "zebras" as they are in the top 90% of probability distribution.

Length

Foundation models typically support parameters that limit the length of the response. Examples of these parameters are provided below.

- **Response length** – An exact value to specify the minimum or maximum number of tokens to return in the generated response.
- **Penalties** – Specify the degree to which to penalize outputs in a response. Examples include the following.
  - The length of the response.

- Repeated tokens in a response.
- Frequency of tokens in a response.
- Types of tokens in a response.

- **Stop sequences** – Specify sequences of characters that stop the model from generating further tokens. If the model generates a stop sequence that you specify, it will stop generating after that sequence.

Get validated JSON results from models

Structured outputs is a capability on Amazon Bedrock that ensures model responses conform to user-defined JSON schemas and tool definitions, reducing the need for custom parsing and validation mechanisms in production AI deployments.

Benefits

Structured outputs addresses critical challenges in production AI applications:

- **Ensures schema compliance** – Eliminates error rates and retry loops from prompt-based approaches
- **Reduced development complexity** – Removes the need for custom parsing and validation logic
- **Lower operational costs** – Reduces failed requests and retries
- **Production reliability** – Enables confident deployment of AI applications requiring predictable, machine-readable outputs

How it works

Structured outputs constrains model responses to follow a specific schema, ensuring valid, parseable output for downstream processing. You can use structured outputs through two complementary mechanisms:

JSON Schema output format

For InvokeModel API with Anthropic Claude models, use the `output_config.format` request field. With open weight models, use the `response_format` request field. For Converse APIs, use the `outputConfig.textFormat` request field. The model's response will conform to the specified JSON schema.

> **Note**
>
> The `output_format` field is deprecated. Use `output_config.format` instead.

Strict tool use

Add the `strict: true` flag to tool definitions to enable schema validation on tool names and inputs. The model's tool calls will then follow the defined tool input schema.

These mechanisms can be used independently or together in the same request. Refer to Bedrock API documentation for more details.

Request workflow

The following describes how Amazon Bedrock processes requests with structured outputs:

1. **Initial request** – You include either a JSON schema through the `outputConfig.textFormat`, `output_config.format`, or `response_format` parameter or a tool definition with the `strict: true` flag in your inference request.
2. **Schema validation** – Amazon Bedrock validates the JSON schema format against the supported JSON Schema Draft 2020-12 subset. If the schema contains unsupported features, Amazon Bedrock returns a 400 error immediately.
3. **First-time compilation** – For new schemas, Amazon Bedrock compiles the grammar, which can take up to approximately 90 seconds.
4. **Caching** – Successfully compiled grammars are cached for 24 hours from first access. Cached grammars are encrypted with AWS-managed keys.
5. **Subsequent requests** – Identical schemas from the same account use cached grammars, resulting in inference latency comparable to standard requests with minimal overhead.
6. **Response** – You receive standard inference responses with strict schema compliance.

Supported JSON Schema features

The following JSON Schema Draft 2020-12 features are supported:

- All basic types: `object`, `array`, `string`, `integer`, `number`, `boolean`, `null`
- `enum` (strings, numbers, booleans, or nulls only)
- `const`, `anyOf`, `allOf` (with limitations)

- `$ref`, `$defs`, and `definitions` (internal references only)
- String formats: `date-time`, `time`, `date`, `duration`, `email`, `hostname`, `uri`, `ipv4`, `ipv6`, `uuid`
- `pattern` (regular expressions, excluding lookaround and backreferences)
- Array `minItems` (only values 0 and 1)

The following features are *not* supported:

- Recursive schemas
- External `$ref` references
- Numerical constraints (`minimum`, `maximum`, `multipleOf`)
- String constraints (`minLength`, `maxLength`)
- `additionalProperties` set to anything other than `false`

When you use structured outputs, every `object` in your schema must explicitly set `additionalProperties` to `false`. If an object omits `additionalProperties`, or sets it to any value other than `false`, Amazon Bedrock returns a 400 `ValidationException`.

Amazon Bedrock supports a subset of regular expressions for `pattern` that excludes lookaround and backreferences. An invalid or unsupported regular expression returns a 400 `ValidationException` with the message "Invalid regex in pattern field."

The `default` keyword is accepted but is not enforced. Constrained decoding does not insert the default value. The model uses it only as a hint when it generates a value, so the value is not guaranteed. A property that specifies a `default` remains optional unless you list it in `required`, so it counts toward the limit of 12 optional properties described in the section called “Limits”.

Limits

The following limits apply to the JSON schemas that you use with structured outputs.

- **Optional properties.** A schema can contain a maximum of 12 optional properties in total, counted across all nested objects in the schema. An optional property is any property that is not listed in `required`, including an optional object-valued property. A schema that exceeds this limit returns a `ValidationException` with the message "Schema is too complex." Amazon Bedrock enforces this limit while it compiles the grammar, so the error can take up to approximately 90 seconds to return.

- **Union-typed properties.** A schema can contain a maximum of 16 properties that use a type array (for example, `"type": ["string", "null"]`) or `anyOf`. A schema that exceeds this limit returns a `ValidationException` immediately.
- **Compilation time.** The first request that uses a new schema compiles a grammar, which can take up to approximately 90 seconds. Subsequent requests that use the same schema reuse the cached grammar and return with standard inference latency. Set your client read timeout to at least 120 seconds so that the first request does not time out during compilation.

To include more than 12 fields that might be absent, list the fields in `required` and make each one nullable by using a type array, such as `"type": ["string", "null"]`. The model returns `null` for any field that it cannot fill. Because nullable fields are union-typed, you can define a maximum of 16 of them.

> **Note**
>
> Set the maximum number of response tokens high enough to contain the complete JSON object. For example, use `max_tokens` for the InvokeModel API or `maxTokens` for the Converse API. If the response reaches the token limit first, the model stops with a `max_tokens` stop reason and returns incomplete JSON, even when structured outputs is enabled.

Supported APIs or features

You can use structured outputs across the following Amazon Bedrock features:

API or feature	Supported	Notes
Converse and ConverseStream APIs	Yes	Conversational inference.
InvokeModel and InvokeModelWithResponseStream APIs	Yes	Single-turn inference.
Cross-Region inference	Yes	Works without any additional setup.
Batch inference	Yes	Works without any additional setup.

API or feature	Supported	Notes
Anthropic Messages API on the `bedrock-mantle` endpoint (`https://bedrock-mantle.{region}.api.aws/anthropic/v1/messages`)	Yes	Supported for Anthropic Claude models through the `output_config.format` parameter. For Claude-specific guidance and examples, see the section called "Structured Outputs".

Note

Structured outputs is incompatible with citations for Anthropic models. If you enable citations while using structured outputs, the model will return a 400 error.

Supported models

To see which models support structured outputs, please go to models at a glance and select the model you are interested in.

Example requests

JSON Schema output format

The following examples show how to use JSON Schema output format with structured outputs.

Converse API

Enhance model responses with model reasoning

Some foundation models are able to perform model reasoning, where they are able to take a larger, complex task and break it down into smaller, simpler steps. This process is often referred to as chain of thought (CoT) reasoning. Chain of thought reasoning can often improve model accuracy by giving the model a chance to think before it responds. Model reasoning is most useful for tasks such as multi-step analysis, math problems, and complex reasoning tasks.

For example, in tackling a mathematical word problem, the model can first identify the relevant variables, then construct equations based on the given information, and finally solve those equations to reach the solution. This strategy not only minimizes errors but also makes the reasoning process more transparent and easier to follow, thereby enhancing the quality of foundation model's output.

Model reasoning is not necessary for all tasks and does come with additional overhead, including increased latency and output tokens. Simple tasks that don't need additional explanations are not good candidates for CoT reasoning.

Note that not all models allow you to configure the number of output tokens that are allocated for model reasoning.

To see which models support reasoning, please visit models at a glance and choose the model you are interested in.

Optimize model inference for latency

> **Note**
>
> The Latency Optimized Inference feature is in preview release for Amazon Bedrock and is subject to change.

Latency-optimized inference for foundation models in Amazon Bedrock delivers faster response times and improved responsiveness for AI applications. The optimized versions of Amazon Nova Pro, Anthropic's Claude 3.5 Haiku model and Meta's Llama 3.1 405B and 70B models offer significantly reduced latency without compromising accuracy.

Accessing the latency optimization capability requires no additional setup or model fine-tuning, allowing for immediate enhancement of existing applications with faster response times. You can set the “Latency” parameter to “optimized” while calling the Amazon Bedrock runtime API. If you select "standard" as your invocation option, your requests will be served by standard inference. By default all requests are routed to through "standard".

```
"performanceConfig" : {
    "latency" : "standard | optimized"
}
```

Once you reach the usage quota for latency optimization for a model, we will attempt to serve the request with Standard latency. In such cases, the request will be charged at Standard latency rates. The latency configuration for a served request is visible in API response and AWS CloudTrail logs. You can also view metrics for latency optimized requests in Amazon CloudWatch logs under "model-id+latency-optimized".

Latency optimized inference is available for Meta’s Llama 3.1 70B and 405B, as well as Anthropic’s Claude 3.5 Haiku in the US East (Ohio) and US West (Oregon) Regions through cross-Region inference.

Latency optimized inference is available for Amazon Nova Pro in the US East (N. Virginia), US East (Ohio), and US West (Oregon) Regions through cross-Region inference.

For more information about pricing, visit the pricing page.

> **Note**
>
> Latency optimized inference for Llama 3.1 405B currently supports requests with total input and output token count up to 11K. For larger token count requests, we will fall back to the standard mode.

The following table shows the inference profiles that support latency optimization:

Provider	Model	Model ID	Cross-region inference profile support
Amazon	Nova Pro	amazon.nova-pro-v1:0	us-east-1 us-east-2
Anthropic	Claude 3.5 Haiku	anthropic.claude-3-5-haiku-20241022-v1:0	us-east-2 us-west-2
Meta	Llama 3.1 405B Instruct	meta.llama3-1-405b-instruct-v1:0	us-east-2
Meta	Llama 3.1 70B Instruct	meta.llama3-1-70b-instruct-v1:0	us-east-2 us-west-2

For more information about inference profiles, see Supported Regions and models for inference profiles.

Supported Regions and models for running model inference

The content from this page has moved. For information about supported Regions and models, see Supported foundation models in Amazon Bedrock.

Use a tool to complete an Amazon Bedrock model response

You can use the Amazon Bedrock API to give a model access to tools that can help it generate responses for messages that you send to the model. For example, you might have a chat application that lets users find out the most popular song played on a radio station. To answer a request for the most popular song, a model needs a tool that can query and return the song information.

> **Note**
>
> You can now use structured outputs with tool use. See Get validated JSON results from models for more details.

In Amazon Bedrock, the model doesn't directly call the tool. When you send a message, you also supply definitions for one or more tools that could help the model generate a response. The model decides when a tool is needed; your application code (or Amazon Bedrock itself, in server-side mode) executes the tool and returns the result for the model to incorporate in its final response.

Amazon Bedrock supports three modes of tool use, depending on which API you call and which model family you use:

Mode	Who runs the tool	When to use it
Client-side tool use	Your application code, after the model returns a tool-call request.	Most use cases. Available with the Responses, Chat Completions, Converse, and InvokeModel APIs.
Server-side tool use	Amazon Bedrock itself. You register a Lambda function or AgentCore Gateway, and Amazon Bedrock invokes the tool on the model's behalf.	Centralized, secure tool execution without managing orchestration in your application. Currently available on the Responses API.
Anthropic Claude tool use	Your application code, using Anthropic-defined tool types (`computer_*` , `bash_*`, `text_editor_*` , `memory_*`)	Computer use, code execution, file editing, persistent memory, or fine-grained tool streaming with

Mode	Who runs the tool	When to use it
	and the Anthropic Messages API request format.	Claude models on `bedrock-runtime` or `bedrock-mantle`.

Client-side tool use

If you use the Responses API, Chat Completions API, Converse API, or InvokeModel API to send the request, then the model uses client-side tool calling. This means that in your code, you call the tool on the model's behalf. In this scenario, assume the tool implementation is an API. The tool could just as easily be a database, Lambda function, or some other software. You decide how you want to implement the tool. You then continue the conversation with the model by supplying a message with the result from the tool. Finally, the model generates a response for the original message that includes the tool results that you sent to the model.

Let us define the tool we will use for tool use. The following Python examples show how to use a tool that returns the most popular song on a fictional radio station.

```
def get_most_popular_song(station_name: str) -> str:
    stations = {
        "Radio Free Mars": "Starman – David Bowie",
        "Neo Tokyo FM": "Plastic Love – Mariya Takeuchi",
        "Cloud Nine Radio": "Blinding Lights – The Weeknd",
    }
    return stations.get(station_name, "Unknown Station – No chart data available")
```

Using Responses API for client-side tooling

You can use the Function calling feature provided by OpenAI to call this tool. Responses API is OpenAI's preferred API. Here is the Python code for Responses API for client-side tooling:

```
from openai import OpenAI
import json

client = OpenAI()

response = client.responses.create(
    model="oss-gpt-120b",
    input="What is the most popular song on Radio Free Mars?",
    tools=[
```

```
        {
            "type": "function",
            "name": "get_most_popular_song",
            "description": "Returns the most popular song on a radio station",
            "parameters": {
                "type": "object",
                "properties": {
                    "station_name": {
                        "type": "string",
                        "description": "Name of the radio station"
                    }
                },
                "required": ["station_name"]
            }
        }
    ]
)

if response.output and response.output[0].content:
    tool_call = response.output[0].content[0]
    args = json.loads(tool_call["arguments"])
    result = get_most_popular_song(args["station_name"])

    final_response = client.responses.create(
        model="oss-gpt-120b",
        input=[
            {
                "role": "tool",
                "tool_call_id": tool_call["id"],
                "content": result
            }
        ]
    )

    print(final_response.output_text)
```

Using Chat Completions API for client-side tooling

You can use the Chat Completions API also. Here is the Python code for using Chat Completions:

```
    from openai import OpenAI
import json
```

```
client = OpenAI()

completion = client.chat.completions.create(
    model="oss-gpt-120b",
    messages=[{"role": "user", "content": "What is the most popular song on Neo Tokyo
 FM?"}],
    tools=[{
        "type": "function",
        "function": {
            "name": "get_most_popular_song",
            "description": "Returns the most popular song on a radio station",
            "parameters": {
                "type": "object",
                "properties": {
                   "station_name": {"type": "string", "description": "Name of the radio
 station"}
                },
                "required": ["station_name"]
            }
        }
    }]
)

message = completion.choices[0].message

if message.tool_calls:
    tool_call = message.tool_calls[0]
    args = json.loads(tool_call.function.arguments)
    result = get_most_popular_song(args["station_name"])

    followup = client.chat.completions.create(
        model="oss-gpt-120b",
        messages=[
            {"role": "user", "content": "What is the most popular song on Neo Tokyo
 FM?"},
            message,
            {"role": "tool", "tool_call_id": tool_call.id, "content": result}
        ]
    )

    print(followup.choices[0].message.content)
```

For more details on the using Function Calling on Responses API and Chat Completions API, see Function Calling in OpenAI.

Using Converse API for client-side tooling

You can use the Converse API to let a model use a tool in a conversation. The following Python examples show how to use a tool that returns the most popular song on a fictional radio station.

```
# Copyright Amazon.com, Inc. or its affiliates. All Rights Reserved.
# SPDX-License-Identifier: Apache-2.0
"""Shows how to use tools with the Converse API and the Cohere Command R model."""

import logging
import json
import boto3
from botocore.exceptions import ClientError

class StationNotFoundError(Exception):
    """Raised when a radio station isn't found."""
    pass

logger = logging.getLogger(__name__)
logging.basicConfig(level=logging.INFO)

def get_top_song(call_sign):
    """Returns the most popular song for the requested station.

    Args:
        call_sign (str): The call sign for the station for which you want
            the most popular song.

    Returns:
        response (json): The most popular song and artist.
    """
    song = ""
    artist = ""

    if call_sign == 'WZPZ':
        song = "Elemental Hotel"
        artist = "8 Storey Hike"
```

```
    else:
        raise StationNotFoundError(f"Station {call_sign} not found.")

    return song, artist

def generate_text(bedrock_client, model_id, tool_config, input_text):
    """Generates text using the supplied Amazon Bedrock model. If necessary,
    the function handles tool use requests and sends the result to the model.

    Args:
        bedrock_client: The Boto3 Bedrock runtime client.
        model_id (str): The Amazon Bedrock model ID.
        tool_config (dict): The tool configuration.
        input_text (str): The input text.

    Returns:
        Nothing.
    """
    logger.info("Generating text with model %s", model_id)

    # Create the initial message from the user input.
    messages = [{"role": "user",
                 "content": [{"text": input_text}]}]

    response = bedrock_client.converse(modelId=model_id,
                                       messages=messages,

```

Choosing which tool the model requests

The optional `toolChoice` field in `toolConfig` controls whether the model has to request a tool. Which settings you can use depends on the individual model that you call, not on the model provider or the model family:

- `auto` (the default) is supported by every model that supports tool use. The model decides whether to request a tool or to generate text instead.

- any, which requires the model to request at least one tool, and `tool`, which requires the model to request one tool that you name, are supported by some models but not others. A model can support one of the two and not the other.

If a model doesn't support the setting that you send, the request fails with a `ValidationException` rather than falling back to `auto`. The message identifies the field to remove, for example `This model doesn't support the toolConfig.toolChoice.tool field. Remove toolConfig.toolChoice.tool and try again.` Some models instead return the error that the model provider reports, such as `The model returned the following errors: tool_choice: type "tool" and "any" are not supported for this model.` For the Anthropic Claude models that don't support `any` or `tool`, see Forced tool use.

A model that doesn't support tool use at all fails with `This model doesn't support tool use.` for every `toolChoice` setting, including `auto`.

Tool use with response streaming

Support for tool use and support for response streaming are independent capabilities. Most models that support tool use also accept a `toolConfig` field on `ConverseStream`, but the following models accept tools only on the non-streaming `Converse` operation and reject them on `ConverseStream` with `This model doesn't support tool use in streaming mode.`:

- Llama 3.1 8B Instruct, Llama 3.1 70B Instruct, and Llama 3.3 70B Instruct
- Llama 4 Scout 17B Instruct and Llama 4 Maverick 17B Instruct
- Mistral Large 1 (24.02), Mistral Large 2 (24.07), and Pixtral Large (25.02)
- Writer Palmyra X4 and Writer Palmyra X5

Response streaming itself works with all of these models. Only the combination of streaming and tool use is unsupported. If you need tool use with one of them, call `Converse` instead.

About the tool use ID

Each tool request in a response carries a `toolUseId` that identifies that request. You echo the same value back in the corresponding `toolResult` block so that the model can match the result to the request. How Amazon Bedrock produces this value depends on the kind of tool and on the model:

- For tools that you define in `toolConfig`, Amazon Bedrock generates the value. It is a randomly generated identifier prefixed with `tooluse_`, and it is not produced by, or derived from, the model's output.
- For Amazon Bedrock server-side tools and MCP tools, Amazon Bedrock computes the value deterministically from the tool request rather than generating it randomly. The value still carries the `tooluse_` prefix.
- For some models, the identifier that the model provider returns is passed through unchanged. Such a value uses the provider's own format, does not carry the `tooluse_` prefix, and can contain text derived from your request, such as the name of the tool.

To tell the two apart at runtime, check the prefix. Every identifier that Amazon Bedrock generates begins with `tooluse_` followed by 22 characters. An identifier that does not begin with `tooluse_` came from the model provider. This behavior can differ between models in the same family, so test the specific model that you call.

> **Important**
>
> If your application redacts model-generated content, for example to meet compliance obligations for protected health information, do not assume that `toolUseId` is generated by Amazon Bedrock for every model. Treat the value as model-derived unless you have confirmed the behavior for the specific model that you call.

Using Invoke APIs for client-side tool use

It is possible to use tools with the base inference operations (InvokeModel or InvokeModelWithResponseStream). To find the inference parameters that you pass in the request body, see the inference parameters for the model that you want to use.

Server-side tool use

If you use the Responses API to invoke the model, then it can use server-side tool calling, in addition to the client-side tool calling we discussed before. Server-side tool calling is a mechanism where tools (APIs, functions, workflows) are executed in a trusted, backend environment, not on the client. This improves the security, reliability, and governance posture of the application. Before Amazon Bedrock executes the Lambda function that implements the tool use, it ensures that the Lambda function has the same IAM policy as that of the application that calls it. Because Amazon

Bedrock handles tool execution, clients can focus on implementing their business logic, rather than adding tool functionality. Amazon Bedrock also supports the highest governance standards such as ISO, SOC, and HIPAA eligible. You can either submit your own custom Lambda function to run the tool or use existing pre-defined tools, such as notes and tasks. Server-side tools using the Responses API are available starting with the GPT OSS 20B/120B models, with support for other models coming soon. You can use the Models API to discover available models that you can use with the Responses API. For more details on the Responses API, see Generate responses using OpenAI APIs.

There are two types of tools you can use with Amazon Bedrock: Custom tools using Lambda, or pre-defined tools supported by Amazon Bedrock. This section covers how to create a custom Lambda tool with the Responses API. The following sections describe each type in detail.

Custom tools using Lambda in Responses API

By using a Lambda function as a custom tool in Amazon Bedrock, you can extend the capabilities of the agent by integrating custom Lambda functions as tools. With this, you can create serverless, scalable tools that can be called by AI assistants and other applications through the Model Context Protocol (MCP). Here are the advantages of this feature:

- Extend Functionality: Add custom business logic, API integrations, or data processing capabilities.
- Run tools securely: Lambda allows tools to access resources inside a VPC without having to grant full VPC access.
- Serverless Architecture: No infrastructure management, Lambda handles scaling automatically.
- Cost Effective: Pay only for execution time, not idle resources.
- Easy Integration: Lambda functions appear alongside built-in tools seamlessly.

To let a model in Amazon Bedrock use a tool to complete a response for a message, you send the message and the definitions for one or more tools to the model. Based on your application's prompt, if the model determines that one of the tools can help generate a response, it returns a request for Amazon Bedrock to use the tool and send the tool results back to the model. The model then uses the results to generate a response to the original message.

The following steps show how to use a tool with the Responses API.

How it works

1. **Lambda function**: Create your Lambda function that implements the MCP protocol

2. **Tool Discovery**: Bedrock calls your Lambda function to discover available tools
3. **Tool Registration**: Your tools are registered with Bedrock
4. **Tool Execution**: When agent request your tool, Bedrock invokes your Lambda function
5. **Response Handling**: Results are returned to the agent through the standard interface

Step 1: Define the Lambda function to get the most popular song

Create a Lambda function that implements the MCP protocol. Here's a simple Python example:

```
import json

def lambda_handler(event, context):
    # Parse JSON-RPC request
    method = event.get('method')
    params = event.get('params', {})
    request_id = event.get('id')

    if method == 'tools/list':
        return {
            "jsonrpc": "2.0",
            "id": request_id,
            "result": {
                "tools": [
                    {
                        "name": "my_custom_tool",
                        "description": "My custom business logic tool",
                        "inputSchema": {
                            "type": "object",
                            "properties": {
                                "input": {
                                    "type": "string",
                                    "description": "Input text to process"
                                }
                            },
                            "required": ["input"]
                        }
                    }
                ]
            }
        }
    elif method == 'tools/call':
        tool_name = params.get('name')
```

```
        arguments = params.get('arguments', {})

        if tool_name == 'my_custom_tool':
            # Your custom logic here
            result = f"Processed: {arguments.get('input', '')}"
            return {
                "jsonrpc": "2.0",
                "id": request_id,
                "result": {
                    "content": [
                        {
                            "type": "text",
                            "text": result
                        }
                    ]
                }
            }

    # Error response for unsupported methods
    return {
        "jsonrpc": "2.0",
        "id": request_id,
        "error": {
            "code": -32601,
            "message": "Method not found"
        }
    }
```

Step 2: Deploy the Lambda function

Next, use your IAM role to deploy this Lambda function to get an ARN. You can read more in Getting started with Lambda in the Lambda Developer Guide.

```
# Example using AWS CLI
aws lambda create-function \
  --function-name my-custom-tool \
  --runtime python3.14 \
  --role arn:aws:iam::YOUR-ACCOUNT:role/lambda-execution-role \
  --handler lambda_function.lambda_handler \
  --zip-file fileb://function.zip
```

Let's say that your ARN is: `arn:aws:lambda:us-west-2:123456789012:function:my-custom-tool`

Step 3: Define the message and tool definition in your inference request

To send the message and tool definition, you use the Responses API operations. Amazon Bedrock uses the connectors and remote MCP servers functionality of the Responses API to provide tool-use capability. The definition of the tool is a JSON schema that you pass in the mcp request parameter to the Create operation. In the `connector_id` field in the Responses connectors API, you can pass in the Lambda ARN that you have created in the previous step. You do not need to provide authorization credentials because Amazon Bedrock uses the same IAM roles and policy that is used for your application that invokes the model. The following is an example schema for a tool that gets the most popular song played on a radio station.

```
from openai import OpenAI

client = OpenAI()

resp = client.responses.create(
    model="oss-gpt-120b",
    tools=[
        {
            "type": "mcp",
            "server_label": "xamzn_arn",
            "connector_id": "arn:aws:lambda:us-west-2:123456789012:function:my-custom-
tool",
            "require_approval": "never",
        },
    ],
    input="My custom prompt.",
)

print(resp.output_text)
```

Step 4: Bedrock calls the tool and passes the response back to the model

The ability to use the connector tool is available in the models that support the Responses API. Check which tools support your model in Generate responses using OpenAI APIs. When you're using tools using the Responses API, you only pay for tokens used when importing tool definitions or making tool calls. There are no additional fees involved per tool call.

When you specify a Lambda function in the `tools` parameter, the API will attempt to get a list of tools from the server. If successful in retrieving the list of tools, a new `mcp_list_tools` output item will appear in the model response output. The `tools` property of this object will show the

tools that were successfully imported. After the model has access to these tool definitions, it might choose to call them depending on what's in the model's context. When the model decides to call a Lambda tool, the API will make a request to the Lambda function to call the tool and put its output into the model's context. You can read more on the list tools and calling tools in the OpenAI documentation. Note that your Lambda function must have the same IAM roles and policy attached to it as that of the application calling the model in Amazon Bedrock, otherwise the Lambda function will fail. The following is the error definition.

```
{
    "jsonrpc": "2.0",
    "id": 1,
    "error": {
        "code": -32000,
        "message": "Tool execution failed",
        "data": "Additional error details"
    }
}
```

Using AWS provided tools in Responses API

There are two AWS provided tools built into the `openai.gpt-oss-20b` and `openai.gpt-oss-120b` models: Note-taking functionality (notes tool) and Task management (tasks tool). These tools are automatically available — you do not need to define them in the `tools` parameter.

Notes Tool Overview

The `notes` tool allows the model to store notes within the same conversation session. This provides a simple memory mechanism for maintaining context across multiple interactions. Memory is scoped to the current conversation only.

When the model uses the notes tool, it emits an `mcp_call` output with `name` set to `"notes"`. The model determines the appropriate arguments based on your request.

You can use either natural language (e.g. "Remember that my favorite color is blue", "What did I tell you about my favorite color?", "Store the fact that I prefer morning meetings", "Recall what I said about meeting preferences") or you can use direct tool calls in your prompt ("Use the notes tool to store my email as john@example.com", "Check the notes for my email address").

Tasks Tool Overview

The `tasks` tool provides a stack for managing tasks within a conversation session. You can push tasks onto the stack and pop them off, making it useful for managing workflows, reminders, or hierarchical task management. Tasks persist throughout the entire conversation session. Memory is scoped to the current conversation only.

When the model uses the tasks tool, it emits an `mcp_call` output with `name` set to `"tasks"`. The model determines the appropriate arguments (such as `method`, `task.title`, and `task.description`) based on your request.

You can call the Tasks tool by either using natural language (e.g. "Add a task to review the budget", "Push a reminder to call the client", "What's the next task I need to do?", "Pop the most recent task", "Get the latest task from my stack") or you can call the tool directly in your prompt ("Use the tasks tool to push 'finish presentation'", "Pop a task from the stack", "Add 'schedule meeting' to my task list").

Code example: Using the notes and tasks tools

The notes and tasks tools are built into the `openai.gpt-oss-20b` and `openai.gpt-oss-120b` models. You do not need to define them explicitly in the `tools` parameter — simply reference them in your prompt:

```
from openai import OpenAI

client = OpenAI(
    base_url="https://bedrock-mantle.us-east-1.api.aws/v1"
)

# The notes tool is built-in — just ask the model to use it
resp = client.responses.create(
    model="openai.gpt-oss-120b",
    input="Use the notes tool to store that my preferred language is Python.",
)

print(resp.output)
# The model automatically calls the notes tool via mcp_call

# Use the tasks tool to push a task
resp = client.responses.create(
    model="openai.gpt-oss-120b",
    input="Use the tasks tool to push a task: review the API documentation",
)
```

```
print(resp.output)
```

Server-side tool-use integration with AgentCore Gateway

Amazon Bedrock now supports AgentCore Gateway as a server-side tool calling integration type. With this feature, you can connect your models directly to AgentCore Gateway endpoints for seamless access to tools managed through the gateway infrastructure.

The AgentCore Gateway integration follows the same pattern as Lambda function integration, with one key difference.

Lambda Integration:

- Uses Lambda function ARNs
- Directly invokes AWS Lambda functions

AgentCore Gateway Integration:

- Uses AgentCore Gateway ARNs
- Routes tool calls through the AgentCore Gateway infrastructure
- Provides centralized tool management and discovery

Configuration

Request Structure

When configuring AgentCore Gateway as a tool source, use the following structure in your `tools` array in your Responses API request.

```
{
  "type":"mcp",
  "server_label":"agentcore_tools",
  "connector_id":"arn:aws:bedrock-agentcore:us-west-2:342789630635:gateway/agentcore-
intro-gateway-v2-swvq44sovp",
  "server_description":"AgentCore Gateway providing custom tools",
  "require_approval":"never"
}
```

Parameters

Parameter	Type	Required	Description
`type`	string	Yes	Must be set to `mcp`
`server_label`	string	Yes	A unique identifier for this tool connector within your request
`connector_id`	string	Yes	The ARN of your AgentCore Gateway
`server_description`	string	No	Human-readable description of the tools provided by this gateway
`require_approval`	string	Yes	Field has to be `"never"`

Complete Request Example

```
{
  "model":"openai.gpt-oss-120b",
  "stream":true,
  "background":false,
  "store":false,
  "tools": [
    {
      "type":"mcp",
      "server_label":"agentcore_tools",
      "connector_id":"arn:aws:bedrock-agentcore:us-west-2:342789630635:gateway/
agentcore-intro-gateway-v2-swvq44sovp",
      "server_description":"AgentCore Gateway providing custom tools",
      "require_approval":"never"
    }
  ],
  "input": [
    {
      "type":"message",
      "role":"user",
      "content": [
        {
          "type":"input_text",
          "text":"What is the weather in Seattle?"
```

```
        }
      ]
    }
  ]
}
```

Prerequisites

Before using AgentCore Gateway integration, make sure you have:

1. **Created an AgentCore Gateway** with configured targets (Lambda functions, API Gateway stages, OpenAPI schemas, or MCP servers)
2. **Configured IAM permissions** allowing your Bedrock service role to invoke the gateway. Note that Bedrock only supports gateways with IAM authentication.
3. **Gateway ARN** in the correct format

Benefits of AgentCore Gateway Integration

- **Centralized Tool Management**: Manage all your tools through a single gateway endpoint
- **Tool Discovery**: Agents can dynamically discover available tools through the gateway
- **Security**: Built-in authentication and authorization through IAM and gateway policies
- **Observability**: Comprehensive monitoring and logging of tool invocations
- **Flexibility**: Support for multiple target types (Lambda, API Gateway, OpenAPI, MCP servers)

IAM Permissions

Your Bedrock execution role needs permission to invoke the AgentCore Gateway:

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "bedrock-agentcore:InvokeGateway"
      ],
      "Resource": "arn:aws:bedrock-agentcore:us-west-2:342789630635:gateway/agentcore-
intro-gateway-v2-swvq44sovp"
    }
```

```
  ]
}
```

Next Steps

- Learn more about creating AgentCore Gateways
- Explore gateway target types
- Review gateway security best practices

Anthropic Claude tool use

Warning

Several functions below are offered in beta as indicated. These features are made available to you as a "Beta Service" as defined in the AWS Service Terms. It is subject to your Agreement with AWS and the AWS Service Terms, and the applicable model EULA.

With Anthropic Claude models, you can specify a tool that the model can use to answer a message. For example, you could specify a tool that gets the most popular song on a radio station. If the user passes the message *What's the most popular song on WZPZ?*, the model determines that the tool you specified can help answer the question. In its response, the model requests that you run the tool on its behalf. You then run the tool and pass the tool result to the model, which then generates a response for the original message. For more information, see Tool use (function calling) in the Anthropic Claude documentation.

Tip

We recommend that you use the Responses API or Messages API for integrating tool use into your application. For more information, see Use a tool to complete an Amazon Bedrock model response.

Important

Claude Sonnet 4.5 now preserves intentional formatting in tool call string parameters. Previously, trailing newlines in string parameters were sometimes incorrectly stripped. This

fix ensures that tools requiring precise formatting (like text editors) receive parameters exactly as intended. This is a behind-the-scenes improvement with no API changes required. However, tools with string parameters may now receive values with trailing newlines that were previously stripped.

Note

Claude Sonnet 4.5 includes automatic optimizations to improve model performance. These optimizations may add small amounts of tokens to requests, but you are not billed for these system-added tokens.

You specify the tools that you want to make available to a model in the `tools` field. The following example is for a tool that gets the most popular songs on a radio station.

```
[
    {
        "name": "top_song",
        "description": "Get the most popular song played on a radio station.",
        "input_schema": {
            "type": "object",
            "properties": {
                "sign": {
                    "type": "string",
                    "description": "The call sign for the radio station for which you
 want the most popular song. Example calls signs are WZPZ and WKRP."
                }
            },
            "required": [
                "sign"
            ]
        }
    }
]
```

When the model needs a tool to generate a response to a message, it returns information about the requested tool, and the input to the tool, in the message `content` field. It also sets the stop reason for the response to `tool_use`.

```
{
    "id": "msg_bdrk_01USsY5m3XRUF4FCppHP8KBx",
    "type": "message",
    "role": "assistant",
    "model": "claude-3-sonnet-20240229",
    "stop_sequence": null,
    "usage": {
        "input_tokens": 375,
        "output_tokens": 36
    },
    "content": [
        {
            "type": "tool_use",
            "id": "toolu_bdrk_01SnXQc6YVWD8Dom5jz7KhHy",
            "name": "top_song",
            "input": {
                "sign": "WZPZ"
            }
        }
    ],
    "stop_reason": "tool_use"
}
```

In your code, you call the tool on the tools behalf. You then pass the tool result (`tool_result`) in a user message to the model.

```
{
    "role": "user",
    "content": [
        {
            "type": "tool_result",
            "tool_use_id": "toolu_bdrk_01SnXQc6YVWD8Dom5jz7KhHy",
            "content": "Elemental Hotel"
        }
    ]
}
```

In its response, the model uses the tool result to generate a response for the original message.

```
{
    "id": "msg_bdrk_012AaqvTiKuUSc6WadhUkDLP",
    "type": "message",
```

```
    "role": "assistant",
    "model": "claude-3-sonnet-20240229",
    "content": [
        {
            "type": "text",
            "text": "According to the tool, the most popular song played on radio
 station WZPZ is \"Elemental Hotel\"."
        }
    ],
    "stop_reason": "end_turn"
}
```

Fine-grained tool streaming

Fine-grained tool streaming is an Anthropic Claude model capability. With fine-grained tool streaming, Claude developers can stream tool use parameters without buffering or JSON validation, reducing the latency to begin receiving large parameters.

> **Note**
>
> When using fine-grained tool streaming, you may potentially receive invalid or partial JSON inputs. Please make sure to account for these edge cases in your code.

To use this feature, set `eager_input_streaming` to `true` on each user-defined tool that you want to stream this way, and stream the response. The field is optional and applies per tool: a tool that omits it gets standard buffered streaming, in which each parameter value is buffered and validated before it is streamed back.

The following example turns on fine-grained tool streaming for a `make_file` tool:

```
{
  "anthropic_version": "bedrock-2023-05-31",
  "max_tokens": 1024,
  "messages": [
    {
      "role": "user",
      "content": "Can you write a long poem and make a file called poem.txt?"
    }
  ],
  "tools": [
    {
```

```
      "name": "make_file",
      "description": "Write text to a file",
      "eager_input_streaming": true,
      "input_schema": {
        "type": "object",
        "properties": {
          "filename": {
            "type": "string",
            "description": "The filename to write text to"
          },
          "lines_of_text": {
            "type": "array",
            "description": "An array of lines of text to write to the file"
          }
        },
        "required": [
          "filename",
          "lines_of_text"
        ]
      }
    }
  ]
}
```

In this example, fine-grained tool streaming enables Claude to stream the lines of a long poem into the tool call `make_file` without buffering to validate if the `lines_of_text` parameter is valid JSON. This means you can see the parameter stream as it arrives, without having to wait for the entire parameter to buffer and validate.

With fine-grained tool streaming, tool use chunks start streaming faster, and are often longer and contain fewer word breaks. This is due to differences in chunking behavior.

For example, without fine-grained streaming (15s delay):

```
Chunk 1: '{"'
Chunk 2: 'query": "Ty'
Chunk 3: 'peScri'
Chunk 4: 'pt 5.0 5.1 '
Chunk 5: '5.2 5'
Chunk 6: '.3'
Chunk 8: ' new f'
Chunk 9: 'eatur'
```

```
...
```

With fine-grained streaming (3s delay):

```
Chunk 1: '{"query": "TypeScript 5.0 5.1 5.2 5.3'
Chunk 2: ' new features comparison'
```

> **Note**
>
> Because fine-grained streaming sends parameters without buffering or JSON validation, there is no guarantee that the resulting stream will complete in a valid JSON string. Particularly, if the stop reason `max_tokens` is reached, the stream may end midway through a parameter and may be incomplete. You will generally have to write specific support to handle when `max_tokens` is reached.

Legacy fine-grained tool streaming header

Before `eager_input_streaming` was available, you turned this feature on for a whole request by adding `fine-grained-tool-streaming-2025-05-14` to `anthropic_beta`. The per-tool field replaces that header. The header still works, and it enables fine-grained streaming for any tool that leaves `eager_input_streaming` unset, so setting the field to `false` keeps buffered streaming for that tool even when the request carries the header.

> **Important**
>
> You can't combine the header with a bundled client toolset. A request that sends both is rejected, for example with `the fine-grained-tool-streaming-2025-05-14 beta header cannot be combined with a computer_toolset_20260801`. Use `eager_input_streaming` on your user-defined tools instead, which works alongside a toolset. For more information about toolsets, see the section called “Client toolsets”.

Claude Sonnet 4.5 supports the header but not `eager_input_streaming`, which it rejects with `tools.0.custom.eager_input_streaming: Extra inputs are not permitted`. Use the header for that model.

Computer use

Computer use lets Anthropic Claude models automate graphical user interface (GUI) tasks. The client toolsets (`computer_toolset_20260801` and `browser_toolset_20260801`) are generally available on the newer Claude models and require no beta value. The `computer_20251124` and `computer_20250124` computer tools are in beta and require the matching beta value. For an overview, the Amazon Bedrock-specific request shape, and an end-to-end example, see Use computer use tools to automate GUI tasks with Amazon Bedrock models. To find which models support computer use on each endpoint, see the *Capabilities and Features* table in each *Models at a glance*.

To enable computer use on a request, set `anthropic_beta` to a computer-use version and include a tool entry whose `type` matches that version. The valid pairings are:

Beta header	Computer tool type
`computer-use-2025-11-24`	`computer_20251124`
`computer-use-2025-01-24`	`computer_20250124`

The beta value is required for `computer_*` tool types. A request that includes a `computer_*` tool without the matching `anthropic_beta` value, or with a beta value for a different version (for example, `computer_20251124` with `computer-use-2025-01-24`), returns a `400 invalid_request_error`.

Each tool type works only with a specific subset of models. Submitting a tool type that a model does not support returns a `400 invalid_request_error` with a message such as `'claude-sonnet-4-5-20250929' does not support tool types: computer_20251124`. The `computer_20241022` tool type isn't accepted by any current Claude model. For the tool type that each model accepts, see Supported models and tool types.

For the underlying tool protocol, the full action vocabulary, and prompt-engineering guidance, see Computer use in the Anthropic documentation.

Client toolsets

Some Claude models accept two bundled client toolsets as `tools[].type` values. A toolset bundles a related group of client tools under a single type, so you don't have to declare each tool individually. No `anthropic_beta` value is required.

Toolset type	Description
`computer_toolset_20260801`	Bundled computer-use tools for desktop interaction.
`browser_toolset_20260801`	Bundled browser-automation tools.

A toolset entry contains only the `type` field. Don't include a `name`; a toolset entry with a `name` returns a `400 invalid_request_error`, because the names of the tools in a toolset are fixed by the toolset type. In its response, the model calls each tool in the toolset by that tool's own name, for example `screenshot` from `computer_toolset_20260801` or `navigate` from `browser_toolset_20260801`, rather than through a single `computer` tool with an `action` field.

As with individual client tools, the model requests actions but does not run them. You execute each requested action and return a `tool_result`. Submitting a toolset type that a model does not support returns a `400 invalid_request_error`. For the models that accept toolsets, see Supported models and tool types.

Anthropic defined tools

Anthropic provides a set of pre-defined tools that Claude models can use to interact with computers. When specifying an Anthropic-defined tool, the `description` and `tool_schema` fields are not necessary or allowed. The model does not execute these tools automatically; you must run each requested action and return a `tool_result` to Claude. To find which of these tools each model accepts, see the *Capabilities and Features* table in the model's *Models at a glance*; submitting a tool type that a model does not support returns a `400 invalid_request_error`.

Tool	Notes
`{ "type": "computer_20251124", "name": "computer" }`	Latest computer-use tool. Use with `"anthropic_beta": ["computer-use-2025-11-24"]` .
`{ "type": "computer_20250124",`	Use with `"anthropic_beta": ["computer-use-2025-01-24"]` .

Tool	Notes
`"name": "computer"` `}`	

`{`
`"type": "text_editor_20250728",`
`"name": "str_replace_based_edit_tool"`
`}`
	Latest text editor tool. No `anthropic_beta` value is required.

`{`
`"type": "text_editor_20250124",`
`"name": "str_replace_editor"`
`}`
	Earlier text editor tool. The `name` must be `str_replace_editor`. Accepted by older models such as Claude Opus 4.1; newer models, including Claude Sonnet 4.5, reject this type. Use `text_editor_20250728` instead.

`{`
`"type": "text_editor_20241022",`
`"name": "str_replace_editor"`
`}`
	Legacy. Use with `"anthropic_beta": ["computer-use-2024-10-22"]`.

`{`
`"type": "bash_20250124",`
`"name": "bash"`
`}`
	No `anthropic_beta` value is required. If you send `bash_20250124` in the same request as a computer tool, include the beta value for that computer tool. Claude Opus 4.1 rejects the `computer-use-2025-11-24` value.

`{`
`"type": "memory_20250818",`
`"name": "memory"`
`}`
	Memory tool. No `anthropic_beta` value is required. Not accepted by Claude Sonnet 4.5 or Claude Opus 4.1.

Tool	Notes
`{ "type": "bash_20241022", "name": "bash" }`	Legacy. Use with `"anthropic_beta": ["computer-use-2024-10-22"]` .

The `type` field identifies the tool and its parameters for validation purposes; the `name` field is the tool name exposed to the model.

If you want to prompt the model to use one of these tools, you can explicitly refer the tool by the `name` field. The `name` field must be unique within the tool list; you cannot define a tool with the same `name` as an Anthropic-defined tool in the same API call.

Automatic tool call clearing (Beta)

Warning

Automatic tool call clearing is made available as a "Beta Service" as defined in the AWS Service Terms.

Note

This feature is currently supported on Claude Sonnet 4/4.5, Claude Haiku 4.5, and Claude Opus 4/4.1/4.5.

Automatic tool call clearing is an Anthropic Claude model capability (in beta). With this feature, Claude can automatically clear old tool use results as you approach token limits, allowing for more efficient context management in multi-turn tool use scenarios. To use tool use clearing, you need to add `context-management-2025-06-27` to the list of beta headers on the anthropic_beta request parameter. You will also need to specify the use of `clear_tool_uses_20250919` and choose from the following configuration options.

These are the available controls for the `clear_tool_uses_20250919` context management strategy. All are optional or have defaults:

Configuration Option	Description
`trigger` default: 100,000 input tokens	Defines when the context editing strategy activates. Once the prompt exceeds this threshold, clearing will begin. You can specify this value in either input_tokens or tool_uses.
`keep` default: 3 tool uses	Defines how many recent tool use/result pairs to keep after clearing occurs. The API removes the oldest tool interacti ons first, preserving the most recent ones. Helpful when the model needs access to recent tool interactions to continue the conversation effectively.
`clear_at_least` (optional)	Ensures a minimum number of tokens are cleared each time the strategy activates. If the API can't clear at least the specified amount, the strategy will not be applied. This is useful for determining whether context clearing is worth breaking your prompt cache for.
`exclude_tools` (optional)	List of tool names whose tool uses and results should never be cleared. Useful for preserving important context.
`clear_tool_inputs` (optional, default False)	Controls whether the tool call parameters are cleared along with the tool results. By default, only the tool results are cleared while keeping Claude's original tool calls visible, so Claude can see what operations were performed even after the results are removed.

Note

Tool clearing will invalidate your cache if your prefixes contain your tools.

Important

The Anthropic `web_search_20250305` server tool is not supported on Amazon Bedrock.

Request

```
from anthropic import Anthropic
from aws_bedrock_token_generator import provide_token

token = provide_token(region="us-east-1")

client = Anthropic(
    base_url="https://bedrock-runtime.us-east-1.amazonaws.com/anthropic",
    api_key=token,
)

response = client.beta.messages.create(
    betas=["context-management-2025-06-27"],
    model="global.anthropic.claude-sonnet-4-20250514-v1:0",
    max_tokens=4096,
    messages=[
        {
            "role": "user",
            "content": "Create a simple command line calculator app using Python"
       }
    ],
    tools=[
        {
            "type": "text_editor_20250728",
            "name": "str_replace_based_edit_tool",
            "max_characters": 10000
        }
    ],
    extra_body={
        "context_management": {

  },
  "usage": {
    "output_tokens": 1024
  },
  "context_management": {
    "applied_edits": [...],
  }
}
```

Note

Bedrock does not currently support `clear_tool_uses_20250919` context management on the CountTokens API.

Memory Tool (Beta)

Warning

Memory Tool is made available as a "Beta Service" as defined in the AWS Service Terms.

Claude Sonnet 4.5 includes a new memory tool. This tool provides you a way to manage memory across conversations. With this feature, you can allow Claude to retrieve information outside the context window by providing access to a local directory. This feature is available in beta. To use this feature, you must include `context-management-2025-06-27` in the `anthropic_beta` parameter.

Tool definition:

```
{
  "type": "memory_20250818",
  "name": "memory"
}
```

Example Request:

```
{
    "max_tokens": 2048,
    "anthropic_version": "bedrock-2023-05-31",
    "anthropic_beta": ["context-management-2025-06-27"],
    "tools": [{
        "type": "memory_20250818",
        "name": "memory"
    }],
    "messages": [
        {
            "role": "user",
            "content": [{"type": "text", "text": "Remember that my favorite color is
 blue and I work at Amazon?"}]
```

```
        }
    ]
}
```

Example Response:

```
{
    "id": "msg_vrtx_014mQ5ficCRB6PEa5k5sKqHd",
    "type": "message",
    "role": "assistant",
    "model": "claude-sonnet-4-20250514",
    "content": [
        {
            "type": "text",
            "text": "I'll start by checking your memory directory and then record this
 important information about you."
        },
        {
            "type": "tool_use",
            "id": "toolu_vrtx_01EU1UrCDigyPMRntr3VYvUB",
            "name": "memory",
            "input": {
                "command": "view",
                "path": "/memories"
            }
        }
    ],
    "stop_reason": "tool_use",
    "stop_sequence": null,
    "usage": {
        "input_tokens": 1403,
        "cache_creation_input_tokens": 0,
        "cache_read_input_tokens": 0,
        "output_tokens": 87
    },
    "context_management": {
        "applied_edits": []
    }
}
```

Cost considerations for tool use

Tool use requests are priced based on the following factors:

1. The total number of input tokens sent to the model (including in the tools parameter).
2. The number of output tokens generated.

Tools are priced the same as all other Claude API requests, but do include additional tokens per request. The additional tokens from tool use come from the following:

- The `tools` parameter in the API requests. For example, tool names, descriptions, and schemas.
- Any `tool_use` content blocks in API requests and responses.
- Any `tool_result` content blocks in API requests.

When you use tools, the Anthropic models automatically include a special system prompt that enables tool use. The number of tool use tokens required for each model is listed in the following table. This table excludes the additional tokens described previously. Note that this table assumes at least one tool is provided. If no tools are provided, then a tool choice of none uses 0 additional system prompt tokens.

Model	Tool choice	Tool use system prompt token count
Claude Opus 4.5 Claude Opus 4.1 Claude Opus 4 Claude Sonnet 4.5 Claude Haiku 4.5 Claude Sonnet 4 Claude 3.7 Sonnet Claude 3.5 Sonnet v2	`auto` or none	346
Claude Opus 4.5 Claude Opus 4.1	any or `tool`	313

Model	Tool choice	Tool use system prompt token count
Claude Opus 4 Claude Sonnet 4.5 Claude Haiku 4.5 Claude Sonnet 4 Claude 3.7 Sonnet Claude 3.5 Sonnet v2		
Claude 3.5 Sonnet	`auto` or none	294
Claude 3.5 Sonnet	any or `tool`	261
Claude 3 Opus	`auto` or none	530
Claude 3 Opus	any or `tool`	281
Claude 3 Sonnet	`auto` or none	159
Claude 3 Sonnet	any or `tool`	235
Claude 3 Haiku	`auto` or none	264
Claude 3 Haiku	any or `tool`	340

Tool search tool (beta)

Tool Search Tool allows Claude to work with hundreds or even thousands of tools without loading all their definitions into the context window upfront. Instead of declaring all tools immediately, you can mark them with `defer_loading: true`, and Claude finds and loads only the tools it needs through the tool search mechanism.

To access this feature, you must include `tool-search-tool-2025-10-19` in the `anthropic_beta` parameter. Note that this feature is currently only available through the InvokeModel and InvokeModelWithResponseStream APIs.

Tool definition:

```
{
    "type": "tool_search_tool_regex",
    "name": "tool_search_tool_regex"
}
```

Request example:

```
{
    "anthropic_version": "bedrock-2023-05-31",
    "anthropic_beta": [
        "tool-search-tool-2025-10-19"
    ],
    "max_tokens": 4096,
    "tools": [{
            "type": "tool_search_tool_regex",
            "name": "tool_search_tool_regex"
        },
        {
            "name": "get_weather",
            "description": "Get current weather for a location",
            "input_schema": {
                "type": "object",
                "properties": {
                    "location": {
                        "type": "string"
                    },
                    "unit": {
                        "type": "string",
                        "enum": ["celsius", "fahrenheit"]
                    }
                },
                "required": ["location"]
            },
            "defer_loading": true
        },
        {
            "name": "search_files",
            "description": "Search through files in the workspace",
            "input_schema": {
                "type": "object",
                "properties": {
```

```
                    "query": {
                        "type": "string"
                    },
                    "file_types": {
                        "type": "array",
                        "items": {
                            "type": "string"
                        }
                    }
                },
                "required": ["query"]
            },
            "defer_loading": true
        }
    ],
    "messages": [{
        "role": "user",
        "content": "What's the weather in Seattle?"
    }]
}
```

Response example

```
{
    "role": "assistant",
    "content": [{
            "type": "text",
            "text": "I'll search for the appropriate tools to help with this task."
        },
        {
            "type": "server_tool_use",
            "id": "srvtoolu_01ABC123",
            "name": "tool_search_tool_regex",
            "input": {
                "pattern": "weather"
            }
        },
        {
            "type": "tool_search_tool_result",
            "tool_use_id": "srvtoolu_01ABC123",
            "content": {
                "type": "tool_search_tool_search_result",
                "tool_references": [{
```

```
                    "type": "tool_reference",
                    "tool_name": "get_weather"
                }]
            }
        },
        {
            "type": "text",
            "text": "Now I can check the weather."
        },
        {
            "type": "tool_use",
            "id": "toolu_01XYZ789",
            "name": "get_weather",
            "input": {
                "location": "Seattle",
                "unit": "fahrenheit"
            }
        }
    ],
    "stop_reason": "tool_use"
}
```

Streaming example

```

    "type": "content_block_start",
    "index": 0,
    "content_block": {
        "type": "server_tool_use",
        "id": "srvtoolu_01ABC123",
        "name": "tool_search_tool_regex"
    }
}

# Event 2: content_block_delta(input JSON streamed) {
    "type": "content_block_delta",
    "index": 0,
    "delta": {
        "type": "input_json_delta",
        "partial_json": "{\"regex\": \".*weather.*\"}"
    }
}
```

```
# Event 3: content_block_stop(tool_use complete) {
    "type": "content_block_stop",
    "index": 0
}

# Event 4: content_block_start(COMPLETE result in single chunk) {
    "type": "content_block_start",
    "index": 1,
    "content_block": {
        "type": "tool_search_tool_result",
        "tool_use_id": "srvtoolu_01ABC123",
        "content": {
            "type": "tool_search_tool_search_result",
            "tool_references": [{
                "type": "tool_reference",
                "tool_name": "get_weather"
            }]
        }
    }
}

# Event 5: content_block_stop(result complete) {
    "type": "content_block_stop",
    "index": 1
}
```

Custom tool search tools

You can implement custom tool search tools (for example, using embeddings) by defining a tool that returns `tool_reference` blocks. The custom tool must have `defer_loading: false` while other tools should have `defer_loading: true`. When you define your own Tool Search Tool, it should return a tool result containing `tool_reference` content blocks that point to the tools you want Claude to use.

The expected customer-defined Tool Search Tool result response format:

```
{
    "type": "tool_result",
    "tool_use_id": "toolu_01ABC123",
    "content": [{
            "type": "tool_reference",
            "tool_name": "get_weather"
        },
```

```
        {
            "type": "tool_reference",
            "tool_name": "weather_forecast"
        }
    ]
}
```

The `tool_name` must match a tool defined in the request with `defer_loading: true`. Claude will then have access to those tools' full schemas.

Custom search tools - Detailed example

You can implement custom tool search tools (for example, using embeddings or semantic search) by defining a tool that returns `tool_reference` blocks. This enables sophisticated tool discovery mechanisms beyond regex matching.

Request example with custom TST:

```
{
    "model": "claude-sonnet-4-5-20250929",
    "anthropic_version": "bedrock-2023-05-31",
    "anthropic_beta": ["tool-search-tool-2025-10-19"],
    "max_tokens": 4096,
    "tools": [{
            "name": "semantic_tool_search",
            "description": "Search for available tools using semantic similarity.
 Returns the most relevant tools for the given query.",
            "input_schema": {
                "type": "object",
                "properties": {
                    "query": {
                        "type": "string",
                        "description": "Natural language description of what kind of
 tool is needed"
                    },
                    "top_k": {
                        "type": "integer",
                        "description": "Number of tools to return (default: 5)"
                    }
                },
                "required": ["query"]
            },
            "defer_loading": false
```

```
        },
        {
            "name": "get_weather",
            "description": "Get current weather for a location",
            "input_schema": {
                "type": "object",
                "properties": {
                    "location": {
                        "type": "string"
                    },
                    "unit": {
                        "type": "string",
                        "enum": ["celsius", "fahrenheit"]
                    }
                },
                "required": ["location"]
            },
            "defer_loading": true
        },
        {
            "name": "search_flights",
            "description": "Search for available flights between locations",
            "input_schema": {
                "type": "object",
                "properties": {
                    "origin": {
                        "type": "string"
                    },
                    "destination": {
                        "type": "string"
                    },
                    "date": {
                        "type": "string"
                    }
                },
                "required": ["origin", "destination", "date"]
            },
            "defer_loading": true
        }
    ],
    "messages": [{
        "role": "user",
        "content": "What's the weather forecast in Seattle for the next 3 days?"
    }]
```

```
}
```

Claude's response (calling custom TST):

```
{
    "role": "assistant",
    "content": [{
            "type": "text",
            "text": "I'll search for the appropriate tools to help with weather
 information."
        },
        {
            "type": "tool_use",
            "id": "toolu_01ABC123",
            "name": "semantic_tool_search",
            "input": {
                "query": "weather forecast multiple days",
                "top_k": 3
            }
        }
    ],
    "stop_reason": "tool_use"
}
```

Customer-provided tool result

After performing semantic search on the tool library, the customer returns matching tool references:

```
{
    "role": "user",
    "content": [{
        "type": "tool_search_tool_result",
        "tool_use_id": "toolu_01ABC123",
        "content": {
            "type": "tool_search_tool_search_result",
            "tool_references": [{
                "type": "tool_reference",
                "tool_name": "get_weather"
            }]
        }
    }]
```

```
}
```

Claude's follow-up (using discovered tool)

```
{
    "role": "assistant",
    "content": [{
            "type": "text",
            "text": "I found the forecast tool. Let me get the weather forecast for
 Seattle."
        },
        {
            "type": "tool_use",
            "id": "toolu_01DEF456",
            "name": "get_weather",
            "input": {
                "location": "Seattle, WA"
            }
        }
    ],
    "stop_reason": "tool_use"
}
```

Error handling

- Setting `defer_loading: true` for all tools (including the Tool Search Tool) will throw a 400 error.
- Passing a `tool_reference` without a corresponding tool definition will throw a 400 error

Tool use examples (beta)

Claude Opus 4.5 supports user-provided examples in tool definitions to increase Claude's tool use performance. You can provide examples as full function calls, formatted exactly as real LLM outputs would be, without needing translation into another format. To use this feature, you must include `tool-examples-2025-10-29` in the `anthropic_beta` parameter.

Tool definition example:

```
{
    "name": "get_weather",
    "description": "Get the current weather in a given location",
```

```
    "input_schema": {
        "type": "object",
        "properties": {
            "location": {
                "type": "string",
                "description": "The city and state, e.g. San Francisco, CA"
            },
            "unit": {
                "type": "string",
                "enum": ["celsius", "fahrenheit"],
                "description": "Temperature unit"
            }
        },
        "required": ["location"]
    },
    "input_examples": [{
            "location": "San Francisco, CA",
            "unit": "fahrenheit"
        },
        {
            "location": "Tokyo, Japan",
            "unit": "celsius"
        },
        {
            "location": "New York, NY"
        }
    ]
}
```

Validation rules

- Schema conformance: Each example in `input_examples` must be valid according to the tool's `input_schema`.
  - Required fields must be present in at least one example.
  - Field types must match the schema.
  - Enum values must be from the allowed set.
  - If validation fails, return a 400 error with details about which example failed validation.
- Array requirements: `input_examples` must be an array (can be empty).
  - Empty array `[]` is valid and equivalent to omitting the field.
  - Single example must still be wrapped in an array: `[{...}]`

- Length limit: start with a limit of 20 examples per tool definition.

Error examples:

```
// Invalid: Example doesn't match schema (missing required field)
{
    "type": "invalid_request_error",
    "message": "tools.0.custom: Example at index 0 is invalid: \"location\" is a
 required property. Each example must match the tool's input_schema."
}

// Invalid: Example has wrong type for field
{
    "type": "invalid_request_error",
    "message": "tools.0.custom: Example at index 1 is invalid: \"cheap\" is not of type
 \"number\". Each example must match the tool's input_schema."
}

// Invalid: input_examples on server-side tool
{
    "type": "invalid_request_error",
    "message": "input_examples is not supported for server-side tool"
}
```

Mid-conversation tool changes (Beta)

Note

By-reference tool changes (the `tool_reference` and MCP variants described in the following section) require the beta flag `mid-conversation-tool-changes-2026-07-01` in `anthropic_beta`. By-value tool definitions (see Inline tool definitions (Beta)) additionally require `inline-tools-2026-09-15`. Sending `inline-tools-2026-09-15` also enables the by-reference blocks, so it can be sent alone or alongside `mid-conversation-tool-changes-2026-07-01`.

Tool changes are supported on Claude Fable 5.2, Claude Mythos 5.2, Claude Opus 5.5, Claude Sonnet 5.5, Claude Mythos 5.1, Claude Fable 5.1, Claude Opus 5, Claude Mythos 5, Claude Fable 5, and Claude Opus 4.8.

Claude Sonnet 5, Claude Opus 4.7, Claude Opus 4.6, Claude Sonnet 4.6, and the Claude 4.5 models return a `400`.

Supported models add and remove tools mid-conversation through `tool_addition` and `tool_removal` content blocks on `role: "system"` messages, instead of re-sending the full top-level `tools` array (which would invalidate the prompt cache).

Request shape

`tool_addition` and `tool_removal` blocks appear in the `content` array of a `role: "system"` message, alongside optional `text` blocks. Each block references **one** tool through its `tool` field. Multiple blocks are allowed and are processed in content order.

```
{
  "role": "system",
  "content": [
    {"type": "tool_removal", "tool": {"type": "tool_reference", "name":
 "get_weather"}},
    {"type": "tool_addition", "tool": {"type": "tool_reference", "name":
 "search_docs"}},
    {"type": "text", "text": "Tool set updated for phase 2."}
  ]
}
```

Both block types support `cache_control` for prompt caching.

Inline tool definitions (Beta)

Instead of a `tool_reference`, a `tool_addition` block in a `role: "system"` message can carry the tool itself as `{"type": "tool_definition", "definition": {…}}` — the same object a `tools[]` entry holds. The tool is available from that position onward, exactly as if it had been declared in `tools[]`, and the model's `tool_use` is parsed against the definition's `input_schema`. Later turns carry only the definition in history, so adding a tool never invalidates the cached prefix or earlier thinking.

> **Note**
>
> Claude Haiku 5.5 supports inline tool definitions (`inline-tools-2026-09-15`), but does not support by-reference mid-conversation tool changes.

The following request declares one tool (`get_time`) in `tools[]`, then adds a second tool (`convert_length`) by value through a `tool_addition` block on a `role: "system"` message, and asks the model to use it:

```
{
  "anthropic_version": "bedrock-2023-05-31",
  "max_tokens": 1024,
  "anthropic_beta": ["inline-tools-2026-09-15"],
  "tools": [
    {
      "name": "get_time",
      "description": "Get the current time in a given time zone.",
      "input_schema": {
        "type": "object",
        "properties": {
          "timezone": {"type": "string"}
        },
        "required": ["timezone"]
      }
    }
  ],
  "messages": [
    {
      "role": "user",
      "content": "What time is it in Tokyo?"
    },
    {
      "role": "assistant",
      "content": [
        {
          "type": "tool_use",
          "id": "toolu_bdrk_01aBcDget_time",
          "name": "get_time",
          "input": {"timezone": "Asia/Tokyo"}
        }
      ]
    },
    {
      "role": "user",
      "content": [
        {
          "type": "tool_result",
          "tool_use_id": "toolu_bdrk_01aBcDget_time",
          "content": "2026-09-19T14:30:00+09:00"
        }
      ]
    },
```

```
    {
      "role": "system",
      "content": [
        {
          "type": "tool_addition",
          "tool": {
            "type": "tool_definition",
            "definition": {
              "name": "convert_length",
              "description": "Convert meters to feet.",
              "input_schema": {
                "type": "object",
                "properties": {
                  "meters": {"type": "integer"}
                },
                "required": ["meters"]
              }
            }
          }
        }
      ]
    },
    {
      "role": "assistant",
      "content": "I can convert lengths now."
    },
    {
      "role": "user",
      "content": "Convert 5 meters to feet."
    }
  ]
}
```

Semantics

- An equal re-definition of the same name is a no-op, so idempotent retries are safe.
- A different definition of the same name replaces the earlier one from that position onward.
- `tool_removal.tool` is always a reference, never a `tool_definition`.
- `computer_*` tools and the `computer_toolset_*` and `browser_toolset_*` toolsets cannot be defined by value; declare them in `tools[]` and reference them.
- MCP references and `mcp_toolset` definitions are not available on this platform.

- `cache_control` can sit on the block **or** inside `definition`, but not both. It is one prompt-cache breakpoint after the rendered definition, and is not allowed with `defer_loading: true`.

Limits

- 10,000 deferred tools.
- 10,000 tools defined after the first user message.
- 4,194,304 bytes of definitions.
- 4,194,304 bytes of rendered tool text in messages.

Under `inline-tools-2026-09-15`, these limits replace the 512 `tool_addition` cap described in Semantics.

Condition	Error (400 invalid_request_error)
`tool_definition` sent without `inline-tools-2026-09-15`	`...tool_addition.tool: Input tag 'tool_definition' found using 'type' does not match any of the expected tags ...`
Tool definitions disabled on the platform	`tool definitions in tool_addition are not available on this platform`
Model does not support tool changes	`tool_addition/tool_removal is not supported on this model` / `...requires a model that supports mid-conversation system content; this model does not`
A `definition` that would be invalid in `tools[]`	Fails with the same message it would produce in `tools[]`, reported at the block's path

Tool reference variants

The `tool` field is a discriminated union on `type`:

type	Fields	Refers to	Additional beta required
`tool_reference`	`name` (string, pattern `^[a-zA-Z0-9_-]{1,128}$`)	A tool declared directly in top-level `tools[]`	—
`mcp_tool_reference`	`server_name`, `name`	A single MCP tool	An `mcp-client-*` beta
`mcp_toolset_reference`	`server_name`	Every tool in the named MCP server's toolset	An `mcp-client-*` beta
`tool_definition`	`definition` — any entry valid in this platform's `tools[]` (`custom`, `bash_*`, `text_editor_*`, `memory_*`, `tool_search_tool_*`)	The tool defined in place, available from that position onward	`inline-tools-2026-09-15` (a dated tool type inside the definition needs its own beta, as in `tools[]`)

`tool_reference` does **not** accept the composed `{server}_{name}` form assigned to MCP-resolved tools; use one of the MCP variants for those.

Semantics

- The available-tool set starts as everything in `tools[]` (after MCP resolution). Each `tool_removal` subtracts the referenced tool(s); each `tool_addition` re-adds them. A tool removed and later re-added is available at the end.
- `tool_removal` renders a brief in-context notice so the model stops planning around the removed tool.
- Mid-conversation tool changes do **not** trigger constrained decoding; `tool_choice` remains the only control for that.
- Maximum 512 `tool_addition` blocks per request. Under `inline-tools-2026-09-15`, this 512-addition cap is replaced by the limits described in Inline tool definitions (Beta).

Error responses (400 invalid_request_error)

Condition	Error
Beta flag missing	Block type rejected as an unknown discriminator
Block outside `role: "system"`	`'tool_addition'/'tool_removal' blocks are only permitted within role: "system" messages`
`tool_reference.name` not in `tools[]`, or names an MCP-resolved tool	`tool_addition/tool_removal references unknown tool '<name>'`
MCP variant with undeclared `server_name`	`tool_addition/tool_removal references unknown server '<name>'`
MCP variant where server has `tool_configuration.enabled: false`	`tool_addition/tool_removal references disabled server '<name>'`
`mcp_tool_reference` in a `tool_addition` where server has no such tool	Error listing all unresolved tool names for that server

> **Note**
>
> `mcp_tool_reference` in a `tool_removal` is lenient — if the server has since dropped that tool, the removal is a no-op (so historical conversations remain replayable).

Forced tool use

Claude Fable 5.2, Claude Mythos 5.2, Claude Opus 5.5, Claude Fable 5.1, and Claude Mythos 5.1 do not support forced tool use. A request that sets `tool_choice` to `{"type": "any"}` or `{"type": "tool", "name": "..."}` returns a `400 invalid_request_error`:

```
tool_choice: type "tool" and "any" are not supported for this model.
```

This applies to the `InvokeModel`, `InvokeModelWithResponseStream`, and `CountTokens` operations. The default `tool_choice` values `{"type": "auto"}` and `{"type": "none"}` are unaffected and work as before. In the Converse API, the equivalent `toolChoice` settings (`tool` and `any`) surface the same error.

Web Search

Web Search is a built-in tool that provides web search capability in Amazon Bedrock. When you enable it, supported models can retrieve current information from the web during a request and use it to ground their answers, instead of relying only on the data they were trained on. Responses include citations to the sources the model used. Web Search is hosted and built by AWS. Retrieval from the external web occurs only when both your request and your IAM permissions allow it.

Data governance

To keep retrieval within the AWS boundary while still allowing cached page content, set `external_web_access` to `false`. Search is then served from the Amazon Bedrock web index and Fetch is served from the Amazon Bedrock cache.

The AmazonBedrockFullAccess policy grants Search and Fetch but not `bedrock-websearch:ExternalWebAccess`. Because `external_web_access` defaults to `true`, omitting the parameter with this policy causes each Fetch attempt to fail its backend authorization check before the cache is read. The overall Responses API request can still complete using Search observations, but Fetch contributes no page content. Explicitly setting the parameter to `false` avoids this failure and keeps retrieval within the AWS boundary. Depending on the model you are using, your data is subject to the automated Amazon Bedrock abuse detection mechanisms.

When to use Web Search

Web Search is useful whenever an answer depends on information that is more recent, more specialized, or more authoritative than a model's parametric knowledge. Recency is one common case: current events, recent product releases, prices, or documentation for a new library version. It is equally useful for long-tail or specialized questions where the model's knowledge is thin or imprecise, such as niche APIs, specific configuration values, or domain-specific facts, and for cases where you want a grounded, citable source rather than a recollection.

How Web Search works

Because the tool runs inside Amazon Bedrock, you do not need to host a search index, manage crawlers, or write the tool-call loop yourself. You add the tool to your Amazon Bedrock inference request, and the model invokes it as needed. Web Search provides current information to the model, enabling the model to return grounded answers with citations.

When Web Search is enabled, the model decides whether a request needs current information. If it does, the model issues one or more search queries to the Web Search tool and receives a set of observations drawn from a web index built and maintained by Amazon. Each observation includes a title, a source URL, and a content snippet. The model then composes an answer grounded in those results and adds citations that point back to the sources.

If the first set of results is not enough to answer the question, the model can reformulate its query using what it found and search again within the same turn. When the results do not support an answer, the model tells you so rather than filling the gap from its training data.

Search and Fetch operations

Web Search is built from two operations:

- **Search** – Returns titles, URLs, and snippets from the Amazon Bedrock web index and knowledge graph for high-confidence facts.
- **Fetch** – Retrieves page content for a specific URL. With `external_web_access` set to `false`, Fetch uses the Amazon Bedrock cache only. With the parameter set to `true` and the required IAM permission granted, Fetch checks the cache first and accesses the external web only on a cache miss.

Search is always served from the Amazon Bedrock web index. The `external_web_access` parameter in the Responses API and the `bedrock-websearch:ExternalWebAccess` IAM permission govern whether Fetch can use the external web after a cache miss. For details, see the section called “Controlling external web access”.

Supported models

Amazon Bedrock supports Web Search for OpenAI GPT-5.4 and later models in the commercial US Regions, served through the `bedrock-mantle` endpoint using the Responses API. In AWS GovCloud (US), it is supported on `openai.gpt-5.6-terra`, `openai.gpt-5.6-luna`, and

`openai.gpt-5.4`. Examples in this guide use `openai.gpt-5.6-terra`. For Web Search pricing, refer to the Amazon Bedrock pricing page.

> **Note**
>
> Web Search is a server-side tool, so it isn't available when you call the Responses API on the `bedrock-runtime` endpoint. To use it, call the Responses API on `bedrock-mantle`. For the other differences between the two endpoints, see Using the Responses API on the bedrock-runtime endpoint.

Regional availability

Web Search processes queries in-Region. See current availability below.

United States

Region	Region code
US East (N. Virginia)	`us-east-1`
US East (Ohio)	`us-east-2`
US West (Oregon)	`us-west-2`

AWS GovCloud (US)

Region	Region code
AWS GovCloud (US-West)	`us-gov-west-1`

Web Search is strictly regional. Each Region operates its own search and fetch tier, and queries, fetches, index data, and results are not routed across Regions. A query issued in a given Region stays within that Region's boundary.

Enable Web Search

To use Web Search, the IAM identity behind your request must be allowed to call the Web Search actions. For the required permissions and example policies, see Identity and access management for Web Search.

Set your environment

Set the following before running the examples:

```
export OPENAI_API_KEY="your-amazon-bedrock-api-key"
export OPENAI_BASE_URL="https://bedrock-mantle.us-west-2.api.aws/openai/v1"
```

Add the Web Search tool to a request

To enable Web Search, add a tool of type `web_search` to the `tools` array in your request. The model uses the tool only when it determines the request needs current information. For runnable examples, see the section called "Code examples".

Control search context size

Use `search_context_size` to control how much context each Search call can return to the model. The supported values are:

Value	Observation budget	When to use
`low`	Up to 5	Smaller context and lower input-token usage for straightforward questions.
`medium`	Up to 11	The default. Balances result coverage and input-token usage.
`high`	Up to 25	More context for complex or multi-hop questions, with higher potential input-token usage.

An observation contains a title, URL, and content snippet. The budget is shared when a Search call contains multiple queries, and the service can return fewer observations than the maximum. Larger

settings can increase the model input tokens and associated inference cost. This parameter does not limit how many Search calls the model can make.

```
tools=[{
    "type": "web_search",
    "search_context_size": "low",
    "external_web_access": False,
}]
```

Controlling external web access

Search is served from the Amazon Bedrock web index. Whether Fetch can retrieve page content from the external web after a cache miss is governed by two controls that work together: the `external_web_access` parameter in the Responses API and the `bedrock-websearch:ExternalWebAccess` IAM permission.

The `external_web_access` parameter defaults to `true`, matching the OpenAI Responses API so that your call does not have to change. The AmazonBedrockFullAccess policy grants the basic Web Search actions — `bedrock-websearch:InvokeSearch` and `bedrock-websearch:InvokeFetch` — but does not grant `bedrock-websearch:ExternalWebAccess`. As a result, a request that leaves `external_web_access` at `true` from an identity that does not hold `ExternalWebAccess` fails the backend authorization check for each Fetch attempt before the cache is read. The caller's Responses API request can still return HTTP `200`: the model can continue using Search observations and return `url_citation` annotations. The model response is not guaranteed to disclose the Fetch failure, and the presence of a citation does not mean the cited page was fetched. The denied `InvokeFetch` call is visible in CloudTrail when Web Search data event logging is enabled. For details, see Monitor Web Search.

Choose one of the following configurations for Fetch.

Keep requests within the AWS boundary

Set `"external_web_access": false` on the tool. This does not require the `ExternalWebAccess` permission, retrieval is served entirely from the Amazon Bedrock web index and cache, and your request data does not leave the AWS boundary. Because AmazonBedrockFullAccess grants `InvokeFetch`, cached Fetch continues to work. Set the parameter explicitly; don't rely on omitting the permission while leaving the parameter at its default of `true`, because that configuration causes Fetch attempts to fail.

```
response = client.responses.create(
    model="openai.gpt-5.6-terra",
    input="Summarize recent guidance on AWS Lambda cold starts.",
    tools=[{"type": "web_search", "external_web_access": False}],
)
```

```
curl "https://bedrock-mantle.us-west-2.api.aws/openai/v1/responses" \
  -H "Authorization: Bearer $OPENAI_API_KEY" \
  -H "Content-Type: application/json" \
  -d '{
    "model": "openai.gpt-5.6-terra",
    "input": "Summarize recent guidance on AWS Lambda cold starts.",
    "tools": [{"type": "web_search", "external_web_access": false}]
  }'
```

Enable external web access

Grant `bedrock-websearch:ExternalWebAccess` to the request identity and set `external_web_access` to `true`. The simplest managed-policy path is to attach either `AmazonBedrockExternalWebSearchReadOnly` or `AmazonBedrockExternalWebSearchFullAccess`. The current versions of these policies grant the same three Web Search actions on the same resources, so either policy enables external retrieval. For details, see Managed policies.

With this configuration, Search continues to use the Amazon Bedrock web index. Fetch checks the Amazon Bedrock cache first and retrieves from the external web only when suitable page content is not in the cache. When Fetch reaches the external web, your request data may leave the AWS boundary. External retrieval takes effect only when you both grant the permission and leave the parameter enabled.

> **Note**
>
> Note that setting `external_web_access` to `true` introduces data exfiltration risk. An agent could encode query data into a URL and then attempt to fetch that URL from the external internet. When you work with sensitive data, set `external_web_access` to `false` to prevent data reaching the external internet.

Using Web Search with Codex

Codex, OpenAI's coding agent, connects to Amazon Bedrock through the `bedrock-mantle` endpoint and can use Web Search on supported models. Web Search is available in the Codex desktop app and the CLI version 0.147.0 or later.

Using Web Search with Codex does not require additional IAM setup beyond the standard Web Search permissions. The IAM identity behind your API key must be allowed to call the Web Search actions `bedrock-websearch:InvokeSearch` and `bedrock-websearch:InvokeFetch`. These actions are granted by the AmazonBedrockFullAccess policy. For the required permissions and example policies, see Identity and access management for Web Search.

On supported Amazon Bedrock models, Codex uses text-only Web Search, returning titles, URLs, and content snippets from the Amazon Bedrock web index and cache. Codex sets `external_web_access` to `false` on each request, so your request data stays within the AWS boundary. For details, see the section called “Controlling external web access”.

Code examples

Responses API

```
from openai import OpenAI

client = OpenAI()

response = client.responses.create(
    model="openai.gpt-5.6-terra",
    input="What are the most significant AWS launches announced this month?",
    tools=[{"type": "web_search", "external_web_access": False}],
)

print(response.output_text)
```

The response includes the grounded answer text together with `url_citation` annotations that point back to the sources:

```
{
  "content": [
    {
      "annotations": [
        {
```

```
          "end_index": 573,
          "start_index": 441,
          "title": "Upgrade Amazon EKS clusters with confidence using Kubernetes
 version rollbacks | AWS News Blog",
          "type": "url_citation",

setup-prompt-openai-gpt-5-6-models-on-bedrock-and-more-july-20-2026/"
        }
      ],
      "logprobs": [],
      "text": "As of **July 30, 2026**, the most significant AWS launches this month:
\n\n1. **Amazon EKS Kubernetes version rollbacks** — EKS now lets admins roll back a
 Kubernetes version upgrade within **seven days**, effectively adding an “undo” path
 for cluster upgrades and reducing upgrade risk for large or regulated Kubernetes
 fleets. It’s available at no additional cost in commercial Regions where EKS is
 available. ([aws.amazon.com](https://aws.amazon.com/blogs/aws/upgrade-amazon-eks-
clusters-with-confidence-using-kubernetes-version-rollbacks/))\n\n2. **AWS Security
 Hub Network Scanning + Azure support** — Security Hub added active Network Scanning to
 find resources actually reachable from the public internet, and also expanded unified
 security management to **Microsoft Azure** resources, making this a notable multi-
cloud security/posture-management move. ([aws.amazon.com](https://aws.amazon.com/blogs/
aws/aws-weekly-roundup-aws-builder-center-at-one-year-network-scanning-in-security-hub-
loom-for-aws-and-more-july-13-2026/))\n\n3. **New frontier models on Amazon Bedrock:
 Claude Sonnet 5, Claude Opus 5, and OpenAI GPT-5.6 models** — AWS added major new
 model choices to Bedrock this month: Anthropic’s Claude Sonnet 5 and Claude Opus
```

```
 5, plus OpenAI GPT-5.6 Sol, Terra, and Luna, expanding Bedrock's role as a multi-
model enterprise AI platform. ([aws.amazon.com](https://aws.amazon.com/blogs/aws/aws-
weekly-roundup-one-click-lambda-setup-prompt-openai-gpt-5-6-models-on-bedrock-and-more-
july-20-2026/))",
      "type": "output_text"
    }
  ],
  "id": "msg_dcda8e4b477f5a1d96bfbcadefef7a77",
  "phase": "final_answer",
  "role": "assistant",
  "status": "completed",
  "type": "message"
}
```

Direct HTTPS request

If you are not using the OpenAI SDK, send the request directly to the Responses endpoint. The `tools` field carries the Web Search tool.

```
curl "https://bedrock-mantle.us-west-2.api.aws/openai/v1/responses" \
  -H "Authorization: Bearer $OPENAI_API_KEY" \
  -H "Content-Type: application/json" \
  -d '{
    "model": "openai.gpt-5.6-terra",
    "input": "What are the most significant AWS launches announced this month?",
    "tools": [{"type": "web_search", "external_web_access": false}]
  }'
```

Reading citations from the response

Web Search returns citations as `url_citation` annotations attached to the text. Each annotation carries the source title and URL and the character span in the answer it supports. Retain and display these to end users.

A citation can be based on a Search observation even when Fetch did not retrieve the full page. Don't use the presence of a citation to determine whether content came from the Amazon Bedrock cache or the external web. To audit Fetch outcomes and retrieval sources, use the `fetchedSources` field in CloudTrail. For details, see Monitor Web Search.

```
from openai import OpenAI

client = OpenAI()
```

```
response = client.responses.create(
    model="openai.gpt-5.6-terra",
    input="What are the most significant AWS launches announced this month?",
    tools=[{"type": "web_search", "external_web_access": False}],
)

# The grounded answer
print(response.output_text)

# The sources behind it
for item in response.output:
    if item.type == "message":
        for block in item.content:
            if block.type == "output_text":
                for ann in block.annotations:
                    if ann.type == "url_citation":
                        print(f"- {ann.title}: {ann.url}")
```

If you are working with the raw JSON (for example, from a direct HTTPS call), the same data lives at `output[].content[].annotations[]`:

```
jq '.output[] | select(.type=="message") | .content[]
      | select(.type=="output_text") | .annotations[]
      | select(.type=="url_citation") | {title, url, start_index, end_index}'
 response.json
```

Streaming responses

The Responses API streams the answer as it is generated. Text arrives as `response.output_text.delta` events, and each citation arrives as a `response.output_text.annotation.added` event as the model grounds a statement.

```
from openai import OpenAI

client = OpenAI()

stream = client.responses.create(
    model="openai.gpt-5.6-terra",
    input="What are the most significant AWS launches announced this month?",
    tools=[{"type": "web_search", "external_web_access": False}],
    stream=True,
```

```
)

for event in stream:
    if event.type == "response.output_text.delta":
        print(event.delta, end="", flush=True)
    elif event.type == "response.output_text.annotation.added":
        ann = event.annotation
        print(f"\n[source] {ann['title']}: {ann['url']}")
```

Over the wire, the annotation event looks like this:

```
event: response.output_text.annotation.added
data: {"type":"response.output_text.annotation.added","annotation":
{"type":"url_citation","title":"News and Updates from the July
 2025 Pokémon Presents","url":"https://www.pokemon.com/us/pokemon-
news/...","start_index":589,"end_index":698},"annotation_index":2,"content_index":0,"item_id":"
```

Domain filtering

Domain filtering restricts Web Search results to a set of domains you specify. On the `web_search` tool, use the `filters` parameter to set up to 100 `allowed_domains` and up to 100 `blocked_domains`.

Omit the `http://` or `https://` prefix when you list a domain, and note that each entry also matches its subdomains — for example, `aws.amazon.com` also covers `docs.aws.amazon.com`.

```
tools=[{
    "type": "web_search",
    "external_web_access": False,
    "filters": {
        "allowed_domains": [
            "aws.amazon.com",
            "docs.aws.amazon.com"
        ]
    }
}]
```

User location

`user_location` is an optional parameter that is used to share location information with the Web Search tool. Depending on the model, location information will be used by a combination of the

model and/or search services to localize the response. When this parameter is not configured or empty, location defaults to United States.

Values for `country` are not case sensitive, so `de` is accepted as `DE`. The value is checked against assigned ISO 3166-1 alpha-2 codes. Unassigned and user-assigned codes such as `UK` and `XK` are rejected. Values for `region` and `city` are accepted as free-form strings. `timezone` is accepted as an IANA time zone identifier.

Customizing user location

```
from openai import OpenAI

client = OpenAI()

response = client.responses.create(
    model="openai.gpt-5.6-terra",
    input="What are the best restaurants near me?",
    tools=[{
        "type": "web_search",
        "external_web_access": False,
        "user_location": {
            "type": "approximate",
            "country": "US",
        },
    }],
)

print(response.output_text)
```

Security

Web Search on Amazon Bedrock uses AWS Identity and Access Management (IAM) to control who can run searches and fetches and in which Regions. The IAM service prefix for Web Search is `bedrock-websearch`. For the full list of actions, managed policies, condition keys, example policies, and administrator controls for disabling Web Search, see Identity and access management for Web Search.

Monitoring with CloudTrail

Web Search on Amazon Bedrock is integrated with AWS CloudTrail. CloudTrail captures API activity for Web Search as data events, so you can audit who invoked the tool, when, and from where.

For the fields captured, how to enable data event logging, and what is intentionally excluded, see Monitor Web Search.

Data retention

This section describes how Web Search tool works and data handling. For more details on how your prompts and model outputs are handled, see Data retention.

How does Web Search work?

The Web Search tool supports two operations: Search and Fetch. Search returns a ranked list of observations as search results for a model generated query. Each observation includes a title, a source URL, and a content snippet. Search results are retrieved from a Web index built by Amazon that includes publicly available web content, licensed content and structured Amazon Knowledge Graph data. Fetch returns the contents of a specific URL to the model. When `external_web_access` is enabled, live web content can be retrieved for URLs present in Amazon's Web index or the public web. URLs fetched from the public web are written to a Live-Fetch cache where they are retained temporarily to avoid exceeding polite request rates against publisher sites.

By default, Web Search retrieves content entirely from Amazon's Web index and data does not leave the AWS boundary. Web Search can retrieve live content from the web only if you explicitly enable `external_web_access`. This distinction determines most of the retention behavior described in the next sections.

What Web Search does not retain

Prompts and search queries

Web Search does not persist your prompt. Your prompt input and model generated search queries are not written into durable storage.

Search results tied to your account

Search results include a title, source URL and content snippets. They are not written into durable storage against your account, your request identity, or your prompt text.

Data sharing

Search operations are served from a Web index and cache that is built and operated by Amazon. Your prompts and model generated tool calls are not sent to a third-party search provider.

Depending on the model you use, your request may be subject to automated Amazon Bedrock abuse detection. Retention of prompts and model outputs by Amazon Bedrock is governed separately by your account or project data retention mode. See Data retention for more details.

External web access

By default, retrieval is served entirely from Amazon's Web index, and no request data leaves the AWS boundary. Only when you choose to enable external web access by granting `bedrock-websearch:ExternalWebAccess` and set `external_web_access` to `true` can Fetch retrieve content live from the web. See Controlling external web access for more details.

Acceptable use

If you use Web Search on Amazon Bedrock, Amazon Bedrock provides Web Search results ("Search Results") to supported models, which the model may use to generate its response. You are responsible for your use, and any use by your end users, of model outputs that incorporate Search Results. You must retain and display the source citations and links provided in model outputs in any output you surface to your end users. You may not use Web Search to (a) extract, store, or reproduce content from Search Results in bulk, or (b) build or populate a competing index or database.

Projects (OpenAI-compatible)

Amazon Bedrock Projects API provides application-level isolation for your generative AI workloads using OpenAI-compatible APIs. Projects enable you to organize and manage your AI applications with improved access control, cost tracking, and observability across your organization.

> **Tip**
>
> For new applications, we recommend the `bedrock-runtime` endpoint. If you don't need the Projects API, use Inference Profiles for isolation, tagging, and cost tracking on `bedrock-runtime`.

> **Note**
>
> Projects can only be used with models that use the OpenAI-compatible APIs against the bedrock-mantle endpoint. If you are using the bedrock-runtime endpoint, please use Inference Profiles instead of tagging and observability.

What is a Project?

A Project is a logical boundary used to isolate workloads such as applications, environments, or experiments within Amazon Bedrock. Projects provide:

- **Access isolation**: Control who can access specific project resources using IAM policies for Amazon Bedrock Projects
- **Cost monitoring**: Track spending at the project level using AWS tags and AWS Cost Explorer

Projects allow you to manage multiple generative AI workloads in production without creating separate AWS accounts or organizations, reducing operational complexity while maintaining security and governance.

Each AWS account has a default project where all inference requests are associated with. You can create more projects in your account using the Projects API.

> **Note**
>
> Support for Projects differs by endpoint. On the `bedrock-mantle` endpoint, you can create and manage your own projects with the Projects API. On the `bedrock-runtime` endpoint, only the default project is available — you can't create projects there yet. Requests to `bedrock-runtime` resolve to your account's default project, whose ARN is `arn:aws:bedrock:`*`region`*`:`*`account-id`*`:project/default`. The default project can't be tagged or deleted, its data retention setting always inherits from the account, and it is never the billing anchor: usage on `bedrock-runtime` is attributed to the inference target, exactly as it is today. For the permissions that reference the default project, see Prerequisites for running model inference.

When to Use Projects

You should use the Projects API when you need to:

- **Organize by business structure**: Manage Bedrock usage based on your organizational taxonomy such as business units, teams, applications, or cost centers
- **Track costs accurately**: Monitor and allocate AI spending to specific teams, projects, or environments
- **Enforce access policies**: Apply granular IAM permissions to control who can access specific AI workloads
- **Scale production workloads**: Run multiple production applications with clear operational boundaries and monitoring

Projects vs. Inference Profiles

Both Projects API and Inference Profiles provide isolation, tagging, and access control capabilities in Amazon Bedrock, but they differ based on the endpoint you use. If you're using OpenAI-compatible APIs with the bedrock-mantle endpoint, use the Projects API. If you're using the bedrock-runtime endpoint (recommended for new applications), use Inference Profiles. The Chat Completions API is available on both endpoints; the Projects API is only available on `bedrock-mantle`.

Feature	Projects API	Inference Profiles
Supported APIs	OpenAI-compatible APIs (Responses, Chat Completions)	Native Bedrock APIs (Invoke, Converse), OpenAI-compatible API (Chat Completions)
Endpoint	`bedrock-mantle.{region}.api.aws`	`bedrock-runtime.{region}.amazonaws.com`
Use Case	Applications using OpenAI-compatible endpoints	Applications using native Bedrock APIs
Access Control	Project as a resource in IAM policies	IAM policies on inference profile ARN

Feature	Projects API	Inference Profiles
Cost Tracking	AWS tags on projects	AWS tags on inference profiles

Projects vs. AWS accounts

AWS Accounts and AWS Organizations represent billing and ownership boundaries at the infrastructure level. Projects represent workload and application boundaries within a single account.

Using Projects instead of separate AWS accounts provides:

- **Faster setup**: Create projects in seconds through API calls.
- **Reduced complexity**: Manage multiple workloads without account sprawl
- **Simplified operations**: Centralized management within a single account
- **Lower overhead**: No need for cross-account IAM roles or resource sharing

Getting started with Projects

This page walks you through creating your first project, associating it with inference requests, and managing project resources.

Prerequisites

Before you begin, make sure you have:

- An AWS account with Amazon Bedrock access
- IAM permissions to create and manage Bedrock projects
- Python 3.7 or later installed
- The OpenAI Python SDK installed: `pip install openai boto3`
- An API key for Amazon Bedrock authentication

Step 1: Set Up Your Environment

Configure your environment variables with your Amazon Bedrock credentials:

```
export OPENAI_API_KEY="<your-bedrock-key>"
export OPENAI_BASE_URL="https://bedrock-mantle.<your-region>.api.aws/v1"
```

Replace `<your-region>` with your AWS region (e.g., us-east-1, us-west-2).

> **Note**
>
> Amazon Bedrock offers two types of keys: short-term and long-term. While you can use long-term API keys for exploration of Amazon Bedrock, we recommend short-term keys for applications with greater security requirements. If you use long-term keys with Projects, note that the default policy attached to long term keys only allows you to get and list projects, but not create/update/archive them. If you would like your long-term key to manage projects, then you will have to assign additional IAM policies to your keys to enable these operations.

Step 2: Discover Available Models

Use the `list()` API to retrieve a list of models compatible with the Projects API:

```
curl -X GET $OPENAI_BASE_URL/models \
  -H "Authorization: Bearer $OPENAI_API_KEY"
```

Step 3: Create Your First Project

Create a project using the Create Project API with tags for cost monitoring and observability. Note that at this time only cURL is supported in the SDK.

```
curl -X POST $OPENAI_BASE_URL/organization/projects \
  -H "Authorization: Bearer $OPENAI_API_KEY" \
  -H "Content-Type: application/json" \
  -d '{
    "name": "Project ABC",
    "tags": {
      "Project": "CustomerChatbot",
      "Environment": "Production",
      "Owner": "TeamAlpha",
      "CostCenter": "21524"
    }
```

```
  }' -v
```

Response:

```
{
  "arn": "arn:aws:bedrock-mantle:ap-northeast-1:673693429514:project/
proj_5d5ykleja6cwpirysbb7",
  "created_at": 1772135628,
  "id": "proj_5d5ykleja6cwpirysbb7",
  "name": "Project ABC",
  "object": "organization.project",
  "status": "active",
  "tags": {
    "Owner": "TeamAlpha",
    "Project": "CustomerChatbot",
    "Environment": "Production",
    "CostCenter": "21524"
  }
}
```

Important Notes:

- The geography parameter in the OpenAI API specification is ignored by Amazon Bedrock.
- The region is determined by your endpoint configuration.
- The arn field is specific to Amazon Bedrock and provides the ARN for IAM policy attachment.
- Tags can be specified during project creation and are returned in all project responses.

Step 4: Associate Inference Requests with Your Project

To associate your project for inference requests, provide the project ID when creating the client:

cURL

```
curl -X POST $OPENAI_BASE_URL/responses \
  -H "Authorization: Bearer $OPENAI_API_KEY" \
  -H "Content-Type: application/json" \
  -H "OpenAI-Project: proj_5d5ykleja6cwpirysbb7" \
  -d '{
    "model": "openai.gpt-oss-120b",
    "input": "Explain the benefits of using projects in Amazon Bedrock"
```

```
  }'
```

Python

```
from openai import OpenAI
client = OpenAI(project="proj_5d5ykleja6cwpirysbb7")
```

All inference requests made with this client will be associated with the specified project, ensuring proper isolation, cost tracking, and access control.

Step 5: Verify Your Project Setup

List all projects to verify your project was created successfully:

```
curl -X GET $OPENAI_BASE_URL/organization/projects \
  -H "Authorization: Bearer $OPENAI_API_KEY"
```

Response:

```
{
  "data": [
    {
      "arn": "arn:aws:bedrock-mantle:ap-northeast-1:673693429514:project/default",
      "created_at": 1764460800,
      "id": "default",
      "name": "default",
      "object": "organization.project",
      "status": "active",
      "tags": {}
    },
    {
      "arn": "arn:aws:bedrock-mantle:ap-northeast-1:673693429514:project/

}
```

Next Steps

Now that you've created your first project, you can:

- **Configure access control**: Attach IAM policies to restrict project access
- **Set up cost tracking**: Add AWS tags for cost allocation
- **Enable monitoring**: Configure CloudWatch metrics and alarms
- **Create additional projects**: Organize workloads by team, environment, or application

Working with Projects

This page provides detailed information about managing projects throughout their lifecycle.

Creating Projects

Basic Project Creation

Create a project with a name, description, and tags:

```
curl -X POST $OPENAI_BASE_URL/organization/projects \
  -H "Authorization: Bearer $OPENAI_API_KEY" \
  -H "Content-Type: application/json" \
  -d '{
    "name": "Development Environment",
    "tags": {
      "Project": "InternalTools",
      "Environment": "Development",
      "Owner": "TeamAlpha",
      "CostCenter": "30156"
    }
  }'
```

You can have up to 1000 projects per account.

Recommended Naming Conventions

Use clear, descriptive names that reflect your organizational structure:

- **By application**: CustomerChatbot-Prod, InternalSearch-Dev
- **By team**: TeamAlpha-Production, DataScience-Experiments
- **By environment**: Production-WebApp, Staging-MobileApp
- **By cost center**: CostCenter-2152-Production

Listing Projects

List All Projects

Retrieve all projects in your account:

```
curl -X GET $OPENAI_BASE_URL/organization/projects \
  -H "Authorization: Bearer $OPENAI_API_KEY"
```

Retrieving Project Details

Get detailed information about a specific project:

```
curl -X GET $OPENAI_BASE_URL/organization/projects/proj_5d5ykleja6cwpirysbb7 \
  -H "Authorization: Bearer $OPENAI_API_KEY"
```

Updating Projects

Modify project properties such as name:

```
curl -X POST $OPENAI_BASE_URL/organization/projects/proj_5d5ykleja6cwpirysbb7 \
  -H "Authorization: Bearer $OPENAI_API_KEY" \
  -H "Content-Type: application/json" \
  -d '{
    "name": "Production Chatbot v2"
  }'
```

Managing Project Tags

Add new tags or update existing tag values:

```
curl -X POST $OPENAI_BASE_URL/organization/projects/proj_5d5ykleja6cwpirysbb7 \
  -H "Authorization: Bearer $OPENAI_API_KEY" \
  -H "Content-Type: application/json" \
  -d '{
    "add_tags": {
      "Application": "WebApp",
      "Version": "2.0",
      "Team": "Engineering"
    }
  }'
```

Remove specific tags by their keys:

```
curl -X POST $OPENAI_BASE_URL/organization/projects/proj_5d5ykleja6cwpirysbb7 \
  -H "Authorization: Bearer $OPENAI_API_KEY" \
  -H "Content-Type: application/json" \
  -d '{
    "remove_tag_keys": ["Version", "OldTagKey"]
  }'
```

⚠ Important Notes

- **No full replacement**: There is no operation to replace the entire tag set at once. You must explicitly specify which tags to add and which to remove.
- **Error handling**: Implement proper error handling and verification

Archiving Projects

Archive projects that are no longer in use:

```
curl -X POST $OPENAI_BASE_URL/organization/projects/proj_abc123/archive \
  -H "Authorization: Bearer $OPENAI_API_KEY" \
  -H "Content-Type: application/json"
```

⚠ Important

Archived projects cannot be used for new inference requests, but historical data and metrics remain accessible for up to 30 days.

Using Projects with Different APIs

Responses API

```
from openai import OpenAI

client = OpenAI(project="proj_abc123")

response = client.responses.create(
    model="openai.gpt-oss-120b",
    input="What are the key features of Amazon Bedrock?"
)
print(response)
```

Chat Completions API

```
from openai import OpenAI

client = OpenAI(project="proj_abc123")

response = client.chat.completions.create(
    model="openai.gpt-oss-120b",
    messages=[
        {"role": "user", "content": "Explain how projects improve security"}
    ]
)

print(response.choices[0].message.content)
```

Best Practices

Recommended Project Structure

One project per application: Create separate projects for each distinct application or service.

```
### CustomerChatbot-Production
### CustomerChatbot-Staging
### CustomerChatbot-Development
### InternalSearch-Production
### InternalSearch-Development
```

- **Separate environments**: Use different projects for development, staging, and production environments.
- **Experiment isolation**: Create dedicated projects for experiments and proof-of-concepts.

Project Lifecycle Management

- **Create projects early**: Set up projects before deploying applications
- **Use consistent naming**: Follow organizational naming conventions
- **Document project purpose**: Include clear descriptions
- **Regular audits**: Periodically review and archive unused projects
- **Monitor usage**: Track project metrics to identify optimization opportunities

Workspaces (Anthropic-compatible)

Amazon Bedrock Workspaces provide application-level isolation for your generative AI workloads using the Anthropic-compatible Messages API on the `bedrock-mantle` endpoint. Workspaces enable you to segment your AI applications for cost tracking, observability, and access control.

> **Tip**
>
> For new applications, we recommend the `bedrock-runtime` endpoint. If you don't need Workspaces, use the Converse or Invoke APIs with Inference Profiles for isolation, tagging, and cost tracking on `bedrock-runtime`.

> **Note**
>
> Workspaces can only be used with models that support the Messages API on the `bedrock-mantle` endpoint. To see which models support the Messages API, see the section called "APIs".
> If you are using the OpenAI-compatible APIs (Responses API, Chat Completions), use the section called "Projects" instead.

What is a Workspace?

A Workspace is a logical boundary used to isolate workloads such as applications, environments, or experiments within Amazon Bedrock when using the Anthropic Messages API. Workspaces are the same underlying resource as the section called "Projects" — they are managed using the Projects API and provide the same capabilities:

- **Access isolation**: Control who can access specific workspace resources using IAM policies for Amazon Bedrock Projects
- **Cost monitoring**: Track spending at the workspace level using AWS tags and AWS Cost Explorer
- **Observability**: Track usage metrics and patterns per workspace for monitoring and optimization.

Workspaces allow you to manage multiple generative AI workloads in production without creating separate AWS accounts or organizations, reducing operational complexity while maintaining security and governance.

Each AWS account has a default workspace (project) where all inference requests are associated. You can create additional workspaces using the Projects API and reference them in Messages API requests using the `anthropic-workspace-id` header.

When to use Workspaces

You should use Workspaces when you need to:

- **Organize by business structure**: Manage Amazon Bedrock usage based on your organizational taxonomy such as business units, teams, applications, or cost centers
- **Track costs accurately**: Monitor and allocate AI spending to specific teams, projects, or environments
- **Enforce access policies**: Apply granular IAM permissions to control who can access specific AI workloads
- **Scale production workloads**: Run multiple production applications with clear operational boundaries and monitoring

Workspaces vs. Projects

Workspaces and the section called "Projects" are the same underlying resource — both are managed through the Projects API. The difference is how you reference them in your inference requests, depending on which API you use:

Feature	Workspaces	Projects
Supported APIs	Anthropic Messages API	OpenAI-compatible APIs (Responses, Chat Completions)
Endpoint	`bedrock-mantle.{region}.api.aws/anthropic/v1/messages`	`bedrock-mantle.{region}.api.aws/v1`
Header	`anthropic-workspace-id: {project-id}`	`OpenAI-Project: {project-id}`
Management API	Projects API	Projects API
Access Control	Project as a resource in IAM policies	Project as a resource in IAM policies
Cost Tracking	AWS tags on projects	AWS tags on projects

Getting started with Workspaces

This section walks you through creating a workspace, associating it with Messages API requests, and verifying your setup.

Prerequisites

Before you begin, make sure you have:

- An AWS account with Amazon Bedrock access
- IAM permissions to create and manage Amazon Bedrock projects
- An API key for Amazon Bedrock authentication
- Access to Claude models (see the section called "Request access to models")

Step 1: Set up your environment

Configure your environment variables with your Amazon Bedrock credentials:

```
export BEDROCK_API_KEY="<your-bedrock-key>"
export BEDROCK_REGION="us-east-1"
```

Step 2: Create a Workspace

Workspaces are created using the Projects API. Create a workspace (project) with a name and tags for cost monitoring:

```
curl -X POST "https://bedrock-mantle.$BEDROCK_REGION.api.aws/v1/organization/projects"
 \
  -H "Authorization: Bearer $BEDROCK_API_KEY" \
  -H "Content-Type: application/json" \
  -d '{
    "name": "Claude Chatbot Production",
    "tags": {
      "Application": "CustomerChatbot",
      "Environment": "Production",
      "Team": "NLPEngineering",
      "CostCenter": "41250"
    }
  }'
```

Response:

```
{
  "arn": "arn:aws:bedrock-mantle:us-east-1:123456789012:project/proj_abc123def456",
  "created_at": 1772135628,
  "id": "proj_abc123def456",
  "name": "Claude Chatbot Production",
  "object": "organization.project",
  "status": "active",
  "tags": {
    "Application": "CustomerChatbot",
    "Environment": "Production",
    "Team": "NLPEngineering",
    "CostCenter": "41250"
  }
}
```

Note the `id` field — this is the value you pass in the `anthropic-workspace-id` header.

Step 3: Associate requests with your Workspace

To associate your Messages API requests with a workspace, include the `anthropic-workspace-id` header with the project ID:

curl

```
curl -X POST "https://bedrock-mantle.$BEDROCK_REGION.api.aws/anthropic/v1/messages"
 \
  -H "x-api-key: $BEDROCK_API_KEY" \
  -H "anthropic-version: 2023-06-01" \
  -H "anthropic-workspace-id: proj_abc123def456" \
  -H "Content-Type: application/json" \
  -d '{
    "model": "anthropic.claude-sonnet-4-6-v1",
    "max_tokens": 1024,
    "messages": [
        {"role": "user", "content": "Hello, how can you help me today?"}
    ]
  }'
```

Python (Anthropic SDK)

```
import anthropic

client = anthropic.Anthropic(
    base_url=f"https://bedrock-mantle.{region}.api.aws/anthropic",
    api_key=bedrock_api_key,
)

response = client.messages.create(
    model="anthropic.claude-sonnet-4-6-v1",
    max_tokens=1024,
    extra_headers={"anthropic-workspace-id": "proj_abc123def456"},
    messages=[
        {"role": "user", "content": "Hello, how can you help me today?"}
    ]
)

print(response.content[0].text)
```

All inference requests made with the same workspace ID are grouped together, enabling per-workspace cost tracking, access control, and observability.

Step 4: Verify your Workspace setup

List all workspaces (projects) to verify your workspace was created successfully:

```
curl -X GET "https://bedrock-mantle.$BEDROCK_REGION.api.aws/v1/organization/projects" \
  -H "Authorization: Bearer $BEDROCK_API_KEY"
```

Managing Workspaces

Since Workspaces are managed through the Projects API, all project management operations apply. See the section called “Working with Projects” for detailed instructions on:

- **Listing workspaces**: Retrieve all workspaces in your account
- **Retrieving details**: Get information about a specific workspace
- **Updating workspaces**: Modify workspace name or tags
- **Managing tags**: Add or remove tags for cost allocation
- **Archiving workspaces**: Archive workspaces that are no longer in use

Best practices

Recommended Workspace structure

One workspace per application: Create separate workspaces for each distinct application or service.

```
### Claude-Chatbot-Production
### Claude-Chatbot-Staging
### Claude-Chatbot-Development
### Claude-Summarizer-Production
### Claude-Summarizer-Development
```

- **Separate environments**: Use different workspaces for development, staging, and production environments.
- **Experiment isolation**: Create dedicated workspaces for experiments and proof-of-concepts.

Workspace lifecycle management

- **Create workspaces early**: Set up workspaces before deploying applications
- **Use consistent naming**: Follow organizational naming conventions
- **Tag for cost allocation**: Always include cost center and team tags
- **Regular audits**: Periodically review and archive unused workspaces
- **Monitor usage**: Track workspace metrics to identify optimization opportunities

API keys

Amazon Bedrock API keys let you authenticate API requests using a bearer token instead of AWS credentials. There are two types:

- **Short-term** – Lasts up to 12 hours (or the duration of your session, whichever is shorter). Inherits permissions from the IAM principal used to generate it. Recommended for production use.
- **Long-term** – Lasts until a configured expiration date. Creates an IAM user with attached policies. Recommended only for exploration.

> **Note**
>
> All API calls are logged in AWS CloudTrail. API keys are passed as authorization headers and are not logged.

Generate a short-term API key

Choose the tab for your preferred method, and then follow the steps:

Console

1. Sign in to the AWS Management Console with an IAM identity that has permissions to use the Amazon Bedrock console. Then, open the Amazon Bedrock console at https://console.aws.amazon.com/bedrock.
2. In the left navigation pane, select **API keys**.
3. In the **Short-term API keys** tab, choose **Generate short-term API keys**.

The key expires when your console session expires (maximum 12 hours). You can use a short-term API key only in the AWS Region where you generated it. To use the key in a different Region, change to that Region in the console and generate a new key.

Python

Install the token generator:

```
pip install aws-bedrock-token-generator
```

Generate a token:

```
from aws_bedrock_token_generator import provide_token

token = provide_token()
print(f"Token: {token}")
```

Javascript

Install the token generator:

```
npm install @aws/bedrock-token-generator
```

Generate a token:

```
import { getTokenProvider } from "@aws/bedrock-token-generator";

const provideToken = getTokenProvider();
const token = await provideToken();
console.log(`Bearer Token: ${token}`);
```

Java

Add the dependency (Maven):

```
<dependency>
    <groupId>software.amazon.bedrock</groupId>
    <artifactId>aws-bedrock-token-generator</artifactId>
    <version>1.1.0</version>
</dependency>
```

Generate a token:

```
import software.amazon.bedrock.token.BedrockTokenGenerator;

BedrockTokenGenerator tokenGenerator = BedrockTokenGenerator.builder().build();
String token = tokenGenerator.getToken();
```

Generate a long-term API key

> **Warning**
>
> Long-term keys are for exploration only. For production, use short-term keys. For more information, see Alternatives to long-term access keys.

Choose the tab for your preferred method, and then follow the steps:

Console

1. Sign in to the AWS Management Console with an IAM identity that has permissions to use the Amazon Bedrock console. Then, open the Amazon Bedrock console at https://console.aws.amazon.com/bedrock.
2. In the left navigation pane, select **API keys**.
3. In the **Long-term API keys** tab, choose **Generate long-term API keys**.
4. Choose an expiration time and optionally add permissions in **Advanced permissions**.
5. Choose **Generate**.

CLI

```
# Create an IAM user
aws iam create-user --user-name bedrock-api-user

# Attach permissions
aws iam attach-user-policy --user-name bedrock-api-user \
    --policy-arn arn:aws:iam::aws:policy/AmazonBedrockLimitedAccess

# Generate the API key (replace NUMBER-OF-DAYS)
```

```
aws iam create-service-specific-credential \
    --user-name bedrock-api-user \
    --service-name bedrock.amazonaws.com \
    --credential-age-days ${NUMBER-OF-DAYS}
```

The `ServiceApiKeyValue` in the response is your API key.

To deactivate or delete the key later, use the `ServiceSpecificCredentialId` from the response:

```
# Deactivate the key
aws iam update-service-specific-credential \
    --user-name bedrock-api-user \
    --service-specific-credential-id ${ServiceSpecificCredentialId} \
    --status Inactive

# Delete the key permanently
aws iam delete-service-specific-credential \
    --user-name bedrock-api-user \
    --service-specific-credential-id ${ServiceSpecificCredentialId}
```

Python

```
import boto3

iam_client = boto3.client("iam")

# Create IAM user
iam_client.create_user(UserName="bedrock-api-user")

# Attach permissions
iam_client.attach_user_policy(
    UserName="bedrock-api-user",
    PolicyArn="arn:aws:iam::aws:policy/AmazonBedrockLimitedAccess"
)

# Generate API key
response = iam_client.create_service_specific_credential(
    UserName="bedrock-api-user",
    ServiceName="bedrock.amazonaws.com",
    CredentialAgeDays=30
)
api_key = response["ServiceSpecificCredential"]["ServiceApiKeyValue"]
```

```
print(api_key)
```

Use an API key

Set the key as an environment variable:

```
# macOS/Linux
export AWS_BEARER_TOKEN_BEDROCK=${api-key}

# Windows
setx AWS_BEARER_TOKEN_BEDROCK "${api-key}"
```

Or pass it directly in the `Authorization` header:

```
Authorization: Bearer ${api-key}
```

Example: Make a Converse request

choose the tab for your preferred method, and then follow the steps:

cURL

```
curl -X POST "https://bedrock-runtime.us-east-1.amazonaws.com/model/
us.anthropic.claude-sonnet-4-6/converse" \
  -H "Content-Type: application/json" \
  -H "Authorization: Bearer $AWS_BEARER_TOKEN_BEDROCK" \
  -d '{
    "messages": [{"role": "user", "content": [{"text": "Hello"}]}]
  }'
```

Python (boto3)

```
import os
import boto3

os.environ['AWS_BEARER_TOKEN_BEDROCK'] = "${api-key}"

client = boto3.client("bedrock-runtime", region_name="us-east-1")
response = client.converse(
    modelId="us.anthropic.claude-sonnet-4-6",
    messages=[{"role": "user", "content": [{"text": "Hello"}]}]
```

```
)
```

Auto-refresh short-term keys

For long-running applications, call the token generator before each request. It returns a cached token if still valid or generates a new one automatically:

Python

```
from aws_bedrock_token_generator import provide_token
import requests

url = "https://bedrock-runtime.us-west-2.amazonaws.com/model/us.anthropic.claude-
sonnet-4-6/converse"
payload = {"messages": [{"role": "user", "content": [{"text": "Hello"}]}]}

# Call provide_token() before each request — it handles caching/refresh
token = provide_token()
headers = {"Content-Type": "application/json", "Authorization": f"Bearer {token}"}
response = requests.post(url, headers=headers, json=payload)
print(response.json())
```

Javascript

```
import { getTokenProvider } from "@aws/bedrock-token-generator";

const provideToken = getTokenProvider();

const url = "https://bedrock-runtime.us-east-1.amazonaws.com/model/
us.anthropic.claude-sonnet-4-6/converse";
const payload = {messages: [{role: "user", content: [{text: "Hello"}]}]};

// provideToken() handles caching/refresh automatically
const headers = {
    "Content-Type": "application/json",
    "Authorization": `Bearer ${await provideToken()}`
};
await fetch(url, {method: 'POST', headers, body: JSON.stringify(payload)});
```

For more examples, see the token generator documentation: Python | Javascript | Java.

Modify permissions

A long-term API key is associated with an IAM user. To change its permissions, modify the policies attached to that user. See Adding and removing IAM identity permissions.

From the console: go to **API keys** > **Long-term API keys** > select your key > **Manage in IAM Console**.

Compromised keys

If a key is compromised, take one of the following actions:

Action	Key type	How
Deactivate	Long-term	Console: **API keys** > select key > **Actions** > **Deactivate**. API: `UpdateServiceSpecificCredential` with `Status=Inactive`.
Reset	Long-term	Console: **Actions** > **Reset key**. API: `ResetServiceSpecificCredential`.
Delete	Long-term	Console: **Actions** > **Delete**. API: `DeleteServiceSpecificCredential`.
Invalidate session	Short-term	Invalidate the session used to generate the key, or attach an IAM policy that denies `CallWithBearerToken` (Deny an identity the ability to make calls with an Amazon Bedrock API key).

Control who can generate and use API keys

IAM actions control API key generation and usage:

- `iam:CreateServiceSpecificCredential` – Controls generation of long-term keys. Use the `iam:ServiceSpecificCredentialAgeDays` condition key to limit expiration (e.g., max 90 days).

- `bedrock:CallWithBearerToken` – Controls usage of an API key through the Amazon Bedrock endpoint. Use the `bedrock:bearerTokenType` condition key with values `SHORT_TERM` or `LONG_TERM` to target specific key types.
- `bedrock-mantle:CallWithBearerToken` – Controls usage of an API key through the Amazon Bedrock Mantle endpoint. Use the `bedrock-mantle:bearerTokenType` condition key with values `SHORT_TERM` or `LONG_TERM` to target specific key types.

Example: Prevent an identity from using any API key

Attach this policy to the identity:

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Deny",
            "Action": [
                "bedrock:CallWithBearerToken",
                "bedrock-mantle:CallWithBearerToken"
            ],
            "Resource": "*"
        }
    ]
}
```

Example: Allow only short-lived keys (max 90 days)

Attach this policy to the identity:

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": "iam:CreateServiceSpecificCredential",
            "Resource": "*",
            "Condition": {
                "NumericLessThanEquals": {
                    "iam:ServiceSpecificCredentialAgeDays": "90"
                },
                "StringEquals": {
```

```
                    "iam:ServiceSpecificCredentialServiceName": "bedrock.amazonaws.com"
                }
            }
        }
    ]
}
```

For more detailed policy examples, see the section called “API keys reference”.

Customize your model to improve its performance for your use case

Model customization is the process of providing training data to a model to improve its performance for specific use-cases. You can customize Amazon Bedrock foundation models to improve their performance and create a better customer experience. Amazon Bedrock currently provides the following customization methods.

- **Supervised fine-tuning**

  Provide *labeled* data to train a model to improve performance on specific tasks. By providing a training dataset of labeled examples, the model learns to associate what types of outputs should be generated for certain types of inputs. The model parameters are adjusted in the process and the model's performance is improved for the tasks represented by the training dataset.

  For more information about using supervised fine-tuning, see Customize a model with fine-tuning in Amazon Bedrock.

- **Reinforcement fine-tuning**

  Reinforcement fine-tuning improves foundation model alignment with your specific use case through feedback-based learning. Instead of providing labeled input-output pairs, you define reward functions that evaluate response quality. The model learns iteratively by receiving feedback scores from these reward functions.

  You can upload your training prompt datasets or provide existing Bedrock invocation logs. You can define reward functions using AWS Lambda to evaluate response quality. Amazon Bedrock automates the training workflow and provides real-time metrics to monitor model learning progress.

  For more information about using reinforcement fine-tuning, see Customize a model with reinforcement fine-tuning in Amazon Bedrock.

- **Distillation**

  Use distillation to transfer knowledge from a larger more intelligent model (known as teacher) to a smaller, faster, and cost-efficient model (known as student). Amazon Bedrock automates the distillation process by using the latest data synthesis techniques to generate diverse, high-quality responses from the teacher model, and fine-tunes the student model.

To use distillation, you select a teacher model whose accuracy you want to achieve for your use case, and a student model to fine-tune. Then, you provide use case-specific prompts as input data. Amazon Bedrock generates responses from the teacher model for the given prompts, and then uses the responses to fine-tune the student model. You can optionally provide labeled input data as prompt-response pairs.

For more information about using distillation see Customize a model with distillation in Amazon Bedrock.

For information about model customization quotas, see Amazon Bedrock endpoints and quotas in the AWS General Reference.

> **Note**
>
> You are charged for model training based on the number of tokens processed by the model (number of tokens in training data corpus × number of epochs) and model storage charged per month per model. For more information, see Amazon Bedrock pricing.

Customize a model with fine-tuning in Amazon Bedrock

With Amazon Bedrock, you can train a foundation model to improve performance on specific tasks (known as fine-tuning). For information about fine-tuning Amazon Nova models, see Fine-tuning Amazon Nova models.

Supported models and Regions for fine-tuning

The following table shows the foundation models that you can fine-tune:

Provider	Model	Model ID	Single-region model support
Amazon	Nova 2 Lite	amazon.nova-2-lite-v1:0:256k	us-east-1
Amazon	Nova Canvas	amazon.nova-canvas-v1:0	us-east-1

Provider	Model	Model ID	Single-region model support
Amazon	Nova Lite	amazon.nova-lite-v1:0:300k	us-east-1
Amazon	Nova Micro	amazon.nova-micro-v1:0:128k	us-east-1
Amazon	Nova Pro	amazon.nova-pro-v1:0:300k	us-east-1
Amazon	Titan Image Generator G1 v2	amazon.titan-image-generator-v2:0	us-east-1 us-west-2
Amazon	Titan Multimodal Embeddings G1	amazon.titan-embed-image-v1:0	us-east-1 us-west-2
Anthropic	Claude 3 Haiku	anthropic.claude-3-haiku-20240307-v1:0:200k	us-west-2
Meta	Llama 3.1 70B Instruct	meta.llama3-1-70b-instruct-v1:0:128k	us-west-2
Meta	Llama 3.1 8B Instruct	meta.llama3-1-8b-instruct-v1:0:128k	us-west-2

For information about model customization hyperparameters for each model, see Custom model hyperparameters.

Prepare data for fine-tuning your models

To prepare training and validation datasets for your custom model, you create `.jsonl` files, where each line is a JSON object corresponding to a record. Before you can begin a model customization job, you must at minimum prepare a training dataset. The files you create must conform to the format for the customization method and model that you choose. The records in it must conform to size requirements depending your model.

For information about model requirments, see Model requirements for training and validation datasets. To see the default quotas that apply for training and validation datasets used for customizing different models, see the **Sum of training and validation records** quotas in Amazon Bedrock endpoints and quotas in the AWS General Reference.

Whether a validation dataset is supported and the format of your training and validation dataset depend on the following factors.

- The type of fine-tuning customization job.
- The input and output modalities of the data.

For information about fine-tuning Amazon Nova models, see Fine-tuning Amazon Nova models.

Supported modalities for fine-tuning

The following sections describe the different fine-tuning capabilities supported by each model, organized by their input and output modalities. For information about fine-tuning Amazon Nova models, see Fine-tuning Amazon Nova models.

Text-to-Text models

Text-to-Text models can be fine-tuned for various text-based tasks, including both conversational and non-conversational applications. For information about preparing data for fine-tuning Text-to-Text models, see Prepare data for fine-tuning text-to-text models.

The following non-conversational models are optimized for tasks like summarization, translation, and question answering:

- Amazon Titan Text G1 - Express
- Amazon Titan Text G1 - Lite
- Amazon Titan Text Premier
- Cohere Command
- Cohere Command Light
- Meta Llama 3.1 8B Instruct
- Meta Llama 3.1 70B Instruct

The following conversational models are designed for single-turn and multi-turn interactions. If a model uses the Converse API, your fine-tuning dataset must follow the Converse API message format and include system, user, and assistant messages. For examples, see Prepare data for fine-tuning text-to-text models. For more information about Converse API operations, see Inference using Converse API.

- Anthropic Claude 3 Haiku
- Meta Llama 3.2 1B Instruct (Converse API format)
- Meta Llama 3.2 3B Instruct (Converse API format)
- Meta Llama 3.2 11B Instruct Vision (Converse API format)
- Meta Llama 3.2 90B Instruct Vision (Converse API format)
- Meta Llama 3.3 70B Vision Instruct (Converse API format)

Text-Image-to-Text & Text-to-Image models

The following models support fine-tuning for image generation and text-image processing. These models process or generate images based on textual input, or generate text based on both textual and image inputs. For information about preparing data for fine-tuning Text-Image-to-Text & Text-to-Image models models, see Prepare data for fine-tuning image and text processing models.

- Amazon Titan Image Generator G1 V1
- Meta Llama 3.2 11B Instruct Vision
- Meta Llama 3.2 90B Instruct Vision
- Meta Llama 3.3 70B Vision Instruct

Image-to-Embeddings

The following models support fine-tuning for tasks like classification and retrieval. These models generate numerical representations (embeddings) from image inputs. For information about preparing data for fine-tuning Image-to-Embeddings models, see Prepare data for fine-tuning image generation and embedding models.

- Amazon Titan Multimodal Embeddings G1
- Amazon Titan Image Generator G1 V1

Model requirements for training and validation datasets

The following sections list the requirements for training and validation datasets for a model. For information about dataset constraints for Amazon Nova models, see Fine-tuning Amazon Nova models.

Amazon Titan Text Premier

Description	Maximum (Fine-tuning)
Sum of input and output tokens when batch size is 1	4,096
Sum of input and output tokens when batch size is 2, 3, or 4	N/A
Character quota per sample in dataset	Token quota x 6 (estimated)
Training dataset file size	1 GB
Validation dataset file size	100 MB

Amazon Titan Text G1 - Express

Description	Maximum (Fine-tuning)
Sum of input and output tokens when batch size is 1	4,096
Sum of input and output tokens when batch size is 2, 3, or 4	2,048
Character quota per sample in dataset	Token quota x 6 (estimated)
Training dataset file size	1 GB
Validation dataset file size	100 MB

Amazon Titan Text G1 - Lite

Description	Maximum (Fine-tuning)
Sum of input and output tokens when batch size is 1 or 2	4,096
Sum of input and output tokens when batch size is 3, 4, 5, or 6	2,048
Character quota per sample in dataset	Token quota x 6 (estimated)
Training dataset file size	1 GB
Validation dataset file size	100 MB

Amazon Titan Image Generator G1 V1

Description	Minimum (Fine-tuning)	Maximum (Fine-tuning)
Text prompt length in training sample, in characters	3	1,024

Description	Minimum (Fine-tuning)	Maximum (Fine-tuning)
Records in a training dataset	5	10,000
Input image size	0	50 MB
Input image height in pixels	512	4,096
Input image width in pixels	512	4,096
Input image total pixels	0	12,582,912
Input image aspect ratio	1:4	4:1

Amazon Titan Multimodal Embeddings G1

Description	Minimum (Fine-tuning)	Maximum (Fine-tuning)
Text prompt length in training sample, in characters	0	2,560
Records in a training dataset	1,000	500,000
Input image size	0	5 MB
Input image height in pixels	128	4096
Input image width in pixels	128	4096
Input image total pixels	0	12,528,912
Input image aspect ratio	1:4	4:1

Meta Llama 3.1

Description	Minimum (Fine-tuning)	Maximum (Fine-tuning)
Input tokens	0	16,000

Description	Minimum (Fine-tuning)	Maximum (Fine-tuning)
Output tokens	0	16,000
Character quota per sample in dataset	0	Token quota x 6 (estimated)
Sum of Input and Output tokens	0	16,000
Sum of training and validation records	100	10,000 (adjustable using service quotas)

Meta Llama 3.2

Supported image formats for Meta Llama-3.2 11B Vision Instruct and Meta Llama-3.2 90B Vision Instruct include: `gif`, `jpeg`, png, and `webp`. For estimating the image-to-token conversion during fine-tuning of these models, you can use this formula as an approximation: `Tokens = min(2, max(Height // 560, 1)) * min(2, max(Width // 560, 1)) * 1601`. Images are converted into approximately 1,601 to 6,404 tokens based on their size.

Description	Minimum (Fine-tuning)	Maximum (Fine-tuning)
Sum of Input and Output tokens	0	16,000 (10000 for Meta Llama 3.2 90B)
Sum of training and validation records	100	10,000 (adjustable using service quotas)
Input image size for Meta Llama 11B and 90B instruct models)	0	10 MB
Input image height in pixels for Meta Llama 11B and 90B instruct models	10	8192

Description	Minimum (Fine-tuning)	Maximum (Fine-tuning)
Input image width in pixels for Meta Llama 11B and 90B90B instruct models	10	8192

Meta Llama 3.3

Description	Minimum (Fine-tuning)	Maximum (Fine-tuning)
Sum of Input and output tokens	0	16000
Sum of training and validatio n records	100	10,000 (adjustable using Service Quotas)

CohereCommand

Description	Maximum (Fine-tuning)
Input tokens	4,096
Output tokens	2,048
Character quota per sample in dataset	Token quota x 6 (estimated)
Records in a training dataset	10,000
Records in a validation dataset	1,000

Anthropic Claude 3 Haiku

Description	Maximum (Fine-tuning)
Minimum number of records	32

Description	Maximum (Fine-tuning)
Maximum training records	10,000
Maximum validation records	1,000
Maximum total records	10,000 (adjustable using service quotas)
Maximum tokens	32,000
Maximum training dataset size	10 GB
Maximum validation dataset size	1 GB

Prepare data for fine-tuning text-to-text models

> **Note**
>
> For information about fine-tuning Amazon Nova models, see Fine-tuning Amazon Nova models.

For fine-tuning text-to-text models, each JSON object is a sample containing structured fields designed to guide the model toward generating the desired textual output based on a provided textual prompt. The data format varies depending on the use case, broadly categorized into non-conversational and conversational use cases.

Non-conversational tasks

Non-conversational tasks involve generating a single output for a given input. Each dataset sample includes a `prompt` field containing the input text and a `completion` field with the expected output. This format supports a range of tasks such as question-answering, summarizing, translation, text completion, and information extraction.

Example format

```
{"prompt": "What is the capital of France?", "completion": "The capital of France is
 Paris."}
```

```
{"prompt": "Summarize the article about climate change.", "completion": "Climate
 change refers to the long-term alteration of temperature and typical weather
 patterns in a place."}
```

Use approximately 6 characters per token to estimate the number of tokens for planning dataset size.

Converse API format (Single turn and Multi turn)

To use the Converse API, you call the `Converse` or `ConverseStream` operations to send messages to a model. To call `Converse`, you require permission for the `bedrock:InvokeModel` operation. To call `ConverseStream`, you require permission for the `bedrock:InvokeModelWithResponseStream` operation. For more information, see Using the Converse API. For more information about Converse API operations, see Inference using Converse API

Example format

```
{
    "schemaVersion": "bedrock-conversation-2024",
    "system": [
        {
            "text": "You are a digital assistant with a friendly personality"
        }
    ],
    "messages": [
        {
            "role": "user",
            "content": [
                {
                    "text": "What is the capital of Mars?"
                }
            ]
        },
        {
            "role": "assistant",
            "content": [
                {
                    "text": "Mars does not have a capital. Perhaps it will one day."
                }
            ]
        }
    ]
```

```
}
```

Anthropic Claude 3 Haiku: Single-turn conversations

Single-turn conversational tasks involve isolated exchanges, where the model generates a response based solely on the current user input without considering prior context. Each dataset sample uses a messages array, with alternating roles of `user` and `assistant`.

Format

```
{"system": "<system message>","messages":[{"role": "user", "content": "<user
 query>"},{"role": "assistant", "content": "<expected generated text>"}]}
```

Example

```
{"system": "You are an helpful assistant.","messages":[{"role": "user", "content":
 "what is AWS"},{"role": "assistant", "content": "it's Amazon Web Services."}]}
```

Anthropic Claude 3 Haiku: Multi-turn conversations

Multi-turn conversational tasks involve extended dialogues where the model must generate responses while preserving the context of previous exchanges. This format captures the dynamic nature of interactive tasks, such as customer support or complex discussions.

Format

```
{"system": "<system message>","messages":[{"role": "user", "content": "<user query
 1>"},{"role": "assistant", "content": "<expected generated text 1>"}, {"role":
 "user", "content": "<user query 2>"},{"role": "assistant", "content": "<expected
 generated text 2>"}]}
```

Example

```
{"system": "system message","messages":[{"role": "user", "content": "Hello there."},
{"role": "assistant", "content": "Hi, how can I help you?"},{"role": "user",
 "content": "what are LLMs?"},{"role": "assistant", "content": "LLM means large
 language model."},]}
```

Prepare data for fine-tuning image and text processing models

> **Note**
>
> For information about fine-tuning Amazon Nova models, see Fine-tuning Amazon Nova models.

For fine-tuning image-text-to-text models, each JSON object is a sample containing a conversation structured as a `messages` array, consisting of alternating JSON objects representing the user's inputs and the assistant's responses. User inputs can include both text and images, while assistant responses are always textual. This structure supports both single-turn and multi-turn conversational flows, enabling the model to handle diverse tasks effectively. Supported image formats for Meta Llama-3.2 11B Vision Instruct and Meta Llama-3.2 90B Vision Instruct include: `gif`, `jpeg`, png, and `webp`.

To allow Amazon Bedrock access to the image files, add an IAM policy similar to the one in Permissions to access training and validation files and to write output files in S3 to the Amazon Bedrock model customization service role that you set up or that was automatically set up for you in the console. The Amazon S3 paths you provide in the training dataset must be in folders that you specify in the policy.

Single-turn conversations

Each JSON object for single-turn conversations consists of a user message and an assistant message. The user message includes a role field set to *user*and a *content* field containing an array with a `type` field (*text* or *image*) that describes the input modality. For text inputs, the `content` field includes a `text` field with the user's question or prompt. For image inputs, the `content` field specifies the image `format` (for example, *jpeg*, *png*) and its `source` with a `uri` pointing to the Amazon S3 location of the image. The `uri` represents the unique path to the image stored in an Amazon S3 bucket, typically in the format `s3://<bucket-name>/<path-to-file>`. The assistant message includes a `role` field set to *assistant* and a `content` field containing an array with a `type` field set to *text* and a `text` field containing the assistant's generated response.

Example format

```
{
    "schemaVersion": "bedrock-conversation-2024",
    "system": [{
```

```
        "text": "You are a smart assistant that answers questions respectfully"
    }],
    "messages": [{
            "role": "user",
            "content": [{
                    "text": "What does the text in this image say?"
                },
                {
                    "image": {
                        "format": "png",
                        "source": {
                            "s3Location": {
                                "uri": "s3://your-bucket/your-path/your-image.png",
                                "bucketOwner": "your-aws-account-id"
                            }
                        }
                    }
                }
            ]
        },
        {
            "role": "assistant",
            "content": [{
                "text": "The text in the attached image says 'LOL'."
            }]
        }
    ]
}
```

Multi-turn conversations

Each JSON object for multi-turn conversations contains a sequence of messages with alternating roles, where user messages and assistant messages are structured consistently to enable coherent exchanges. User messages include a `role` field set to *user* and a `content` field that describes the input modality. For text inputs, the `content` field includes a `text` field with the user's question or follow-up, while for image inputs, it specifies the image `format` and its `source` with a `uri` pointing to the Amazon S3 location of the image. The `uri` serves as a unique identifier in the format s3://<bucket-name>/<path-to-file> and allows the model to access the image from the designated Amazon S3 bucket. Assistant messages include a `role` field set to *assistant* and a `content` field containing an array with a `type` field set to *text* and a `text` field containing the assistant's generated response. Conversations can span multiple exchanges, allowing the assistant to maintain context and deliver coherent responses throughout.

Example format

```
{
    "schemaVersion": "bedrock-conversation-2024",
    "system": [{
        "text": "You are a smart assistant that answers questions respectfully"
    }],
    "messages": [{
            "role": "user",
            "content": [{
                    "text": "What does the text in this image say?"
                },
                {
                    "image": {
                        "format": "png",
                        "source": {
                            "s3Location": {
                                "uri": "s3://your-bucket/your-path/your-image.png",
                                "bucketOwner": "your-aws-account-id"
                            }
                        }
                    }
                }
            ]
        },
        {
            "role": "assistant",
            "content": [{
                "text": "The text in the attached image says 'LOL'."
            }]
        },
        {
            "role": "user",
            "content": [{
                    "text": "What does the text in this image say?"
                }
            ]
        },
        {
            "role": "assistant",
            "content": [{
                "text": "The text in the attached image says 'LOL'."
            }]
        }
```

```
    ]
}
```

Prepare data for fine-tuning image generation and embedding models

> **Note**
>
> Amazon Nova models have different fine-tuning requirements. To fine-tune these models, follow the instructions at Fine-tuning Amazon Nova models.

For text-to-image or image-to-embedding models, prepare a training dataset. Validation datasets are not supported. Each JSON object is a sample containing an `image-ref`, the Amazon S3 URI for an image, and a `caption` that could be a prompt for the image.

The images must be in JPEG or PNG format and meet the following requirements:

- **Dimensions** – Each side must be between 512 and 4,096 pixels.
- **Aspect ratio** – Between 1:4 and 4:1.
- **Total pixels** – Must not exceed 12,582,912 (approximately 3,547 x 3,547).
- **File size** – Must not exceed 50 MB per image.
- **Caption length** – Between 3 and 1,024 characters.

For the full list of constraints, see Amazon Titan Image Generator G1 V1.

```
{"image-ref": "s3://bucket/path/to/image001.png", "caption": "<prompt text>"}
{"image-ref": "s3://bucket/path/to/image002.png", "caption": "<prompt text>"}{"image-
ref": "s3://bucket/path/to/image003.png", "caption": "<prompt text>"}
```

The following is an example item:

```
{"image-ref": "s3://amzn-s3-demo-bucket/my-pets/cat.png", "caption": "an orange cat
 with white spots"}
```

To allow Amazon Bedrock access to the image files, add an IAM policy similar to the one in Permissions to access training and validation files and to write output files in S3 to the Amazon

Bedrock model customization service role that you set up or that was automatically set up for you in the console. The Amazon S3 paths you provide in the training dataset must be in folders that you specify in the policy.

Fine-tune Amazon Nova models with supervised fine-tuning

Amazon Nova 2.0 SFT data uses the same Converse API format as Amazon Nova 1.0, with the addition of optional reasoning content fields. For complete format specifications, see ReasoningContentBlock and Converse API schema.

Supported features:

- **Input types** – Text, image, or video in user content blocks
- **Assistant content** – Text-only responses and reasoning content
- **Dataset composition** – Must be homogeneous. Choose one of the following: text-only turns, text + image turns, or text + video turns

> **Important**
>
> You cannot mix images and videos within the same dataset or across different turns.

Current limitations:

- **Tool usage** – Although tool usage is supported in the input format, it is not currently supported by Amazon Nova 2.0 SFT. Adding tool sections might cause your job to fail.
- **Multimodal reasoning content** – Although the Converse format supports image-based reasoning content, this is not supported by Amazon Nova 2.0 SFT.
- **Validation sets** – Providing a validation set might be supported through the UI but will not be supported during SFT training.

Supported media formats:

- **Images** – PNG, JPEG, GIF
- **Videos** – MOV, MKV, MP4

Data format examples

Text-only

This example shows a basic text-only format compatible with Amazon Nova 1.0.

```
{
  "schemaVersion": "bedrock-conversation-2024",
  "system": [
    {
      "text": "You are a digital assistant with a friendly personality"
    }
  ],
  "messages": [
    {
      "role": "user",
      "content": [
        {
          "text": "What country is right next to Australia?"
        }
      ]
    },
    {
      "role": "assistant",
      "content": [
        {
          "text": "The closest country is New Zealand"
        }
      ]
    }
  ]
}
```

Text with reasoning

This example shows text with optional reasoning content for Amazon Nova 2.0.

```
{
  "schemaVersion": "bedrock-conversation-2024",
  "system": [
    {
      "text": "You are a digital assistant with a friendly personality"
    }
```

```
  ],
  "messages": [
    {
      "role": "user",
      "content": [
        {
          "text": "What country is right next to Australia?"
        }
      ]
    },
    {
      "role": "assistant",
      "content": [
        {
          "reasoningContent": {
            "reasoningText": {
              "text": "I need to use my world knowledge of geography to answer this
 question"
            }
          }
        },
        {
          "text": "The closest country to Australia is New Zealand, located to the
 southeast across the Tasman Sea."
        }
      ]
    }
  ]
}
```

Note

Currently, only `reasoningText` is supported within `reasoningContent`. Multimodal reasoning content is not yet available.

Image + text

This example shows how to include image input with text.

```
{
  "schemaVersion": "bedrock-conversation-2024",
```

```
  "system": [
    {
      "text": "You are a helpful assistant."
    }
  ],
  "messages": [
    {
      "role": "user",
      "content": [
        {
          "image": {
            "format": "jpeg",
            "source": {
              "s3Location": {
                "uri": "s3://your-bucket/your-path/your-image.jpg",
                "bucketOwner": "your-aws-account-id"
              }
            }
          }
        },
        {
          "text": "Which country is highlighted in the image?"
        }
      ]
    },
    {
      "role": "assistant",
      "content": [
        {
          "reasoningContent": {
            "reasoningText": {
              "text": "I will determine the highlighted country by examining its
 location on the map and using my geographical knowledge"
            }
          }
        },
        {
          "text": "The highlighted country is New Zealand"
        }

```

Reasoning content

Reasoning content (also called chain-of-thought) captures the model's intermediate thinking steps before generating a final answer. In the `assistant` turn, use the `reasoningContent` field to include these reasoning traces.

How loss is calculated:

- **With reasoning content** – Training loss includes both reasoning tokens and final output tokens
- **Without reasoning content** – Training loss is calculated only on the final output tokens

When to enable reasoning mode: Set `reasoning_enabled: true` in your training configuration when you want the model to generate thinking tokens before producing final outputs or need improved performance on complex reasoning tasks. Set `reasoning_enabled: false` when you're training on straightforward tasks that don't benefit from explicit reasoning steps.

> **Note**
>
> You can enable reasoning mode regardless of whether your training data contains reasoning content. However, including reasoning traces in your training data is recommended so the model can learn from these examples and improve reasoning quality.

Formatting guidelines:

- Use plain text for reasoning content.
- Avoid markup tags like `<thinking>` and `</thinking>` unless specifically required by your task.
- Ensure reasoning content is clear and relevant to the problem-solving process.

Effective reasoning content should include:

- Intermediate thoughts and analysis

- Logical deductions and inference steps
- Step-by-step problem-solving approaches
- Explicit connections between steps and conclusions

If your dataset lacks reasoning traces, you can create them using a reasoning-capable model like Nova Premier. Provide your input-output pairs to the model and capture its reasoning process to build a reasoning-augmented dataset.

Dataset preparation guidelines

The following table provides guidelines for preparing your training dataset.

Dataset preparation guidelines

Guideline	Description
Size and quality	• Recommended size: 2,000-10,000 samples • Minimum samples: 200 • Prioritize quality over quantity. Ensure examples are accurate and well-annotated. • Dataset should closely reflect your production use cases.
Diversity	Include diverse examples that do the following: • Cover the full range of expected inputs • Represent different difficulty levels • Include edge cases and variations • Prevent overfitting to narrow patterns
Output formatting	Clearly specify the desired output format in assistant responses . Examples include JSON structures, tables, CSV format, or custom formats specific to your application.
Multi-turn conversations	• Loss is calculated only on assistant turns, not user turns. • Each assistant response should be properly formatted. • Maintain consistency across conversation turns.
Quality checklist	• Sufficient dataset size (2,000-10,000 samples)

Guideline	Description
	• Diverse examples covering all use cases • Clear, consistent output formatting • Accurate labels and annotations • Representative of production scenarios • Free from contradictions or ambiguities

Custom model hyperparameters

The following reference content covers the hyperparameters that are available for training each Amazon Bedrock custom model.

A hyperparameter is a parameter that controls the training process, such as the learning rate or epoch count. You set hyperparameters for custom model training when you submit the fine tuning job with the Amazon Bedrock console or by calling the CreateModelCustomizationJob API operation.

Amazon Nova Understanding model customization hyperparameters

The Amazon Nova Lite, Amazon Nova Micro, and Amazon Nova Pro models support the following three hyperparameters for model customization. For more information, see Customize your model to improve its performance for your use case.

For information about fine tuning Amazon Nova models, see Fine-tuning Amazon Nova models.

The number of epochs you specify increases your model customization cost by processing more tokens. Each epoch processes the entire training dataset once. For information about pricing, see Amazon Bedrock pricing.

Hyperparameter (console)	Hyperparameter (API)	Definition	Type	Minimum	Maximum	Default
Epochs	epochCount	The number of iterations through	integer	1	5	2

Hyperparameter (console)	Hyperparameter (API)	Definition	Type	Minimum	Maximum	Default
		the entire training dataset				
Learning rate	learningRate	The rate at which model parameters are updated after each batch	float	1.00E-6	1.00E-4	1.00E-5
Learning rate warmup steps	learningRateWarmupSteps	The number of iterations over which the learning rate is gradually increased to the specified rate	integer	0	100	10

The default epoch number is 2, which works for most cases. In general, larger data sets require fewer epochs to converge, while smaller data sets require more epochs to converge. A faster convergence might also be achieved by increasing the learning rate, but this is less desirable because it might lead to training instability at convergence. We recommend starting with the default hyperparameters, which are based on our assessment across tasks of different complexity and data sizes.

The learning rate will gradually increase to the set value during warm up. Therefore, we recommend that you avoid a large warm up value when the training sample is small because the learning rate might never reach the set value during the training process. We recommend setting the warmup steps by dividing the dataset size by 640 for Amazon Nova Micro, 160 for Amazon Nova Lite, and 320 for Amazon Nova Pro.

Amazon Nova Canvas model customization hyperparameters

The Amazon Nova Canvas model supports the following hyperparameters for model customization.

Hyperparameter (console)	Hyperparameter (API)	Definition	Minimum	Maximum	Default
Batch size	batchSize	Number of samples processed before updating model parameters	8	192	8
Steps	stepCount	Number of times the model is exposed to each batch	10	20,000	500
Learning rate	learningRate	Rate at which model parameters are updated after each batch	1.00E-7	1.00E-4	1.00E-5

Amazon Titan text model customization hyperparameters

Amazon Titan Text Premier model supports the following hyperparameters for model customization. The number of epochs you specify increases your model customization cost by processing more tokens. Each epoch processes the entire training dataset once. For information about pricing, see Amazon Bedrock pricing.

Hyperparameter (console)	Hyperparameter (API)	Definition	Type	Minimum	Maximum	Default
Epochs	epochCount	The number of iterations through the entire training dataset	integer	1	5	2
Batch size (micro)	batchSize	The number of samples processed before updating model parameters	integer	1	1	1
Learning rate	learningRate	The rate at which model parameters are updated after each batch	float	1.00E-07	1.00E-05	1.00E-06

Hyperparameter (console)	Hyperparameter (API)	Definition	Type	Minimum	Maximum	Default
Learning rate warmup steps	learningRateWarmupSteps	The number of iterations over which the learning rate is gradually increased to the specified rate	integer	0	20	5

Amazon Titan Text models, such as Lite and Express, support the following hyperparameters for model customization. The number of epochs you specify increases your model customization cost by processing more tokens. Each epoch processes the entire training dataset once. For information about pricing, see Amazon Bedrock pricing.

Hyperparameter (console)	Hyperparameter (API)	Definition	Type	Minimum	Maximum	Default
Epochs	epochCount	The number of iterations through the entire training dataset	integer	1	10	5
Batch size (micro)	batchSize	The number of	integer	1	64	1

Hyperparameter (console)	Hyperparameter (API)	Definition	Type	Minimum	Maximum	Default
		samples processed before updating model parameters				
Learning rate	learningRate	The rate at which model parameters are updated after each batch	float	0.0	1	1.00E-5
Learning rate warmup steps	learningRateWarmupSteps	The number of iterations over which the learning rate is gradually increased to the specified rate	integer	0	250	5

Amazon Titan Image Generator G1 models customization hyperparameters

The Amazon Titan Image Generator G1 model supports the following hyperparameters for model customization.

> **Note**
>
> `stepCount` has no default value and must be specified. `stepCount` supports the value `auto`. `auto` prioritizes model performance over training cost by automatically determining a number based on the size of your dataset. Training job costs depend on the number that `auto` determines. To understand how job cost is calculated and to see examples, see Amazon Bedrock Pricing.

Hyperparameter (console)	Hyperparameter (API)	Definition	Minimum	Maximum	Default
Batch size	batchSize	Number of samples processed before updating model parameters	8	192	8
Steps	stepCount	Number of times the model is exposed to each batch	10	40,000	N/A
Learning rate	learningRate	Rate at which model parameters are updated	1.00E-7	1	1.00E-5

Hyperparameter (console)	Hyperparameter (API)	Definition	Minimum	Maximum	Default
		after each batch			

Amazon Titan Multimodal Embeddings G1 customization hyperparameters

The Amazon Titan Multimodal Embeddings G1 model supports the following hyperparameters for model customization. The number of epochs you specify increases your model customization cost by processing more tokens. Each epoch processes the entire training dataset once. For information about pricing, see Amazon Bedrock pricing.

Note

`epochCount` has no default value and must be specified. `epochCount` supports the value `Auto`. `Auto` prioritizes model performance over training cost by automatically determining a number based on the size of your dataset. Training job costs depend on the number that `Auto` determines. To understand how job cost is calculated and to see examples, see Amazon Bedrock Pricing.

Hyperparameter (console)	Hyperparameter (API)	Definition	Type	Minimum	Maximum	Default
Epochs	epochCount	The number of iterations through the entire training dataset	integer	1	100	N/A
Batch size	batchSize	The number of	integer	256	9,216	576

Hyperparameter (console)	Hyperparameter (API)	Definition	Type	Minimum	Maximum	Default
		samples processed before updating model parameters				
Learning rate	learningRate	The rate at which model parameters are updated after each batch	float	5.00E-8	1	5.00E-5

Anthropic Claude 3 model customization hyperparameters

Anthropic Claude 3 models support the following hyperparameters for model customization. The number of epochs you specify increases your model customization cost by processing more tokens. Each epoch processes the entire training dataset once. For information about pricing, see Amazon Bedrock pricing.

Console Name	API Name	Definition	Default	Minimum	Maximum	
Epoch count	epochCount	The maximum number of iterations through the entire	2	1	10	

Console Name	API Name	Definition	Default	Minimum	Maximum	
		training dataset				
Batch size	batchSize	Number of samples processed before updating model parameters	32	4	256	
Learning rate multiplier	learningRateMultiplier	Multiplier that influences the learning rate at which model parameters are updated after each batch	1	0.1	2	

Console Name	API Name	Definition	Default	Minimum	Maximum	
Early stopping threshold	earlyStoppingThreshold	Minimum improvement in validation loss required to prevent premature termination of the training process	0.001	0	0.1	
Early stopping patience	earlyStoppingPatience	Tolerance for stagnation in the validation loss metric before stopping the training process	2	1	10	

Cohere Command model customization hyperparameters

The Cohere Command and Cohere Command Light models support the following hyperparameters for model customization. The number of epochs you specify increases your model customization cost by processing more tokens. Each epoch processes the entire training dataset once. For information about pricing, see Amazon Bedrock pricing. For more information, see Customize your model to improve its performance for your use case.

For information about fine tuning Cohere models, see the Cohere documentation at https://docs.cohere.com/docs/fine-tuning.

> **Note**
>
> The epochCount quota is adjustable.

Hyperparameter (console)	Hyperparameter (API)	Definition	Type	Minimum	Maximum	Default
Epochs	epochCount	The number of iterations through the entire training dataset	integer	1	100	1
Batch size	batchSize	The number of samples processed before updating model parameters	integer	8	8 (Command) 32 (Light)	8
Learning rate	learningRate	The rate at which model parameters are updated after each	float	5.00E-6	0.1	1.00E-5

Hyperparameter (console)	Hyperparameter (API)	Definition	Type	Minimum	Maximum	Default
		batch. If you use a validation dataset, we recommend that you don't provide a value for `learningRate`.				
Early stopping threshold	earlyStoppingThreshold	The minimum improvement in loss required to prevent premature termination of the training process	float	0	0.1	0.01

Hyperparameter (console)	Hyperparameter (API)	Definition	Type	Minimum	Maximum	Default
Early stopping patience	earlyStoppingPatience	The tolerance for stagnation in the loss metric before stopping the training process	integer	1	10	6
Evaluation percentage	evalPercentage	The percentage of the dataset allocated for model evaluation, if you don't provide a separate validation dataset	float	5	50	20

Meta Llama 3.1 model customization hyperparameters

The Meta Llama 3.1 8B and 70B models support the following hyperparameters for model customization. The number of epochs you specify increases your model customization cost by processing more tokens. Each epoch processes the entire training dataset once. For information about pricing, see Amazon Bedrock pricing. For more information, see Customize your model to improve its performance for your use case.

For information about fine tuning Meta Llama models, see the Meta documentation at https://ai.meta.com/llama/get-started/#fine-tuning.

> **Note**
>
> The epochCount quota is adjustable.

Hyperparameter (console)	Hyperparameter (API)	Definition	Minimum	Maximum	Default	
Epochs	epochCount	The number of iterations through the entire training dataset	1	10	5	
Batch size	batchSize	The number of samples processed before updating model parameters	1	1	1	
Learning rate	learningRate	The rate at which model parameters are updated	5.00E-6	0.1	1.00E-4	

Hyperparameter (console)	Hyperparameter (API)	Definition	Minimum	Maximum	Default	
		after each batch				

Meta Llama 3.2 model customization hyperparameters

The Meta Llama 3.2 1B, 3B, 11B, and 90B models support the following hyperparameters for model customization. The number of epochs you specify increases your model customization cost by processing more tokens. Each epoch processes the entire training dataset once. For information about pricing, see Amazon Bedrock pricing. For more information, see Customize your model to improve its performance for your use case.

For information about fine tuning Meta Llama models, see the Meta documentation at https://ai.meta.com/llama/get-started/#fine-tuning.

Hyperparameter (console)	Hyperparameter (API)	Definition	Minimum	Maximum	Default	
Epochs	epochCount	The number of iterations through the entire training dataset	1	10	5	
Batch size	batchSize	The number of samples processed before updating model	1	1	1	

Hyperparameter (console)	Hyperparameter (API)	Definition	Minimum	Maximum	Default	
		parameters				
Learning rate	learningRate	The rate at which model parameters are updated after each batch	5.00E-6	0.1	1.00E-4	

Submit a model customization job for fine-tuning

You can create a custom model by using fine-tuning in the Amazon Bedrock console or API. You can further fine tune an existing custom model. The customization job can take several hours. The duration of the job depends on the size of the training data (number of records, input tokens, and output tokens), number of epochs, and batch size.

Prerequisites

- Create an AWS Identity and Access Management (IAM) service role to access the S3 bucket where you want to store your model customization training and validation data. You can create this role automatically by using the AWS Management Console or manually. For more information on the manual option, see Create an IAM service role for model customization.
- (Optional) Encrypt input and output data, your customization job, or inference requests made to custom models. For more information, see Encryption of custom models.
- (Optional) Create a virtual private cloud (VPC) to protect your customization job. For more information, see (Optional) Protect your model customization jobs using a VPC.

Submit your job

Choose the tab for your preferred method, and then follow the steps:

Console

To submit a model customization job in the console, carry out the following steps.

1. Sign in to the AWS Management Console with an IAM identity that has permissions to use the Amazon Bedrock console. Then, open the Amazon Bedrock console at https://console.aws.amazon.com/bedrock.
2. From the left navigation pane, choose **Custom models** under **Tune**.
3. In the **Models** tab, choose **Customize model** and then **Create Fine-tuning job**.
4. In the **Model details** section, do the following.
   a. Choose the model that you want to customize with your own data and give your resulting model a name. You can choose either a foundation model or a previously customized model (fine-tuned or distilled) as your base model.
   b. (Optional) By default, Amazon Bedrock encrypts your model with a key owned and managed by AWS. To use a custom KMS key, select **Model encryption** and choose a key.
   c. (Optional) To associate tags with the custom model, expand the **Tags** section and select **Add new tag**.
5. In the **Job configuration** section, enter a name for the job and optionally add any tags to associate with the job.
6. (Optional) To use a virtual private cloud (VPC) to protect your training data and customization job, select a VPC that contains the input data and output data Amazon S3 locations, its subnets, and security groups in the **VPC settings** section.

   > **Note**
   >
   > If you include a VPC configuration, the console cannot create a new service role for the job. Create a custom service role and add permissions similar to the example described in Attach VPC permissions to a model customization role.

7. In the **Input data** section, select the S3 location of the training dataset file and, if applicable, the validation dataset file.
8. In the **Hyperparameters** section, input values for hyperparameters to use in training.

9. In the **Output data** section, enter the Amazon S3 location where Amazon Bedrock should save the output of the job. Amazon Bedrock stores the training loss metrics and validation loss metrics for each epoch in separate files in the location that you specify.
10. In the **Service access** section, select one of the following:
    - **Use an existing service role** – Select a service role from the dropdown list. For more information on setting up a custom role with the appropriate permissions, see Create a service role for model customization.
    - **Create and use a new service role** – Enter a name for the service role.
11. Choose **Fine-tune model** to begin the job.

API

Request

Send a CreateModelCustomizationJob (see link for request and response formats and field details) request with an Amazon Bedrock control plane endpoint to submit a model customization job. Minimally, you must provide the following fields.

- `roleArn` – The ARN of the service role with permissions to customize models. Amazon Bedrock can automatically create a role with the appropriate permissions if you use the console, or you can create a custom role by following the steps at Create a service role for model customization.

  > **Note**
  >
  > If you include a `vpcConfig` field, make sure that the role has the proper permissions to access the VPC. For an example, see Attach VPC permissions to a model customization role.

- `baseModelIdentifier` – The model ID or ARN of the foundation model or previously customized model (fine-tuned or distilled) to customize.
- `customModelName` – The name to give the newly customized model.
- `jobName` – The name to give the training job.
- `hyperParameters` – Hyperparameters that affect the model customization process.
- `trainingDataConfig` – An object containing the Amazon S3 URI of the training dataset. Depending on the customization method and model, you can also include a

`validationDataConfig`. For more information about preparing the datasets, see Prepare data for fine-tuning your models.

- `validationDataconfig` – An object containing the Amazon S3 URI of the validation dataset.
- `outputDataConfig` – An object containing the Amazon S3 URI to write the output data to.

If you don't specify the `customizationType`, the model customization method defaults to `FINE_TUNING`.

To prevent the request from completing more than once, include a `clientRequestToken`.

You can include the following optional fields for extra configurations.

- `jobTags` and/or `customModelTags` – Associate tags with the customization job or resulting custom model.
- `customModelKmsKeyId` – Include a custom KMS key to encrypt your custom model.
- `vpcConfig` – Include the configuration for a virtual private cloud (VPC) to protect your training data and customization job.

Response

The response returns a `jobArn` that you can use to monitor or stop the job.

See code examples

Customize a model with reinforcement fine-tuning in Amazon Bedrock

Reinforcement fine-tuning is a model customization technique in Amazon Bedrock that improves foundation model performance by teaching models what constitutes a "good" response through feedback signals called rewards. Unlike traditional fine-tuning methods that depend on labeled datasets, reinforcement fine-tuning uses a feedback-driven approach that iteratively optimizes the model to maximize these rewards.

Reinforcement fine-tuning applications and scenarios

Use reinforcement fine-tuning when you can define clear, measurable success criteria for evaluating response quality. Reinforcement fine-tuning excels in domains where output quality can be objectively measured, especially when multiple valid responses exist or when optimal responses are difficult to define upfront. It's ideal for:

- Mathematical problem-solving and code generation (using rule-based graders for objective evaluation)
- Scientific reasoning and structured data analysis
- Subjective tasks like instruction following, content moderation, and creative writing (using AI-based judges)
- Tasks requiring step-by-step reasoning or multi-turn problem solving
- Scenarios with multiple valid solutions where some are clearly better than others
- Applications balancing multiple objectives (accuracy, efficiency, style)
- Applications requiring iterative improvement, personalization, or adherence to complex business rules
- Scenarios where success can be verified programmatically through execution results or performance metrics
- Cases where collecting high-quality labeled examples is expensive or impractical

Benefits of reinforcement fine-tuning

- **Improved model performance** – Reinforcement fine-tuning improves model accuracy by up to 66% on average compared to base models. This enables optimization for price and performance by fine-tuning smaller, faster, and more efficient model variants.
- **Ease of use** – Amazon Bedrock automates the complexity of reinforcement fine-tuning, making it accessible to developers building AI applications. You can fine-tune models using your uploaded datasets or existing API invocation logs. You can define reward functions that grade model outputs with custom code using Lambda or model-as-a-judge grader, with built-in templates that help with quick setup.
- **Security and compliance** – Your proprietary data never leaves AWS's secure, governed environment during the customization process.

Supported models for reinforcement fine-tuning

The following table shows the foundation models that you can customize with reinforcement fine-tuning:

Supported models for reinforcement fine-tuning

Provider	Model	Model ID	Region name	Region
Amazon	Nova 2 Lite	amazon.nova-2-lite-v1:0:256k	US East (N. Virginia)	us-east-1
OpenAI	gpt-oss-20B	openai.gpt-oss-20b	US West (Oregon)	us-west-2
Qwen	Qwen3 32B	qwen.qwen3-32b	US West (Oregon)	us-west-2

How reinforcement fine-tuning works

Amazon Bedrock fully automates the reinforcement fine-tuning workflow. The model receives prompts from your training dataset and generates several responses per prompt. These responses are then scored by a reward function. Amazon Bedrock uses the prompt-response pairs with scores to train the model through policy-based learning using Group Relative Policy Optimization (GRPO). The training loop continues until it reaches the end of your training data or you stop the job at a chosen checkpoint, producing a model optimized for the metric that matters to you.

Reinforcement fine-tuning best practices

- **Start small** – Begin with 100-200 examples, validate reward function correctness, and scale gradually based on results
- **Pre fine-tuning evaluation** – Test baseline model performance before reinforcement fine-tuning. If rewards are consistently 0 percent, use supervised fine-tuning first to establish basic capabilities. If rewards are greater than 95 percent, reinforcement fine-tuning might be unnecessary
- **Monitor training** – Track average reward scores and distribution. Watch for overfitting (training rewards increase while validation rewards decrease). Look for concerning patterns such as

rewards plateauing below 0.15, increasing reward variance over time, and declining validation performance

- **Optimize reward functions** – Execute within seconds (not minutes), minimize external API calls, use efficient algorithms, implement proper error handling, and take advantage of Lambda's parallel scaling
- **Iteration strategy** – If rewards aren't improving, adjust reward function design, increase dataset diversity, add more representative examples, and verify reward signals are clear and consistent

Topics

- Fine-tune Amazon Nova models with reinforcement fine-tuning
- Fine-tune open-weight models using OpenAI-compatible APIs
- Evaluate your RFT model

Fine-tune Amazon Nova models with reinforcement fine-tuning

Before fine-tuning, make sure you have the pre-requisites as Amazon Bedrock needs specific permissions to create and manage the fine-tuning process. For comprehensive security and permissions information, see Access and security for Amazon Nova models.

Run reinforcement fine-tuning for Amazon Nova models in 5 steps:

1. **Provide Training Dataset** – Upload prompts in required format (e.g., JSONL) as the reinforcement fine-tuning training dataset. For more information, see Prepare data for Amazon Nova models.
2. **Configure Reward Function (grader)** – Define a grader to score model responses based on correctness, structure, tone, or other objectives. The reward function can be executed using Lambda to compute objective scores. You can also choose a model as a judge (via console) and grade responses based on criteria and principles you configure (the console converts these into Lambda functions automatically). For more information, see Setting up reward functions for Amazon Nova models.
3. **Submit reinforcement fine-tuning Job** – Launch the reinforcement fine-tuning job by specifying base model, dataset, reward function, and other optional settings such as hyperparameters. For more information, see Create and manage fine-tuning jobs for Amazon Nova models.

4. **Monitor Training** – Track job status, reward metrics, and training progress until completion. For more information, see Monitor your RFT training job.
5. **Use Fine-Tuned Model** – After job completion, deploy the resulting RFT model with one click for on-demand inference. You can also use Provisioned Throughput for mission-critical workloads that require consistent performance. See Set up inference for a custom model. Use **Test in Playground** to evaluate and compare responses with the base model.

> **Important**
>
> You can provide a maximum of 20K prompts to Amazon Bedrock for reinforcement fine-tuning the model.

Supported Nova models

The following table shows the Amazon Nova models that you can customize with reinforcement fine-tuning:

> **Note**
>
> For information about additional supported models including open-weight models, see Fine-tune open-weight models using OpenAI-compatible APIs.

Supported models for reinforcement fine-tuning

Provider	Model	Model ID	Single-region model support
Amazon	Nova 2 Lite	amazon.nova-2-lite-v1:0:256k	us-east-1

Access and security for Amazon Nova models

Before you begin reinforcement fine-tuning, make sure that you understand what kind of access Amazon Bedrock needs for RFT-specific operations. RFT requires additional permissions beyond standard fine-tuning due to its reward function execution capabilities.

For basic model customization security setup including trust relationships, Amazon S3 permissions, and KMS encryption, see Create an IAM service role for model customization.

Prerequisites

Before adding RFT-specific IAM permissions, you must add the following IAM service roles:

- Trust relationship
- Permissions to access training and validation files and to write output files in S3

RFT-specific IAM permissions

Add these permissions to your existing model customization service role for RFT functionality.

Lambda permissions for reward functions

You must add Lambda invocation permissions. The following shows an example policy you can use:

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "lambda:InvokeFunction"
            ],
            "Resource": [
                "arn:aws:lambda:*:*:function:reward-function-name"
            ]
        }
    ]
}
```

Invocation log access

To use existing Amazon Bedrock model invocation logs as training data, add permissions to access your Amazon S3 bucket where invocation logs are stored.

You need to provide Amazon S3 bucket access permissions for the input bucket. The following shows an example policy you can use:

```
{
```

```
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "s3:GetObject",
                "s3:ListBucket"
            ],
            "Resource": [
                "arn:aws:s3:::s3-invocation-logs-bucket",
                "arn:aws:s3:::s3-invocation-logs-bucket/*"
            ]
        }
    ]
}
```

For security setup including basic IAM roles, Amazon S3 permissions, and encryption, see Create an IAM service role for model customization.

Grader Lambda function permissions for RLAIF

If you create your own Lambda function for Reinforcement Learning from AI Feedback (RLAIF) reward functions, you need to add specific permissions to the Lambda execution role.

Bedrock permissions for LLM judges

For LLM-as-Judge reward functions (RLAIF), add permissions to invoke foundation models. The following shows an example policy you can use for your Lambda execution role.

> **Note**
>
> Only add these permissions to your Lambda execution role if you create your own Lambda function. The console handles this automatically when creating Lambda functions through the console.

The following is an example for bedrock LLM as judge invocation using foundation models:

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
```

```
            "Effect": "Allow",
            "Action": [
                "bedrock:InvokeModel"
            ],
            "Resource": [
                "arn:aws:bedrock:*:*:foundation-model/*"
            ]
        }
    ]
}
```

The following is an example for bedrock LLM as judge invocation using inference profile:

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "bedrock:InvokeModel"
            ],
            "Resource": [
                "arn:aws:bedrock:us-east-1::foundation-model/amazon.nova-premier-v1:0",
                "arn:aws:bedrock:us-east-2::foundation-model/amazon.nova-premier-v1:0",
                "arn:aws:bedrock:us-west-2::foundation-model/amazon.nova-premier-v1:0"
            ],
            "Condition": {
                "StringLike": {
                    "bedrock:InferenceProfileArn": "arn:aws:bedrock:us-
east-1:111122223333:inference-profile/us.amazon.nova-premier-v1:0"
                }
            }
        },
        {
            "Effect": "Allow",
            "Action": [
                "bedrock:InvokeModel"
            ],
            "Resource": [
                "arn:aws:bedrock:us-east-1:111122223333:inference-
profile/us.amazon.nova-premier-v1:0"
            ]
        }
```

```
    ]
}
```

For information about inference profile prerequisites, see Prerequisites for inference profiles.

Prepare data for Amazon Nova models

When you fine-tune an Amazon Nova model with reinforcement fine-tuning, you can bring your own prompts or use existing Amazon Bedrock API invocation logs as training data.

Training data requirements and sources

You can provide training data through one of the following options:

> **Note**
>
> We only support the OpenAI chat completion format.

Option 1: Provide your own prompts

Collect your prompts and store them in `.jsonl` file format. You can upload custom datasets in JSONL format or select existing datasets from Amazon S3. Each record in the JSONL must use the OpenAI chat completion format in the following structure:

- `messages`: In this field, include the user, system or assistant role containing the input prompt provided to the model.
- `reference_answer`: In this field, it should contain the expected output or evaluation criteria that your reward function uses to score the model's response. It is not limitedto structured outputs—it can contain any format that helps your reward function evaluate quality.
- [Optional] You can add fields used by grader Lambda for grading.

Requirements:

- JSONL format with prompts in OpenAI chat completion format (one prompt per line)
- A minimum of 100 records in training dataset
- Amazon Bedrock automatically validates training dataset format

Example: General question-answering

```
{
            "messages": [
                {
                    "role": "system",
                    "content": "You are a helpful assistant"
                },
                {
                    role": "user",
                    "content": "What is machine learning?"}
            ],
            "reference_answer": "Machine learning is a subset of artificial
 intelligence that enables computers to learn and make decisions from data without
 being explicitly programmed."
            }
```

Example: Math problem

```
{
  "id": "sample-001",
  "messages": [
    {
      "role": "system",
      "content": "You are a math tutor"
    },
    {
      "role": "user",
      "content": "Solve: 2x + 5 = 13"
    }
  ],
  "reference_answer": {
    "solution": "x = 4",
    "steps": ["2x = 13 - 5", "2x = 8", "x = 4"]
  }
}
```

Option 2: Use invocation logs

When you create a reinforcement fine-tuning job, you can have Amazon Bedrock use existing invocation logs from your S3 bucket as training data. For Amazon Bedrock, an invocation log is a detailed record of model invocations.

You can use customer-side stored Invoke/Converse API invocation logs from Amazon S3 for training.

Requirements:

- API logging must be enabled for your Amazon Bedrock usage
- Logs must be in a supported format (Amazon Bedrock Invoke/Converse API)
- A minimum of 100 prompt examples

To use invocation logs for reinforcement fine-tuning, set the model invocation logging on, use one of the model invocation operations, and make sure that you've set up an Amazon S3 bucket as the destination for the logs. For more information about setting up the invocation logs, see Monitor model invocation using CloudWatch Logs and Amazon S3.

Before you start the reinforcement fine-tuning job with invocation logs from an S3 bucket as input, provide Amazon Bedrock permissions to access the logs. For more information, see Model customization access and security.

You can optionally add request metadata to the prompt-response pairs in the invocation log using one of the model invocation operations and then later use it to filter the logs. Amazon Bedrock can use the filtered logs to fine-tune the model.

Add request metadata to prompts and responses in your invocation logs

With invocation logs, you can identify the training dataset prompts that you want Amazon Bedrock to use for reinforcement fine-tuning using request metadata attached to invocation logs.

The following is an example of an invocation log from an `InvokeModel` call with the `requestMetadata`:

```
{
"schemaType": "ModelInvocationLog",
    "schemaVersion": "1.0",
    "timestamp": "2024-09-11T17:16:18Z",
    "accountId": "XXXXX",
    "identity": {
"arn": "arn:aws:sts::XXXXXXX:assumed-role/Admin/XXXXXX"
    },
    "region": "us-east-1",
    "requestId": "7ee514f3-9eff-467c-af75-8fd564ce58e5",
    "operation": "InvokeModel",
```

```
    "modelId": "meta.llama3-1-405b-instruct-v1:0",
    "input": {
"inputContentType": "application/json",
        "inputBodyJson": {
"prompt": "story of two dogs",
            "max_tokens_to_sample": 300
        },
        "inputTokenCount": 13
    },
    "output": {
"outputContentType": "application/json",
        "outputBodyJson": {
"type": "completion",
            "completion": " Here is a story about two dogs:\n\nRex and Charlie were
 best friends who lived next door to each other. Every morning, their owners would
 let them out into the backyard to play. Rex was a golden retriever with long, shaggy
 fur. He loved to run and chase sticks. Charlie was a corgi with short legs and a
 big smile. He was happy just sniffing the grass and rolling around. \n\nThe two dogs
 spent every day playing together. Rex would grab a stick and bring it over to Charlie,
 wagging his tail excitedly. Charlie would take the other end of the stick in his mouth
 and they'd have a friendly game of tug-of-war. After tiring themselves out, they'd
 flop down in the warm sunshine for a nap. \n\nAt lunchtime, their owners would call
 them in for food. Rex would gobble up his kibble hungrily while Charlie ate his at
 a more leisurely pace. After lunch, it was right back outside for more playtime.
 The afternoon sunbeams would light up their fur as they chased each other around the
 yard. \n\nWhen it started getting late, their owners called them in for the night. Rex
 and Charlie would head inside, tired but happy after another fun day of play. After
 slurping up fresh water from their bowls, they'd curl up on their beds, Rex's fluffy
 golden tail tucked over his nose and little",
            "stop_reason": "max_tokens",
            "stop": null
        },
        "outputTokenCount": 300
    },
    "requestMetadata": {
"project": "CustomerService",
        "intent": "ComplaintResolution",
        "priority": "High"
    }
}
```

You can specify the invocation log as your input data source when you start a reinforcement fine-tuning job. You can start a reinforcement fine-tuning job through the Amazon Bedrock console, using the API, AWS CLI, or SDK.

Requirements for providing request metadata

The request metadata must meet the following requirements:

- Provided in the JSON `key:value` format.
- Key and value pair must be a string of 256 characters maximum.
- Provide a maximum of 16 key-value pairs.

Using request metadata filters

Once invocation logs with request metadata are available, you can apply filters based on the request metadata to selectively choose which prompts to include for fine-tuning the model. For example, you might want to include only those with `"project": "CustomerService"` and `"priority": "High"` request metadata.

To filter the logs using multiple request metadata, use a single Boolean operator `AND` or `OR`. You cannot combine these operators. For single request metadata filtering, use the `Equals` or `Not Equals` operator.

Characteristics of effective training data

Effective RFT training data requires three key characteristics:

- **Clarity and consistency** – Use clear, unambiguous prompts with consistent formatting. Avoid contradictory labels, ambiguous instructions, or conflicting reference answers that mislead training.
- **Diversity** – Include varied input formats, edge cases, and difficulty levels that reflect production usage patterns across different user types and scenarios.
- **Efficient reward functions** – Design functions that execute quickly (seconds, not minutes), parallelize with AWS Lambda, and return consistent scores for cost-effective training.

Additional properties

The RFT data format supports custom fields beyond the core schema requirements (`messages` and `reference_answer`). This flexibility allows you to add any additional data your reward function needs for proper evaluation.

> **Note**
>
> You don't need to configure this in your recipe. The data format inherently supports additional fields. Simply include them in your training data JSON, and they will be passed to your reward function in the `metadata` field.

Common additional properties

- `task_id` – Unique identifier for tracking
- `difficulty_level` – Problem complexity indicator
- `domain` – Subject area or category
- `expected_reasoning_steps` – Number of steps in solution

These additional fields are passed to your reward function during evaluation, enabling sophisticated scoring logic tailored to your specific use case.

Examples with additional properties

Chemistry problem

```
{
  "id": "chem-001",
  "messages": [
    {
      "role": "system",
      "content": "You are a helpful chemistry assistant"
    },
    {
      "role": "user",
      "content": "Predict hydrogen bond donors and acceptors for this SMILES:
 CCN(CC)CCC(=O)c1sc(N)nc1C"
    }
```

```
  ],
  "reference_answer": {
    "donor_bond_counts": 2,
    "acceptor_bond_counts": 4
  }
}
```

The `reference_answer` field contains the expected output or evaluation criteria that your reward function uses to score the model's response. It is not limited to structured outputs—it can contain any format that helps your reward function evaluate quality.

Math problem with metadata

```
{
  "messages": [
    {
      "role": "system",
      "content": "You are a math tutor"
    },
    {
      "role": "user",
      "content": "Solve: 2x + 5 = 13"
    }
  ],
  "reference_answer": {
    "solution": "x = 4",
    "steps": ["2x = 13 - 5", "2x = 8", "x = 4"]
  },
  "task_id": "algebra_001",
  "difficulty_level": "easy",
  "domain": "algebra",
  "expected_reasoning_steps": 3
}
```

Setting up reward functions for Amazon Nova models

Reward functions evaluate response quality and provide feedback signals for model training. You can set up reward functions using custom Lambda functions or Amazon Bedrock-hosted foundation models as judges. Guided templates are available to simplify reward function creation for common tasks like instruction following and format validation. Choose the approach that matches your task requirements.

Reinforcement Learning through Verifiable Rewards (RLVR)

RLVR optimizes models for objective tasks such as code generation or math reasoning using verifiable rule-based graders or ready-to-use templates.

You have two options for RLVR (Custom Code):

Option 1: Use console-provided templates

Amazon Bedrock console provides sample templates for grader Lambda functions:

- Mathematical reasoning with ground truth verification
- Format validation and constraint checking
- Generic grader Lambda template with boilerplate code

Follow the instructions in the provided template on the **Create RFT job** page in the Amazon Bedrock console.

Option 2: Bring your own Lambda function

Create custom reward functions using your own Lambda ARN for complex logic, external APIs, multi-step calculations, or combining multiple evaluation criteria.

> **Note**
>
> If you bring your own Lambda function, keep the following in mind:
>
> - Increase the Lambda timeout from default 3 seconds to maximum 15 minutes for complex evaluations.
> - The Lambda execution role needs permissions to invoke models as described in Access and security for Amazon Nova models.

Reinforcement Learning through AI Feedback (RLAIF)

RLAIF optimizes models for subjective tasks such as instruction following or chatbot interactions using AI-based judges with ready-to-use templates.

For RLAIF (Model as Judge):

- Select an Amazon Bedrock hosted base Model as Judge
- Configure instructions for evaluation
- Define evaluation criteria and scoring guidelines

Available LLM-as-Judge prompt templates in the Amazon Bedrock console:

- Instruction following (Judge model training)
- Summarization (Multi-turn dialogs)
- Reasoning evaluation (CoT for specialized domains)
- RAG faithfulness (Context-grounded Q&A)

> **Note**
>
> The console's **Model as Judge** option automatically converts your configuration into a Lambda function during training.

Lambda function implementation details

When implementing custom Lambda reward functions, your function must accept and return data in the following format.

Input structure

```
[{
  "id": "123",
  "messages": [
    {
      "role": "user",
      "content": "Do you have a dedicated security team?"
    },
    {
      "role": "assistant",
      "content": "As an AI developed by Amazon, I don not have a dedicated security
 team..."
    }
  ],
  "metadata": {
    "reference_answer": {
```

```
      "compliant": "No",
      "explanation": "As an AI developed by Company, I do not have a traditional
 security team..."
    },
    "my_key": "sample-001"
  }
}]
```

Output structure

```
[{
  "id": "123",
  "aggregate_reward_score": 0.85,
  "metrics_list": [
    {
      "name": "accuracy",
      "value": 0.9,
      "type": "Reward"
    },
    {
      "name": "policy_compliance",
      "value": 0.8,
      "type": "Metric"
    }
  ]
}]
```

Design guidelines

- **Rank responses** – Give the best answer a clearly higher score
- **Use consistent checks** – Evaluate task completion, format adherence, safety, and reasonable length
- **Maintain stable scaling** – Keep scores normalized and non-exploitable

Create and manage fine-tuning jobs for Amazon Nova models

You can create a reinforcement fine-tuning (RFT) job using the Amazon Bedrock console or API. The RFT job can take a few hours depending on the size of your training data, number of epochs, and complexity of your reward functions.

Prerequisites

- Create an IAM service role with the required permissions. For comprehensive security and permissions information including RFT-specific permissions, see Access and security for Amazon Nova models.
- (Optional) Encrypt input and output data, your RFT job, or inference requests made to custom models. For more information, see Encryption of custom models.

Create your RFT job

Choose the tab for your preferred method, and then follow the steps:

Console

To submit an RFT job in the console, carry out the following steps:

1. Open the Amazon Bedrock console and navigate to **Custom models** under **Tune**.
2. Choose **Create**, then **Create reinforcement fine-tuning job**.
3. In the **Model details** section, choose **Amazon Nova 2 Lite** as your base model.
4. In the **Customization details** section, enter the customization name.
5. In the **Training data** section, choose your data source. Either select from your available invocation logs stored in Amazon S3, or select the Amazon S3 location of your training dataset file, or upload a file directly from your device.

   > **Note**
   >
   > Your training dataset should be in the OpenAI Chat Completions data format. If you provide invocation logs in the Amazon Bedrock invoke or converse format, Amazon Bedrock automatically converts them to the Chat Completions format.

6. In the **Reward function** section, set up your reward mechanism:

   - **Model as judge (RLAIF)** - Select a Bedrock hosted base model as judge and configure the instructions for evaluation. Use this for subjective tasks like content moderation.

> **Note**
>
> The console's **Model as judge** option automatically converts your configuration into a Lambda function during training.

- **Custom code (RLVR)** - Create custom reward functions using Python code executed through Lambda functions. Use this for objective tasks like code generation.

For more information, see Setting up reward functions for Amazon Nova models.

7. (Optional) In the **Hyperparameters** section, adjust training parameters or use default values.
8. In the **Output data** section, enter the Amazon S3 location where Amazon Bedrock should save job outputs.
9. In the **Role configuration** section, either choose an existing role from the dropdown list or enter a name for the service role to create.
10. (Optional) In the **Additional configuration** section, configure the validation data by pointing to an Amazon S3 bucket, KMS encryption settings, and job and model tags.
11. Choose **Create reinforcement fine-tuning job** to begin the job.

API

Send a CreateModelCustomizationJob request with `customizationType` set to `REINFORCEMENT_FINE_TUNING`.

Required fields: `roleArn`, `baseModelIdentifier`, `customModelName`, `jobName`, `trainingDataConfig`, `outputDataConfig`, `rftConfig`

Example request:

```
{
    "roleArn": "arn:aws:iam::123456789012:role/BedrockRFTRole",
    "baseModelIdentifier": "amazon.nova-2.0",
    "customModelName": "my-rft-model",
    "jobName": "my-rft-job",
    "customizationType": "REINFORCEMENT_FINE_TUNING",
    "trainingDataConfig": {
        "s3Uri": "s3://my-bucket/training-data.jsonl"
```

```
    },
    "customizationConfig": {
        "rftConfig" : {
            "graderConfig": {
                "lambdaGrader": {
                    "lambdaArn": "arn:aws:lambda:us-
east-1:123456789012:function:function-name"
                }
            },
            "hyperParameters": {
                "batchSize": 64,
                "epochCount": 2,
                "evalInterval": 10,
                "inferenceMaxTokens": 8192,
                "learningRate": 0.00001,
                "maxPromptLength": 4096,
                "reasoningEffort": "high",
                "trainingSamplePerPrompt": 4
            }
        }
    },
    "outputDataConfig": {
        "s3Uri": "s3://my-bucket/rft-output/"
    }
}
```

Python API sample request:

```
import boto3

bedrock = boto3.client(service_name='bedrock')

# Set parameters
customizationType = "REINFORCEMENT_FINE_TUNING"
baseModelIdentifier = "arn:aws:bedrock:us-east-1::foundation-model/amazon.nova-2-
lite-v1:0:256k"
roleArn = "${your-customization-role-arn}"
jobName = "MyFineTuningJob"
customModelName = "MyCustomModel"

customizationConfig = {
    'rftConfig' : {
        'graderConfig': {
```

```
            'lambdaGrader': {
                'lambdaArn': 'arn:aws:lambda:us-
east-1:123456789012:function:function-name'
            }
        },
        'hyperParameters': {
            'batchSize': 64,
            'epochCount': 2,
            'evalInterval': 10,
            'inferenceMaxTokens': 8192,
            'learningRate':0.00001,
            'maxPromptLength': 4096,
            'reasoningEffort': 'high',
            'trainingSamplePerPrompt':4
        }
    }
}

trainingDataConfig = {"s3Uri": "s3://${training-bucket}/myInputData/train.jsonl"}
outputDataConfig = {"s3Uri": "s3://${output-bucket}/myOutputData"}

# Create job
response_ft = bedrock.create_model_customization_job(
    jobName=jobName,
    customModelName=customModelName,
    roleArn=roleArn,
    baseModelIdentifier=baseModelIdentifier,
    customizationConfig=customizationConfig,
    trainingDataConfig=trainingDataConfig,
    outputDataConfig=outputDataConfig,
    customizationType=customizationType
)

jobArn = response_ft['jobArn']
```

Monitor your RFT training job

Amazon Bedrock provides real-time monitoring with visual graphs and metrics during RFT training. These metrics help you understand whether the model converges properly and if the reward function effectively guides the learning process.

Job status tracking

You can monitor your RFT job status through the validation and training phases in the Amazon Bedrock console.

Completion indicators:

- Job status changes to **Completed** when training completes successfully
- Custom model ARN becomes available for deployment
- Training metrics reach convergence thresholds

Real-time training metrics

Amazon Bedrock provides real-time monitoring during RFT training with visual graphs displaying training and validation metrics.

Core training metrics

- **Training loss** - Measures how well the model is learning from the training data
- **Training reward statistics** - Shows reward scores assigned by your reward functions
- **Reward margin** - Measures the difference between good and bad response rewards
- **Accuracy on training and validation sets** - Shows model performance on both the training and held-out data

Detailed metric categories

- **Reward metrics** – `critic/rewards/mean`, `critic/rewards/max`, `critic/rewards/min` (reward distribution), and `val-score/rewards/mean@1` (validation rewards)
- **Model behavior** – `actor/entropy` (policy variation; higher equals more exploratory)
- **Training health** – `actor/pg_loss` (policy gradient loss), `actor/pg_clipfrac` (frequency of clipped updates), and `actor/grad_norm` (gradient magnitude)
- **Response characteristics** – `prompt_length/mean`, `prompt_length/max`, `prompt_length/min` (input token statistics), `response_length/mean`, `response_length/max`, `response_length/min` (output token statistics), and `response/aborted_ratio` (incomplete generation rate; 0 equals all completed)
- **Performance** – `perf/throughput` (training throughput), `perf/time_per_step` (time per training step), and `timing_per_token_ms/*` (per-token processing times)

- **Resource usage** – `perf/max_memory_allocated_gb`, `perf/max_memory_reserved_gb` (GPU memory), and `perf/cpu_memory_used_gb` (CPU memory)

Training progress visualization

The console displays interactive graphs that update in real-time as your RFT job progresses. These visualizations can help you:

- Track convergence toward optimal performance
- Identify potential training issues early
- Determine optimal stopping points
- Compare performance across different epochs

Set up inference

After job completion, deploy the RFT model for on-demand inference or use Provisioned Throughput for consistent performance. For setting up inference, see Set up inference for a custom model.

Use **Test in Playground** to evaluate and compare responses with the base model. For evaluating your completed RFT model, see Evaluate your RFT model.

Fine-tune open-weight models using OpenAI-compatible APIs

Amazon Bedrock provides OpenAI compatible API endpoints for fine-tuning foundation models. These endpoints allow you to use familiar OpenAI SDKs and tools to create, monitor, and manage fine-tuning jobs with Amazon Bedrock models. This page highlights using these APIs for reinforcement fine-tuning.

Key capabilities

- **Upload training files** – Use the Files API to upload and manage training data for fine-tuning jobs
- **Create fine-tuning jobs** – Start fine-tuning jobs with custom training data and reward functions
- **List and retrieve jobs** – View all fine-tuning jobs and get detailed information about specific jobs
- **Monitor job events** – Track fine-tuning progress through detailed event logs
- **Access checkpoints** – Retrieve intermediate model checkpoints created during training

- **Immediate inference** – After fine-tuning completes, use the resulting fine-tuned model for on-demand inference through Amazon Bedrock's OpenAI-compatible APIs (Responses/chat completions API) without additional deployment steps
- **Easy migration** – Compatible with existing OpenAI SDK codebases

Reinforcement fine-tuning workflow for open-weight models

Before fine-tuning, make sure you have the pre-requisites as Amazon Bedrock needs specific permissions to create and manage the fine-tuning process. For comprehensive security and permissions information, see Access and security for open-weight models.

Run reinforcement fine-tuning for open-weight models in 5 steps:

1. **Upload Training Dataset** – Use the Files API to upload prompts in required format (e.g., JSONL) with purpose "fine-tune" as the reinforcement fine-tuning training dataset. For more information, see Prepare data for open-weight models.
2. **Configure Reward Function** – Define a grader to score model responses based on correctness, structure, tone, or other objectives using Lambda functions. For more information, see Setting up reward functions for open-weight models.
3. **Create Fine-tuning Job** – Launch the reinforcement fine-tuning job using the OpenAI-compatible API by specifying base model, dataset, reward function, and other optional settings such as hyperparameters. For more information, see Create fine-tuning job.
4. **Monitor Training Progress** – Track job status, events, and training metrics using the fine-tuning jobs APIs. For more information, see List fine-tuning events. Access intermediate model checkpoints to evaluate performance at different training stages, see List fine-tuning checkpoints.
5. **Run Inference** – Use the fine-tuned model ID directly for inference through Amazon Bedrock's OpenAI-compatible Responses or Chat Completions APIs. For more information, see Run inference with fine-tuned model.

Supported regions and endpoints

The following table shows the foundation models and regions that support OpenAI compatible fine-tuning APIs:

Supported models and regions for OpenAI compatible fine-tuning APIs

Provider	Model	Model ID	Region name	Region	Endpoint
OpenAI	Gpt-oss-20B	openai.gpt-oss-20b	US West (Oregon)	us-west-2	bedrock-mantle.us-west-2.api.aws
Qwen	Qwen3 32B	qwen.qwen3-32b	US West (Oregon)	us-west-2	bedrock-mantle.us-west-2.api.aws

Access and security for open-weight models

Before you begin reinforcement fine-tuning (RFT), make sure that you understand what kind of access Amazon Bedrock needs for RFT-specific operations. RFT requires additional permissions beyond standard fine-tuning due to its reward function execution capabilities.

Prerequisites

Before using Amazon Bedrock's OpenAI-compatible fine-tuning APIs, make sure you have the following:

1. An AWS account with appropriate permissions to access Amazon Bedrock
2. **Authentication** – You can authenticate using:
   - Amazon Bedrock API key (required for OpenAI SDK and available for HTTP requests)
   - AWS credentials (supported for HTTP requests)

   > **Note**
   >
   > If you are using Amazon Bedrock short-term/long-term API keys, then make sure that your role has access to the following IAM policy permissions: `AmazonBedrockMantleFullAccess` and Lambda permissions for reward functions.

3. **OpenAI SDK (optional)** – Install the OpenAI Python SDK if using SDK-based requests.
4. **Environment variables** – Set the following environment variables:

- `OPENAI_API_KEY` – Set to your Amazon Bedrock API key
- `OPENAI_BASE_URL` – Set to the Amazon Bedrock endpoint for your region (for example, `https://bedrock-mantle.us-west-2.api.aws/v1`)

For more information, see Responses API.

5. **Training data** formatted as JSONL files with the purpose `fine-tune`. For more information, see Prepare data for open-weight models.

Lambda permissions for reward functions

You must add Lambda invocation permissions. The following shows an example policy you can use:

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "lambda:InvokeFunction"
            ],
            "Resource": [
                "arn:aws:lambda:*:*:function:reward-function-name"
            ]
        }
    ]
}
```

You can also use Amazon Bedrock hosted models as Judges for setting up reward functions. You will need to add specific permissions to invoke foundation models to the Lambda execution role. In your lambda role, you can configure these managed policies for LLMs for grading. See AmazonBedrockLimitedAccess.

The following is an example for invoking Amazon Bedrock foundation models as judge using the Invoke API:

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
```

```
            "Action": [
                "bedrock:InvokeModel"
            ],
            "Resource": [
                "arn:aws:bedrock:*:*:foundation-model/*"
            ]
        }
    ]
}
```

Prepare data for open-weight models

When you fine-tune open-weight models with reinforcement fine-tuning using OpenAI-compatible APIs, provide training data by bringing your own prompts in JSONL format with the purpose `fine-tune`.

Training data format and requirements

Training data must follow the OpenAI chat completions format with 100-20K examples. Each training example contains:

- `messages`: In this field, include the user, system or assistant role containing the input prompt provided to the model.
- `reference_answer`: In this field, it should contain the expected output or evaluation criteria that your reward function uses to score the model's response. It is not limitedto structured outputs—it can contain any format that helps your reward function evaluate quality.
- [Optional] You can add fields used by grader Lambda for grading.

Requirements:

- JSONL format with prompts in OpenAI chat completion format (one prompt per line)
- Purpose must be set to `fine-tune`
- A minimum of 100 records in training dataset
- Amazon Bedrock automatically validates training dataset format

Example: General question-answering

```
{
            "messages": [
```

```
                {
                    "role": "system",
                    "content": "You are a helpful assistant"
                },
                {
                    role": "user",
                    "content": "What is machine learning?"}
            ],
            "reference_answer": "Machine learning is a subset of artificial
 intelligence that enables computers to learn and make decisions from data without
 being explicitly programmed."
            }
```

Example: Math problem

```
{
  "id": "sample-001",
  "messages": [
    {
      "role": "system",
      "content": "You are a math tutor"
    },
    {
      "role": "user",
      "content": "Solve: 2x + 5 = 13"
    }
  ],
  "reference_answer": {
    "solution": "x = 4",
    "steps": ["2x = 13 - 5", "2x = 8", "x = 4"]
  }
}
```

Files API

You can use OpenAI-compatible files api to upload your training data for fine-tuning jobs. Files are stored securely in Amazon Bedrock, and are used when creating fine-tuning jobs. For complete API details, see the OpenAI Files documentation.

Upload training file

To upload a training file, choose the tab for your preferred method, and then follow the steps:

OpenAI SDK (Python)

```
# Requires OPENAI_API_KEY and OPENAI_BASE_URL environment variables
from openai import OpenAI
client = OpenAI()

# Upload training file
with open(TRAINING_FILE_PATH, 'rb') as f:
    file_response = client.files.create(
        file=f,
        purpose='fine-tune'
    )

# Store file ID for next steps
training_file_id = file_response.id
print(f"# Training file uploaded successfully: {training_file_id}")
```

HTTP request

Make a POST request to `/v1/files`:

```
curl https://bedrock-mantle.us-west-2.api.aws/v1/files \
  -H "Authorization: Bearer $OPENAI_API_KEY" \
  -F purpose="fine-tune" \
  -F file="@training_data.jsonl"
```

Retrieve file details

To retrieve details about a specific file, choose the tab for your preferred method, and then follow the steps:

OpenAI SDK (Python)

```
# Requires OPENAI_API_KEY and OPENAI_BASE_URL environment variables
from openai import OpenAI
client = OpenAI()

# Retrieve file details
file_details = client.files.retrieve(training_file_id)

# Print raw response
```

```
print(json.dumps(file_details.model_dump(), indent=2))
```

HTTP request

Make a GET request to `/v1/files/{file_id}`:

```
curl https://bedrock-mantle.us-west-2.api.aws/v1/files/file-abc123 \
  -H "Authorization: Bearer $OPENAI_API_KEY"
```

List files

To list uploaded files, choose the tab for your preferred method, and then follow the steps:

OpenAI SDK (Python)

```
# Requires OPENAI_API_KEY and OPENAI_BASE_URL environment variables
from openai import OpenAI
client = OpenAI()

# List files
files_response = client.files.list(purpose='fine-tune')

# Print raw response
print(json.dumps(files_response.model_dump(), indent=2))
```

HTTP request

Make a GET request to `/v1/files`:

```
curl https://bedrock-mantle.us-west-2.api.aws/v1/files?purpose=fine-tune \
  -H "Authorization: Bearer $OPENAI_API_KEY"
```

Delete file

To delete a file, choose the tab for your preferred method, and then follow the steps:

OpenAI SDK (Python)

```
# Requires OPENAI_API_KEY and OPENAI_BASE_URL environment variables
from openai import OpenAI
```

```
client = OpenAI()

# Delete file
delete_response = client.files.delete(training_file_id)
```

HTTP request

Make a DELETE request to `/v1/files/{file_id}`:

```
curl -X DELETE https://bedrock-mantle.us-west-2.api.aws/v1/files/file-abc123 \
  -H "Authorization: Bearer $OPENAI_API_KEY"
```

Characteristics of effective training data

Effective RFT training data requires three key characteristics:

- **Clarity and consistency** – Use clear, unambiguous prompts with consistent formatting. Avoid contradictory labels, ambiguous instructions, or conflicting reference answers that mislead training.
- **Diversity** – Include varied input formats, edge cases, and difficulty levels that reflect production usage patterns across different user types and scenarios.
- **Efficient reward functions** – Design functions that execute quickly (seconds, not minutes), parallelize with AWS Lambda, and return consistent scores for cost-effective training.

Additional properties

The RFT data format supports custom fields beyond the core schema requirements (`messages` and `reference_answer`). This flexibility allows you to add any additional data your reward function needs for proper evaluation.

> **Note**
>
> You don't need to configure this in your recipe. The data format inherently supports additional fields. Simply include them in your training data JSON, and they will be passed to your reward function in the `metadata` field.

Common additional properties

- `task_id` – Unique identifier for tracking
- `difficulty_level` – Problem complexity indicator
- `domain` – Subject area or category
- `expected_reasoning_steps` – Number of steps in solution

These additional fields are passed to your reward function during evaluation, enabling sophisticated scoring logic tailored to your specific use case.

Examples with additional properties

Chemistry problem

```
{
  "id": "chem-001",
  "messages": [
    {
      "role": "system",
      "content": "You are a helpful chemistry assistant"
    },
    {
      "role": "user",
      "content": "Predict hydrogen bond donors and acceptors for this SMILES:
 CCN(CC)CCC(=O)c1sc(N)nc1C"
    }
  ],
  "reference_answer": {
    "donor_bond_counts": 2,
    "acceptor_bond_counts": 4
  }
}
```

The `reference_answer` field contains the expected output or evaluation criteria that your reward function uses to score the model's response. It is not limited to structured outputs—it can contain any format that helps your reward function evaluate quality.

Math problem with metadata

```
{
  "messages": [
    {
      "role": "system",
```

```
      "content": "You are a math tutor"
    },
    {
      "role": "user",
      "content": "Solve: 2x + 5 = 13"
    }
  ],
  "reference_answer": {
    "solution": "x = 4",
    "steps": ["2x = 13 - 5", "2x = 8", "x = 4"]
  },
  "task_id": "algebra_001",
  "difficulty_level": "easy",
  "domain": "algebra",
  "expected_reasoning_steps": 3
}
```

Setting up reward functions for open-weight models

Reward functions evaluate response quality and provide feedback signals for model training. You can set up reward functions using custom Lambda functions. Choose the approach that matches your task requirements.

Custom Lambda functions for reward evaluation

You can set up reward functions using custom Lambda functions. Within your Lambda function, you have flexibility in how you implement the evaluation logic:

- **Objective tasks** – For objective tasks like code generation or math reasoning, use verifiable rule-based graders that check correctness against known standards or test cases.
- **Subjective tasks** – For subjective tasks like instruction following or chatbot interactions, call Amazon Bedrock foundation models as judges within your Lambda function to evaluate response quality based on your criteria.

Your Lambda function can implement complex logic, integrate external APIs, perform multi-step calculations, or combine multiple evaluation criteria depending on your task requirements.

> **Note**
>
> When using custom Lambda functions:

- Increase the Lambda timeout from default 3 seconds to maximum 15 minutes for complex evaluations.
- The Lambda execution role needs permissions to invoke the Lambda function as described in Lambda permissions for reward functions.

Lambda function implementation details

When implementing custom Lambda reward functions, your function must accept and return data in the following format.

Input structure

```
[{
  "id": "123",
  "messages": [
    {
      "role": "user",
      "content": "Do you have a dedicated security team?"
    },
    {
      "role": "assistant",
      "content": "As an AI developed by Amazon, I don not have a dedicated security
 team..."
    }
  ],
  "metadata": {
    "reference_answer": {
      "compliant": "No",
      "explanation": "As an AI developed by Company, I do not have a traditional
 security team..."
    },
    "my_key": "sample-001"
  }
}]
```

Output structure

```
[{
  "id": "123",
  "aggregate_reward_score": 0.85,
```

```
  "metrics_list": [
    {
      "name": "accuracy",
      "value": 0.9,
      "type": "Reward"
    },
    {
      "name": "policy_compliance",
      "value": 0.8,
      "type": "Metric"
    }
  ]
}]
```

Design guidelines

- **Rank responses** – Give the best answer a clearly higher score
- **Use consistent checks** – Evaluate task completion, format adherence, safety, and reasonable length
- **Maintain stable scaling** – Keep scores normalized and non-exploitable

Create and manage fine-tuning jobs for open-weight models using OpenAI APIs

The OpenAI-compatible fine-tuning job APIs allow you to create, monitor, and manage fine-tuning jobs. This page highlights using these APIs for reinforcement fine-tuning. For complete API details, see the OpenAI Fine-tuning documentation.

Create fine-tuning job

Creates a fine-tuning job that begins the process of creating a new model from a given dataset. For complete API details, see the OpenAI Create fine-tuning jobs documentation.

Examples

To create a fine-tuning job with RFT method, choose the tab for your preferred method, and then follow the steps:

OpenAI SDK (Python)

```
# Requires OPENAI_API_KEY and OPENAI_BASE_URL environment variables
```

```
from openai import OpenAI
client = OpenAI()

# Create fine-tuning job with RFT method
job_response = client.fine_tuning.jobs.create(
    model=MODEL_ID,
    training_file=training_file_id,
    # Suffix field is not supported so commenting for now.
    # suffix="rft-example",  # Optional: suffix for fine-tuned model name
    extra_body={
        "method": {
            "type": "reinforcement",
            "reinforcement": {
                "grader": {
                    "type": "lambda",
                    "lambda": {
                        "function": "arn:aws:lambda:us-
west-2:123456789012:function:my-reward-function"  # Replace with your Lambda ARN
                    }
                },
                "hyperparameters": {
                    "n_epochs": 1,  # Number of training epochs
                    "batch_size": 4,  # Batch size
                    "learning_rate_multiplier": 1.0  # Learning rate multiplier
                }
            }
        }
    }
)

# Store job ID for next steps
job_id = job_response.id
print({job_id})
```

HTTP request

Make a POST request to `/v1/fine_tuning/jobs`:

```
curl https://bedrock-mantle.us-west-2.api.aws/v1/fine_tuning/jobs \
  -H "Content-Type: application/json" \
  -H "Authorization: Bearer $OPENAI_API_KEY" \
  -d '{
    "training_file": "file-abc123",
    "model": "gpt-4o-mini",
```

```
    "method": {
      "type": "reinforcement",
      "reinforcement": {
        "grader": {
          "type": "lambda",
          "lambda": {
            "function": "arn:aws:lambda:us-west-2:123456789012:function:my-grader"
          }
        },
        "hyperparameters": {
          "n_epochs": 1,
          "batch_size": 4,
          "learning_rate_multiplier": 1.0
        }
      }
    }
  }'
```

List fine-tuning events

Lists events for a fine-tuning job. Fine-tuning events provide detailed information about the progress of your job, including training metrics, checkpoint creation, and error messages. For complete API details, see the OpenAI List fine-tuning events documentation.

Examples

To list fine-tuning events, choose the tab for your preferred method, and then follow the steps:

OpenAI SDK (Python)

```
# Requires OPENAI_API_KEY and OPENAI_BASE_URL environment variables
from openai import OpenAI
client = OpenAI()

# List fine-tuning events
events = client.fine_tuning.jobs.list_events(
    fine_tuning_job_id="ftjob-abc123",
    limit=50
)

for event in events.data:
    print(f"[{event.created_at}] {event.level}: {event.message}")
    if event.data:
```

```
        print(f"  Metrics: {event.data}")
```

HTTP request

Make a GET request to /v1/fine_tuning/jobs/{fine_tuning_job_id}/events:

```
curl https://bedrock-mantle.us-west-2.api.aws/v1/fine_tuning/jobs/ftjob-abc123/
events?limit=50
```

Events include information such as:

- Training started and completed messages
- Checkpoint creation notifications
- Training metrics (loss, accuracy) at each step
- Error messages if the job fails

To paginate through all events, choose the tab for your preferred method, and then follow the steps:

OpenAI SDK (Python)

```
# Requires OPENAI_API_KEY and OPENAI_BASE_URL environment variables
from openai import OpenAI
client = OpenAI()

# Paginate through all events
all_events = []
after = None

while True:
    events = client.fine_tuning.jobs.list_events(
        fine_tuning_job_id="ftjob-abc123",
        limit=100,
        after=after
    )

    all_events.extend(events.data)

    if not events.has_more:
        break
```

```
    after = events.data[-1].id
```

HTTP request

Make multiple GET requests with the `after` parameter:

```
# First request
curl https://bedrock-mantle.us-west-2.api.aws/v1/fine_tuning/jobs/ftjob-abc123/
events?limit=100

# Subsequent requests with 'after' parameter
curl "https://bedrock-mantle.us-west-2.api.aws/v1/fine_tuning/jobs/ftjob-abc123/
events?limit=100&after=ft-event-abc123"
```

Retrieve fine-tuning job

Get detailed information about a fine-tuning job. For complete API details, see the OpenAI Retrieve fine-tuning job documentation.

Examples

To retrieve specific job details, choose the tab for your preferred method, and then follow the steps:

OpenAI SDK (Python)

```
# Requires OPENAI_API_KEY and OPENAI_BASE_URL environment variables
from openai import OpenAI
client = OpenAI()

# Retrieve specific job details
job_details = client.fine_tuning.jobs.retrieve(job_id)

# Print raw response
print(json.dumps(job_details.model_dump(), indent=2))
```

HTTP request

Make a GET request to `/v1/fine_tuning/jobs/{fine_tuning_job_id}`:

```
curl https://bedrock-mantle.us-west-2.api.aws/v1/fine_tuning/jobs/ftjob-abc123 \
```

```
  -H "Authorization: Bearer $OPENAI_API_KEY"
```

List fine-tuning jobs

Lists your organization's fine-tuning jobs with pagination support. For complete API details, see the OpenAI List fine-tuning jobs documentation.

Examples

To list fine-tuning jobs with limit and pagination, choose the tab for your preferred method, and then follow the steps:

OpenAI SDK (Python)

```
# Requires OPENAI_API_KEY and OPENAI_BASE_URL environment variables
from openai import OpenAI
client = OpenAI()

# List fine-tuning jobs with limit and pagination
response = client.fine_tuning.jobs.list(
    limit=20  # Maximum number of jobs to return
)

# Print raw response
print(json.dumps(response.model_dump(), indent=2))
```

HTTP request

Make a GET request to `/v1/fine_tuning/jobs`:

```
curl https://bedrock-mantle.us-west-2.api.aws/v1/fine_tuning/jobs?limit=20 \
  -H "Authorization: Bearer $OPENAI_API_KEY"
```

Cancel fine-tuning job

Cancels a fine-tuning job that is in progress. Once cancelled, the job cannot be resumed. For complete API details, see the OpenAI Cancel fine-tuning job documentation.

Examples

To cancel a fine-tuning job, choose the tab for your preferred method, and then follow the steps:

OpenAI SDK (Python)

```
# Requires OPENAI_API_KEY and OPENAI_BASE_URL environment variables
from openai import OpenAI
client = OpenAI()

# Cancel fine-tuning job
cancel_response = client.fine_tuning.jobs.cancel("ftjob-abc123")

print(f"Job ID: {cancel_response.id}")
print(f"Status: {cancel_response.status}")  # Should be "cancelled"
```

HTTP request

Make a POST request to `/v1/fine_tuning/jobs/{fine_tuning_job_id}/cancel`:

```
curl -X POST https://bedrock-mantle.us-west-2.api.aws/v1/fine_tuning/jobs/ftjob-
abc123/cancel \
  -H "Authorization: Bearer $OPENAI_API_KEY"
```

List fine-tuning checkpoints

Lists checkpoints for a fine-tuning job. Checkpoints are intermediate model snapshots created during fine-tuning that can be used for inference to evaluate performance at different training stages. For more information, see the OpenAI List fine-tuning checkpoints documentation.

Examples

To list checkpoints for a fine-tuning job, choose the tab for your preferred method, and then follow the steps:

OpenAI SDK (Python)

```
# Requires OPENAI_API_KEY and OPENAI_BASE_URL environment variables
from openai import OpenAI
client = OpenAI()

# List checkpoints for a fine-tuning job
checkpoints = client.fine_tuning.jobs.checkpoints.list(
    fine_tuning_job_id="ftjob-abc123",
    limit=10
)
```

```
for checkpoint in checkpoints.data:
    print(f"Checkpoint ID: {checkpoint.id}")
    print(f"Step: {checkpoint.step_number}")
    print(f"Model: {checkpoint.fine_tuned_model_checkpoint}")
    print(f"Metrics: {checkpoint.metrics}")
    print("---")
```

HTTP request

Make a GET request to `/v1/fine_tuning/jobs/{fine_tuning_job_id}/checkpoints`:

```
curl https://bedrock-mantle.us-west-2.api.aws/v1/fine_tuning/jobs/ftjob-abc123/
checkpoints?limit=10
```

Each checkpoint includes:

- **Checkpoint ID** – Unique identifier for the checkpoint
- **Step number** – Training step at which the checkpoint was created
- **Model checkpoint** – Model identifier that can be used for inference
- **Metrics** – Validation loss and accuracy at this checkpoint

To use a checkpoint model for inference, choose the tab for your preferred method, and then follow the steps:

OpenAI SDK (Python)

```
# Requires OPENAI_API_KEY and OPENAI_BASE_URL environment variables
from openai import OpenAI
client = OpenAI()

# Test inference with a checkpoint
response = client.chat.completions.create(
    model=checkpoint.fine_tuned_model_checkpoint,
    messages=[{"role": "user", "content": "What is AI?"}],
    max_tokens=100
)

print(response.choices[0].message.content)
```

HTTP request

Make a POST request to `/v1/chat/completions`:

```
curl https://bedrock-mantle.us-west-2.api.aws/v1/chat/completions \
  -H "Content-Type: application/json" \
  -d '{
    "model": "ft:gpt-4o-mini:openai:custom:7p4lURel:ckpt-step-1000",
    "messages": [{"role": "user", "content": "What is AI?"}],
    "max_tokens": 100
  }'
```

Run inference with fine-tuned model

Once your fine-tuning job is complete, you can use the fine-tuned model for inference through the Responses API or Chat Completions API.

Responses API

Use the Responses API for single-turn text generation with your fine-tuned model:

OpenAI SDK (Python)

```
# Requires OPENAI_API_KEY and OPENAI_BASE_URL environment variables
from openai import OpenAI
client = OpenAI()

# Get the fine-tuned model ID
job_details = client.fine_tuning.jobs.retrieve("ftjob-abc123")

if job_details.status == 'succeeded' and job_details.fine_tuned_model:
    fine_tuned_model = job_details.fine_tuned_model
    print(f"Using fine-tuned model: {fine_tuned_model}")

    # Run inference with Responses API
    response = client.completions.create(
        model=fine_tuned_model,
        prompt="What is the capital of France?",
        max_tokens=100,
        temperature=0.7
    )
```

```
    print(f"Response: {response.choices[0].text}")
else:
    print(f"Job status: {job_details.status}")
    print("Job must be in 'succeeded' status to run inference")
```

HTTP request

Make a POST request to `/v1/completions`:

```
curl https://bedrock-mantle.us-west-2.api.aws/v1/completions \
  -H "Content-Type: application/json" \
  -H "Authorization: Bearer $OPENAI_API_KEY" \
  -d '{
    "model": "ft:gpt-4o-mini:openai:custom-model:7p4lURel",
    "prompt": "What is the capital of France?",
    "max_tokens": 100,
    "temperature": 0.7
  }'
```

Chat Completions API

Use the Chat Completions API for conversational interactions with your fine-tuned model:

OpenAI SDK (Python)

```
# Requires OPENAI_API_KEY and OPENAI_BASE_URL environment variables
from openai import OpenAI
client = OpenAI()

# Get the fine-tuned model ID
job_details = client.fine_tuning.jobs.retrieve("ftjob-abc123")

if job_details.status == 'succeeded' and job_details.fine_tuned_model:
    fine_tuned_model = job_details.fine_tuned_model
    print(f"Using fine-tuned model: {fine_tuned_model}")

    # Run inference
    inference_response = client.chat.completions.create(
        model=fine_tuned_model,
        messages=[
            {"role": "user", "content": "What is the capital of France?"}
        ],
```

```
        max_tokens=100
    )

    print(f"Response: {inference_response.choices[0].message.content}")
else:
    print(f"Job status: {job_details.status}")
    print("Job must be in 'succeeded' status to run inference")
```

HTTP request

Make a POST request to `/v1/chat/completions`:

```
curl https://bedrock-mantle.us-west-2.api.aws/v1/chat/completions \
  -H "Content-Type: application/json" \
  -H "Authorization: Bearer $OPENAI_API_KEY" \
  -d '{
    "model": "ft:gpt-4o-mini:openai:custom-model:7p4lURel",
    "messages": [
      {"role": "user", "content": "What is the capital of France?"}
    ],
    "max_tokens": 100
  }'
```

Evaluate your RFT model

After your reinforcement fine-tuning job completes successfully, you can evaluate your custom model's performance using multiple assessment methods. Amazon Bedrock provides built-in evaluation tools to help you compare your RFT model against the base model and validate improvements.

Topics

- Evaluation methods
- Setting up inference for evaluation
- Evaluation best practices

Evaluation methods

Amazon Bedrock offers several ways to assess your RFT model performance.

Validation metrics

If you upload a validation dataset, you will see two additional graphs in training metrics.

- **Validation rewards** - Shows how well your model generalizes beyond training examples. Lower scores than training rewards are normal and expected.
- **Validation episode lengths** - Average response length on unseen validation data. Shows how efficiently your model responds to new inputs compared to the training examples.

Test in Playground

Use the Test in Playground feature for quick, ad-hoc evaluations. To use the Test in Playground feature, inference needs to be set up. For more information, see Setting up inference for evaluation.

This interactive tool allows you to:

- Test prompts directly with your RFT model
- Compare responses side-by-side between your custom model and the base model
- Evaluate response quality improvements in real-time
- Experiment with different prompts to assess model capabilities

Bedrock Model Evaluation

Use Amazon Bedrock's Model Evaluation to assess your RFT model using your own datasets. This provides comprehensive performance analysis with standardized metrics and benchmarks. Here are some examples of the Amazon Bedrock Model Evaluation benefits.

- Systematic evaluation using custom test datasets
- Quantitative performance comparisons
- Standardized metrics for consistent assessment
- Integration with existing Amazon Bedrock evaluation workflows

Setting up inference for evaluation

Before evaluating your RFT model, set up inference using one of these options:

On-demand inference

Create a custom model on-demand deployment for flexible, pay-per-use evaluation. This option includes token-based pricing that charges based on the number of tokens processed during inference.

Evaluation best practices

- **Compare systematically** - Always evaluate your RFT model against the base model using the same test prompts and evaluation criteria.
- **Use diverse test cases** - Include various prompt types and scenarios that represent your real-world use cases.
- **Validate reward alignment** - Ensure your model improvements align with the reward functions used during training.
- **Test edge cases** - Evaluate model behavior on challenging or unusual inputs to assess robustness.
- **Monitor response consistency** - Check that your model provides consistent quality across multiple runs with similar prompts.

Customize a model with distillation in Amazon Bedrock

Model distillation is the process of transferring knowledge from a larger more intelligent model (known as teacher) to a smaller, faster, cost-efficient model (known as student). In this process, the student model's performance improves for a specific use case. Amazon Bedrock Model Distillation uses the latest data synthesis techniques to generate diverse, high-quality responses (known as synthetic data) from the teacher model, and fine-tunes the student model.

How to use Amazon Bedrock Model Distillation

To use Amazon Bedrock Model Distillation, you do the following:

1. **Choose a teacher model and a student model** – For more information, see Prerequisites for model distillation.
2. **Prepare your training data for distillation** – Your training data is a collection of prompts stored in `.jsonl` files. Amazon Bedrock uses the input data to generate responses from the teacher model and uses the responses to fine-tune the student model.

- **Optimize prompts** – Format your input prompts for the use case that you want. For more information, see Optimize your input prompts for synthetic data generation.
- **Use labeled examples** – Prepare labeled input data as prompt-response pairs. Amazon Bedrock can use these pairs as golden examples while generating responses from the teacher model. For more information, see Option 1: Provide your own prompts for data preparation.
- **Use invocation logs** – If you enable CloudWatch Logs invocation logging, you can use existing teacher responses from invocation logs stored in Amazon S3 as training data. An invocation log in Amazon Bedrock is a detailed record of model invocations. For more information, see Option 2: Use invocation logs for data preparation.

3. **Create a distillation job** – This job creates a smaller, faster, and more cost-effective model for your use case. Only you can access the final distilled model. Amazon Bedrock doesn't use your data to train any other teacher or student model for public use. For more information, see Submit a model distillation job in Amazon Bedrock. For more information on setting up on demand inference, see Set up inference for a custom model.

How Amazon Bedrock Model Distillation works

Amazon Bedrock Model Distillation is a single workflow that automates the process of creating a distilled model. In this workflow, Amazon Bedrock generates responses from a teacher model, adds data synthesis techniques to improve response generation, and fine-tunes the student model with the generated responses. The augmented dataset is split into separate datasets to use for training and validation. Amazon Bedrock uses only the data in the training dataset to fine-tune the student model.

After you've identified your teacher and student models, you can choose how you want Amazon Bedrock to create a distilled model for your use case. Amazon Bedrock can either generate teacher responses by using the prompts that you provide, or you can use responses from your production data through invocation logs. Amazon Bedrock Model Distillation uses these responses to fine-tune the student model.

> **Note**
>
> If Amazon Bedrock Model Distillation uses its proprietary data synthesis techniques to generate higher-quality teacher responses, then your AWS account will incur additional charges for inference calls to the teacher model. These charges will be billed at the on-demand inference rates of the teacher model. Data synthesis techniques may increase

the size of the fine-tuning dataset to a maximum of 15k prompt-response pairs. For more information about Amazon Bedrock charges, see Amazon Bedrock Pricing.

Creating a distilled model using prompts that you provide

Amazon Bedrock uses the input prompts that you provide to generate responses from the teacher model. Amazon Bedrock then uses the responses to fine-tune the student model that you've identified. Depending on your use case, Amazon Bedrock might add proprietary data synthesis techniques to generate diverse and higher-quality responses. For example, Amazon Bedrock might generate similar prompts to generate more diverse responses from the teacher model. Or, if you optionally provide a handful of labeled input data as prompt-response pairs, then Amazon Bedrock might use these pairs as golden examples to instruct the teacher to generate similar high-quality responses.

Creating a distilled model using production data

If you already have responses generated by the teacher model and stored them in the invocation logs, you can use those existing teacher responses to fine-tune the student model. For this, you will need to provide Amazon Bedrock access to your invocation logs. An invocation log in Amazon Bedrock is a detailed record of model invocations. For more information, see Monitor model invocation using CloudWatch Logs.

If you choose this option, then you can continue to use Amazon Bedrocks inference API operations, such as InvokeModel or Converse API, and collect the invocation logs, model input data (prompts), and model output data (responses) for all invocations used in Amazon Bedrock.

When you generate responses from the model using the `InvokeModel` or `Converse` API operations, you can optionally add `requestMetadata` to the responses. When you create a Distillation job, you can filter by this metadata as part of the invocation logs configuration. You can filter by your specific use cases, and then Amazon Bedrock only uses the filtered responses to fine-tune your student model. When you choose to use invocation logs to fine-tune your student model, you can have Amazon Bedrock use the prompts only, or use prompt-response pairs.

Choosing prompts with invocation logs

If you choose to have Amazon Bedrock use only the prompts from the invocation logs, then Amazon Bedrock uses the prompts to generate responses from the teacher model. In this case, Amazon Bedrock uses the responses to fine-tune the student model that you've identified.

Depending on your use case, Amazon Bedrock Model Distillation might add proprietary data synthesis techniques to generate diverse and higher-quality responses.

Choosing prompt-response pairs with invocation logs

If you choose to have Amazon Bedrock use prompt-response pairs from the invocation logs, then Amazon Bedrock won't re-generate responses from the teacher model and use the responses from the invocation log to fine-tune the student model. For Amazon Bedrock to read the responses from the invocation logs, the teacher model specified in your model distillation job must match the model used in the invocation log. If they don't match, the invocation logs aren't used. If you've added request metadata to the responses in the invocation log, then to fine-tune the student model, you can specify the request metadata filters so that Amazon Bedrock reads only specific logs that are valid for your use case.

Prerequisites for model distillation

Before you can begin, make sure that you understand access and security controls for Model Distillation. You must also choose a teacher and student model for your distillation job.

Permissions

Before you can begin, make sure that you understand access and security controls for Model Distillation. You must have an IAM service role that can access the Amazon S3 bucket where you want to store your Model Distillation training and validation data. Amazon Bedrock also has options for encrypting and further securing your distillation jobs and artifacts. For more information, see Model customization access and security.

To use a cross-region inference profile for a teacher model in a Distillation job, your service role must have permissions to invoke the inference profile in an AWS Region, in addition to the model in each Region in the inference profile. For a policy example, see (Optional) Permissions to create a Distillation job with a cross-region inference profile. For more information about cross-region inference, see Route model inference requests across AWS Regions with cross-Region inference.

Choose teacher and student models for distillation

Model Type	Selection Criteria	Key Considerations	Requirements
Teacher Model	Choose a teacher model that's significantly larger and more capable than the student model, and whose accuracy you want to achieve for your use case.	To make distillation more effective, choose a model that's already trained on tasks similar to your use case. For some teacher models, you can choose a Cross-Region inference profile.	Must have permissions to invoke inference profiles and models in each Region. See cross-region inference documentation for policy examples.
Student Model	Choose a student model that's significantly smaller in size than the teacher model.	The student model must be one of the student models paired with your teacher model in the supported models table.	Must be compatible with selected teacher model as shown in the following table.

The following section lists the supported models and regions for Amazon Bedrock Model Distillation. After you choose your teacher and student models, you prepare and optimize your training datasets for distillation. For more information, see Prepare your training datasets for distillation.

Supported models and Regions for Amazon Bedrock Model Distillation

The following table shows which models and AWS Regions Amazon Bedrock Model Distillation supports for teacher and student models. If you use a Cross Region Inference Profile, only System

Inference Profiles are supported for model distillation. For more information, see Route model inference requests across AWS Regions with cross-Region inference.

Important

Distillation is not currently available for Anthropic models on Amazon Bedrock. There is no confirmed timeline for when Anthropic distillation will be restored. For currently supported teacher–student combinations, see the table below.

Provider	Teacher	Teacher ID	Inference profile support	Student	Student ID	Region
Amazon	Nova Pro	amazon.nova-pro-v1:0	Both	Nova Lite Nova Micro	amazon.nova-lite-v1:0:300k amazon.nova-micro-v1:0:128k	US East (N. Virginia)
	Nova Premier	amazon.nova-premier-v1:0	Inference profile only	Nova Lite Nova Micro Nova Pro	amazon.nova-lite-v1:0:300k amazon.nova-micro-v1:0:128k amazon.nova-pro-v1:0:300k	US East (N. Virginia)
Meta	Llama 3.1 405B	meta.llama3-1-405b-instruct-v1:0	On demand	Llama 3.1 8B Llama 3.1 70B	meta.llama3-1-8b-instruct-v1:0:128k	US West (Oregon)

Provider	Teacher	Teacher ID	Inference profile support	Student	Student ID	Region
				Llama 3.2 1B Llama 3.3 70B	meta.llama3-1-70b-instruct-v1:0:128k meta.llama3-2-1b-instruct-v1:0:128k meta.llama3-3-70b-instruct-v1:0:128k	
	Llama 3.1 70B	meta.llama3-1-70b-instruct-v1:0	Both	Llama 3.1 8B Llama 3.2 1B Llama 3.2 3B	meta.llama3-1-8b-instruct-v1:0:128k meta.llama3-2-1b-instruct-v1:0:128k meta.llama3-2-3b-instruct-v1:0:128k	US West (Oregon)

Provider	Teacher	Teacher ID	Inference profile support	Student	Student ID	Region
	Llama 3.3 70B	meta.llama3-3-70b-instruct-v1:0	Inference profile only	Llama 3.1 8B Llama 3.2 1B Llama 3.2 3B	meta.llama3-1-8b-instruct-v1:0:128k meta.llama3-2-1b-instruct-v1:0:128k meta.llama3-2-3b-instruct-v1:0:128k	US West (Oregon)

Note

- For Claude and Llama models, the distillation job is run in US West (Oregon). You can either buy provisioned throughput in US West (Oregon) or copy distilled model to another Region and then buy provisioned throughput.

Prepare your training datasets for distillation

Before you can begin a model customization job, you need to minimally prepare a training dataset. To prepare input datasets for your custom model, you create `.jsonl` files, each line of which is a JSON object corresponding to a record. The files you create must conform to the format for model distillation and model that you choose. The records in it must also conform to size requirements.

Provide the input data as prompts. Amazon Bedrock uses the input data to generate responses from the teacher model and uses the generated responses to fine-tune the student model. For more information about inputs Amazon Bedrock uses, and for choosing an option that works best

for your use case, see How Amazon Bedrock Model Distillation works. There are a couple options for preparing your input dataset.

> **Note**
>
> Amazon Nova models have different requirements for distillation. For more information, see Distilling Amazon Nova models.

Supported modalities for distillation

The models listed in Supported models and Regions for Amazon Bedrock Model Distillation support only the text-to-text modality.

Optimize your input prompts for synthetic data generation

During model distillation, Amazon Bedrock generates a synthetic dataset that it uses to fine tune your student model for your specific use case. For more information, see How Amazon Bedrock Model Distillation works.

You can optimize the synthetic data generation process by formatting your input prompts for the use case that you want. For example, if your distilled model's use case is retrieval augmented generation (RAG), you would format your prompts differently than if you want the model to focus on agent use cases.

The following are examples for how you can format your input prompts for RAG or agent use cases.

RAG prompt example

```
{
  "schemaVersion": "bedrock-conversation-2024",
  "system": [
    {
      "text": "You are a financial analyst charged with answering questions about
 10K and 10Q SEC filings. Given the context below, answer the following question."
    }
  ],
  "messages": [
    {
      "role": "user",
      "content": [
```

```
        {
          "text": "<context>\nDocument 1: Multiple legal actions have been filed
 against us as a result of the October 29, 2018 accident of Lion Air Flight 610
 and the March 10, 2019 accident of Ethiopian Airlines Flight 302.\n</context>\n
\n<question>Has Boeing reported any materially important ongoing legal battles from
 FY2022?</question>"
        }
      ]
    }
  ]
}
```

Agent prompt example

```
{
    "schemaVersion": "bedrock-conversation-2024",
    "system": [
        {
            "text": 'You are an expert in composing functions. You are given a
 question and a set of possible functions. Based on the question, you will need to
 make one or more function/tool calls to achieve the purpose.
                    Here is a list of functions in JSON format that you can invoke.
                    [
                        {
                            "name": "lookup_weather",
                            "description: "Lookup weather to a specific location",
                            "parameters": {
                                "type": "dict",
                                "required": [
                                    "city"
                                ],
                                "properties": {
                                    "location": {
                                        "type": "string",
                                    },
                                    "date": {
                                        "type": "string",
                                    }
                                }
                            }
                        }
                    ]'
        }
```

```
    ],
    "messages": [
        {
            "role": "user",
            "content": [
                {
                    "text": "What's the weather tomorrow?"
                }
            ]
        },
        {
            "role": "assistant",
            "content": [
               {
                   "text": "[lookup_weather(location=\"san francisco\", date=
\"tomorrow\")]"
               }
            ]
        }
    ]
}
```

Option 1: Provide your own prompts for data preparation

Collect your prompts and store them in `.jsonl` file format. Each record in the JSONL must use the following structure.

- Include the `schemaVersion` field that must have the value `bedrock-conversion-2024`.
- [Optional] Include a system prompt that indicates the role assigned to the model.
- In `messages` field, include the user role containing the input prompt provided to the model.
- [Optional] In the `messages` field, include assistant role containing the desired response.

Anthropic and Meta Llama models support only single-turn conversation prompts, meaning you can only have one user prompt. The Amazon Nova models support multi-turn conversations, allowing you to provide multiple user and assistant exchanges within one record.

Example format

```
{
    "schemaVersion": "bedrock-conversation-2024",
```

```
    "system": [{
        "text": "A chat between a curious User and an artificial intelligence Bot. The
 Bot gives helpful, detailed, and polite answers to the User's questions."
    }],
    "messages": [{
            "role": "user",
            "content": [{
                "text": "why is the sky blue"
            }]
        },
        {
            "role": "assistant",
            "content": [{
                "text": "The sky is blue because molecules in the air scatter blue
 light from the Sun more than other colors."
            }]
        }
    ]
}
```

Validate your dataset

Before you run your distillation job, you can validate your input dataset using a Python script.

Option 2: Use invocation logs for data preparation

When you create a distillation job, you can have Amazon Bedrock use existing teacher responses from CloudWatch Logs invocation logs as training data. For Amazon Bedrock, an invocation log is a detailed record of model invocations.

To use invocation logs for model distillation, set the model invocation logging on, use one of the model invocation operations, and make sure that you've set up an Amazon S3 bucket as the destination for the logs. Before you can start the model distillation job, you must provide Amazon Bedrock permissions to access the logs. For more information about setting up the invocation logs, see Monitor model invocation using Amazon CloudWatch Logs.

With this option, you can specify if you want Amazon Bedrock to use only the prompts, or to use prompt-response pairs from the invocation log. If you want Amazon Bedrock to use only prompts, then Amazon Bedrock might add proprietary data synthesis techniques to generate diverse and higher-quality responses from the teacher model. If you want Amazon Bedrock to use prompt-response pairs, then Amazon Bedrock won't re-generate responses from the teacher model.

Amazon Bedrock will directly use the responses from the invocation log to fine-tune the student model.

> **Important**
>
> You can provide a maximum of 15K prompts or prompt-response pairs to Amazon Bedrock for fine-tuning the student model. To ensure that the student model is fine-tuned to meet your specific requirements, we highly recommend the following:
>
> - If you want Amazon Bedrock to use prompts only, make sure that there are at least 100 prompt-response pairs generated from across all models.
> - If you want Amazon Bedrock to use responses from your invocation logs, make sure that you have at least 100 prompt-response pairs generated from the model in your invocation logs that exactly match with the teacher model you've chosen.

You can optionally add request metadata to the prompt-response pairs in the invocation log using one of the model invocation operations and then later use it to filter the logs. Amazon Bedrock can use the filtered logs to fine-tune the student model.

To filter the logs using multiple request metadata, use a single operation Boolean operator AND, OR, or NOT. You cannot combine operations. For single request metadata filtering, use the Boolean operator NOT.

Add request metadata to prompts and responses in your invocation logs for model distillation

The model invocation logging collects invocation logs, model input data (prompts), and model output data(responses) for all invocations used in Amazon Bedrock. If you've enabled logging, you can collect the logs whenever you interact with Amazon Bedrock foundation models through any `Invoke` or `Converse` API operations. If you want Amazon Bedrock to use the prompts and associated responses from the invocation log to fine-tune the student model, then you must give Amazon Bedrock access to these logs. Using the responses that a model has already generated makes it quicker to fine-tune the student model. Using responses from the invocation logs also makes model distillation more cost-effective, however, Amazon Bedrock's proprietary data synthesis techniques are not added which may result in a more performant distilled model.

With invocation logs, you can identify the prompt-response pairs that you want Amazon Bedrock to use for model distillation. These prompt-response pairs can be for specific use cases. To be able to identify the prompt-response pairs to use for distillation, you must add a request metadata

string to the prompt-response pairs when you invoke a model or use the `Converse` API operation. The request metadata is provided in the format: "*priority*" : "*High*".

As you continue to interact with the model using the `Invoke` or `Converse` API operations, the interactions and the request metadata are logged in the invocation logs. The following is an example of an invocation log from an `InvokeModel` call that shows the request metadata:

```
{
    "schemaType": "ModelInvocationLog",
    "schemaVersion": "1.0",
    "timestamp": "2024-09-11T17:16:18Z",
    "accountId": "XXXXX",
    "identity": {
        "arn": "arn:aws:sts::XXXXXXX:assumed-role/Admin/XXXXXX"
    },
    "region": "us-east-1",
    "requestId": "7ee514f3-9eff-467c-af75-8fd564ce58e5",
    "operation": "InvokeModel",
    "modelId": "meta.llama3-1-405b-instruct-v1:0",
    "input": {
        "inputContentType": "application/json",
        "inputBodyJson": {
            "prompt": "story of two dogs",
            "max_tokens_to_sample": 300
        },
        "inputTokenCount": 13
    },
    "output": {
        "outputContentType": "application/json",
        "outputBodyJson": {
            "type": "completion",
            "completion": " Here is a story about two dogs:\n\nRex and Charlie were
best friends who lived next door to each other. Every morning, their owners would
let them out into the backyard to play. Rex was a golden retriever with long, shaggy
fur. He loved to run and chase sticks. Charlie was a corgi with short legs and a
big smile. He was happy just sniffing the grass and rolling around. \n\nThe two dogs
spent every day playing together. Rex would grab a stick and bring it over to Charlie,
wagging his tail excitedly. Charlie would take the other end of the stick in his mouth
and they'd have a friendly game of tug-of-war. After tiring themselves out, they'd
flop down in the warm sunshine for a nap. \n\nAt lunchtime, their owners would call
them in for food. Rex would gobble up his kibble hungrily while Charlie ate his at
a more leisurely pace. After lunch, it was right back outside for more playtime.
The afternoon sunbeams would light up their fur as they chased each other around the
```

```
 yard. \n\nWhen it started getting late, their owners called them in for the night. Rex
 and Charlie would head inside, tired but happy after another fun day of play. After
 slurping up fresh water from their bowls, they'd curl up on their beds, Rex's fluffy
 golden tail tucked over his nose and little",
            "stop_reason": "max_tokens",
            "stop": null
        },
        "outputTokenCount": 300
    },
    "requestMetadata": {
        "project": "CustomerService",
        "intent": "ComplaintResolution",
        "priority": "High"
    }
}
```

You can specify the invocation log as your input data source when you start a model distillation job. You can start model distillation job in the Amazon Bedrock console, using the API, AWS CLI, or AWS SDK.

Requirements for providing request metadata

The request metadata must meet the following requirements:

- Provided in the JSON `key:value` format.
- Key and value pair must be a string of 256 characters maximum.
- Provide a maximum of 16 key-value pairs.

Using request metadata filters

You can apply filters to the request metadata to selectively choose which prompt-response pairs to include in distillation for fine-tuning the student model. For example, you might want to include only those with "project" : "CustomerService" and "priority" : "High" request metadata.

To filter the logs using multiple request metadata, use a single Boolean operator AND, OR, or NOT. You cannot combine operations. For single request metadata filtering, use the Boolean operator NOT.

You can specify the invocation log as your input data source and what filters to use to select the prompt-response pairs when you start a model distillation job. You can start model distillation job

in the Amazon Bedrock console, using the API, AWS CLI, or AWS SDK. For more information, see Submit a model distillation job in Amazon Bedrock.

Validate your dataset

Before you run your distillation job, you can validate your input dataset using a Python script.

Submit a model distillation job in Amazon Bedrock

You can perform model distillation through the Amazon Bedrock console or by sending a CreateModelCustomizationJob request with an Amazon Bedrock control plane endpoint.

Prerequisites

- Create an IAM service role with the required permissions. For comprehensive security and permissions information, see Model customization access and security.
- (Optional) Encrypt input and output data, your customization job, or inference requests made to custom models. For more information, see Encryption of custom models.
- (Optional) Create a Virtual Private Cloud (VPC) to protect your customization job. For more information, see (Optional) Protect your model customization jobs using a VPC.

For more information on setting up on demand inference, see Set up inference for a custom model.

Submit your job

Console

1. Sign in to the AWS Management Console with an IAM identity that has permissions to use the Amazon Bedrock console. Then, open the Amazon Bedrock console at https://console.aws.amazon.com/bedrock.
2. From the left navigation pane, choose **Custom models** under **Tune**.
3. Choose **Create distillation job**.
4. For **Distilled model details**, do the following:

    a. For **Distilled model name**, enter a name for your distilled model.

    b. (Optional) For **Model encryption**, select the checkbox if you want to provide a KMS key for encrypting your job and its related artifacts.

    For more information, see Encryption of custom models.

c. (Optional) Apply **Tags** to your distilled model.

5. For **Job configuration**, do the following:

   a. For **Job name**, enter a name for your distillation job.

   b. (Optional) For **Model encryption**, select the checkbox if you want to provide a KMS key for encrypting your job and its related artifacts.

      For more information, see Encryption of custom models.

   c. (Optional) Apply **Tags** to your job.

6. For **Teacher model – Student model details**, choose the teacher and student models for creating your distilled model.

   For more information, see Prerequisites for model distillation.

7. For **Synthetic data generation**, do the following:

   a. For **Max response length**, specify the maximum length of the synthetic responses generated by the teacher model.

   b. For **Distillation input dataset**, choose one of the following options:

      - **Directly upload to S3 location** – Specify the S3 location where you're storing the input dataset (prompts) that'll be used for distillation. For more information, see Option 1: Provide your own prompts for data preparation.
      - **Provide access to invocation logs** – Specify the S3 location where you're storing the invocation logs with the input dataset (prompts) that'll be used for distillation. For more information, see Option 2: Use invocation logs for data preparation.
        - (Optional) For **Request Metadata Filters**, specify filters if you want Amazon Bedrock to only use certain prompts in your logs for distillation.
        - Choose **Read prompts** or **Read prompt-response pairs** depending on what you want Amazon Bedrock to access from your logs. Keep in mind that responses are read only if your teacher model matches the model in your logs.

8. For **Distillation output**, specify the S3 location where you want to upload the metrics and reports about your distillation job.

   For more information, see Analyze the results of a model customization job.

9. For **VPC settings**, choose a VPC configuration for accessing the S3 bucket with your training data.

For more information, see (Optional) Protect your model customization jobs using a VPC.

10. For **Service access**, specify the IAM role for accessing the S3 bucket with your training data. Unless you use a Cross Region inference profile or VPC configurations, you can create the role in the Amazon Bedrock console with the correct permissions automatically configured. Or you can use an existing service role.

    For a job that has Amazon VPC configurations or uses a Cross Region inference profile, you must create a new service role in IAM that has the required permissions.

    For more information, see Create an IAM service role for model customization.
11. Choose **Create distillation job** to start the distillation job. After you customize a model, you can set up inference for the model. For more information, see Set up inference for a custom model.

API

At minimum, you must provide the following fields to submit your model distillation job when using the Amazon Bedrock API.

Field	Description
baseModelIdentifier	The model identifier of the student model
customModelName	The name of the new distilled model
jobName	The name of the model distillation job
roleArn	Role that gives Amazon Bedrock permissio ns to read training and validation files and write to the output path
trainingDataConfig	The Amazon S3 path that has your training data
outputDataConfig	The Amazon S3 path that contains your training and validation metrics
distillationConfig	Inputs required for distillation job

Field	Description
customModelKmsKeyId	To encrypt the custom model
clientRequestToken	Token to prevent the request from completin g more than once

The following fields are optional:

Field	Description
customizationType	Set to `DISTILLATION` by default for distillation jobs
validationDataConfig	List of validation data Amazon S3 paths
jobTags	To associate tags with the job
customModelTags	To associate tags with the resulting custom model
vpcConfig	VPC to protect your training data and distillation job

To prevent the request from completing more than once, include a `clientRequestToken`.

You can include the following optional fields for extra configurations.

- `jobTags` and/or `customModelTags` – Associate tags with the customization job or resulting custom model.
- `vpcConfig` – Include the configuration for a virtual private cloud (VPC) to protect your training data and customization job.

The following is an example snippet from CreateModelCustomizationJob API. This example uses the prompt-response pairs in the invocation log as the input data source and specifies the filter for selecting prompt-response pairs.

```
"trainingDataConfig": {
    "invocationLogsConfig": {
        "usePromptResponse": true,
        "invocationLogSource": {
            "s3Uri": "string"
        },
        "requestMetadataFilters": {
            "equals": {
                "priority": "High"
            }
        }
    }
}
```

Response

The response returns a `jobArn` of the model distillation job.

Next steps

- Monitor your distillation job. For more information on setting up on demand inference, see Set up inference for a custom model.

Clone a distillation job

You can use the Amazon Bedrock console to clone your distillation job. Clone your distillation job to run multiple jobs with similar settings. Use cloning to try again with a job that you stopped or had an issue. The new job inherits all settings except Service access configuration, any VPC settings, and any Tags.

1. Sign in to the AWS Management Console with an IAM identity that has permissions to use the Amazon Bedrock console. Then, open the Amazon Bedrock console at https://console.aws.amazon.com/bedrock.
2. From the left navigation pane, choose **Custom models** under **Tune**.
3. Choose the distillation job that you want to clone, then choose **Clone job**.
4. If needed, adjust your job's settings.
5. Choose **Create distillation job** to start the new job.

Import a pre-trained model into Amazon Bedrock

You can create a custom model in Amazon Bedrock by importing a model you customized in other environments, such as Amazon SageMaker AI. For example, you might have a model that you have created in Amazon SageMaker AI that has proprietary model weights. You can now import that model into Amazon Bedrock and then use Amazon Bedrock features to make inference calls to the model.

Amazon Bedrock provides two methods for importing custom models. You can import open-source foundation models that you customized, or you can import Amazon Nova models that you fine-tuned in SageMaker AI.

- **Import open-source models with custom model import jobs** — Choose this method to import customized open-source foundation models. For example, Mistral AI or Llama models. It supports on-demand inference and multiple customization patterns.
- **Import a customized Amazon Nova model by creating a custom model in Amazon Bedrock** — Choose this method to import an Amazon Nova model that you fine-tuned in SageMaker AI. It requires specialized SageMaker AI training recipes.

Topics

- Use Custom model import to import a customized open-source model into Amazon Bedrock
- Import a SageMaker AI-trained Amazon Nova model

Use Custom model import to import a customized open-source model into Amazon Bedrock

You can create a custom model in Amazon Bedrock by using the Amazon Bedrock Custom Model Import feature to import Foundation Models that you have customized in other environments, such as Amazon SageMaker AI. For example, you might have a model that you have created in Amazon SageMaker AI that has proprietary model weights. You can now import that model into Amazon Bedrock and then use Amazon Bedrock features to make inference calls to the model.

If you want to use a current open-weight model without customizing it yourself, check the Amazon Bedrock model catalog first. To see the models that are available to you, see models at a glance.

You can use a model that you import with on demand throughput. Use the InvokeModel or InvokeModelWithResponseStream operations to make inference calls to the model. For more information, see Submit a single prompt with InvokeModel.

Custom model import is supported in the following regions:

- eu-central-1
- us-east-1
- us-east-2
- us-west-2

> **Note**
>
> Make sure that your import and use of the models in Amazon Bedrock complies with the terms or licenses applicable to the models.
> You can't use Custom Model Import with the following Amazon Bedrock features.
>
> - Batch inference
> - CloudFormation

With Custom Model Import you can create a custom model that supports the following patterns.

- **Fine-tuned model** — You can customize the model weights using proprietary data, but retain the configuration of the base model.
- **Adaptation** You can customize the model to your domain for use cases where the model doesn't generalize well. Domain adaptation modifies a model to generalize for a target domain and deal with discrepancies across domains, such as a financial industry wanting to create a model which generalizes well on pricing. Another example is language adaptation. For example you could customize a model to generate responses in Portuguese or Tamil. Most often, this involves changes to the vocabulary of the model that you are using.
- **Pretrained from scratch** — In addition to customizing the weights and vocabulary of the model, you can also change model configuration parameters such as the number of attention heads, hidden layers, or context length.

For information regarding pricing for custom model import, select the Custom Model Import tab in the Model pricing details section of Amazon Bedrock pricing.

Topics

- Supported architectures
- Import a model source from Amazon S3
- Prerequisites for importing custom model
- Submit a model import job
- Invoke your imported model
- Handling Custom Chat Templates and Tokenizers
- Calculate the cost of running a custom model
- Code samples for custom model import

Supported architectures

The model you import must be in one of the following architectures.

- **Mistral** — A decoder-only Transformer based architecture with Sliding Window Attention (SWA) and options for Grouped Query Attention (GQA). For more information, see Mistral in the Hugging Face documentation.
- **Mixtral** — A decoder-only transformer model with sparse Mixture of Experts (MoE) models. For more information, see Mixtral in the Hugging Face documentation.
- **Flan** — An enhanced version of the T5 architecture, an encoder-decoder based transformer model. For more information, see Flan T5 in the Hugging Face documentation.
- **Llama 2, Llama3, Llama3.1, Llama3.2, Llama 3.3, and Mllama** — An improved version of Llama with Grouped Query Attention (GQA). For more information, see Llama 2, Llama 3, Llama 3.1, Llama 3.2, Llama 3.3, and Mllama in the Hugging Face documentation.
- **GPTBigCode** — An optimized version of GPT-2 with Multi-Query action. For more information, see GPTBigCode in the Hugging Face documentation.
- **Qwen2, Qwen2.5, Qwen2-VL, Qwen2.5-VL, Qwen3** — An LLM family with comprehensive multimodal perception and high speed vision encoding. Any model using the Qwen2, Qwen2-VL, and Qwen2.5-VL architectures can be imported. For Qwen3 architecture, only Qwen3ForCausalLM and Qwen3MoeForCausalLM are supported. Converse is also not supported

for Qwen3 models. For more information, see Qwen2, Qwen2.5, Qwen2-VL, Qwen2.5-VL, and Qwen3 in the Hugging Face documentation.

- **GPT-OSS** — OpenAI based GPT-OSS architecture. Amazon Bedrock supports both 20B and 120B based custom models. GPT-OSS model architecture is only supported in the US East (N. Virginia) region.

> **Note**
>
> - The size of the imported model weights must be less than 100GB for multimodal models and 200GB for text models.
> - The maximum positional embeddings or the maximum context length supported by the model should be less than 128K.
> - Amazon Bedrock supports transformer version 4.51.3. Make sure that you are using transformer version 4.51.3 when you fine tune your model.
> - Custom Model Import does not support embedding models.

Import a model source from Amazon S3

You import a model into Amazon Bedrock by creating a model import job in the Amazon Bedrock console or API. In the job you specify the Amazon S3 URI for the source of the model files. During model training, the import job automatically detects your model's architecture.

You need to supply the model files in the Hugging Face weights format. You can create the files by using the Hugging Face transformer library. To create model files for a Llama model, see convert_llama_weights_to_hf.py. To create the files for a Mistral AI model, see convert_mistral_weights_to_hf.py.

To import the model from Amazon S3, you minimally need the following files that the Hugging Face transformer library creates.

- **.safetensor** — the model weights in *Safetensor* format. Safetensors is a format created by Hugging Face that stores a model weights as tensors. You must store the tensors for your model in a file with the extension `.safetensors`. For more information, see Safetensors. For information about converting model weights to Safetensor format, see Convert weights to safetensors.

- **config.json** — For examples, see LlamaConfig and MistralConfig.

> **Note**
>
> Amazon Bedrock overrides llama3 `rope_scaling` value with the following values:
>
> - `original_max_position_embeddings=8192`
> - `high_freq_factor=4`
> - `low_freq_factor=1`
> - `factor=8`

- **tokenizer_config.json** For an example, see LlamaTokenizer.
- **tokenizer.json**
- **tokenizer.model**

Supported tokenizers

Amazon Bedrock Custom Model Import supports the following tokenizers. You can use these tokenizers with any model.

- T5Tokenizer
- T5TokenizerFast
- LlamaTokenizer
- LlamaTokenizerFast
- CodeLlamaTokenizer
- CodeLlamaTokenizerFast
- GPT2Tokenizer
- GPT2TokenizerFast
- GPTNeoXTokenizer
- GPTNeoXTokenizerFast
- PreTrainedTokenizer
- PreTrainedTokenizerFast
- Qwen2Tokenizer

- Qwen2TokenizerFast

Prerequisites for importing custom model

Before you can start a custom model import job, you need to fulfill the following prerequisites:

1. If you are importing your model from Amazon S3 bucket, prepare your model files in the Hugging Face weights format. For more information see, Import a model source from Amazon S3.
2. If you are using cross-account Amazon S3 or KMS keys, make sure to grant access to Amazon S3 bucket or the KMS key. For more information, see Cross-account access to Amazon S3 bucket for custom model import jobs.
3. (Optional) Create a custom AWS Identity and Access Management (IAM) service role with the proper permissions by following the instructions at Create a service role for importing pre-trained models to set up the role. You can skip this prerequisite if you plan to use the AWS Management Console to automatically create a service role for you.
4. (Optional) Set up extra security configurations.
   - You can encrypt input and output data, import jobs, or inference requests made to imported models. For more information see Encryption of custom model import.
   - You can create a virtual private cloud (VPC) to protect your customization jobs. For more information, see (Optional) Protect custom model import jobs using a VPC.

(Optional) Protect custom model import jobs using a VPC

When you run a custom model import job, the job accesses your Amazon S3 bucket to download the input data and to upload job metrics. To control access to your data, we recommend that you use a virtual private cloud (VPC) with Amazon VPC. You can further protect your data by configuring your VPC so that your data isn't available over the internet and instead creating a VPC interface endpoint with AWS PrivateLink to establish a private connection to your data. For more information about how Amazon VPC and AWS PrivateLink integrate with Amazon Bedrock, see Protect your data using Amazon VPC and AWS PrivateLink.

Carry out the following steps to configure and use a VPC for importing your custom models.

Topics

- Set up a VPC

- Create an Amazon S3 VPC Endpoint
- (Optional) Use IAM policies to restrict access to your S3 files
- Attach VPC permissions to a custom model import role.
- Add the VPC configuration when submitting a model import job

Set up a VPC

You can use a default VPC for your model import data or create a new VPC by following the guidance at Get started with Amazon VPC and Create a VPC.

When you create your VPC, we recommend that you use the default DNS settings for your endpoint route table, so that standard Amazon S3 URLs (for example, `http://s3-aws-region.amazonaws.com/`*`model-bucket`*) resolve.

Create an Amazon S3 VPC Endpoint

If you configure your VPC with no internet access, you need to create an Amazon S3 VPC endpoint to allow your model import jobs to access the S3 buckets that store your training and validation data and that will store the model artifacts.

Create the S3 VPC endpoint by following the steps at Create a gateway endpoint for Amazon S3.

> **Note**
>
> If you don't use the default DNS settings for your VPC, you need to ensure that the URLs for the locations of the data in your training jobs resolve by configuring the endpoint route tables. For information about VPC endpoint route tables, see Routing for Gateway endpoints.

(Optional) Use IAM policies to restrict access to your S3 files

You can use resource-based policies to more tightly control access to your S3 files. You can the following type of resource-based policy.

- **Endpoint policies** – Endpoint policies restrict access through the VPC endpoint. The default endpoint policy allows full access to Amazon S3 for any user or service in your VPC. While creating or after you create the endpoint, you can optionally attach a resource-based policy to the endpoint to add restrictions, such as only allowing the endpoint to access a specific bucket or

only allowing a specific IAM role to access the endpoint. For examples, see Edit the VPC endpoint policy.

The following is an example policy you can attach to your VPC endpoint to only allow it to access the bucket containing your model weights.

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Sid": "RestrictAccessToModelWeightsBucket",
            "Effect": "Allow",
            "Principal": "*",
            "Action": [
                "s3:GetObject",
                "s3:ListBucket"
            ],
            "Resource": [
                "arn:aws:s3:::model-weights-bucket",
                "arn:aws:s3:::model-weights-bucket/*"
            ]
        }
    ]
}
```

Attach VPC permissions to a custom model import role.

After you finish setting up your VPC and endpoint, you need to attach the following permissions to your model import IAM role. Modify this policy to allow access to only the VPC resources that your job needs. Replace the *subnet-ids* and *security-group-id* with the values from your VPC.

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
```

```
                "ec2:DescribeNetworkInterfaces",
                "ec2:DescribeVpcs",
                "ec2:DescribeDhcpOptions",
                "ec2:DescribeSubnets",
                "ec2:DescribeSecurityGroups"
            ],
            "Resource": "*"
        },
        {

                    ]
                }
            }
        }
    ]
```

```
}
```

Add the VPC configuration when submitting a model import job

After you configure the VPC and the required roles and permissions as described in the previous sections, you can create a model import job that uses this VPC.

When you specify the VPC subnets and security groups for a job, Amazon Bedrock creates *elastic network interfaces* (ENIs) that are associated with your security groups in one of the subnets. ENIs allow the Amazon Bedrock job to connect to resources in your VPC. For information about ENIs, see Elastic Network Interfaces in the *Amazon VPC User Guide*. Amazon Bedrock tags ENIs that it creates with `BedrockManaged` and `BedrockModelImportJobArn` tags.

We recommend that you provide at least one subnet in each Availability Zone.

You can use security groups to establish rules for controlling Amazon Bedrock access to your VPC resources.

You can configure the VPC to use in either the console or through the API. Choose the tab for your preferred method, and then follow the steps:

Console

For the Amazon Bedrock console, you specify VPC subnets and security groups in the optional **VPC settings** section when you create the model import job. For more information about configuring model import jobs, see Submit a model import job.

API

When you submit a CreateModelCustomizationJob request, you can include a `VpcConfig` as a request parameter to specify the VPC subnets and security groups to use, as in the following example.

```
"VpcConfig": {
"SecurityGroupIds": [
    "sg-0123456789abcdef0"
    ],
    "Subnets": [
          "subnet-0123456789abcdef0",
          "subnet-0123456789abcdef1",
```

```
            "subnet-0123456789abcdef2"
        ]
    }
```

Submit a model import job

You import a model into Amazon Bedrock by submitting a model import job in the Amazon Bedrock console, using the API, using the AWS CLI or using AWS SDK. In the job you specify the Amazon S3 URI for the source of the model files. Alternatively, if you've created the model in Amazon SageMaker AI, you can specify the SageMaker AI model. During model import, the import job automatically detects your model's architecture. The model import job can take several minutes. During the job, Amazon Bedrock validates that the model that is being imported is using a compatible the model architecture.

The following procedure shows you how to create a custom model by importing a model that you have already customized. Select the tab corresponding to your method of choice and follow the steps.

Console

To submit a model import job in the console, complete the following steps.

1. If you are importing your model files from Amazon S3, convert the model to the Hugging Face format.
   a. If your model is a Mistral AI model, use convert_mistral_weights_to_hf.py.
   b. If your model is a Llama model, see convert_llama_weights_to_hf.py.
   c. Upload the model files to an Amazon S3 bucket in your AWS account. For more information, see Upload an object to your bucket.
   d. If you are using cross-account Amazon S3 or KMS keys to import your custom model, give Amazon Bedrock access to your AWS account's Amazon S3 or KMS key. For more information, see Cross-account access to Amazon S3 bucket for custom model import jobs.
2. In the Amazon Bedrock console, choose **Imported models** under **Foundation models** from the left navigation pane.
3. Choose the **Models** tab.
4. Choose **Import model**.

5. In the **Imported** tab, choose **Import model** to open the **Import model** page.
6. In the **Model details** section, do the following:
   a. In **Model name** enter a name for the model.
   b. (Optional) To associate tags with the model, expand the **Tags** section and select **Add new tag**.
7. In the **Import job name** section, do the following:
   a. In **Job name** enter a name for the model import job.
   b. (Optional) To associate tags with the custom model, expand the **Tags** section and select **Add new tag**.
8. In **Model import settings**, select the import options you want to use.
   - Select **Amazon S3 bucket** or **Amazon SageMaker AI model** to specify the import source.
   - If you are importing your model files from an Amazon S3 bucket, enter the Amazon S3 location in **S3 location**. Optionally, you can choose **Browse S3** to choose the file location.
   - If you are importing your model from Amazon SageMaker AI, choose **Amazon SageMaker AI model** and then choose the SageMaker AI model that you want to import in **SageMaker AI models**.
9. Enter **VPC settings** (optional) to choose a VPC configuration to access your Amazon Amazon S3 data source located in your VPC. You can create and manage a VPC, subnets, and security groups in Amazon VPC. For more information on Amazon VPC, see (Optional) Protect custom model import jobs using a VPC.
10. Select **Encryption**, to encrypt your data by default with an AWS key that is owned and managed by you. You can also choose a different key if you select **Customize encryption settings (advanced).**.
11. In the **Service access** section, select one of the following:
    - **Create and use a new service role** – Enter a name for the service role.
    - **Use an existing service role** – Select a service role from the drop-down list. To see the permissions that your existing service role needs, choose **View permission details**.

      For more information on setting up a service role with the appropriate permissions, see Create a service role for importing pre-trained models.

> **Note**
>
> if you are using cross-account Amazon S3 or KMS keys, edit the service role policy and replace the account id specified for `aws:ResourceAccount` with the AWS account id of the bucket owner.

12. Choose **Import**.
13. On the **Custom models** page, choose **Imported**.
14. In the **Jobs** section, check the status of the import job. The model name you chose identifies the model import job. The job is complete if the value of **Status** for the model is **Complete**.
15. Get the model ID for your model by doing the following.
    a. On the **Imported models** page, choose the **Models** tab.
    b. Copy the ARN for the model that you want to use from the **ARN** column.
16. Use your model for inference calls. For more information, see Submit a single prompt with InvokeModel. You can use the model with on demand throughput.

    You can also use your model in the Amazon Bedrock text playground.

API

Request

Send a CreateModelImportJob (see link for request and response format and field details) request with an Amazon Bedrock control plane endpoint to submit a custom model import job. Minimally, you must provide the following fields.

- `roleArn` – The ARN of the service role with permissions to import models. Amazon Bedrock can automatically create a role with the appropriate permissions if you use the console, or you can create a custom role by following the steps at Create a service role for importing pre-trained models.

> **Note**
>
> If you include a `vpcConfig` field, make sure that the role has the proper permissions to access the VPC. For an example, see Attach VPC permissions to a custom model import role.

- `importedModelName` – The name to give the newly imported model.
- `jobName` – The name to give the import job.
- `modelDataSource` – The data source for the imported model.

To prevent the request from completing more than once, include a `clientRequestToken`.

You can include the following optional fields for extra configurations.

- `jobTags` and/or `importedModelTags` – Associate tags with the import job or the imported model.
- `importedModelKmsKeyId` – Include a Encryption of custom model import KMS key to encrypt your imported model.
- `vpcConfig` – Include the vpc configuration to (Optional) Protect custom model import jobs using a VPC.

Response

The response returns a `jobArn` for the import job that you use to identify the import job in other operations.

The import job will take a while to complete. You can check the current status by calling the GetModelImportJob operation and checking the `Status` field in the response. You can list the current import jobs with the ListModelImportJobs.

To get a list of models that you have imported, call ListImportedModels. To get information about a specific imported model, call GetImportedModel.

To delete an imported model, call DeleteImportedModel.

Invoke your imported model

The model import job can take several minutes to import your model after you send CreateModelImportJob request. You can check the status of your import job in the console or by calling the GetModelImportJob operation and checking the `Status` field in the response. The import job is complete if the Status for the model is **Complete**.

After your imported model is available in Amazon Bedrock, you can use the model with on demand throughput by sending InvokeModel or InvokeModelWithResponseStream requests to make inference calls to the model. For more information, see Submit a single prompt with InvokeModel.

To interface with your imported model using the messages format, you can call the Converse or ConverseStream operations. For more information, see Using the Converse API.

> **Note**
>
> Converse API is not supported for Qwen2.5, Qwen2-VL, Qwen2.5-VL, and GPT-OSS models.

Enhanced API Support: Multiple API Formats

Starting November 17, 2025, Amazon Bedrock Custom Model Import supports comprehensive OpenAI-compatible API formats, providing flexibility in how you integrate and deploy your custom models. All models imported after November 11, 2025, will automatically benefit from these enhanced capabilities with no additional configuration required.

Custom Model Import now supports three API formats:

- **BedrockCompletion (Text)** - Compatible with current Bedrock workflows
- **OpenAICompletion (Text)** - OpenAI Completions Schema compatibility
- **OpenAIChatCompletion (Text and Images)** - Full conversational Schema compatibility

These enhanced capabilities include structured outputs for enforcing JSON schemas and patterns, enhanced vision support with multi-image processing, log probabilities for model confidence insights, and tool calling capabilities for GPT-OSS models.

For detailed API reference documentation, see the official OpenAI documentation:

- Completion: OpenAI Completions API

- ChatCompletion: OpenAI Chat API

API Format Examples

The following examples demonstrate how to use each of the four supported API formats with your imported models.

BedrockCompletion

BedrockCompletion format is compatible with current Bedrock workflows and supports text-based inference requests.

Example request:

```
import json
import boto3

client = boto3.client('bedrock-runtime', region_name='us-east-1')

payload = {
    "prompt": "How is the rainbow formed?",
    "max_gen_len": 100,
    "temperature": 0.5
}

response = client.invoke_model(
    modelId='your-model-arn',
    body=json.dumps(payload),
    accept='application/json',
    contentType='application/json'
)

response_body = json.loads(response['body'].read())
```

Example response:

```
{
    "generation": " - A scientific explanation\nA rainbow is a beautiful natural
 phenomenon that occurs when sunlight passes through water droplets in the air. It
 is formed through a process called refraction, which is the bending of light as
 it passes from one medium to another.\nHere's a step-by-step explanation of how a
 rainbow is formed:\n1. Sunlight enters the Earth's atmosphere: The first step in
```

```
 forming a rainbow is for sunlight to enter the Earth's atmosphere. This sunlight is
 made up of a spectrum of",
    "prompt_token_count": 7,
    "generation_token_count": 100,
    "stop_reason": "length",
    "logprobs": null
}
```

BedrockCompletion supports structured outputs using `response_format` parameter with `json_object` and `json_schema` types.

OpenAICompletion

OpenAICompletion format provides OpenAI Completions Schema compatibility. To use this format, include the `max_tokens` parameter instead of `max_gen_len`.

Example request:

```
import json
import boto3

client = boto3.client('bedrock-runtime', region_name='us-east-1')

payload = {
    "prompt": "How is the rainbow formed?",
    "max_tokens": 100,
    "temperature": 0.5
}

response = client.invoke_model(
    modelId='your-model-arn',
    body=json.dumps(payload),
    accept='application/json',
    contentType='application/json'
)

response_body = json.loads(response['body'].read())
```

Example response:

```
{
    "id": "cmpl-b09d5810bd64428f8a853be71c31f912",
```

```
    "object": "text_completion",
    "created": 1763166682,
    "choices": [
        {
            "index": 0,
            "text": " The formation of a rainbow is a complex process that involves
 the interaction of sunlight with water droplets in the air. Here's a simplified
 explanation: 1. Sunlight enters the Earth's atmosphere and is refracted, or bent,
 as it passes through the air. 2. When sunlight encounters a water droplet, such as
 a cloud, mist, or fog, it is refracted again and split into its individual colors,
 a process known as dispersion. 3. The refracted and",
            "finish_reason": "length"
        }
    ],
    "usage": {
        "prompt_tokens": 7,
        "total_tokens": 107,
        "completion_tokens": 100
    }
}
```

OpenAICompletion supports full structured outputs capabilities including `json`, `regex`, `choice`, and `grammar` constraints using the `structured_outputs` parameter.

OpenAIChatCompletion

OpenAIChatCompletion format provides full conversational Schema compatibility and supports both text and image inputs.

Example request:

```
import json
import boto3

client = boto3.client('bedrock-runtime', region_name='us-east-1')

payload = {
    "messages": [
        {
            "role": "user",
            "content": "How is the rainbow formed?"
        }
    ],
```

```
    "max_tokens": 100,
    "temperature": 0.5
}

response = client.invoke_model(
    modelId='your-model-arn',
    body=json.dumps(payload),
    accept='application/json',
    contentType='application/json'
)

response_body = json.loads(response['body'].read())
```

Example response:

```
{
    "id": "chatcmpl-1d84ce1d3d61418e8c6d1973f87173db",
    "object": "chat.completion",
    "created": 1763166683,
    "choices": [
        {
            "index": 0,
            "message": {
                "role": "assistant",
                "content": "A rainbow is a beautiful natural phenomenon that occurs
 when sunlight passes through water droplets in the air. The process of forming a
 rainbow involves several steps:\n\n1. **Sunlight**: The first requirement for a
 rainbow is sunlight. The sun should be shining brightly, but not directly overhead.
\n2. **Water droplets**: The second requirement is water droplets in the air..."
            },
            "finish_reason": "length"
        }
    ],
    "usage": {
        "prompt_tokens": 41,
        "completion_tokens": 100,
        "total_tokens": 141
    }
}
```

OpenAIChatCompletion supports structured outputs using both `response_format` and `structured_outputs` parameters. For vision capabilities, include images in the content array with base64-encoded image data.

> **Note**
>
> To use ChatCompletion format, the chat template needs to be part of the `tokenizer_config.json`. Custom Model Import will not apply any default chat templates to the request.

Advanced API features for imported models

This page provides detailed examples of advanced features available for models imported after November 11, 2025. These capabilities include structured outputs for controlled generation, enhanced vision support for multi-image processing, log probabilities for confidence insights, and tool calling for GPT-OSS models.

Structured Outputs

Structured outputs enable controlled generation following specific formats, schemas, or patterns. This feature ensures that the model's response adheres to predefined constraints, making it ideal for applications requiring consistent data formats, API integrations, or automated processing pipelines.

Structured outputs on Custom Model Import are supported through two parameters:

- `response_format` - Supports `json_object` and `json_schema` types
- `structured_outputs` - Supports `json`, `regex`, `choice`, and `grammar` types

> **Note**
>
> When using structured outputs on Custom Model Import, customers should expect performance trade-offs due to constraint validation during generation. Simple constraints like `choice` and `json_object` have minimal impact, while complex constraints like `json_schema` and `grammar` can significantly increase latency and reduce throughput. For optimal performance, use simpler constraint types when possible and keep schemas flat rather than deeply nested.

The following examples demonstrate structured outputs support across different API formats. The Pydantic model definition is:

```
from pydantic import BaseModel
from enum import Enum

class CarType(str, Enum):
    sedan = "sedan"
    suv = "SUV"
    truck = "Truck"
    coupe = "Coupe"

class CarDescription(BaseModel):
    brand: str
    model: str
    car_type: CarType
```

BedrockCompletion

BedrockCompletion supports structured outputs using the `response_format` parameter with `json_object` and `json_schema` types only.

Example: JSON Schema

```
payload = {
    "prompt": "Generate a JSON with the brand, model and car_type of the most iconic
 car from the 90's",
    "response_format": {
        "type": "json_schema",
        "json_schema": CarDescription.model_json_schema()
    }
}

response = client.invoke_model(
    modelId='your-model-arn',
    body=json.dumps(payload),
    accept='application/json',
    contentType='application/json'
)

response_body = json.loads(response['body'].read())
```

Example response:

```
{
```

```
    "generation": "{\n    \"brand\": \"Ferrari\",\n    \"model\": \"F40\",\n
 \"car_type\": \"SUV\"\n  }",
    "prompt_token_count": 22,
    "generation_token_count": 30,
    "stop_reason": "stop",
    "logprobs": null
}
```

OpenAICompletion

OpenAICompletion supports both `response_format` (json_object, json_schema) and `structured_outputs` (json, regex, choice, grammar) parameters. Use `max_tokens` instead of `max_gen_len` to route requests to OpenAICompletion.

Example: Structured Outputs - Choice

```
payload = {
    "prompt": "Classify the sentiment of this sentence. Amazon Bedrock CMI is
 Amazing!",
    "max_tokens": 10,
    "structured_outputs": {
        "choice": ["positive", "negative"]
    }
}

response = client.invoke_model(
    modelId='your-model-arn',
    body=json.dumps(payload),
    accept='application/json',
    contentType='application/json'
)

response_body = json.loads(response['body'].read())
```

Example response:

```
{
    "id": "cmpl-01f94c4652d24870bbb4d5418a01c384",
    "object": "text_completion",
    "choices": [
        {
            "index": 0,
            "text": "positive",
```

```
            "finish_reason": "stop"
        }
    ],
    "usage": {
        "prompt_tokens": 17,
        "completion_tokens": 4
    }
}
```

OpenAIChatCompletion

OpenAIChatCompletion supports both `response_format` (json_object, json_schema) and `structured_outputs` (json, regex, choice, grammar) parameters.

Example: Response Format - JSON Schema

```
payload = {
    "messages": [
        {"role": "user", "content": "Generate a JSON with the brand, model and
 car_type of the most iconic car from the 90's"}
    ],
    "max_tokens": 100,
    "response_format": {
        "type": "json_schema",
        "json_schema": {
            "name": "car-description",
            "schema": CarDescription.model_json_schema()
        }
    }
}

response = client.invoke_model(
    modelId='your-model-arn',
    body=json.dumps(payload),
    accept='application/json',
    contentType='application/json'
)

response_body = json.loads(response['body'].read())
```

Example response:

```
{
```

```
    "id": "chatcmpl-cae5a43b0a924b8eb434510cbf978a19",
    "object": "chat.completion",
    "choices": [
        {
            "index": 0,
            "message": {
                "role": "assistant",
                "content": "{\"brand\": \"Dodge\", \"model\": \"Viper\", \"car_type
\": \"Coupe\"}"
            },
            "finish_reason": "stop"
        }
    ],
    "usage": {
        "prompt_tokens": 56,
        "completion_tokens": 23
    }
}
```

Vision Support

Vision capabilities enable processing of images alongside text inputs, with enhanced multi-image support for complex visual analysis tasks. Custom Model Import now supports up to 3 images per request, enhanced from previous single-image limitation.

Supported API: OpenAIChatCompletion only. All models imported after November 11, 2025 will default to this API for vision capabilities.

Image Requirements:

- Base64 encoding required - Image URLs will cause request failures
- Maximum 3 images per request
- High resolution images significantly increase processing time and memory usage

> **Warning**
>
> High resolution images significantly increase processing time, memory usage, and may cause timeout errors. Multiple high-resolution images compound performance impact

exponentially. For optimal performance, resize images appropriately and use lower detail levels when possible.

OpenAIChatCompletion

Example: Multi-Image Processing

```
import json
import boto3
import base64

client = boto3.client('bedrock-runtime', region_name='us-east-1')

# Load and encode images
with open('/path/to/car_image_1.jpg', 'rb') as f:
    image_data_1 = base64.b64encode(f.read()).decode('utf-8')

with open('/path/to/car_image_2.jpg', 'rb') as f:
    image_data_2 = base64.b64encode(f.read()).decode('utf-8')

payload = {
    "messages": [
        {
            "role": "system",
            "content": "You are a helpful assistant that can analyze images."
        },
        {
            "role": "user",
            "content": [
                {
                    "type": "text",
                    "text": "Spot the difference between the two images?"
                },
                {
                    "type": "image_url",
                    "image_url": {
                        "url": f"{image_data_1}"
                    }
                },
                {
                    "type": "image_url",
                    "image_url": {
```

```
                        "url": f"{image_data_2}"
                    }
                }
            ]
        }
    ],
    "max_tokens": 300,
    "temperature": 0.5
}

response = client.invoke_model(
    modelId='your-model-arn',
    body=json.dumps(payload),
    accept='application/json',
    contentType='application/json'
)

response_body = json.loads(response['body'].read())
```

Example response:

```
{
    "id": "chatcmpl-ccae8a67e62f4014a9ffcbedfff96f44",
    "object": "chat.completion",
    "created": 1763167018,
    "model": "667387627229-g6vkuhd609s4",
    "choices": [
        {
            "index": 0,
            "message": {
                "role": "assistant",
                "content": "There are no differences between the two images
 provided. They appear to be identical.",
                "refusal": null,
                "annotations": null,
                "audio": null,
                "function_call": null,
                "tool_calls": [],
                "reasoning_content": null
            },
            "logprobs": null,
            "finish_reason": "stop",
            "stop_reason": null,
```

```
            "token_ids": null
        }
    ],
    "service_tier": null,
    "system_fingerprint": null,
    "usage": {
        "prompt_tokens": 2795,
        "total_tokens": 2812,
        "completion_tokens": 17,
        "prompt_tokens_details": null
    },
    "prompt_logprobs": null,
    "prompt_token_ids": null,
    "kv_transfer_params": null
}
```

Log Probabilities

Log probabilities represent the likelihood of each token in a sequence, calculated as log(p) where p is the probability of a token at any position given its previous token in the context. Since log probs are additive, sequence probability equals the sum of individual token log probs, making them useful for ranking generations by average per-token scores. Custom Model Import will always return the raw logprob values for requested tokens.

Key applications include classification tasks where log probs enable custom confidence thresholds, retrieval Q&A systems that use confidence scores to reduce hallucinations, autocomplete suggestions based on token likelihood, and perplexity calculations for comparing model performance across prompts. Log probs also provide token-level analysis capabilities, allowing developers to examine alternative tokens the model considered.

> **Note**
>
> Logprobs are not cached. For a request requiring prompt logprobs, the system will ignore the prefix cache and recompute the prefill of full prompt to generate the logprobs. This presents an obvious performance tradeoff when using logprobs.

Log probability support varies by API format:

- BedrockCompletion - Output tokens only

- OpenAICompletion - Prompt and output tokens
- OpenAIChatCompletion - Prompt and output tokens

BedrockCompletion

BedrockCompletion only supports output token logprobs. This will return top 1 logprob for each output token.

```
payload = {
    "prompt": "How is the rainbow formed?",
    "max_gen_len": 10,
    "temperature": 0.5,
    "return_logprobs": True
}

response = client.invoke_model(
    modelId='your-model-arn',
    body=json.dumps(payload),
    accept='application/json',
    contentType='application/json'
)

response_body = json.loads(response['body'].read())
```

Example response (truncated):

```
{
    "generation": " A rainbow is formed when sunlight passes through water dro",
    "prompt_token_count": 7,
    "generation_token_count": 10,
    "stop_reason": "length",
    "logprobs": [
        {
            "362": -2.1413702964782715
        },
        {
            "48713": -0.8180374503135681
        },
        {
            "374": -0.09657637774944305
        },
        ...
```

```
    ]
}
```

OpenAIChatCompletion

OpenAIChatCompletion supports both prompt and output token logprobs. You can set `top_logprobs=N` and `prompt_logprobs=N` where N is an integer representing log probabilities for the N most likely tokens at each position.

```
payload = {
    "messages": [
        {
            "role": "user",
            "content": "How is the rainbow formed?"
        }
    ],
    "max_tokens": 10,
    "temperature": 0.5,
    "logprobs": True,
    "top_logprobs": 1,
    "prompt_logprobs": 1
}

response = client.invoke_model(
    modelId='your-model-arn',
    body=json.dumps(payload),
    accept='application/json',
    contentType='application/json'
)

response_body = json.loads(response['body'].read())
```

Example response (truncated):

```
{
    "id": "chatcmpl-xxx",
    "object": "chat.completion",
    "choices": [
        {
            "index": 0,
            "message": {
                "role": "assistant",
                "content": "A rainbow is formed..."
```

```
            },
            "logprobs": {

            "finish_reason": "length"
        }
    ],
    "usage": {
        "prompt_tokens": 41,
        "completion_tokens": 10,
        "total_tokens": 51
    }
}
```

You'll need the model ARN to make inference calls to your newly imported model. After the successful completion of the import job and after your imported model is active, you can get the model ARN of your imported model in the console or by sending a ListImportedModels request.

When you invoke your imported model using `InvokeModel` or `InvokeModelWithStream`, your request is served within 5 minutes or you might get `ModelNotReadyException`. To understand the ModelNotReadyException, follow the steps in this next section for handling ModelNotreadyException.

Frequently Asked Questions

Q: What API format should I use?

A: For maximum compatibility with various SDKs, we recommend using OpenAICompletion or OpenAIChatCompletion formats as they provide OpenAI-compatible schemas that are widely supported across different tools and libraries.

Q: Does GPT-OSS on Amazon Bedrock Custom Model Import support the Converse API?

A: No. GPT-OSS based custom model import models do not support the Converse API or ConverseStream API. You must use the InvokeModel API with OpenAI-compatible schemas when working with GPT-OSS based custom models.

Q: What models support tool calling?

A: GPT-OSS based custom models support tool calling capabilities. Tool calling enables function calling for complex workflows.

Q: What about models imported before November 11, 2025?

A: Models imported before November 11, 2025, continue to work as is with their existing API formats and capabilities.

Q: What about `generation_config.json` for OpenAI-based models?

A: It is critical that you include the correct `generation_config.json` file when importing OpenAI-based models such as GPT-OSS. You must use the updated configuration file (updated August 13, 2024) available at https://huggingface.co/openai/gpt-oss-20b/blob/main/generation_config.json. The updated configuration includes three end-of-sequence token IDs (`[200002, 199999, 200012]`), whereas older versions only included two tokens (`[200002, 199999]`). Using an outdated `generation_config.json` file will cause runtime errors during model invocation. This file is essential for proper model behavior and must be included with your OpenAI-based model imports.

Handling ModelNotReadyException

Amazon Bedrock Custom Model Import optimizes the hardware use by removing the models that are not active. If you try to invoke a model that has been removed, you'll get a `ModelNotReadyException`. After the model is removed and you invoke the model for the first

time, Custom Model Import starts to restore the model. The restoration time depends on the on-demand fleet size and the model size.

If your `InvokeModel` or `InvokeModelWithStream` request returns `ModelNotReadyException`, follow the steps to handle the exception.

1. **Configure retries**

   By default, the request is automatically retried with exponential backoff. You can configure the maximum number of retries.

   The following example shows how to configure the retry. Replace *`${region-name}`*, *`${model-arn}`*, and *`10`* with your Region, model ARN, and maximum attempts.

```
import json
import boto3
from botocore.config import Config

REGION_NAME = ${region-name}
MODEL_ID= '${model-arn}'

config = Config(
    retries={
        'total_max_attempts': 10, //customizable
        'mode': 'standard'
    }
)
message = "Hello"

session = boto3.session.Session()
br_runtime = session.client(service_name = 'bedrock-runtime',
                                region_name=REGION_NAME,
                                config=config)

try:
    invoke_response = br_runtime.invoke_model(modelId=MODEL_ID,
                                              body=json.dumps({'prompt': message}),
                                              accept="application/json",
                                              contentType="application/json")
    invoke_response["body"] =
 json.loads(invoke_response["body"].read().decode("utf-8"))
```

```
    print(json.dumps(invoke_response, indent=4))
except Exception as e:
    print(e)
    print(e.__repr__())
```

2. **Monitor response codes during retry attempts**

   Each retry attempt starts model restoration process. The restoration time depends on the availability of the on-demand fleet and the model size. Monitor the response codes while the restoration process is going on.

   If the retries are consistently failing, continue with the next steps.

3. **Verify model was successfully imported**

   You can verify if the model was successfully imported by checking the status of your import job in the console or by calling the GetModelImportJob operation. Check the `Status` field in the response. The import job is successful if the Status for the model is **Complete**.

4. **Contact Support for further investigation**

   Open a ticket with Support For more information, see Creating support cases.

   Include relevant details such as model ID and timestamps in the support ticket.

Handling Custom Chat Templates and Tokenizers

Custom chat templates and tokenizers are essential components for properly formatting conversational inputs and managing token generation in your imported models. Custom Model Import supports importing models with custom chat templates that define how multi-turn conversations are structured and tokenized.

Importing Models with Custom Chat Templates

When importing a model with custom chat templates, make sure that you follow the best practices outlined in the main Custom Model Import documentation, including bringing in model weights in safe tensors format and providing all necessary configuration files.

Chat Template Format Requirements

If your model uses a custom chat template and you want to use that template with Amazon Bedrock, you must include the chat template file in one of the following formats:

- **`chat_template.jinja`** — A Jinja2-based template file that defines how messages are formatted.
- **`chat_template.json`** — A JSON file containing the chat template as a string value.
- **`tokenizer_config.json` with embedded chat template** — Alternatively, you can include the chat template directly within your `tokenizer_config.json` file as a `chat_template` field. For an example, see the Hermes-2-Pro tokenizer_config.json on Hugging Face.

Custom Model Import will automatically process these files and include them in the correct directories during the import process.

Chat Template Precedence

If you provide multiple chat template sources, Amazon Bedrock applies the following precedence rules:

1. **Separate chat template files take precedence** — If you include both a separate chat template file (`chat_template.jinja` or `chat_template.json`) AND a `chat_template` field in your `tokenizer_config.json`, the separate file will be used and the embedded template in `tokenizer_config.json` will be ignored.
2. **Embedded template as fallback** — If you do not provide a separate chat template file, Amazon Bedrock will use the `chat_template` field from your `tokenizer_config.json` if present.

> **Warning**
>
> **Choose one approach:** To avoid confusion and ensure predictable behavior, we strongly recommend using only ONE of these approaches:
>
> - **Option 1:** Provide separate chat template files (`chat_template.jinja` or `chat_template.json`) without including a `chat_template` field in your `tokenizer_config.json`.
> - **Option 2:** Include the `chat_template` field directly in your `tokenizer_config.json` and do not provide separate template files.

If you have custom tool templates or complex chat template configurations, we recommend using Option 2 (embedding the template in `tokenizer_config.json`) as it allows you to define multiple named templates (such as "default" and "tool_use") within a single configuration file.

Note

The chat template file must follow the Hugging Face format and naming conventions. Make sure that your template is compatible with the Transformers library.

Chat Template Format Examples

Here are examples of the two supported chat template formats:

Jinja Format (chat_template.jinja)

A simplified example of a Jinja2-based chat template:

```
{% for message in messages %}
{% if loop.first and message['role'] != 'system' %}
<|im_start|>system
You are a helpful assistant.<|im_end|>
{% endif %}
<|im_start|>{{ message['role'] }}
{{ message['content'] }}<|im_end|>
{% endfor %}
{% if add_generation_prompt %}
<|im_start|>assistant
{% endif %}
```

For a complete example, see the GPT-OSS chat template on Hugging Face.

JSON Format (chat_template.json)

A simplified example of a JSON-based chat template with vision support:

```
{
```

```
    "chat_template": "{% for message in messages %}{% if loop.first and
 message['role'] != 'system' %}<|im_start|>system\nYou are a helpful assistant.<|
im_end|>\n{% endif %}<|im_start|>{{ message['role'] }}\n{% if message['content']
 is string %}{{ message['content'] }}<|im_end|>\n{% else %}{% for content in
 message['content'] %}{% if content['type'] == 'image' %}<|vision_start|><|
image_pad|><|vision_end|>{% elif 'text' in content %}{{ content['text'] }}{% endif
 %}{% endfor %}<|im_end|>\n{% endif %}{% endfor %}{% if add_generation_prompt %}<|
im_start|>assistant\n{% endif %}"
}
```

For a complete example with multimodal support, see the Qwen2-VL chat template on Hugging Face.

Important

Make sure that your chat template file follows the exact naming convention (`chat_template.jinja` or `chat_template.json`) and format shown in the examples above. Incorrectly formatted templates may cause import or inference failures.

Invoking Models with Custom Chat Templates

Once you have imported a model with a custom chat template, you have two options for invoking the model with properly formatted conversational inputs:

Using OpenAI ChatCompletion API with Messages

If you are providing inputs in the messages schema format, you should use the **OpenAI ChatCompletion API**. When you use this API format with a model that has an uploaded chat template (`chat_template.jinja` or `chat_template.json`), Amazon Bedrock will automatically convert your input messages into the correct format using the chat template.

This is the recommended approach as it provides the most seamless integration and allows Amazon Bedrock to handle the chat template application automatically.

Example: Using OpenAI ChatCompletion API with custom chat template

```
import json
import boto3
```

```
# Initialize Bedrock Runtime client
client = boto3.client('bedrock-runtime', region_name='us-east-1')

# Define the model ARN for your imported model with custom chat template
model_id = 'arn:aws:bedrock:us-east-1:123456789012:imported-model/your-model-id'

# Prepare the request payload using messages format
payload = {
    "messages": [
        {
            "role": "system",
            "content": "You are a helpful assistant."
        },
        {
            "role": "user",
            "content": "Hello, how are you?"
        }
    ],
    "max_tokens": 150,
    "temperature": 0.7
}

# Invoke the model
response = client.invoke_model(
    modelId=model_id,
    body=json.dumps(payload),
    accept='application/json',
    contentType='application/json'
)

# Parse and display the response
response_body = json.loads(response['body'].read())
print(json.dumps(response_body, indent=2))
```

In this example, Amazon Bedrock will automatically apply your custom chat template to the messages array, converting it into the appropriate format for your model.

Manual Tokenization Approach

Alternatively, if you prefer to have full control over the chat template application and tokenization process, you can manually apply the chat template to your conversation and then use the **Completion API** (not ChatCompletion) with the pre-formatted text.

This approach is useful when you need to customize the template application logic or when working with specialized tokenization requirements.

Step 1: Apply Chat Template Locally

Use the following code snippet to load your custom chat template and apply it to a conversation locally:

```
from transformers import AutoTokenizer

# Configuration paths - update these with your actual paths
TOKENIZER_PATH = ""  # Path to tokenizer directory

# Load tokenizer with updated chat template
tokenizer = AutoTokenizer.from_pretrained(TOKENIZER_PATH)

# Test chat template with sample conversation
chat_history = [
    {"role": "system", "content": "You are a helpful assistant."},
    {"role": "user", "content": "Hello, how are you?"},
]

# Apply chat template and display formatted output to make sure chat template works as
 expected
formatted_chat = tokenizer.apply_chat_template(chat_history, tokenize=False)
print(formatted_chat)
```

This code demonstrates how to:

1. Load your tokenizer configuration from the model files
2. Add the custom chat template to the tokenizer configuration
3. Apply the chat template to a conversation history
4. Generate the formatted text that can be sent to the model

Step 2: Invoke with Completion API

After applying the chat template locally, use the formatted text with the Completion API:

```
import json
```

```
import boto3

# Initialize Bedrock Runtime client
client = boto3.client('bedrock-runtime', region_name='us-east-1')

# Define the model ARN for your imported model
model_id = 'arn:aws:bedrock:us-east-1:123456789012:imported-model/your-model-id'

# Use the formatted_chat output from Step 1 as the prompt
payload = {
    "prompt": formatted_chat,
    "max_tokens": 150,
    "temperature": 0.7
}

# Invoke the model using Completion format (not ChatCompletion)
response = client.invoke_model(
    modelId=model_id,
    body=json.dumps(payload),
    accept='application/json',
    contentType='application/json'
)

# Parse and display the response
response_body = json.loads(response['body'].read())
print(json.dumps(response_body, indent=2))
```

Warning

Always use `max_tokens` parameter: When using the Completion API with custom model imports, always use the `max_tokens` parameter to ensure OpenAI completion schema compatibility. This avoids any translation confusion and ensures consistent behavior across different SDK implementations. Do not use model-specific parameter names like `max_gen_len` or similar variants.

Important

When using the manual tokenization approach, you must use the **Completion API** format (with `prompt` field), not the ChatCompletion API format (with `messages` field). The

ChatCompletion API expects raw messages and will attempt to apply the chat template again, resulting in incorrect formatting.

Best Practices

- **Use ChatCompletion API when possible** — The OpenAI ChatCompletion API with messages format provides the most seamless experience and allows Amazon Bedrock to handle chat template application automatically.
- **Validate your chat template** — Before importing your model, test your chat template locally using the Transformers library to ensure it produces the expected output format.
- **Include all special tokens** — Ensure your chat template includes all necessary special tokens (such as beginning-of-sequence, end-of-sequence, and role markers) that your model expects.
- **Test with multi-turn conversations** — Validate that your chat template correctly handles multi-turn conversations with alternating user and assistant messages.
- **Consider vision support** — If your model supports multimodal inputs, make sure your chat template includes logic for handling image and video content markers.

Warning

Incorrectly formatted chat templates can result in poor model performance, unexpected outputs, or inference failures. Always test your chat template thoroughly before deploying to production.

Calculate the cost of running a custom model

You are charged for running inference with custom models that you import into Amazon Bedrock. Use the following information to estimate the cost of running a custom model.

A Custom Model Unit (CMU) is an abstract view of the hardware use that Amazon Bedrock needs to host a a single copy of your custom model. A model copy represents a single instance of your imported model that is ready to serve inference requests. Amazon Bedrock determines the number of custom model units that a model copy needs when you import the custom model. As inference demand changes, Amazon Bedrock can increase or decrease the number of running model copies that are running.

You can use CMUs to estimate the cost of running your custom model by using the following formula.

Total cost = Number of running model copies × Number of CMUs per copy × billing rate per CMU per min × ((Number of 5-min windows)/60)

- *Number of running model copies* – Get from the `ModelCopy` metric in Amazon CloudWatch.
- *Number of CMUs per copy* – Get the value from the model details page in the Amazon Bedrock details page. Alternatively, call the GetImportedModel operation and get the number of CMUs per copy from the `customModelUnitsPerModelCopy` field.
- *Billing rate per CMU per min* – Get the custom model units version from the model details page in the Amazon Bedrock console. Alternatively, call the GetImportedModel operation and get the custom model units version from the `customModelUnitsVersion` field.

  Then, get the billing rate (**Price per Custom Model Unit per min***) for the model version (**Custom Model Unit version**) on the **Custom Model Import** section of the Amazon Bedrock pricing page.

Billing is charged over 5-minute billing windows from the first successful inference call.

For more information, see Amazon Bedrock pricing.

Code samples for custom model import

The following code samples show how to set up permissions, create a custom model import job, view the details of your import jobs and imported models, and delete imported model. These code samples apply to Mistral AI, Llama, Qwen, Flan, GPTBigCode, and Mixtral architectures.

Important: Model Architecture Support

GPT-OSS Model Limitations:

- **Converse API Not Supported:** GPT-OSS based custom model import models do NOT support the Converse API or ConverseStream API.
- **Use InvokeModel API Instead:** Customers must use the InvokeModel API when working with GPT-OSS based custom models.
- **API Schema Requirement:** GPT-OSS models require OpenAI-compatible API schemas:
  - Completion format for completion requests

- ChatCompletion format for chat requests
- Response format follows OpenAI API specifications

- **Supported Models for Converse API:** The Converse API is supported for Mistral AI, Llama, Qwen, Flan, GPTBigCode, and Mixtral architectures only.

For GPT-OSS model usage examples with InvokeModel API, refer to the OpenAI API documentation for request/response schemas.

1. Prepare model files for import

   a. If you are importing from an Amazon S3 bucket, you need to supply the model files in the Hugging Face weights format. For more information, see Import a model source from Amazon S3.

   b. Create an Amazon S3 bucket for your model files (the names must be unique).

   c. Upload the model files into the bucket.

2. Create a policy to access your model files and attach it to an IAM role with an Amazon Bedrock trust relationship. Choose the tab for your preferred method, and then follow the steps:

   Console

   1. Create Amazon S3 policy to access the Amazon S3 bucket that contains your model files

      a. Navigate to the IAM console at https://console.aws.amazon.com/iam and choose **Policies** from the left navigation pane.

      b. Select **Create policy** and then choose **JSON** to open the **Policy editor**.

      c. Paste the following policy, replacing *${model-file-bucket}* with your bucket name, and then select **Next**.

         JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
```

```
                "s3:GetObject",
                "s3:ListBucket"
            ],
            "Resource": [
                "arn:aws:s3:::${model-file-bucket}",
                "arn:aws:s3:::${model-file-bucket}/*"
            ]
          }
        ]
      }
```

d. Name the policy *S3BucketPolicy* and select **Create policy**.

2. Create an IAM role and attach the policy.

a. From the left navigation pane, choose **Roles** and then select **Create role**.

b. Select **Custom trust policy**, paste the following policy, and select **Next**.

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Principal": {
                "Service": "bedrock.amazonaws.com"
            },
            "Action": "sts:AssumeRole"
        }
    ]
}
```

c. Search for the *S3BucketPolicy* policy you created, select the checkbox, and choose **Next**.

d. Name the role *MyImportModelRole* and select *Create role*.

CLI

1. Create a file called *BedrockTrust.json* and paste the following policy into it.

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Principal": {
                "Service": "bedrock.amazonaws.com"
            },
            "Action": "sts:AssumeRole"
        }
    ]
}
```

2. Create another file called *S3BucketPolicy.json* and paste the following policy into it, replacing *${model-file-bucket}* with your bucket names.

   JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "s3:GetObject",
                "s3:ListBucket"
            ],
            "Resource": [
                "arn:aws:s3:::${model-file-bucket}",
                "arn:aws:s3:::${model-file-bucket}/*"
            ]
        }
     ]
}
```

3. In a terminal, navigate to the folder containing the policies you created.
4. Make a CreateRole request to create an IAM role called *MyImportModelRole* and attach the *BedrockTrust.json* trust policy that you created.

```
aws iam create-role \
    --role-name MyImportModelRole \
    --assume-role-policy-document file://BedrockTrust.json
```

5. Make a CreatePolicy request to create the S3 data access policy with the *S3BucketPolicy.json* file you created. The response returns an `Arn` for the policy.

```
aws iam create-policy \
    --policy-name S3BucketPolicy \
    --policy-document file://S3BucketPolicy.json
```

6. Make an AttachRolePolicy request to attach the S3 data access policy to your role, replacing the `policy-arn` with the ARN in the response from the previous step:

```
aws iam attach-role-policy \
    --role-name MyImportModelRole \
    --policy-arn ${policy-arn}
```

Python

1. Run the following code to make a CreateRole request to create an IAM role called *MyImportModel* and to make a CreatePolicy request to create an S3 data access policy called *S3BucketPolicy*. For the S3 data access policy, replace *${model-file-bucket}* with your S3 bucket names.

```
import boto3
import json

iam = boto3.client("iam")

iam.create_role(
    RoleName="MyImportModelRole",
    AssumeRolePolicyDocument=json.dumps({
        "Version": "2012-10-17",
        "Statement": [
            {
                "Effect": "Allow",
                "Principal": {
                    "Service": "bedrock.amazonaws.com"
                },
```

```
                "Action": "sts:AssumeRole"
            }
        ]
    })
)

iam.create_policy(
    PolicyName="S3BucketPolicy",
    PolicyDocument=json.dumps({
        "Version": "2012-10-17",
        "Statement": [
            {
                "Effect": "Allow",
                "Action": [
                    "s3:GetObject",
                    "s3:ListBucket"
                ],
                "Resource": [
                    "arn:aws:s3:::${training-bucket}",
                    "arn:aws:s3:::${training-bucket}/*"
                ]
            }
          ]
       })
     )
```

2. An `Arn` is returned in the response. Run the following code snippet to make an AttachRolePolicy request, replacing *`${policy-arn}`* with the returned `Arn`.

```
iam.attach_role_policy(
    RoleName="MyImportModelRole",
    PolicyArn="${policy-arn}"
)
```

3. Select a language to see code samples to call the custom model import API operations.

CLI

To submit a custom model import job, in a terminal run the following command in the command line, replacing *`${my-import-model-role-arn}`* with the model role that you set up and the *`s3-bucket-path`* with the S3 bucket path of your model files.

```
aws bedrock create-model-import-job
    --job-name MyImportedModelJobName
    --imported-model-name MyImportedModelName
    --role-arn ${my-import-model-role-arn}
    --model-data-source '{"s3DataSource": {"s3Uri": s3-bucket-path }}
```

The response returns a *jobArn*. The custom import job will take some time to complete. You can use the `jobArn` with the following command to check the status of the import job.

The following fields are optional:

- To add a VPC configuration, add the following argument to the preceding command to specify the security group and subnets:

  ```
    -\\-vpc-config '{securityGroupIds": ["sg-xx"], "subnetIds": ["subnet-yy",
  "subnet-zz"]}'
  ```

- To encrypt your model with a KMS key, add the following argument to the preceding command, replacing the values to specify the key with which you want to encrypt your model.

  ```
    -\\-customModelKmsKeyId 'arn:aws:kms:region:account-id:key/key-id'
  ```

- To add tags, add the following argument to the preceding command, replacing the keys and values with the tags you want to attach to the job and/or output model and making sure to separate key/value pairs with a space:

  ```
    -\\-tags key=key1,value=value1 key=key2,value=value2
  ```

The response returns a *jobArn*. The custom import job will take some time to complete. You can use the `jobArn` with the following command to check the status of the import job.

```
aws bedrock get-model-import-job \
```

```
    --job-identifier "jobArn"
```

The response looks similar to this:

```
{
    "jobArn": ${job-arn} ,
    "jobName": MyImportedModelJobName,
    "importedModelName": MyImportedModelName,
    "roleArn": ${my-role-arn},
    "modelDataSource": {
        "s3DataSource": {
            "s3Uri": "${S3Uri}"
        }
    },
    "status": "Complete",
    "creationTime": "2024-08-13T23:38:42.457Z",
    "lastModifiedTime": "2024-08-13T23:39:25.158Z"
```

When the `status` is `Complete`. the import job is complete.

To run inference on your newly imported model, you must provide the ARN of the imported model as the `model-id`. Get ARN of the imported model.

```
aws bedrock list-imported-models
```

The response contains the model name and the model ARN. Use the model ARN to invoke the imported model. For more information, see Submit a single prompt with InvokeModel.

```
{
    "modelSummaries": [
        {
            "modelArn": model-arn,
            "modelName": "MyImportedModelName",
            "modelArchitecture":model-architecture,
            "instructSupported":Y,
            "creationTime": "2024-08-13T19:20:14.058Z"

        }
```

```
    ]
}
```

To delete your imported model, in a terminal run the following command in the command line, using the model name or the model ARN of the imported model you want to delete.

```
aws bedrock delete-imported-model
                --model-identifier MyImportedModelName
```

Python

Run the following code snippet to submit an custom model import job. Replace *my-region* with the Region where you imported the model, *${my-import-model-role-arn}* with the ARN of the *MyImportModelRole* that you set up and replace *${model-file-bucket}* with your S3 bucket name.

```
import boto3
import json

REGION_NAME = my-region
bedrock = boto3.client(service_name='bedrock',
                       region_name=REGION_NAME)

JOB_NAME = MyImportedModelJobName
ROLE_ARN = ${my-import-model-role-arn}
IMPORTED_MODEL_NAME = ImportedModelName
S3_URI = ${S3Uri}

# createModelImportJob API
create_job_response = bedrock.create_model_import_job(
    jobName=JOB_NAME,
    importedModelName=IMPORTED_MODEL_NAME,
    roleArn=ROLE_ARN,
    modelDataSource={
        "s3DataSource": {
            "s3Uri": S3_URI
        }
    },
)
job_arn = create_job_response.get("jobArn")
```

The following fields are optional.

- To add a VPC configuration, add the following argument to the preceding command to specify the security group and subnets:

```
   vpc-config = {'securityGroupIds: ["sg-xx".], 'subnetIds': [subnet-yy, 'subnet-
zz']}'
```

- To encrypt your model with a KMS key, add the following argument to the preceding command, replacing the values to specify the key with which you want to encrypt your model.

```
   importedModelKmsKeyId = 'arn:aws:kms:region:account-id:key/key-id'
```

- To add tags, add the following argument to the preceding command, replacing the keys and values with the tags you want to attach to the job and/or output model and making sure to separate key/value pairs with a space:

```
   jobTags key=key1,value=value1 key=key2,value=value2
```

The response returns a jobArn

```
            job_arn = create_job_response.get("jobArn")
```

The custom import job will take some time to complete. You can use the `jobArn` with the following command to check the status of the import job.

```
bedrock.get_model_import_job(jobIdentifier=jobArn)
```

When the `status` is `Completed`, the import job is complete.

To run inference on your newly imported model, you must provide the ARN of the imported model as the `model-id`. Get ARN of the imported model.

```
response_pt = bedrock.list_imported_models(
    creationTimeBefore=datetime (2015,1,1,
    creationTimeAfter= datetime (2015,1,1,
    nameContains = 'MyImportedModelName,
    maxresults = 123
    nextToken = 'none',
    sortBy = 'creationTime',
    sortOrder = 'Ascending'
```

The response returns the `modelArn` along with other details of the imported model.

```
{
    'nextToken': '',
    'modelSummaries': [
        {
            'modelArn': 'your-model-arn',
            'modelName': 'MyImportedModelName',
            'modelArchitecture':model-architecture,
            'instructSupported':Y,
            'creationTime': datetime(2015, 1, 1)
        },
    ]
```

Use the model ARN to invoke the imported model. For more information, see Submit a single prompt with InvokeModel.

To delete your imported model, use the following command using the model name or the model ARN of the imported model you want to delete.

```
response = client.delete_imported_model(
    modelIdentifier='MyImportedModelName'
            )
```

Converse API code samples for custom model import

If you're importing a Mistral, Llama, or Qwen type instruct model and you want to use the Converse or the ConverseStream API, make sure to include the `chat_template` for the model type you are importing in the `tokenizer_config.json`. Select the tab corresponding to the model type you are importing in the following table.

Llama 3.2 Text
