- **Handle actions behind the scenes.** Your Connect AI agent stays in the conversation with the customer. When it decides to invoke the collaborator, it builds a text message that describes the work. The collaborator does the work (looks up an order, files a claim, runs a calculation) and returns the result. The customer never interacts with the collaborator directly. This mode is also called delegation.
- **Talk to the customer.** The collaborator speaks or chats with the customer directly, then returns control to your Connect AI agent when it finishes. This mode is also called handoff. On voice contacts, this mode works in one of two ways:
  - **Text streaming.** Connect Customer converts the caller's speech to text, sends it to the collaborator, and converts the collaborator's text responses back to speech. The collaborator doesn't need any voice infrastructure.

- **Audio streaming.** Available for external collaborators only. Connect Customer streams the caller's audio to the collaborator, and the collaborator streams audio back. Audio streaming uses WebSocket (`wss://`) only.

For a comparison of the modes, see Compare collaboration modes.

How Connect Customer manages the collaboration

Connect Customer handles the infrastructure so your Connect AI agent and the collaborator can focus on the conversation:

- **Invocation.** Connect Customer establishes the A2A session with the collaborator when your Connect AI agent's instructions call for it. For details, see How your Connect AI agent decides to use a collaborator.
- **Context.** In talk to the customer mode, Connect Customer passes context to the collaborator, such as the conversation so far. For details, see What a collaborator can see. In handle actions behind the scenes mode, the collaborator receives the text message that your Connect AI agent builds.
- **Observability.** Connect Customer publishes traces automatically for Connect AI agent collaborators. External collaborators must send trace data back to Connect Customer. If Connect Customer detects that an external agent is not sending the required trace data, Connect Customer disables that endpoint for new contacts. For details, see Observability for collaborating AI agents.
- **Failures.** If a collaboration fails, the contact returns to the error branch of your contact flow, where you configure the fallback. For external collaborators, Connect Customer first retries a WebSocket connection attempt once for certain errors. In talk to the customer mode on voice contacts over WebSocket, it also reconnects once if the connection drops during the session. For details, see Connection retries, reconnects, and close codes.

Requirements

The following requirements apply to all agent-to-agent collaboration:

- Your instance must be on the **Connect Customer** tier. Agent-to-agent collaboration is not available on Customer Basic.

- You configure collaboration through the Connect Customer API. There is no console interface for this feature. You use the `CreateAIAgent` and `UpdateAIAgent` API operations to add collaborators to your Connect AI agent's configuration. You use the `CreateAIAgentVersion` API operation to publish a version that you can deploy.
- Your contact flow reaches your Connect AI agent through an Amazon Lex V2 bot with the `AMAZON.QInConnectIntent`. Audio streaming requires a bot locale that uses Amazon Nova Sonic speech-to-speech, with a single `AMAZON.QInConnectIntent`.

The following additional requirements apply to Connect AI agent collaborators:

- A collaborator that talks to the customer must have the reserved Complete tool, and should also have the Escalate tool, so it can give control back to the main Connect AI agent. The main Connect AI agent is invoked again with the reason that the collaborator gives. It can continue the conversation, invoke another collaborator, or use its Complete or Escalate tool to return the contact to the flow. For more information, see Tools for orchestrator AI agents.

The following additional requirements apply to external collaborators:

- The external agent must implement the A2A protocol with the Connect Customer A2A extensions. For details, see Build an external AI agent server.
- You register the external agent as an Connect Customer AppIntegrations application of type `A2A_SERVER`. The application stores the endpoint URL and a reference to the API key, which you keep in AWS Secrets Manager.
- In either mode, a text endpoint can use `https://` (HTTP JSON-RPC) or `wss://` (WebSocket). Audio streaming, in talk to the customer mode with immediate handoff, requires `wss://`.
- External agents must send trace data to Connect Customer. Connect Customer disables external agent endpoints that do not send the required trace data. For details, see Trace data requirements for external AI agents.

Permissions summary

Agent-to-agent collaboration uses two kinds of permissions: the permissions that you need when you configure collaboration, and the permissions that Connect Customer needs at runtime, when your Connect AI agent invokes a collaborator.

You need the following permissions when you configure collaboration:

- **IAM permissions.** The principal that configures collaboration needs permissions to call the AI agent API operations. For the list, see Required permissions. Setting up an external collaborator also requires permissions to create the application and the secret. For details, see Set up an external AI agent integration.
- **API key secret for external collaborators.** You store the external agent's API key as an AWS Secrets Manager secret that is encrypted with a customer managed KMS key. For the required secret and key configuration, see Store the external agent's API key.

Connect Customer uses the following permissions at runtime:

- **Security profile for external collaborators.** The security profile of your Connect AI agent must allow the external application (type `THIRD_PARTY`). You must also associate the security profile with your Connect AI agent (entity type `AI_AGENT`).
- **Amazon Lex and Connect AI agent permissions.** Your Amazon Lex bot uses the `AMAZON.QInConnectIntent` to reach your Connect AI agent. The existing permissions for that setup apply. For the required permissions, see AMAZON.QInConnectIntent in the *Amazon Lex V2 Developer Guide*. For how to create the intent from your Connect Customer instance, see Create an agent assist intent.
- **Contact context for external collaborators.** To pass contact context (customer address, system address, and channel) to an external collaborator that talks to the customer, the security profile of your Connect AI agent must grant the **Access Contact Control Panel** permission.

For more information about security profiles for AI agents, see Assign security profile permissions to AI agents.

Set up collaboration

For setup instructions, see the following pages:

- Set up collaboration with another Connect Customer AI agent (for AI agents in your instance)
- Set up an external AI agent integration (for external agents, including agents on Amazon Bedrock AgentCore)
  - Build an external AI agent server (how to build and host the external agent's server)

How agent-to-agent collaboration works

Agent-to-agent collaboration lets your Connect AI agent bring in another AI agent during a live contact. The collaborating agent performs work or talks to the customer, and then returns control to your Connect AI agent.

Collaboration uses the Agent-to-Agent (A2A) protocol, an open standard originally developed by Google and now governed by the Linux Foundation. Amazon Connect Customer adds A2A extensions that the base protocol does not provide. For details, see the A2A protocol contract for external AI agents. This page explains what happens at runtime when your Connect AI agent uses a collaborator.

What collaborating agents can do

A collaborating agent works in one of two modes during a contact:

Handle actions behind the scenes. The collaborator works behind the scenes while your Connect AI agent continues the conversation with the customer. When your Connect AI agent decides to invoke the collaborator, it builds a text message that describes the work. The collaborator does the work (looks up an order, files a claim, scores a transaction) and returns the result. The customer never interacts with the collaborator directly. This mode is also called delegation.

Talk to the customer. The collaborator takes over the conversation and speaks or chats with the customer directly. This mode is also called handoff. The main Connect AI agent steps aside until

the collaborator finishes. When the collaborator is done, it signals an outcome and your Connect AI agent resumes. On voice contacts, this mode uses text streaming or audio streaming. For details, see Voice contacts in talk-to-the-customer mode.

Compare collaboration modes

The following table compares the collaboration modes.

Collaboration modes

Mode	Who talks to the customer	Connection behavior (external agents)	Audio support	Returning control to the main Connect AI agent	Collaborator types
Handle actions behind the scenes	Your Connect AI agent	A new connection and session initialization for each invocation, reusing the same session (`contextId`).	Not applicable. The collaborator exchanges text with your Connect AI agent.	The collaborator returns its result to your Connect AI agent. The collaborator doesn't need hand-back tools.	Connect AI agent and external collaborators
Talk to the customer (text)	The collaborator. On voice, Connect Customer converts speech to text and text to speech.	Voice over WebSocket (`wss://`): one persistent connection for the session. HTTP JSON-RPC (`https://`): a request and response for each exchange, with no persistent connection. Chat: a new connection for each customer message.	No. Connect Customer provides the voice.	**Connect AI agent collaborator:** uses its Complete or Escalate tool. **External collaborator:** sends a FINISH event with COMPLETE or ESCALATE.	Connect AI agent and external collaborators

Mode	Who talks to the customer	Connection behavior (external agents)	Audio support	Returning control to the main Connect AI agent	Collaborator types
				Control returns to the main Connect AI agent.	
Talk to the customer (audio)	The collaborator, using its own AI voice	One persistent `wss://` connection for the session.	Yes, bidirectional audio on voice contacts, over WebSocket (`wss://`) only	The collaborator sends a FINISH event with COMPLETE or ESCALATE. Control returns to the main Connect AI agent.	External only

When a collaborator that talks to the customer completes or escalates, control returns to the main Connect AI agent, which is invoked again with the collaborator's reason. The main Connect AI agent can continue the conversation, invoke another collaborator, or use its Complete or Escalate tool to return the contact to the flow. For more information about these tools, see Tools for orchestrator AI agents.

For Connect AI agent collaborators, Connect Customer manages the connection for you.

Which AI agents can collaborate

Your Connect AI agent can work with the following types of AI agents:

- **Another AI agent in your instance (Connect AI agent collaborator).** An AI agent that you have already created in the same Connect Customer instance. Connect Customer routes the collaboration internally and manages the A2A protocol for you.
- **An external agent (third-party).** An agent hosted outside of your Connect Customer instance, including an agent that runs on Amazon Bedrock AgentCore. The agent must implement the A2A protocol with the Connect Customer A2A extensions. It must expose a public endpoint that

Connect Customer can reach over WebSocket (`wss://`) or HTTP JSON-RPC (`https://`, text only). Audio streaming is supported over WebSocket (`wss://`) only.

You register an external agent as an AppIntegrations application in your account. The external agent authenticates Connect Customer with an API key. You store the key in AWS Secrets Manager, and Connect Customer sends it to the external agent as a bearer token when it connects. External agents must also send trace data to Connect Customer.

For setup instructions, see Set up an external AI agent integration. For what the external agent must implement, see Build an external AI agent server.

How your Connect AI agent decides to use a collaborator

The decision to bring in a collaborator is instruction-driven. When you configure your Connect AI agent, you write instructions that tell it when and how to use each collaborator. Your Connect AI agent reads those instructions, evaluates the conversation, and decides whether to invoke a collaborator based on what the customer needs.

For example, you might write an instruction such as the following: "When the customer asks about the status of an insurance claim, use the claims collaborator to look up the claim and return the result." Or: "When the customer wants to speak with a specialist about an investment portfolio review, bring in the portfolio advisor collaborator and let it talk to the customer."

For a collaborator that talks to the customer, you can instead set `immediateHandoff` to `true`. With immediate handoff, the collaborator takes over the conversation on the first turn, and your Connect AI agent does not evaluate instructions first.

How a talk-to-the-customer collaboration ends

A collaborator that handles actions behind the scenes returns its result to your Connect AI agent for each request, so it doesn't signal an outcome. In talk to the customer mode, when the collaborator finishes, it signals one of two outcomes back to your Connect AI agent:

Outcome	What it means
Complete	The collaborator finished its part of the conversation. Control returns to your Connect AI agent.

Outcome	What it means
Escalate	The collaborator determined that the contact needs a human agent. Control returns to your Connect AI agent. If your Connect AI agent has the Escalate tool, it can call Escalate to return the contact to the Escalate path of your contact flow, which typically transfers the contact to a human agent.

In either case, control returns to the main Connect AI agent, which is invoked again with the collaborator's reason. The main Connect AI agent can continue the conversation, invoke another collaborator, or use its Complete or Escalate tool to return the contact to the flow. For more information, see Tools for orchestrator AI agents.

How the collaborator signals the outcome depends on the collaborator type:

- **Connect AI agent collaborators.** In talk to the customer mode, a Connect AI agent collaborator must have the reserved Complete tool, and should also have the Escalate tool, so it can give control back to the main Connect AI agent. For more information about these tools, see Tools for orchestrator AI agents.
- **External collaborators.** The external agent sends a FINISH event with the type COMPLETE or ESCALATE.

With either outcome, the collaborator can include a reason. Connect Customer passes the reason back and invokes your Connect AI agent again so it can handle the outcome gracefully. For example, a collaborator can complete with a reason that explains why it couldn't finish the task, and your Connect AI agent can offer another option.

This is different from a failure. A failure occurs when the connection to the collaborator fails or drops before the collaborator signals an outcome. A failure also occurs when an external agent ends a task as failed, canceled, or rejected. That ends the collaboration, not just the turn, and the contact returns to the Error branch of your flow. For more information, see the following section.

When a collaborator fails

For some WebSocket connection errors, Connect Customer retries before it treats the collaboration as failed:

- If a connection attempt fails, Connect Customer retries a WebSocket connection attempt once for certain errors.
- In talk to the customer mode on voice contacts over WebSocket, if the connection drops unexpectedly during the session, Connect Customer reconnects one time. For which connection closes trigger a reconnect, see Connection retries, reconnects, and close codes.

If the retry or reconnect also fails, the collaboration fails. The contact returns to the error branch of your contact flow. Configure your fallback on that error branch. For example, you can route the customer to a human agent queue or play a message.

The error branch handles failures, where no outcome arrives. To handle a problem gracefully within the conversation, the collaborator can instead finish with a reason, as described in the preceding section. Your Connect AI agent then decides how to continue.

What a collaborator can see

In talk to the customer mode, Connect Customer passes the conversation history automatically, so the collaborator knows what the customer already said. For external collaborators in talk to the customer mode, Connect Customer passes the following at the start of the session:

- The conversation history of the Connect AI agent session, up to the handoff
- The contact ARN and instance ARN
- Contact context: the customer address, the system address, and the channel. Connect Customer includes contact context only when the security profile of your Connect AI agent grants the **Access Contact Control Panel** permission.

Connect Customer doesn't pass custom contact attributes to external collaborators. You can't choose which context is shared. For details about what the external agent receives, see Build an external AI agent server.

In talk to the customer mode, the collaborator also builds its own conversation history with the customer for the duration of its turn. When the collaborator finishes and control returns to your Connect AI agent, Connect Customer merges the collaborator's conversation history into your Connect AI agent's session. Your Connect AI agent then has context about what happened during the collaboration.

Voice contacts in talk-to-the-customer mode

Collaborators that handle actions behind the scenes exchange text with your Connect AI agent and never interact with the customer, so voice options don't apply to them.

For Connect AI agent collaborators, Connect Customer manages voice for you with text streaming. For external collaborators, you choose text streaming or audio streaming with the `audioStreamingEnabled` field.

Aspect	Text streaming	Audio streaming
Setting	`audioStreamingEnabled` set to `false` or omitted	`audioStreamingEnabled` and `immediateHandoff` set to `true`
Collaborator types	Connect AI agent and external collaborators	External only
Speech recognition and speech synthesis	Connect Customer converts the caller's speech to text and converts the collaborator's text responses to speech using Connect Agentic voices.	The external agent receives the caller's audio, runs its own speech recognition, and streams audio back in its own AI voice. The Amazon Lex bot doesn't perform speech-to-speech for the collaborator.
Transport (external agents)	Text over WebSocket (`wss://`) or HTTP JSON-RPC (`https://`)	PCM audio over WebSocket (`wss://`) only
Connection (external agents)	WebSocket: one persistent connection for the session. HTTP JSON-RPC: a request and response for each exchange, with no persistent connection.	One persistent WebSocket connection for the session
Amazon Lex bot locale	Any Amazon Lex speech recognition and text-to-speech settings	Amazon Nova Sonic speech-to-speech, with a single `AMAZON.QInConnectIntent`

Audio streaming has the following additional constraints:

- The audio collaborator must be the only collaborator on that AI agent. An AI agent can have at most one immediate handoff.
- The orchestrating AI agent can't have an orchestration prompt or a guardrail. Its only tools can be the reserved Complete tool (required) and Escalate tool. For more information, see Tools for orchestrator AI agents.
- Each collaborator has a single `audioStreamingEnabled` setting. You can't switch between text streaming and audio streaming for the same collaborator during a contact.

For setup details, see Set up an external AI agent integration. For audio requirements on the external agent, see Build an external AI agent server.

Chat contacts

On chat contacts, collaboration is always text. For Connect AI agent collaborators, Connect Customer manages the exchange for you.

For external collaborators that talk to the customer, Connect Customer opens a new connection for each customer message. Each connection uses the same session (`contextId`), and Connect Customer sends the conversation history again when it initializes the session. If you set `audioStreamingEnabled` to `true`, Connect Customer doesn't negotiate audio on chat. The external agent must handle text.

Trace data and observability

Connect Customer uses trace data for contact analytics, quality management, and compliance. Trace data includes the messages exchanged, tool calls made, and timing information.

- **Connect AI agent collaborators.** Connect Customer publishes traces automatically for each collaborating AI agent.
- **External collaborators.** The external agent must publish trace data from its server as `TRACING_SPAN` events. For details, see Tracing in the A2A protocol contract.

Connect Customer disables external agent endpoints that do not send the required trace data. After Connect Customer disables an external endpoint, it doesn't invoke that endpoint for new contacts. In-flight contacts that are already using the collaborator complete normally, but no new collaborations start with that collaborator until the trace data issue is resolved.

For the full list of required and encouraged trace fields, and details about how trace enforcement works, see Observability for collaborating AI agents.

Set up collaboration with another Connect Customer AI agent

This page describes how to add a collaborating AI agent that runs in your Connect Customer instance. You configure collaborators through the Connect Customer API. Connect Customer manages the A2A protocol between your AI agents for you.

Prerequisites

Before you begin, confirm that you have the following:

- **An AI agent created and published in your Connect Customer instance.** This is the orchestrating agent that calls the collaborator during a live contact. You need its `aiAgentId`.
- **A collaborating agent that exists and is reachable.** The collaborator is another AI agent in your Connect Customer instance. You need the collaborator's `aiAgentId`.
- **IAM permissions to call the QConnect API.** For the specific actions, see Required permissions.
- **An Amazon Lex V2 bot with the `AMAZON.QInConnectIntent`.** All agent-to-agent collaboration requires this bot, associated with your Connect Customer instance. Any Amazon Lex speech recognition and text-to-speech settings work. For more information, see Add the Amazon Lex bot to your Connect Customer instance and AMAZON.QInConnectIntent in the *Amazon Lex V2 Developer Guide*.

Add a collaborator that handles actions behind the scenes

To have a collaborator handle actions behind the scenes, use `delegateAgentConfiguration`. The collaborator works behind the scenes and returns results to your Connect AI agent. Your Connect AI agent stays in control of the conversation. The customer never interacts with the collaborator directly.

This is the right choice when the collaborator performs a discrete job: looking up an order, scoring a fraud risk, retrieving a claim status, or running a calculation.

Call `UpdateAIAgent` and add the collaborator under `orchestrationAIAgentConfiguration.multiAgentConfigurations`:

```
{
  "assistantId": "YOUR_ASSISTANT_ID",
  "aiAgentId": "YOUR_ORCHESTRATING_AGENT_ID",
  "visibilityStatus": "PUBLISHED",
  "configuration": {
    "orchestrationAIAgentConfiguration": {
      "orchestrationAIPromptId": "YOUR_PROMPT_ID",
      "multiAgentConfigurations": [
        {
          "delegateAgentConfiguration": {
            "agentTarget": {
              "aiAgentId": "COLLABORATOR_AGENT_ID"
            },
            "instruction": {
              "instruction": "Use this agent to look up insurance claim status.
 Send the claim number and the customer's policy ID. The agent returns claim status,
 approval dates, and expected payment timeline."
            }
          }
        }
      ]
    }
  }
}
```

The following table describes the fields in this request.

Field	What it does
`delegateAgentConfiguration`	Tells Connect Customer that this collaborator handles actions behind the scenes. Your Connect AI agent stays in control of the conversation.
`agentTarget.aiAgentId`	The identifier of the collaborating AI agent in your instance.
`instruction`	Tells your Connect AI agent when to call this collaborator, what information to send, and what to expect back. For more information, see Write a useful description.

You can add multiple collaborators by including additional objects in the `multiAgentConfigurations` array. Each collaborator has its own instruction and target.

Add a collaborator that talks to the customer

To have a collaborator talk to the customer, use `handoffAgentConfiguration`. The collaborator takes over the conversation and speaks or chats with the customer directly. Your Connect AI agent steps aside while the collaborator handles the interaction, then resumes control when the collaborator finishes.

This is the right choice when the collaborator needs to have a multi-turn conversation with the customer: gathering information, asking follow-up questions, walking through a process, or handling a specialized interaction end to end.

Before you add a collaborator that talks to the customer, review the following requirements:

- **Hand-back tools on the collaborator.** The collaborating AI agent must have the reserved Complete tool, and should also have the Escalate tool, so it can give control back to your orchestrating AI agent. Your orchestrating AI agent is invoked again with the reason that the collaborator gives. It can continue the conversation, invoke another collaborator, or use its Complete or Escalate tool to return the contact to your flow. For more information about these tools, see Tools for orchestrator AI agents.
- **Conversation history.** Connect Customer passes the conversation history to the collaborator automatically. You don't need to configure it.

- **Voice.** Connect Customer handles speech for collaborators in your instance with text streaming. Collaborators in your instance don't support audio streaming (`audioStreamingEnabled`).

Call `UpdateAIAgent` and add the collaborator under `orchestrationAIAgentConfiguration.multiAgentConfigurations`:

```
{
  "assistantId": "YOUR_ASSISTANT_ID",
  "aiAgentId": "YOUR_ORCHESTRATING_AGENT_ID",
  "visibilityStatus": "PUBLISHED",
  "configuration": {
    "orchestrationAIAgentConfiguration": {
      "orchestrationAIPromptId": "YOUR_PROMPT_ID",
      "multiAgentConfigurations": [
        {
          "handoffAgentConfiguration": {
            "agentTarget": {
              "aiAgentId": "COLLABORATOR_AGENT_ID"
            },
            "instruction": {
              "instruction": "Transfer the customer to this agent when they need to
 schedule, reschedule, or cancel an appointment. Tell the agent the customer's account
 number and the type of appointment before transferring."
            },
            "immediateHandoff": false
          }
        }
      ]
    }
  }
}
```

The following table describes the fields in this request.

Field	What it does
`handoffAgentConfiguration`	Tells Connect Customer that this collaborator takes over the conversation with the customer. Your Connect AI agent steps aside until the collaborator finishes.

Field	What it does
`agentTarget.aiAgentId`	The identifier of the collaborating AI agent in your instance.
`instruction`	Tells your Connect AI agent when to transfer the customer to this collaborator and what context to pass along.
`immediateHandoff`	Controls when the handoff happens. Set to `false` to have your Connect AI agent transfer the customer when its instruction calls for it. Set to `true` to have the collaborator take over the conversation on the first turn, without your Connect AI agent evaluating the instruction first. An AI agent can have at most one immediate handoff.
`audioStreamingEnabled`	Not supported for collaborators in your instance. Omit this field.

Write a useful description

The `instruction` field determines when your Connect AI agent calls the collaborator and what context it passes. A vague instruction leads to missed invocations or calls with insufficient context. A specific instruction produces reliable collaboration.

Be explicit about when to use the collaborator. State the trigger conditions clearly.

Less effective	More effective
"Claims agent."	"Use this agent when the customer asks about the status of an existing insurance claim, a pending payment, or a claim denial reason."

Specify the inputs the collaborator needs. Your Connect AI agent passes only the information that the instruction tells it to pass.

Less effective	More effective
"Send the claim info."	"Send the claim number and the customer's policy ID. If the customer does not have the claim number, ask for the date of incident and the type of claim instead."

Describe what the collaborator returns. This helps your Connect AI agent understand the response and use it naturally in the conversation.

Less effective	More effective
"Returns claim data."	"The agent returns the claim status (open, approved, denied, or under review), the date of the most recent update, and the expected payment amount and timeline if approved."

Set boundaries. Tell your Connect AI agent what the collaborator does not handle, so it does not send requests the collaborator cannot fulfill.

Less effective	More effective
(no boundaries)	"Do not use this agent for new claim submissions, payment disputes, or policy changes. Those require a human agent."

Publish the updated configuration

After you add or modify collaborators, create a new version to make the configuration live. The updated collaborator settings do not take effect on new contacts until you publish a version.

```
aws qconnect create-ai-agent-version \
  --assistant-id YOUR_ASSISTANT_ID \
  --ai-agent-id YOUR_ORCHESTRATING_AGENT_ID
```

The response includes the new version number. Contacts that start after this point use the new configuration. Contacts that are already in progress continue with the version that was active when they started.

Required permissions

The IAM principal that makes these API calls needs the following permissions on the relevant Connect Customer resources. Attach these as an IAM policy to the user or role that manages your Connect AI agent configuration.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "wisdom:UpdateAIAgent",
        "wisdom:CreateAIAgentVersion",
        "wisdom:GetAIAgent",
        "wisdom:ListAIAgentVersions"
      ],
      "Resource": "arn:aws:wisdom:REGION:ACCOUNT_ID:ai-agent/ASSISTANT_ID/*"
    },
    {
      "Effect": "Allow",
      "Action": [
        "wisdom:CreateAIAgent",
        "wisdom:ListAIAgents"
      ],
      "Resource": "arn:aws:wisdom:REGION:ACCOUNT_ID:assistant/ASSISTANT_ID"
    }
  ]
}
```

The following table describes what each action is required for.

Action	Required for
`wisdom:CreateAIAgent`	Creating a new AI agent with collaborators already configured
`wisdom:UpdateAIAgent`	Adding or modifying collaborators on an existing AI agent
`wisdom:CreateAIAgentVersion`	Publishing a version so the updated configuration takes effect

Action	Required for
`wisdom:GetAIAgent`	Retrieving the current configuration before you update it, and verifying changes
`wisdom:ListAIAgents`	Listing agents in your instance to find agent IDs
`wisdom:ListAIAgentVersions`	Listing published versions to verify that the new version was created

Set up an external AI agent integration

This page explains how to configure your Connect AI agent to collaborate with an external AI agent. An external agent runs outside of your Amazon Connect Customer instance, on infrastructure that you or a third-party provider manages. Agents that you host on Amazon Bedrock AgentCore are also external agents, and you set them up the same way.

External agents communicate with Connect Customer over the Agent-to-Agent (A2A) protocol with the Connect Customer A2A extensions. This page covers the setup that you perform in your AWS account. For information about what the external agent's server must implement, see Build an external AI agent server and the A2A protocol contract for external AI agents.

By the end of this setup, your Connect AI agent can bring in the external agent during a live contact. The external agent can either handle actions behind the scenes or talk to the customer directly.

Complete the following sections in order:

1. Store the external agent's API key

2. Register the A2A server application
3. Associate the application with your Connect instance
4. Add the external collaborator
5. Configure the security profile for your Connect AI agent
6. Publish the updated configuration

Before you start, review the Prerequisites.

This is an API-only feature. All setup requests must be SigV4-signed. You can drive every step with the AWS CLI or an AWS SDK.

All steps target public service endpoints in your instance's Region: `secretsmanager.REGION.amazonaws.com`, `app-integrations.REGION.amazonaws.com`, `connect.REGION.amazonaws.com`, and `wisdom.REGION.amazonaws.com` (the qconnect API).

Prerequisites

Before you start, confirm that you have the following:

- **Connect Customer tier.** Your instance must be on the Connect Customer tier. Agent-to-agent collaboration is not available on Customer Basic.
- **A Connect assistant associated with your instance.** You create the orchestrating Connect AI agent, which calls the collaborator during a live contact, under this assistant in Add the external collaborator. For how to set up AI agents, see Initial set-up for AI agents.
- **An external agent that supports the A2A protocol with the Connect Customer A2A extensions.** For text, the agent can accept JSON-RPC over a secure WebSocket (`wss://`) or over HTTPS (`https://`). Audio streaming is supported over secure WebSocket (`wss://`) only. The provider gives you the endpoint URL and an API key. For the full requirements, see Build an external AI agent server.
- **Voice streaming review.** If the external agent uses audio streaming (bidirectional audio), work with your AWS account team or Solutions Architect. They can help you validate that the agent meets the latency and audio quality requirements before you deploy to production.
- **IAM permissions.** Use AWS credentials for an IAM principal in the account that owns your Connect instance. At minimum, the principal needs the following permissions:
  - `secretsmanager:CreateSecret`, `secretsmanager:PutResourcePolicy` (Store the external agent's API key)

- `kms:CreateKey`, `kms:CreateAlias` (Store the external agent's API key, if you create the customer managed key)
- `app-integrations:CreateApplication` (Register the A2A server application)
- `connect:CreateIntegrationAssociation`, `connect:UpdateSecurityProfile`, `connect:AssociateSecurityProfiles` (Associate the application with your Connect instance and Configure the security profile for your Connect AI agent)
- `wisdom:CreateAIAgent`, `wisdom:UpdateAIAgent`, `wisdom:CreateAIAgentVersion` (Add the external collaborator and Publish the updated configuration). IAM actions for Connect AI agents use the `wisdom` service prefix.

- **Security profile permissions.** Your Connect AI agent needs a security profile that allows the external agent's application. If you want the external agent to receive contact context, the security profile must also grant the **Access Contact Control Panel** permission. You configure both in Configure the security profile for your Connect AI agent.
- **An Amazon Lex V2 bot with the `AMAZON.QInConnectIntent`.** All agent-to-agent collaboration requires this bot, associated with your Connect Customer instance. For more information, see Add the Amazon Lex bot to your Connect Customer instance and AMAZON.QInConnectIntent in the *Amazon Lex V2 Developer Guide*.

  For external collaborators, the bot locale settings depend on audio streaming:

  - **Audio streaming** (`audioStreamingEnabled` is `true`): The bot locale must use Amazon Nova Sonic speech-to-speech and contain a single `AMAZON.QInConnectIntent`. The bot does not perform speech-to-speech for the collaborator. Audio streams directly between Connect Customer and the external agent.
  - **Audio streaming off**: You can use any Amazon Lex speech recognition and text-to-speech settings.

Store the external agent's API key

Your external agent authenticates inbound requests with an API key. Connect Customer presents the key as a bearer token (`Authorization: Bearer`) when it connects to the agent. Store the API key in AWS Secrets Manager.

1. **Create a customer managed KMS key** whose key policy lets Connect Customer decrypt the secret. This is required. Connect Customer cannot read a secret encrypted with the default `aws/secretsmanager` key. Add the following statement to the key policy, alongside your account's

existing administrator statements. Connect Customer needs only `kms:Decrypt`, and only through AWS Secrets Manager.

```
{
  "Sid": "AllowConnectToDecryptSecret",
  "Effect": "Allow",
  "Principal": { "Service": "connect.amazonaws.com" },
  "Action": "kms:Decrypt",
  "Resource": "*",
  "Condition": {
    "StringEquals": { "kms:ViaService": "secretsmanager.REGION.amazonaws.com" }
  }
}
```

2. **Create the secret** encrypted with that customer managed key, containing the API key value.
3. **Attach a resource policy** to the secret with `PutResourcePolicy`. The policy lets Connect Customer read the secret with `secretsmanager:GetSecretValue`:

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "AllowConnectToRetrieveSecret",
      "Effect": "Allow",
      "Principal": { "Service": "connect.amazonaws.com" },
      "Action": "secretsmanager:GetSecretValue",
      "Resource": "*",
      "Condition": {
        "StringEquals": { "aws:SourceAccount": "ACCOUNT_ID" },
        "ArnEquals": { "aws:SourceArn": "arn:aws:connect:REGION:ACCOUNT_ID:instance/
INSTANCE_ID" }
      }
    }
  ]
}
```

The conditions restrict access to your Connect Customer instance, whose ARN is the `aws:SourceArn` value, so that another account's Connect Customer instance can't use the secret.

Important

Do not use the default AWS managed key (`aws/secretsmanager`). AWS managed keys do not support cross-service grant policies, and Connect Customer cannot access secrets encrypted with them. You must create a customer managed KMS key and use it to encrypt the secret.

Register the A2A server application

Register the external agent's endpoint as an AppIntegrations application. The `ApplicationType` must be `A2A_SERVER`, and `AuthConfig` is required.

```
aws appintegrations create-application \
  --name my-agent \
  --namespace my-agent-ns \
  --description "My external A2A agent" \
  --application-source-config '{"ExternalUrlConfig":{"AccessUrl":"wss://
agent.example.com"}}' \
  --application-type A2A_SERVER \
  --auth-config '{"AuthType":"API_KEY","CredentialProviderIdentifier":"SECRET_ARN"}' \
  --region REGION
```

The response contains the application ID and ARN:

```
{"Id": "APPLICATION_ID", "Arn": "APPLICATION_ARN"}
```

The following rules apply to the application:

- **Application type.** You cannot change `ApplicationType` after you create the application. If you create the application with the wrong type, delete it and create a new one.
- **Namespace.** The namespace can be up to 32 characters. It cannot start with `aws.` or `amazon.`, and it must be unique in your account.
- **Access URL.** `AccessUrl` must point to a public host and use TLS: `https://` for text over HTTP, or `wss://` for WebSocket. Audio streaming requires `wss://`.
- **Authentication.** `AuthConfig` is required for `A2A_SERVER` applications. Set `CredentialProviderIdentifier` to the ARN of the secret that you created in Store the external agent's API key. Without `AuthConfig`, the request fails.

Record the returned `Id` (referenced from your Connect AI agent configuration) and `Arn` (used in Associate the application with your Connect instance and Configure the security profile for your Connect AI agent).

Associate the application with your Connect instance

To make the application available to your instance, run the following command:

```
aws connect create-integration-association \
  --instance-id INSTANCE_ID \
  --integration-type APPLICATION \
  --integration-arn APPLICATION_ARN \
  --region REGION
```

Add the external collaborator

Create your Connect AI agent through the qconnect API to reference the external agent. The configuration you use depends on the collaboration mode:

- **Handle actions behind the scenes** (`delegateAgentConfiguration`). When your Connect AI agent decides to invoke the external agent, it builds a text message for it. The external agent performs the work and returns a text result, which your Connect AI agent uses to invoke another action or to formulate a response to the customer.
- **Talk to the customer** (`handoffAgentConfiguration`). The external agent takes over the conversation. On voice contacts, either Connect Customer handles speech (text) or the external agent provides its own speech (audio).

Save the request body to a file (for example, `create-ai-agent.json`) and send it:

```
aws qconnect create-ai-agent \
  --cli-input-json file://create-ai-agent.json \
  --region REGION
```

For a comparison of the collaboration modes, see Compare collaboration modes. For limits on the number of collaborators, see Quotas and limitations for agent-to-agent collaboration.

Add a collaborator that handles actions behind the scenes

Use `delegateAgentConfiguration` when the external agent performs work and returns a result, while your Connect AI agent continues talking to the customer. The customer does not

interact with the collaborator. When your Connect AI agent decides to invoke the collaborator, it builds a text message for it.

```
{
  "assistantId": "YOUR_ASSISTANT_ID",
  "name": "my-orchestrator",
  "type": "ORCHESTRATION",
  "visibilityStatus": "PUBLISHED",
  "configuration": {
    "orchestrationAIAgentConfiguration": {
      "orchestrationAIPromptId": "YOUR_PROMPT_ID",
      "connectInstanceArn": "arn:aws:connect:REGION:ACCOUNT_ID:instance/INSTANCE_ID",
      "multiAgentConfigurations": [
        {
          "delegateAgentConfiguration": {
            "agentTarget": {
              "applicationId": "YOUR_APPLICATION_ID"
            },
            "instruction": {
              "instruction": "Use this agent to run a credit check. Send the customer's
 account number and requested loan amount. The agent returns an approval decision,
 credit score, and any conditions."
            }
          }
        }
      ]
    }
  }
}
```

The `delegateAgentConfiguration` field tells Connect Customer that this collaborator handles actions behind the scenes. Your Connect AI agent sends the message, waits for the result, and uses it to continue the conversation with the customer.

Each time your Connect AI agent decides to invoke the collaborator, Connect Customer opens a new connection and initializes a new session with the same session ID.

Add a collaborator that talks to the customer

Set `audioStreamingEnabled` to `false` when the external agent works with text.

On voice contacts, Connect Customer converts the caller's speech to text, sends text to the collaborator, receives text responses, and converts them to speech. If you omit the field, the default is `false`.

```
{
  "assistantId": "YOUR_ASSISTANT_ID",
  "name": "my-orchestrator",
  "type": "ORCHESTRATION",
  "visibilityStatus": "PUBLISHED",
  "configuration": {
    "orchestrationAIAgentConfiguration": {
      "orchestrationAIPromptId": "YOUR_PROMPT_ID",
      "connectInstanceArn": "arn:aws:connect:REGION:ACCOUNT_ID:instance/INSTANCE_ID",
      "multiAgentConfigurations": [
        {
          "handoffAgentConfiguration": {
            "agentTarget": {
              "applicationId": "YOUR_APPLICATION_ID"
            },
            "instruction": {
              "instruction": "Transfer the conversation to this agent when the customer
 wants to file a new insurance claim. The agent asks for claim details, verifies the
 information, and files the claim. It returns a claim confirmation number when done."
            },
            "audioStreamingEnabled": false,
            "immediateHandoff": false
          }
        }
      ]
    }
  }
}
```

The `handoffAgentConfiguration` field tells Connect Customer that this collaborator talks to the customer directly. The `immediateHandoff` field controls when the handoff happens:

- `false`: Your Connect AI agent decides when to hand off, based on the collaborator's instruction.
- `true`: The external agent takes over the conversation on the first turn, without your Connect AI agent evaluating the instruction first. Each Connect AI agent can have at most one collaborator with immediate handoff.

When the external agent finishes, it sends a `COMPLETE` or `ESCALATE` finish type with a reason. Control returns to your main Connect AI agent, which is invoked again with the reason. It can continue the conversation, invoke another collaborator, or use its Complete or Escalate tool to return the contact to the flow. For details, see Build an external AI agent server. For the Complete and Escalate tools, see Tools for orchestrator AI agents.

Add a collaborator that talks to the customer with audio streaming

Set `audioStreamingEnabled` to `true` when the external agent has its own speech capabilities and you want it to handle the caller's audio directly. Connect Customer streams the caller's audio to the collaborator's endpoint, and the collaborator streams audio back.

```
{
  "assistantId": "YOUR_ASSISTANT_ID",
  "name": "my-orchestrator",
  "type": "ORCHESTRATION",
  "visibilityStatus": "PUBLISHED",
  "configuration": {
    "orchestrationAIAgentConfiguration": {
      "connectInstanceArn": "arn:aws:connect:REGION:ACCOUNT_ID:instance/INSTANCE_ID",
      "multiAgentConfigurations": [
        {
          "handoffAgentConfiguration": {
            "agentTarget": {
              "applicationId": "YOUR_APPLICATION_ID"
            },
            "instruction": {
              "instruction": "Transfer the conversation to this agent for all self-
service voice interactions. The agent uses its own voice and handles account inquiries,
 balance checks, and general service questions. It returns a summary of what was
 resolved."
            },
            "audioStreamingEnabled": true,
            "immediateHandoff": true
          }
        }
      ]
    }
  }
}
```

Audio streaming has the following constraints:

- **External agents only.** Audio streaming is not supported when the collaborator is another Connect AI agent.
- **Immediate handoff only.** You must set `immediateHandoff` to `true`.
- **Only collaborator.** The audio collaborator must be the only collaborator on the Connect AI agent.
- **Orchestrating AI agent restrictions.** The Connect AI agent that hands off to the audio collaborator must not have an orchestration prompt or a guardrail. It must have the reserved **Complete** tool, and it can also have the reserved **Escalate** tool. It cannot have any other tools. If the configuration does not meet these rules, validation fails. The preceding example does not show tool configuration. For how to add these tools, see Tools for orchestrator AI agents.
- **Amazon Lex bot.** The bot locale must use Amazon Nova Sonic speech-to-speech and contain a single `AMAZON.QInConnectIntent`. For details, see Prerequisites.
- **Secure WebSocket endpoint.** Audio streaming is supported over WebSocket only. The application's `AccessUrl` must use `wss://`. The external agent must send and receive PCM audio.
- **Voice contacts only.** On chat contacts, Connect Customer does not negotiate audio, even when `audioStreamingEnabled` is `true`. The external agent must also handle text. To tell voice from chat, the external agent can read the channel from contact context, which requires the **Access Contact Control Panel** permission (Configure the security profile for your Connect AI agent).
- **One setting per collaborator.** You cannot switch a collaborator between text and audio during a contact.

> **Note**
>
> For audio streaming, work with your AWS account team or Solutions Architect to validate that the external agent meets the latency and audio quality requirements.

Configure the security profile for your Connect AI agent

The security profile attached to your Connect AI agent must explicitly allow the third-party application, or collaboration fails at runtime. Update the security profile to include the application ARN with type `THIRD_PARTY` in its allowed AI agents.

```
aws connect update-security-profile \
```

```
  --instance-id INSTANCE_ID \
  --security-profile-id SECURITY_PROFILE_ID \
  --allowed-ai-agents '[{"Arn":"APPLICATION_ARN","Type":"THIRD_PARTY"}]' \
  --region REGION
```

Then associate the security profile with your Connect AI agent. Run the following command once for each agent ARN: once with the unversioned ARN, and once with the versioned ARN.

```
aws connect associate-security-profiles \
  --instance-id INSTANCE_ID \
  --entity-arn YOUR_ORCHESTRATING_AGENT_ARN \
  --entity-type AI_AGENT \
  --security-profiles Id=SECURITY_PROFILE_ID
```

Contact context. To share contact context with an external agent that talks to the customer, add the **Access Contact Control Panel** permission to the same security profile. Contact context contains the customer address, system address, and channel. Without this permission, Connect Customer does not send contact context. For a complete list of what Connect Customer sends, see Build an external AI agent server.

Publish the updated configuration

Create a new version to make the change live. Changes to your Connect AI agent configuration do not take effect until you publish a version.

```
aws qconnect create-ai-agent-version \
  --assistant-id YOUR_ASSISTANT_ID \
  --ai-agent-id YOUR_ORCHESTRATING_AGENT_ID
```

After you publish, new contacts that reach your Connect AI agent use the updated configuration with the external collaborator.

Trace data requirements

External collaborators must send trace data for every turn. This includes input and output messages, tool inputs and results, and valid start and end times.

Connect Customer disables external agent endpoints that do not send the required trace data. When Connect Customer disables an external endpoint, the endpoint remains in your Connect AI

agent's configuration, but Connect Customer does not invoke it for new contacts. In-flight contacts that are already using the collaborator complete normally.

For the required fields, see Trace data requirements for external AI agents. For information about how to send traces, see Tracing in the A2A protocol contract.

Build an external AI agent server

This page contains information on how to build and host an external AI agent, including an agent that you host on Amazon Bedrock AgentCore. It describes what your agent server must do, and what Connect Customer does, in each collaboration mode. For account setup, see Set up an external AI agent integration.

Your server must implement the Agent-to-Agent (A2A) protocol with the Connect Customer A2A extensions. The contract targets A2A protocol v1.0. This page explains how your server must behave in each collaboration mode. For event names, fields, and headers, see the A2A protocol contract for external AI agents. For example payloads, see A2A sample events.

Your agent can collaborate in the following modes:

- **Handle actions behind the scenes.** When the Connect AI agent decides to invoke your agent, it builds a text message for it. Your agent performs the work and returns a text result, which the Connect AI agent uses to invoke another action or to formulate a response to the customer. The Connect AI agent keeps talking to the customer.
- **Talk to the customer.** Your agent takes over the conversation. Your agent exchanges text, or, with audio streaming, exchanges audio on voice contacts.

For how to configure a collaborator in one of these modes, see Set up an external AI agent integration.

Transport and authentication

Your server must meet the following transport and authentication requirements:

- **Transport.** For text, your server can accept JSON-RPC over a secure WebSocket (`wss://`) or over HTTPS (`https://`). Audio streaming is supported over secure WebSocket (`wss://`) only.
- **Authentication.** Connect Customer sends your API key as a bearer token when it connects. The Connect Customer administrator stores this key in AWS Secrets Manager during setup. Check the bearer token on each incoming connection or request, and reject the connection or request if the token doesn't match the API key that you issued.

Connect Customer also sends headers that activate the Connect Customer A2A extensions and carry trace context. For the header names and values, see Transport and discovery in the A2A protocol contract.

Session initiation

Each session starts when Connect Customer sends an `INIT_SESSION` event. Your server replies with `INIT_SESSION_RESPONSE`. You do not configure what Connect Customer sends. What happens next depends on the mode.

Talk to the customer. A session starts in the following order:

1. Connect Customer sends `INIT_SESSION`, and your server replies with `INIT_SESSION_RESPONSE`. `INIT_SESSION` carries session details, such as the conversation so far and information that identifies the contact, so the customer doesn't have to repeat their request.
2. Connect Customer sends `CHANNEL_STATE` with state `READY`. Wait for it before you send output to the customer.
3. Connect Customer sends customer turns, and your agent responds. For more information, see Turn lifecycle.

In this mode, Connect Customer shares contact context, such as the channel, only when the Connect AI agent's security profile grants the **Access Contact Control Panel** permission. Connect

Customer does not send custom contact attributes. For details on all of the context that Connect Customer shares, see Session initiation in the A2A protocol contract.

Handle actions behind the scenes. For each invocation, Connect Customer sends `INIT_SESSION`, and then the message that the Connect AI agent builds for your agent. There is no `CHANNEL_STATE` in this mode.

For example payloads, see INIT_SESSION and INIT_SESSION_RESPONSE in A2A sample events.

Connections by mode and channel

How often Connect Customer opens a connection depends on the mode and the channel. Your server must handle a new `INIT_SESSION` on each new connection. The following table summarizes the behavior.

Mode	Voice contacts	Chat contacts
Handle actions behind the scenes	A new connection and `INIT_SESSION` each time the Connect AI agent invokes your agent. Each connection uses the same session (`contextId`).	
Talk to the customer (text)	WebSocket: one persisten t connection for the whole session. HTTPS: separate requests, with no persistent connection. For the request flow, see the HTTPS table that follows.	A new connection for each customer message, with the same `contextId` . Connect Customer sends the conversat ion history again in each `INIT_SESSION` .
Talk to the customer (audio)	One persistent secure WebSocket connection for the whole session, carrying audio.	Same as text. Connect Customer doesn't negotiate audio, so your agent must handle text.

Persistent connections apply only to talk to the customer sessions over WebSocket on voice contacts. Audio always uses a persistent secure WebSocket connection.

Over HTTPS, no socket stays open between messages. Connect Customer sends each step as a separate `SendMessage` request. The following table shows the request flow for each mode.

Mode	What Connect Customer sends	What your server returns
Talk to the customer	`SendMessage` requests in this order: `INIT_SESSION`, then `CHANNEL_STATE` with state `READY`, then the customer message.	For the customer message, the response or a task (`taskId`). If your server returns a task, Connect Customer polls for the response with `GetTask`.
Handle actions behind the scenes	`SendMessage` requests with `INIT_SESSION`, then the message that the Connect AI agent builds for your agent. There is no `CHANNEL_STATE` in this mode.	The result, or a task (`taskId`) that Connect Customer polls with `GetTask`.

Turn lifecycle

In talk to the customer mode, text and audio, your agent handles each customer turn in the following order:

1. Stream a response message as an artifact. Each artifact carries one partial but complete message, streamed in chunks. End the message when it's complete. For how to mark the end of a message, see Event conventions in the A2A protocol contract.
2. Optionally, send another partial message as a new artifact.
3. Send the turn's `TRACING_SPAN` events. For more information, see Tracing.
4. Close the turn with a terminal task status update.

If your agent leaves an artifact or a task open, the customer's playback runs dry (an underrun). Connect Customer then closes the connection, and the collaboration ends with an error.

In talk to the customer mode, a normal turn doesn't end the collaboration. To end it, send `FINISH`. For more information, see Finishing a collaboration. For example payloads, see Text response chunk and Terminal status update with FINISH in A2A sample events.

Audio streaming

In talk to the customer mode with audio streaming on voice contacts, your agent receives and sends audio. Audio streaming always uses immediate handoff, and it is supported only over secure

WebSocket (`wss://`). In this mode, your agent handles speech itself. Connect Customer does not convert speech to text or text to speech for your agent.

Audio streaming is available only for external agents. An external agent that uses audio streaming must be the only collaborator on its Connect AI agent.

Your server must handle audio as follows:

- **Agree on the audio format.** At session start, Connect Customer proposes a format for the caller's audio and a format for your agent's audio, so both sample rates are negotiated. Your server can accept them or counter-propose a different supported sample rate for either one. Every proposal and counter-proposal must be linear PCM, 16-bit, mono, at 8 kHz, 16 kHz, or 24 kHz. The format is fixed for the session, and Connect Customer resamples for the caller.
- **Detect turns from the audio.** Caller audio streams continuously, with no turn boundary markers. Your agent detects turn-taking itself, for example with voice activity detection.
- **Stream one response at a time.** Send each spoken response as a single audio artifact, as part of a distinct task. Do not open a second audio artifact while one is still open. Connect Customer treats conflicting artifacts as a protocol violation and closes the connection.
- **Keep audio chunks small.** Don't split audio across fragments. Fragmented audio can't be played until all the parts arrive. Instead, keep each audio chunk small enough to fit in one WebSocket frame, so that each chunk can be played on its own.
- **Finish every audio response.** End each audio artifact when the response is complete, and close each turn's task. An unfinished audio artifact causes an underrun, and Connect Customer closes the connection. For more information, see Turn lifecycle.
- **Handle interruptions.** When the caller speaks over your agent, send an `INTERRUPTION` event so that Connect Customer can flush buffered audio. Then close the current artifact and task, including the turn's trace, before you send a new response.
- **Handle chat as text.** If the same collaborator serves chat contacts, Connect Customer does not negotiate audio. Your agent must accept and return text. To identify the channel, read it from contact context.

Latency. The latency that the caller experiences depends on both Connect Customer and your agent's processing time. Optimize your agent's response time to keep a natural conversational pace. We recommend that you work with your AWS account team or Solutions Architect to validate latency and audio quality before you go to production.

For the audio format fields and frame rules, see Session initiation, Transport fragmentation, and Interruptions in the A2A protocol contract. For example payloads, see Audio input chunk and Audio response chunk in A2A sample events.

Finishing a collaboration

Finishing applies to talk to the customer mode only. Handle actions behind the scenes mode doesn't support `FINISH`. In that mode, each invocation is a request and response with the Connect AI agent, whenever it decides to invoke your agent, so there is no collaboration to finish.

In talk to the customer mode, your agent ends its participation by sending a `FINISH` event. Send `FINISH` only when your agent is done with the conversation, not at the end of every turn. After you send `FINISH`, do not send more messages on the session.

When your agent sends `FINISH`, control returns to the main Connect AI agent, which is invoked again with your reason. The main Connect AI agent can continue the conversation, invoke another collaborator, or use its Complete or Escalate tool to return the contact to the flow.

Your agent can send the following finish types:

- **`COMPLETE`**. The request is fulfilled. To return the contact to the flow, the main Connect AI agent can use its Complete tool, which follows the flow's Complete path.
- **`ESCALATE`**. The conversation needs a human agent. To return the contact to the flow, the main Connect AI agent can use its Escalate tool, which follows the flow's Escalate path. There, the administrator can transfer the contact to a human agent.

For more information about the Complete and Escalate tools, see Tools for orchestrator AI agents.

When you finish, explain why. The main Connect AI agent may process your reason before the contact continues, and a specific reason helps it handle the outcome gracefully.

For the `FINISH` payload, see Finishing: hand-back and terminal outcomes in the A2A protocol contract. For an example, see Terminal status update with FINISH in A2A sample events.

Errors and retries

When a turn starts but cannot complete, send a terminal status update that marks the task as failed and includes a structured error. Connect Customer also treats a JSON-RPC error from your agent as a failure. A terminal failed, canceled, or rejected task ends the collaboration, not just the turn, and the contact returns to the flow's Error branch.

Connect Customer retries as follows:

- If a WebSocket connection attempt fails with certain errors, Connect Customer retries it once.
- In talk to the customer mode on voice contacts over WebSocket, if an established connection drops unexpectedly, Connect Customer reconnects once. On chat contacts, Connect Customer doesn't reconnect. For details, see Connection retries, reconnects, and close codes.

If the retry or reconnect fails, the collaboration fails. The contact returns to the error branch of the contact flow, where the administrator configures a fallback.

For the error levels, codes, and fields, see Errors in the A2A protocol contract. For an example, see Task failure with structured error in A2A sample events.

Connection retries, reconnects, and close codes

Connection attempts. Connect Customer retries a failed connection attempt once for certain errors. This applies to every WebSocket connection, including each chat message's connection. For which errors, see Connection attempt retries in the A2A protocol contract.

Reconnects. In talk to the customer mode on voice contacts over WebSocket, with text or audio streaming, Connect Customer handles a dropped connection as follows. The reconnect attempt gets the same upgrade retry as any other connection attempt.

If the WebSocket connection drops during the session, Connect Customer tries to reconnect once before the collaboration fails. Connect Customer also reconnects when the socket fails with no close frame, or when the connection closes with one of the following codes:

- `1005` – No Status Received
- `1006` – Abnormal Closure
- `1012` – Service Restart
- `1013` – Try Again Later
- `1014` – Bad Gateway

Any other close code, including `1000` (Normal Closure), ends the collaboration without a reconnect. Don't close the connection mid-session to end a conversation. Send `FINISH` instead. For more information, see Finishing a collaboration. If you must restart your server during a deployment, close the persistent voice connection with `1012` so that Connect Customer reconnects.

The following rules apply to reconnects:

- **One reconnect per session.** Connect Customer reconnects at most once per collaboration session. A successful reconnect doesn't reset this limit, so a second drop ends the collaboration.
- **New session initialization.** A reconnect re-initializes the session. Connect Customer opens a new connection, sends a new `INIT_SESSION` with the same `contextId`, and then sends `CHANNEL_STATE` with state `READY`. Your server must handle a repeated `INIT_SESSION` for the same `contextId`.
- **Failure.** If the reconnect fails, or a second drop occurs, Connect Customer ends the collaboration and closes your connection with code `1011`. The contact returns to the contact flow's Error branch. For more information, see Errors and retries.

Chat contacts. Each customer message uses its own WebSocket connection, which closes after the turn. If the connection drops during a turn, Connect Customer doesn't reconnect, whatever the close code, and the collaboration fails. The next customer message opens a new connection, unless the collaboration has already ended.

In handle actions behind the scenes mode, each invocation uses its own connection. Connect Customer doesn't reconnect a dropped invocation.

Tracing

Your server must publish `TRACING_SPAN` events for every turn, covering the turn's input, output, and tool activity. Connect Customer disables external agent endpoints that do not send the required trace data. For the requirements and how enforcement works, see Trace data requirements for external AI agents. For the field names and wire format, see Tracing in the A2A protocol contract and TRACING_SPAN in A2A sample events.

Observability for collaborating AI agents

When an AI agent collaborates with other agents during a contact, Connect Customer collects trace data from every collaboration. This trace data provides visibility into what each collaborator did during the contact, including the messages exchanged, tools invoked, and time spent on each step. How the trace data reaches Connect Customer depends on the collaborator type:

- **Connect AI agent collaborators.** For AI agents in your Connect Customer instance, Connect Customer publishes traces automatically. You see a trace for each AI agent that is active in the collaboration. For more information, see AI agent traces.
- **External collaborators.** The external agent must publish trace data from its own server as `TRACING_SPAN` events. The required and encouraged fields on this page apply to external collaborators. For information about how to publish traces, see Tracing in the A2A protocol contract and the TRACING_SPAN sample event.

You can use trace data to evaluate collaborator quality, debug unexpected behavior, and verify that collaborators are meeting your operational standards.

What trace data Connect Customer collects

Each time your Connect AI agent brings in a collaborator, Connect Customer opens a trace context and records the collaborator's activity as OpenTelemetry spans. External agents send their spans in OpenTelemetry OTLP/JSON format inside `TRACING_SPAN` events. The trace captures the full lifecycle of the collaboration, from the initial request through the final response or conversation transfer.

For external collaborators, trace data falls into two categories: required fields that the external agent must send, and encouraged fields that improve observability but are not enforced.

Required trace data

External agents must send the following trace data for each turn. These fields are mandatory, and Connect Customer monitors their delivery.

1. **Input and output messages.** The input message that the collaborator received and the output message that it sent, recorded as `aws.connect.span.message` span events. Each event carries the `role`, `participant`, `type`, and `content` attributes.
2. **Tool input and result.** For each tool span, both the tool input and the tool result must be present in the trace.
3. **Per-span timing.** Each span must include `startTimeUnixNano` and `endTimeUnixNano` with valid timestamps.

If an external agent does not send these fields, Connect Customer treats the trace as incomplete. For how Connect Customer enforces these requirements, see Trace data requirements for external AI agents.

Encouraged trace data

We strongly recommend that external agents send the following fields. They improve your ability to evaluate collaborator performance and debug issues, but they are not enforced.

1. **Token counts.** Input and output token counts, in the `gen_ai.usage.input_tokens` and `gen_ai.usage.output_tokens` attributes.
2. **Model identifier.** The foundation model that the collaborator used, in the `gen_ai.request.model` attribute.
3. **Total tokens.** The total token count, in the `aws.connect.usage.total_tokens` attribute.
4. **Agent name.** The name of the collaborating agent, in the `gen_ai.agent.name` attribute.
5. **Operation name.** The type of operation for the span, in the `gen_ai.operation.name` attribute.
6. **Error type.** The type of error when a span fails, in the `aws.connect.error.type` attribute.

For the full list of recognized attributes, see Tracing in the A2A protocol contract.

Voice collaboration transcripts

For voice collaborations that use bidirectional audio streaming, which is available only for external collaborators, trace data also includes transcripts that are used to maintain conversation history across the collaboration.

Trace data requirements for external AI agents

Connect Customer uses trace data to give you full visibility into everything that happens on a contact, across all Connect AI agents and external AI agents. Every external AI agent endpoint must send the required trace data during every collaboration. This page explains what is required, how Connect Customer monitors compliance, and what happens if an external AI agent stops sending trace data.

This page applies to external AI agents only. When the collaborator is another Connect AI agent, Connect Customer publishes its traces automatically.

Connect Customer disables external AI agent endpoints that do not send the required trace data. This protects the observability and quality management capabilities that your team depends on for every contact. If you do not provide traces, you operate without visibility, and we have limited ways to support you.

What is required

Every external AI agent must publish `TRACING_SPAN` events from its server for every turn of every collaboration. Each turn's traces must include the following:

1. **Input and output messages.** The input message that the external AI agent received and the output message that it sent, recorded as span events.
2. **Tool inputs and results.** If the external AI agent invokes tools during processing, each tool span must include both the tool input and the tool result.

3. **Valid timing.** Each span must include `startTimeUnixNano` and `endTimeUnixNano` with valid timestamps.

If an external AI agent does not send these fields, Connect Customer treats the trace as incomplete. Other fields, such as token usage, model, and agent name, are encouraged but not enforced. For more information about encouraged fields, see Observability for collaborating AI agents.

For information about how to build and send trace spans, see Tracing in the A2A protocol contract and the TRACING_SPAN sample in A2A sample events. For a summary of server requirements, see Build an external AI agent server.

How enforcement works

Connect Customer monitors trace delivery from every external AI agent endpoint on every contact. If Connect Customer detects that an external AI agent endpoint is not sending the required trace data, Connect Customer disables that endpoint for new contacts.

This monitoring is automatic and continuous. External AI agents must send complete trace data from the first contact onward.

Quotas and limitations for agent-to-agent collaboration

This page lists the requirements, service quotas, and design constraints for agent-to-agent collaboration in Connect Customer.

Requirements

Agent-to-agent collaboration has the following requirements:

- **Connect Customer tier required.** Agent-to-agent collaboration requires an Connect Customer instance on the Connect Customer tier. It is not available on Customer Basic, which does not

include the session state, tracing, and audio streaming capabilities that collaboration requires. For tier details, see Connect Customer pricing.

- **Amazon Lex V2 bot required.** All agent-to-agent collaboration requires an Amazon Lex V2 bot configured with the `AMAZON.QInConnectIntent`. The bot routes customer input to your Connect AI agent. When audio streaming is off, you can use any Amazon Lex speech recognition and text-to-speech settings. Audio streaming requires a bot locale that uses Amazon Nova Sonic speech-to-speech, with a single `AMAZON.QInConnectIntent`. When audio streaming is on, the bot doesn't perform speech-to-speech for the collaborator. Audio streams directly between Connect Customer and the external agent.

Service quotas

The following quotas apply to agent-to-agent collaboration. All quotas are adjustable. For the limit on collaboration depth, see Design constraints.

Quota	Value	Adjustable	Description
Collaborators per AI agent	5	Yes	The maximum number of collaborators that you can configure on a single AI agent.
Handoffs per customer turn	10	Yes	The maximum number of handoffs between agents during a single customer turn.
Concurrent outbound third-party agent connections per instance	5	Yes	The maximum number of concurrent outbound connections to third-party agents across a single Connect Customer instance.

Design constraints

The following constraints are architectural properties of agent-to-agent collaboration. They reflect how the feature is designed.

- **API-only configuration.** You configure agent-to-agent collaboration through the Connect Customer API. There is no console interface for configuring collaborators, collaboration modes,

or trace settings. You use the `CreateAIAgent`, `UpdateAIAgent`, and `CreateAIAgentVersion` API operations.

- **One level of collaboration.** Collaborators can't have their own collaborators.
- **One collaborator talks to the customer at a time.** In talk-to-the-customer mode, one collaborator holds the conversation with the customer until it hands back control. Your Connect AI agent can hand off to different collaborators at different points in the same contact. In handle-actions-behind-the-scenes mode, your Connect AI agent stays in the conversation. It invokes collaborators as its instructions require, and each invocation returns a result to your Connect AI agent.
- **Audio streaming is available only for external collaborators.** For AI agents in your instance, Connect Customer handles voice automatically, so you don't need to set `audioStreamingEnabled`. Audio streaming (`audioStreamingEnabled` set to `true`) is for external collaborators, with the following constraints:
  - It requires `immediateHandoff` set to `true`.
  - The audio collaborator must be the only collaborator on that AI agent. An AI agent can have at most one immediate handoff.
  - The orchestrating AI agent can't have an orchestration prompt or a guardrail. Its only tools can be the reserved Complete tool (required) and Escalate tool. For more information, see Tools for orchestrator AI agents.
  - Audio streaming is supported over WebSocket (`wss://`) only. The external agent must accept a secure WebSocket connection.
  - Audio streaming applies only to voice contacts. On chat, Connect Customer doesn't negotiate audio, and the external agent must handle text.

Pricing

Agent-to-agent collaboration pricing depends on the collaboration mode. For current pricing, see Connect Customer pricing.

Troubleshoot AI agent issues

Use this topic to help diagnose and resolve common issues with AI agents.

Topics

- Logging and tracing for AI agents
- Troubleshoot agentic self-service issues
- Common issues
- (Legacy) Self-service issues

Logging and tracing for AI agents

To troubleshoot AI agent issues effectively, use the following logging and tracing options.

- **ListSpans API (recommended for orchestrator AI agents)**: Use the ListSpans API to retrieve AI agent execution traces for a session. This is the recommended starting point for debugging orchestrator AI agent interactions, as it provides granular visibility into agent orchestration flows, LLM interactions, and tool invocations, allowing you to trace how the AI agent reasoned through a request and which tools it selected and executed.
- **CloudWatch Logs**: Enable CloudWatch Logging for your AI agents by following the steps in Monitor AI agents using CloudWatch.

  Legacy self-service interactions generate log entries with the event type `TRANSCRIPT_SELF_SERVICE_MESSAGE` in the following format:

```
{
    "assistant_id": "{UUID}",
    "event_timestamp": 1751414298692,
    "event_type": "TRANSCRIPT_SELF_SERVICE_MESSAGE",
    "session_id": "{UUID}",
    "utterance": "[CUSTOMER]...",
    "prompt": "{prompt used}",
    "prompt_type": "SELF_SERVICE_PRE_PROCESS|SELF_SERVICE_ANSWER_GENERATION",
    "completion": "{Response from model}",
    "model_id": "{model id e.g.: us.amazon.nova-pro-v1:0}",
    "session_message_id": "{UUID}",
    "parsed_response": "{model response}"
}
```

Agentic self-service interactions generate log entries with the event type `TRANSCRIPT_LARGE_LANGUAGE_MODEL_INVOCATION`. These entries include the full orchestration context such as the prompt with tool configurations, conversation history with tool calls and results, the model completion, and the AI agent configuration. The following example shows the key fields:

```
{
    "assistant_id": "{UUID}",
    "event_timestamp": 1772748470993,
    "event_type": "TRANSCRIPT_LARGE_LANGUAGE_MODEL_INVOCATION",
    "session_id": "{UUID}",
    "prompt": "{full prompt including system instructions, tool configs, and
 conversation history}",
    "prompt_type": "ORCHESTRATION",
    "completion": "{model response with message and tool use}",
    "model_id": "{model id e.g.: us.anthropic.claude-haiku-4-5-20251001-v1:0}",
    "parsed_response": "{parsed customer-facing message}",
    "generation_id": "{UUID}",
    "ai_agent_id": "{UUID}"
}
```

- **Amazon Lex logging (self-service only)**: Enable Amazon Lex logging by following the steps in Logging errors with error logs in Amazon Lex V2.
- **Connect Customer logging**: Enable Connect Customer logging by adding a Set logging behavior flow block in your Connect Customer flow.

Troubleshoot agentic self-service issues

The following issues are specific to agentic self-service.

AI agent is not responding to customers

If your AI agent is processing requests but customers are not seeing any responses, the orchestration prompt might be missing the required message formatting instructions.

Orchestrator AI agents only display messages to customers when the model's response is wrapped in `<message>` tags. If your prompt does not instruct the model to use these tags, responses will not be rendered to the customer.

Solution: Ensure your orchestration prompt includes formatting instructions that require the model to wrap responses in `<message>` tags. For more information, see Message parsing.

MCP tool invocation failures

If your AI agent fails to invoke MCP tools during a conversation, check the following:

- **Security profile permissions** – Verify that the AI agent's security profile grants access to the specific MCP tools it needs. The AI agent can only invoke tools it has explicit permission to access.
- **Gateway connectivity** – Confirm that the Amazon Bedrock AgentCore Gateway is correctly configured and that the discovery URL is valid. Verify that the inbound authentication audiences are set to the gateway ID. Check the gateway status in the AgentCore console.
- **API endpoint health** – Verify that the backend API or Lambda function behind the MCP tool is running and responding correctly. Check CloudWatch Logs for errors in the target service.

IAM permissions for MCP tools

If MCP tool calls return access denied errors, verify that the IAM roles have the required permissions:

- **Amazon Bedrock AgentCore Gateway role** – The gateway's execution role must have permission to invoke the backend APIs or Lambda functions that your MCP tools connect to.

Common issues

Bundle the latest AWS SDK with your Lambda functions

If you are calling AI agents APIs directly from Lambda functions, you must package and bundle the latest version of the AWS SDK along with your function code. The Lambda runtime environment might include an older version of the SDK that does not support the latest AI agents API models and features.

Symptoms: You might experience parameter validation exceptions or request input parameters being silently ignored when using an outdated SDK version.

To avoid API model drift, include the latest AWS SDK as a dependency in your deployment package or as a Lambda layer rather than relying on the SDK provided by the Lambda runtime. The steps to bundle the SDK vary by language. For example, for Node.js, see Creating a deployment

package with dependencies. For other languages, refer to the corresponding Lambda deployment packaging documentation. For sharing the SDK across multiple functions, see Lambda layers.

(Legacy) Self-service issues

The following issues are specific to legacy self-service.

Customers are unexpectedly receiving "Escalating to agent..."

Unexpected agent escalation occurs when there's an error during the self-service bot interaction or when the model doesn't produce a valid `tool_use` response for `SELF_SERVICE_PRE_PROCESS`.

Troubleshooting steps

1. **Check the AI agent logs**: Examine the `completion` attribute in the associated log entry.
2. **Validate the stop reason**: Confirm that the `stop_reason` is `tool_use`.
3. **Verify parsed response**: Check if the `parsed_response` field is populated, as this represents the response you'll receive from the model.

Known issue with Claude 3 Haiku

If you're using Claude 3 Haiku for self-service pre-processing, there's a known issue where it generates the `tool_use` JSON as text, resulting in a `stop_reason` of `end_turn` instead of `tool_use`.

Solution: Update your custom prompt to wrap the `tool_use` JSON string inside `<tool>` tags by adding this instruction:

```
You MUST enclose the tool_use JSON in the <tool> tag
```

Self-service chat or voice call is unexpectedly terminating

This issue can occur due to timeouts from Amazon Lex or incorrect Amazon Nova Pro configuration. These issues are described below.

Timeouts from Amazon Lex

- **Symptoms**: Connect Customer logs show "Internal Server Error" for the Get customer input block

- **Cause**: Your self-service bot timed out while providing results within the 10-second limit. Timeout errors won't appear in AI agent logs.
- **Solution**: Simplify your prompt by removing complex reasoning to reduce processing time.

Amazon Nova Pro configuration

If you're using Amazon Nova Pro for your custom AI prompts, make sure that the tool_use examples follow Python-compatible format.

Monitor AI agent performance with observability and analytics

After you set up your AI agents, you can monitor their performance using AI agent observability and analytics. Connect Customer provides the following capabilities to track AI agent performance:

- **ListSpans API:** Detailed span-level data about each AI agent invocation, including tool calls and nested operations. This data is available in real-time. To learn more, see ListSpans API guide.
- **GetMetricDataV2 API:** Programmatic access to AI agent metrics with support for filtering and grouping. To learn more, see GetMetricDataV2 in the Connect Customer API Reference and see Metric definitions for metric definitions and calculation logic details. For the full list of AI agent metrics, see AI agent metrics.
- **Amazon Connect data lake:** Raw metric data available through the Connect Customer data lake for custom reporting and analysis. To learn more, see Data type definitions. The following AI agent data lake tables are refreshed every 15 minutes:
  - AI Agent
  - AI Agent Knowledge Base
  - AI Prompt
  - AI Session
  - AI Tool
- **CloudWatch Streaming:** CloudWatch Logs into the entire AI journey including the conversation, spans, triggers, intents, recommendations, tools. To learn more, see Monitor AI agents using CloudWatch.
- **AI agent performance dashboard:** Pre-built visualizations that you can access from the Connect Customer admin website by choosing Dashboard, AI agent performance dashboard. To learn more, see AI Agent performance dashboard.

Active AI Agents

This metric measures the total number of unique AI Agents, where each AI Agent is identified by its unique combination of Name and Version.

- **Metric type:** Integer
- **Metric category:** AI Agent
- **GetMetricDataV2 API metric identifier:** `ACTIVE_AI_AGENTS`
- **Dashboard location:** AI Agent Performance Dashboard, Active AI Agents

AI Agent Invocations

This metric measures the total count of AI Agent invocations across all AI Agents per instance.

- **Metric type:** Integer
- **Metric category:** AI Agent
- **GetMetricDataV2 API metric identifier:** `AI_AGENT_INVOCATIONS`
- **Dashboard location:** AI Agent Performance Dashboard, AI Agent Invocation Count

AI Agent Invocation Success

This metric measures the number of AI Agent invocations that executed successfully without technical failures such as API errors, timeouts, or system issues.

- **Metric type:** Integer
- **Metric category:** AI Agent
- **GetMetricDataV2 API metric identifier:** `AI_AGENT_INVOCATION_SUCCESS`

AI Agent Invocation Success Rate

This metric measures the percentage of AI Agent invocations that executed successfully without technical failures.

- **Metric type:** Percent
- **Metric category:** AI Agent
- **GetMetricDataV2 API metric identifier:** `AI_AGENT_INVOCATION_SUCCESS_RATE`

- **Dashboard location:** AI Agent Performance Dashboard, AI Agent Invocation Success Rate

AI Agent Collaborators

This metric measures the distinct number of AI agents that participated in a multi-agent interaction, including the orchestrator and each sub-agent it collaborated with via handoff or delegation.

- **Metric type:** Integer
- **Metric category:** AI Agent
- **GetMetricDataV2 API metric identifier:** `AI_AGENT_COLLABORATORS`
- **Dashboard location:** AI Agent Performance Dashboard, AI Agent Collaborators

AI Agent Collaboration Invocations

This metric measures the total number of times an AI agent received a handoff or delegation from another AI agent.

- **Metric type:** Integer
- **Metric category:** AI Agent
- **GetMetricDataV2 API metric identifier:** `AI_AGENT_COLLABORATION_INVOCATIONS`
- **Dashboard location:** AI Agent Performance Dashboard, AI Agent Collaboration Invocations

AI Agent Response Helpful

This metric measures the count of AI suggestions rated as helpful with a thumbs-up.

- **Metric type:** Integer
- **Metric category:** AI Agent
- **GetMetricDataV2 API metric identifier:** `AI_AGENT_RESPONSE_HELPFUL`
- **Dashboard location:** AI Agent Performance Dashboard, AI Agent Response Helpful

> **Note**
>
> This metric is available as part of Connect Customer AI.

AI Agent Response Not Helpful

This metric measures the count of AI suggestions rated as unhelpful with a thumbs-down.

- **Metric type:** Integer
- **Metric category:** AI Agent
- **GetMetricDataV2 API metric identifier:** `AI_AGENT_RESPONSE_NOT_HELPFUL`
- **Dashboard location:** AI Agent Performance Dashboard, AI Agent Response Not Helpful

> **Note**
>
> This metric is available as part of Connect Customer AI.

AI Agent Selection Accuracy

This metric measures the average accuracy score (0-1) evaluating whether the orchestrator AI agent routed tasks to the correct sub-agent. A value of 1 indicates optimal selection.

- **Metric type:** Double
- **Metric category:** AI Agent
- **GetMetricDataV2 API metric identifier:** `AI_AGENT_SELECTION_ACCURACY`
- **Dashboard location:** AI Agent Performance Dashboard, AI Agent Selection Accuracy

> **Note**
>
> This metric is available as part of Connect Customer AI.

Evaluation Criteria:

This metric uses an automated LLM-based evaluation that analyzes each routing decision made by the orchestrator AI agent. Each routing decision is scored as either correct or incorrect based on the following criteria:

- **Appropriateness:** Was the selected sub-agent the right one for the customer's request?

- **Capability match:** Does the selected sub-agent have the tools and knowledge to handle the task?
- **Optimal routing:** Was there a more suitable sub-agent available that the orchestrator missed?

AI Handoffs

This metric measures the total count of contacts handled by AI agents that escalated to human agents. This metric is specifically applicable to self-service use cases where AI agents initially handle customer inquiries.

- **Metric type:** Integer
- **Metric category:** AI Session
- **GetMetricDataV2 API metric identifier:** `AI_HANDOFFS`

AI Handoff Rate

This metric measures the percentage of contacts handled by AI agents that had escalation to human agents or additional support.

- **Metric type:** Percent
- **Metric category:** AI Session
- **GetMetricDataV2 API metric identifier:** `AI_HANDOFF_RATE`
- **Dashboard location:** AI Agent Performance Dashboard, Handoff Rate

AI Response Completion Rate

This metric measures the percentage of AI sessions that successfully responded to incoming customer requests.

- **Metric type:** Percent
- **Metric category:** AI Session
- **GetMetricDataV2 API metric identifier:** `AI_RESPONSE_COMPLETION_RATE`
- **Dashboard location:** AI Agent Performance Dashboard, Response Completion Rate

AI Involved Contacts

This metric measures the total count of customer contacts where AI Agents were involved, either providing self-service automation or assisting human agents in resolving customer inquiries.

- **Metric type:** Integer
- **Metric category:** AI Session
- **GetMetricDataV2 API metric identifier:** `AI_INVOLVED_CONTACTS`
- **Dashboard location:** AI Agent Performance Dashboard, AI Involved Contacts

AI Prompt Invocation Success

This metric measures the number of AI Prompt invocations that executed successfully without errors.

- **Metric type:** Integer
- **Metric category:** AI Prompt
- **GetMetricDataV2 API metric identifier:** `AI_PROMPT_INVOCATION_SUCCESS`

AI Prompt Invocation Success Rate

This metric measures the percentage of AI Prompt invocations that executed successfully.

- **Metric type:** Percent
- **Metric category:** AI Prompt
- **GetMetricDataV2 API metric identifier:** `AI_PROMPT_INVOCATION_SUCCESS_RATE`
- **Dashboard location:** AI Agent Performance Dashboard, AI Prompt Invocation Success Rate

AI Prompt Invocations

This metric measures the total count of AI Prompt invocations.

- **Metric type:** Integer
- **Metric category:** AI Prompt
- **GetMetricDataV2 API metric identifier:** `AI_PROMPT_INVOCATIONS`

- **Dashboard location:** AI Agent Performance Dashboard, AI Prompt Invocation Count

AI Tool Invocation Success

This metric measures the total number of AI Tool invocations that executed successfully.

- **Metric type:** Integer
- **Metric category:** AI Tool
- **GetMetricDataV2 API metric identifier:** `AI_TOOL_INVOCATION_SUCCESS`

AI Tool Invocation Success Rate

This metric measures the percentage of AI Tool invocations that executed successfully.

- **Metric type:** Percent
- **Metric category:** AI Tool
- **GetMetricDataV2 API metric identifier:** `AI_TOOL_INVOCATION_SUCCESS_RATE`
- **Dashboard location:** AI Agent Performance Dashboard, AI Tool Invocation Success Rate

AI Tool Invocations

This metric measures the total count of AI Tool invocations.

- **Metric type:** Integer
- **Metric category:** AI Tool
- **GetMetricDataV2 API metric identifier:** `AI_TOOL_INVOCATIONS`
- **Dashboard location:** AI Agent Performance Dashboard, AI Tool Invocation Count

AI Tool Parameter Accuracy

This metric measures the rate of tool invocations where AI Agents provided the correct parameters. Value is between 0-1, where 1 indicates perfect parameter accuracy.

- **Metric type:** Double
- **Metric category:** AI Tool
- **GetMetricDataV2 API metric identifier:** `AI_TOOL_PARAMETER_ACCURACY`

- **Dashboard location:** AI Agent Performance Dashboard, AI Tool Parameter Accuracy

Evaluation Criteria:

This metric uses an automated LLM-based evaluation that analyzes the parameters passed to each tool call against the conversation context and the tool's parameter definitions. Each tool call is scored as either correct or incorrect based on the following criteria:

- **Presence:** Are all required parameters present and correctly populated?
- **Accuracy:** Are parameter values explicitly justified by the conversation context, rather than inferred or assumed?
- **Precision:** Are there any extra, irrelevant, or fabricated parameters included?

> **Note**
>
> This metric is available as part of Connect Customer AI.

AI Tool Selection Accuracy

This metric measures the rate of correct tool selections by AI Agents. Value is between 0-1, where 1 indicates optimal selection.

- **Metric type:** Double
- **Metric category:** AI Tool
- **GetMetricDataV2 API metric identifier:** `AI_TOOL_SELECTION_ACCURACY`
- **Dashboard location:** AI Agent Performance Dashboard, AI Tool Selection Accuracy

Evaluation Criteria:

This metric uses an automated LLM-based evaluation that analyzes each tool call made by the AI agent. Each tool call is scored as either correct or incorrect based on the following criteria:

- **Appropriateness:** Was the selected tool the right one for fulfilling the customer's request?
- **Necessity:** Did the AI agent avoid unnecessary or incorrect tool calls?
- **Optimal selection:** Was there a more appropriate tool available that the AI agent missed?

> **Note**
>
> This metric is available as part of Connect Customer AI.

AI Tool Utilization Accuracy

This metric measures the rate of correct tool utilization by AI Agents, including proper parameters and selection. Value is between 0-1, where 1 indicates perfect utilization.

- **Metric type:** Double
- **Metric category:** AI Tool
- **GetMetricDataV2 API metric identifier:** `AI_TOOL_UTILIZATION_ACCURACY`
- **Dashboard location:** AI Agent Performance Dashboard, AI Tool Utilization Accuracy

Evaluation Criteria:

This metric is the combined score of AI Tool Selection Accuracy and AI Tool Parameter Accuracy.

> **Note**
>
> This metric is available as part of Connect Customer AI.

Average AI Agent Conversation Turns

This metric measures the average number of conversation turns that AI Agents took to reach an outcome.

- **Metric type:** Double
- **Metric category:** AI Agent
- **GetMetricDataV2 API metric identifier:** `AVG_AI_AGENT_CONVERSATION_TURNS`
- **Dashboard location:** AI Agent Performance Dashboard, Avg. AI agent conversation turns

Average AI Agent Invocation Latency

This metric measures the average time an AI agent takes before completing its task in milliseconds. It may involve multiple LLM calls (1 or more) and tool calls (0 or more).

- **Metric type:** Double
- **Metric category:** AI Agent
- **GetMetricDataV2 API metric identifier:** `AVG_AI_AGENT_INVOCATION_LATENCY`
- **Dashboard location:** AI Agent Performance Dashboard, Avg. AI Agent Invocation Latency

Average AI Conversation Turns

This metric measures the average number of conversation turns across all AI involved contacts.

- **Metric type:** Double
- **Metric category:** AI Session
- **GetMetricDataV2 API metric identifier:** `AVG_AI_CONVERSATION_TURNS`
- **Dashboard location:** AI Agent Performance Dashboard, Avg. AI Conversation Turns

Average AI Prompt Invocation Latency

This metric measures the average invocation latency of AI Prompts in milliseconds.

- **Metric type:** Double
- **Metric category:** AI Prompt
- **GetMetricDataV2 API metric identifier:** `AVG_AI_PROMPT_INVOCATION_LATENCY`
- **Dashboard location:** AI Agent Performance Dashboard, Avg. AI Prompt Invocation Latency

Average AI Tool Invocation Latency

This metric measures the average invocation latency of AI Tools in milliseconds.

- **Metric type:** Double
- **Metric category:** AI Tool
- **GetMetricDataV2 API metric identifier:** `AVG_AI_TOOL_INVOCATION_LATENCY`
- **Dashboard location:** AI Agent Performance Dashboard, Avg. AI Tool Invocation Latency

Completeness Score

This metric measures the proportion of sessions where the Orchestration AI Agent responses fully address all parts of customer requests rather than providing partial or incomplete answers. Value is between 0-1, where 1 indicates complete responses across all sessions.

- **Metric type:** Double
- **Metric category:** AI Session
- **GetMetricDataV2 API metric identifier:** `COMPLETENESS_SCORE`
- **Dashboard location:** AI Agent Performance Dashboard, Avg. Completeness Score

Evaluation Criteria:

This metric uses an automated LLM-based evaluation that analyzes each customer turn and the AI agent's response. When a customer message contains multiple requests or questions, the evaluation checks whether each one was addressed. This metric is evaluated using the following criteria:

- **Multi-request coverage:** Were all explicit requests within a single turn identified and addressed by the agent?
- **Definition of covered:** Was each request either directly answered, acknowledged with intent to act on, or explained as not possible due to policy/constraints?
- **Immediate response scope:** Only the agent's responses before the next message are evaluated; later resolution doesn't count retroactively

> **Note**
>
> This metric is available as part of Connect Customer AI.

Context Fidelity Score

This metric measures the average fidelity score (0-1) evaluating whether the AI agent provided accurate and complete context to the downstream agent during collaboration. A value of 1 indicates perfect context fidelity.

- **Metric type:** Double

- **Metric category:** AI Agent
- **GetMetricDataV2 API metric identifier:** `CONTEXT_FIDELITY_SCORE`
- **Dashboard location:** AI Agent Performance Dashboard, Context Fidelity Score

> **Note**
>
> This metric is available as part of Connect Customer AI.

Evaluation Criteria:

This metric uses an automated LLM-based evaluation that analyzes the context passed between agents during handoff or delegation. Each context transfer is scored based on the following criteria:

- **Completeness:** Was all relevant conversation context included in the handoff?
- **Accuracy:** Was the context accurately represented without distortion or omission?
- **Relevance:** Was unnecessary or misleading context excluded from the transfer?

Faithfulness Score

This metric measures the proportion of sessions where the Orchestration AI Agent responses remain faithful to the conversational context, including messages and tool call results. Value is between 0-1, where 1 indicates perfect contextual fidelity.

- **Metric type:** Double
- **Metric category:** AI Session
- **GetMetricDataV2 API metric identifier:** `FAITHFULNESS_SCORE`
- **Dashboard location:** AI Agent Performance Dashboard, Avg. Faithfulness Score

Evaluation Criteria:

This metric uses an automated LLM-based evaluation that analyzes each AI agent response against the conversation context. Each response is assessed for faithfulness and checked for hallucination based on the following criteria:

- **Accuracy of representation:** Does the response accurately represent information from the conversation context?
- **Consistency:** Does the response maintain consistency with facts stated in the conversation?
- **Supported inferences:** Are any inferences the response makes reasonably supported by the context?
- **Correct attribution:** Does the response correctly attribute statements and information to the right source in the conversation without fabricating or misaligning claims?

> **Note**
>
> This metric is available as part of Connect Customer AI.

Goal Success Rate

This metric measures the proportion of sessions where the Orchestration AI Agent successfully resolved customer issues. Value is between 0-1, where 1 indicates successful resolution across all sessions.

- **Metric type:** Double
- **Metric category:** AI Session
- **GetMetricDataV2 API metric identifier:** `GOAL_SUCCESS_RATE`
- **Dashboard location:** AI Agent Performance Dashboard, Goal Success Rate

Evaluation Criteria:

This metric uses an automated LLM-based evaluation that analyzes the complete conversation trace for each AI agent session. Each session is scored as either successful or unsuccessful based on four dimensions:

- **Goal achievement:** Did the AI agent fulfill the customer's primary objective?
- **Outcome quality:** Is the final result accurate and free of errors?
- **Completeness:** Were all aspects of the request addressed?
- **Appropriateness:** Did the AI agent use suitable tools and approaches?

> **Note**
>
> This metric is available as part of Connect Customer AI.

Knowledge Content References

This metric measures the count of knowledge content articles referenced by AI Agents.

- **Metric type:** Integer
- **Metric category:** AI Knowledge Base
- **GetMetricDataV2 API metric identifier:** `KNOWLEDGE_CONTENT_REFERENCES`
- **Dashboard location:** AI Agent Performance Dashboard, Knowledge Base Reference Count

Proactive Intents Answered

This metric measures the number of proactive intents (customer queries) that were successfully answered by AI Agents during AI sessions.

- **Metric type:** Integer
- **Metric category:** AI Session
- **GetMetricDataV2 API metric identifier:** `PROACTIVE_INTENTS_ANSWERED`

Proactive Intents Detected

This metric measures the number of proactive intents (customer queries) detected during AI sessions, particularly for Agent Assistance use cases.

- **Metric type:** Integer
- **Metric category:** AI Session
- **GetMetricDataV2 API metric identifier:** `PROACTIVE_INTENTS_DETECTED`

Proactive Intents Engaged

This metric measures the number of proactive intents (customer queries) that were engaged with by human agents during AI sessions.

- **Metric type:** Integer
- **Metric category:** AI Session
- **GetMetricDataV2 API metric identifier:** `PROACTIVE_INTENTS_ENGAGED`

Proactive Intent Engagement Rate

This metric measures the percentage of detected proactive intents that were clicked or engaged with by human agents.

- **Metric type:** Percent
- **Metric category:** AI Session
- **GetMetricDataV2 API metric identifier:** `PROACTIVE_INTENT_ENGAGEMENT_RATE`
- **Dashboard location:** AI Agent Performance Dashboard, Proactive Intent Engagement Rate

Proactive Intent Response Rate

This metric measures the percentage of engaged proactive intents that were successfully fulfilled by AI Agents.

- **Metric type:** Percent
- **Metric category:** AI Session
- **GetMetricDataV2 API metric identifier:** `PROACTIVE_INTENT_RESPONSE_RATE`
- **Dashboard location:** AI Agent Performance Dashboard, Proactive Intent Response Rate

AI agent traces using Contact search and Contact details

You can use AI agent traces to review, investigate, and improve your automated customer interactions. Drill down into AI agent trace details from the Connect Customer analytics dashboards, or directly through Contact search. The AI agent trace details appear on the **Contact details** page and include the following information:

- Flow, Lex bot, and AI agent invocation and span details alongside the self-service transcript. This experience is powered by the Automated Interaction Log. For more details, see Monitor automated interactions (IVR) in Connect Customer.

Enable AI agent trace details

Complete the following steps to verify that AI agent trace details are enabled for your Connect Customer instance.

> **Note**
>
> Currently, Connect Customer doesn't support S3 buckets with Object Lock enabled.

1. Open the Connect Customer console at `https://console.aws.amazon.com/connect/`.
2. Verify that your automated interaction logs are saved to the S3 bucket you configured for call recordings. If call recordings are not yet enabled for your instance, enable them now:
    1. In the navigation pane, choose **Data storage**, **Call recordings**, **Edit**, **Enable call recording**, and then create or select your S3 bucket.
3. In the navigation pane, choose **Flows**.
4. Under the **Amazon Lex Bots** section, select **Enable Bot Analytics, Transcripts, and AI Agent Traces in Amazon Connect**. Choose this option to log a full transcript of the Amazon Lex portion of the customer's experience. The transcript and traces is then available for you to read on the **Contact details** page.

    > **Note**
    >
    > If you previously enabled **Bot Analytics, Transcripts, and AI Agent Traces in Amazon Connect** (prior to June 5, 2026), you must disable and re-enable this setting to activate the AI agent traces feature.

5. Under the **Automated interaction logs** section, select **Enable Automated Interaction Logs**. With Automated Interaction Logs enabled, you can view Flow details, Lex bot, and AI agent traces on the **Contact details** page.

Permissions for automated interaction logs

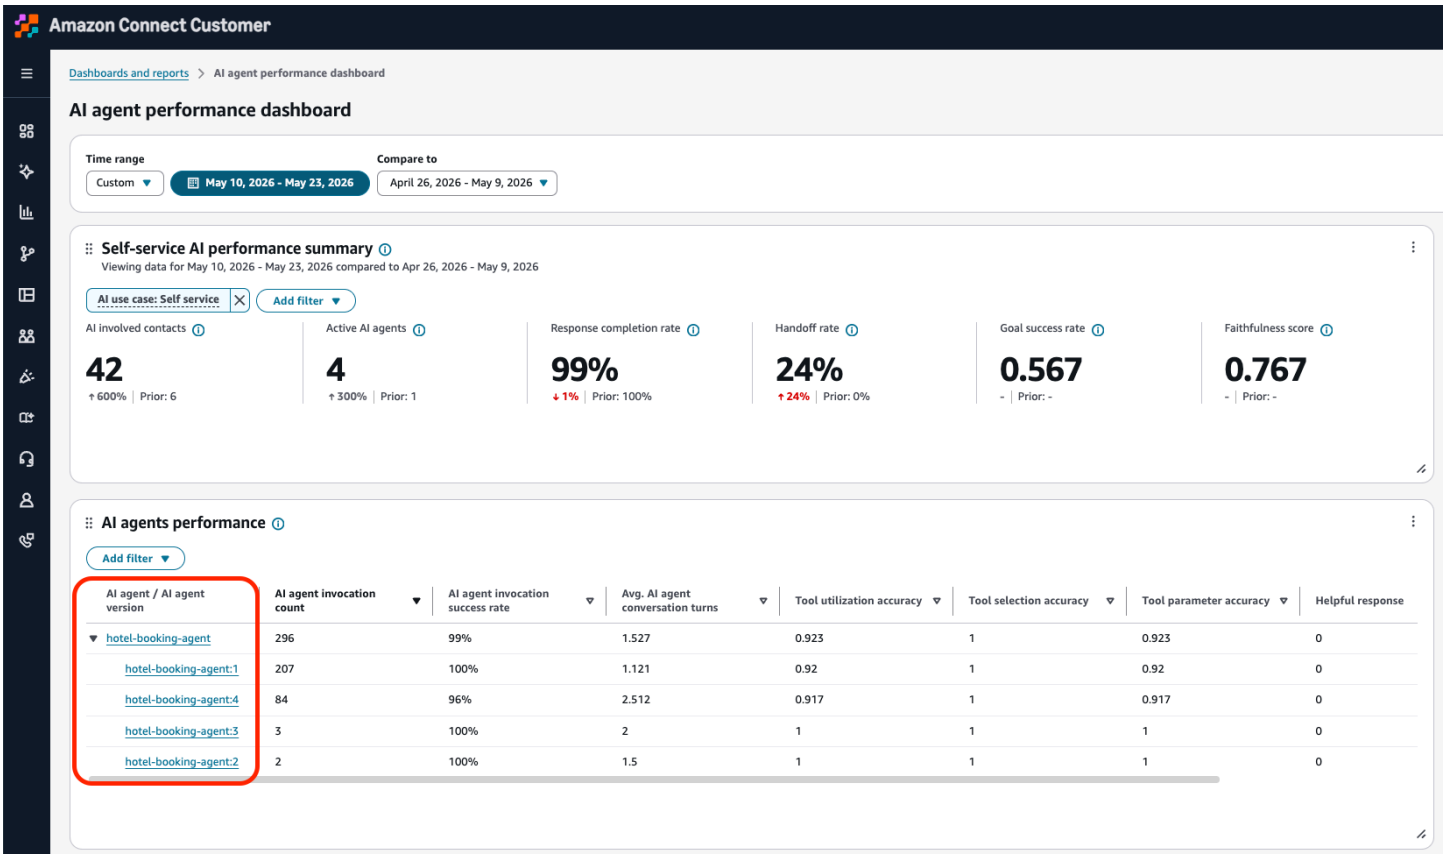
To keep customer data secure, you need to set up permissions for granular control over who can access automated interaction logs. Access is gated by the following security profile permissions:

- **Flows** and **Flow modules – View** permissions: These permissions are required to see flow and module specific data on the automated interaction logs.
- **Analytics and Optimization** - **Automated interaction voice (IVR) transcripts (unredacted)** permissions: These permissions are required to access logs of the IVR interaction such as keypad inputs in response to IVR prompts, transcripts of Lex interactions, AI agent traces and more.

Navigate to AI agent trace details

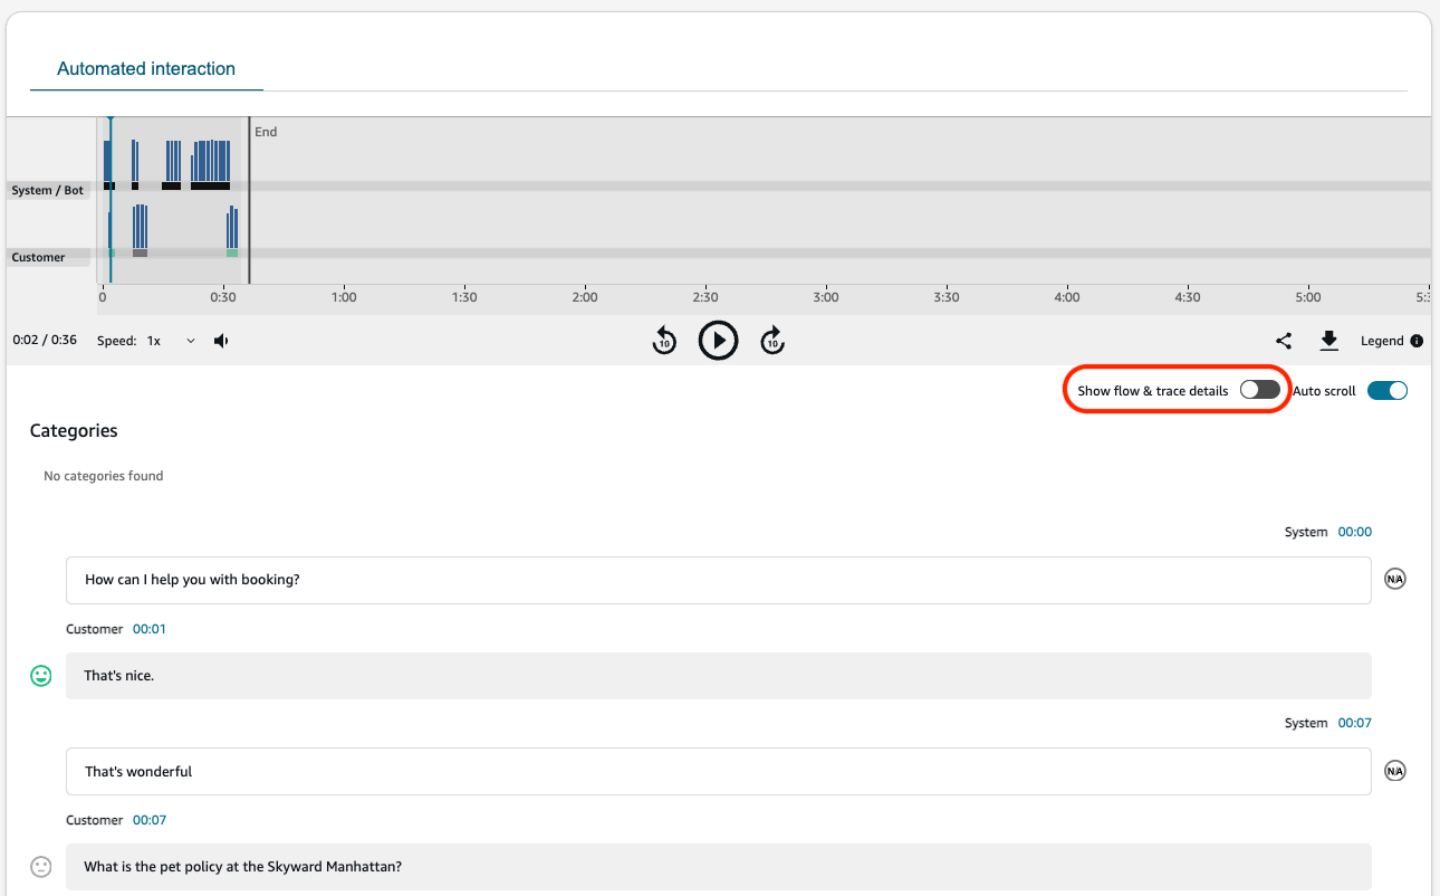
You can drill down into AI agent trace details in two ways:

- **From the AI agent performance dashboard:** Navigate to the AI agent performance widget and drill into the AI agent of your interest. This automatically redirects you to the Contact search page, pre-filtered to the AI agent and time range you selected. You see all contacts handled by that AI agent. Choose the **Contact ID** hyperlink to open Contact details.
- **From Contact search:** Search for a contact directly through Contact search. For more information, see Search for completed and in-progress contacts.

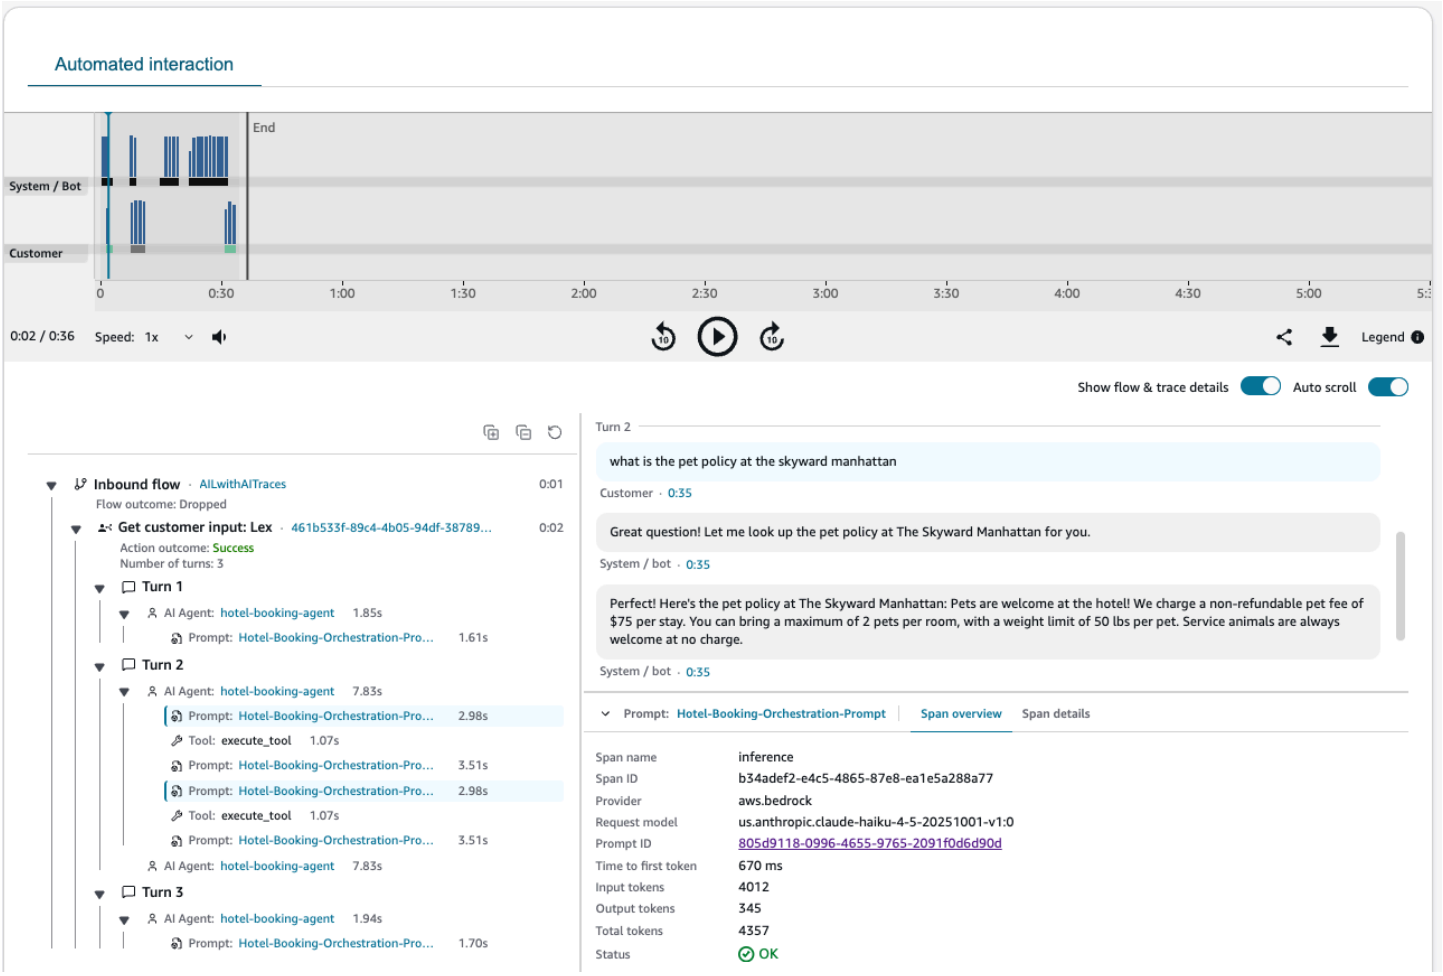


On the **Contact details** page, under the **Automated Interaction** tab, toggle **Show flow & trace details** to show or hide automated interaction details for Flows, Lex bots, and AI agents.

> **Note**
>
> Please allow up to 30 minutes after a contact terminates for the Automated Interaction Log to become available, and the toggle to be activated.



The following image shows an example of AI agent trace details on the **Contact details** page.



AI agent performance metrics

The following AI agent performance metrics are available for your contact:

- **Completeness score:** This metric measures the proportion of sessions where the Orchestration AI agent responses fully address all parts of customer requests rather than providing partial or incomplete answers. Value is between 0-1, where 1 indicates complete responses across all sessions.
- **Faithfulness score:** This metric measures the proportion of sessions where the Orchestration AI agent responses remain faithful to the conversational context, including messages and tool call results. Value is between 0-1, where 1 indicates perfect contextual fidelity.
- **Goal success rate:** This metric measures the proportion of sessions where the Orchestration AI agent successfully resolved customer issues. Value is between 0-1, where 1 indicates successful resolution across all sessions.

- **Tool utilization accuracy:** This metric measures the rate of correct tool utilization by AI agents, including proper parameters and selection. Value is between 0-1, where 1 indicates perfect utilization.

> **Note**
>
> This set of metrics becomes available after 24 hours and is included as part of the Connect Customer AI.

AI agent trace details

> **Note**
>
> AI agent trace details are currently available for the voice channel.

Flows

- Choose the flow and block hyperlinks to open the flow designer in a new tab, enabling you to quickly follow along with your flow.
- Select **Play** to play the specific prompt within your audio recording file.

> **Note**
>
> If no audio recording is available, the Play option does not appear.

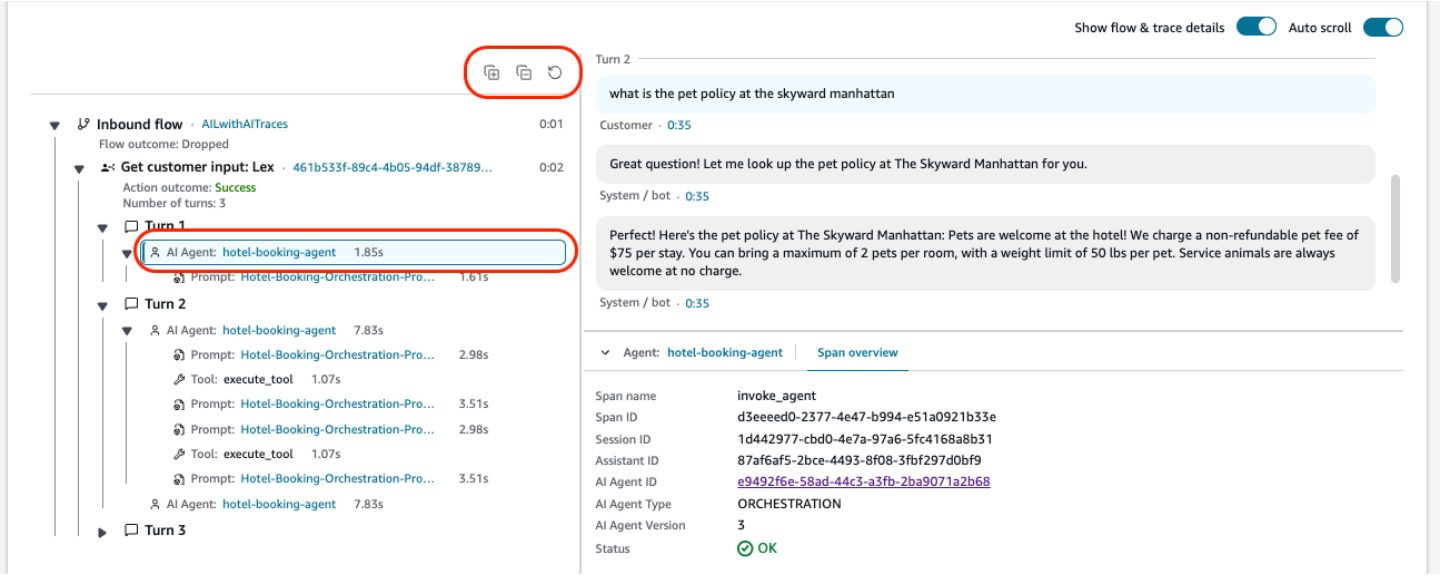
- Quickly identify where errors have occurred, including customer timeouts or Lambda function errors.

Lex bot

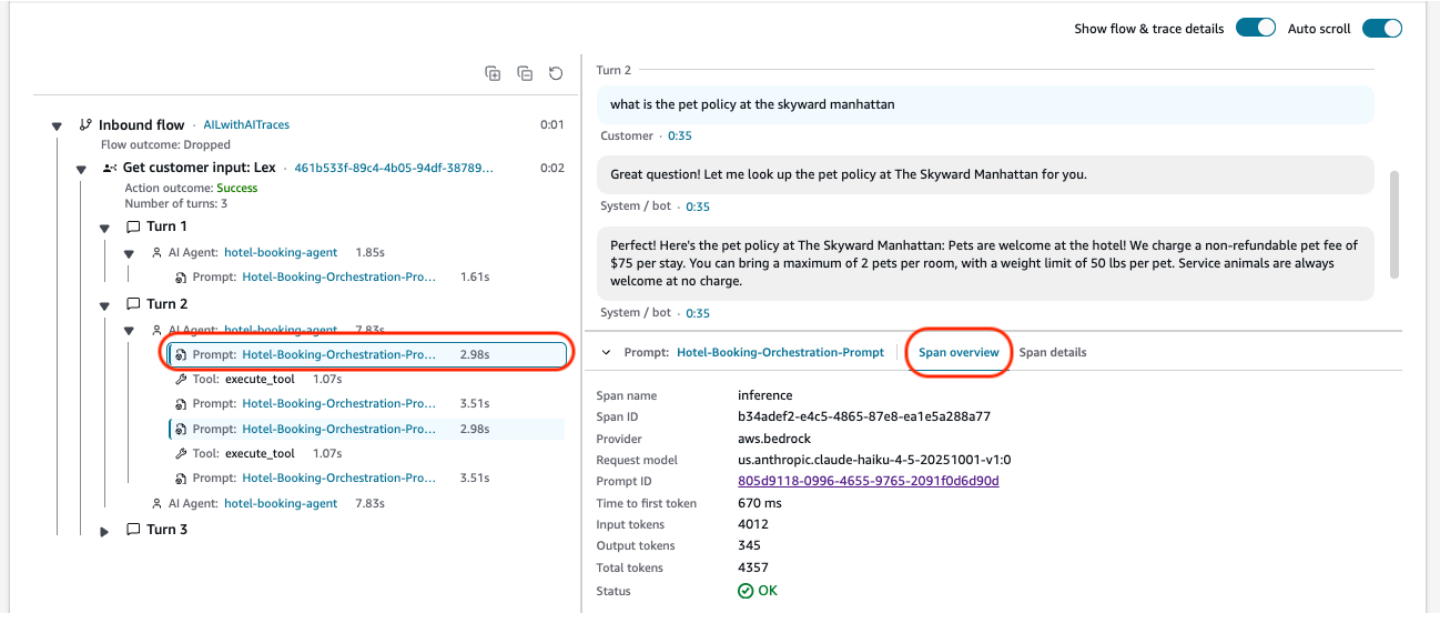
- The hyperlink redirects to the Get customer input block configured in your flow.
- You can see where bot intents are detected and resolved, with the Action outcome status.

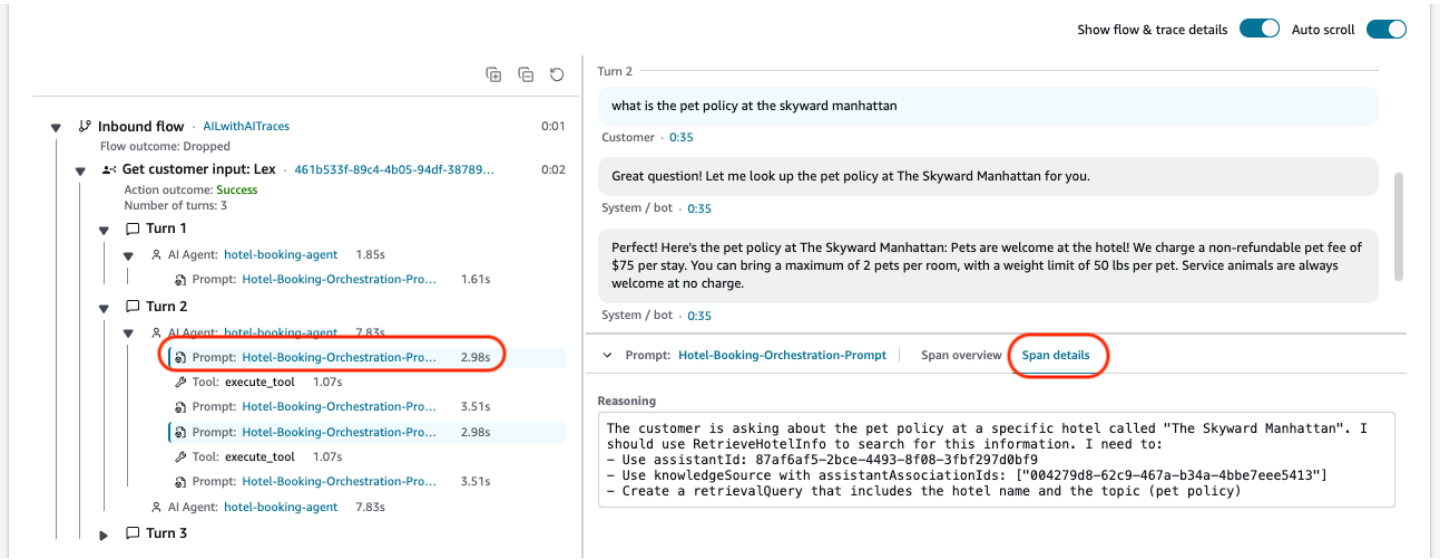
AI agents

- You can choose to expand all trace details using the (+) icon, and collapse all trace details with (-) icon. You can also manually refresh your traces.
- Choose an AI agent invocation activity to see AI agent trace details.



- When your AI agent calls a Prompt (executed through an inference span), the AI agent is invoking an LLM through Amazon Bedrock. The trace details show model reasoning and tool call information.
- Knowledge base citation reference is available under the Prompt (inference span) under Span details, when configured and available. To make sure you have your citations configured, see Knowledge base retrieval configuration.
- For each tool call, you can view the Tool metadata along with the input parameters passed into the tool call.
- Latency for each span is displayed on the right to each activity.
- Choose the **AI agent** or **Prompt** hyperlink to navigate to the AI agent configuration page or the AI agent prompt page, respectively.





The following labels might appear in the trace:

- **ESC:** Stands for Escalate. Shows you when the AI agent escalated to a human agent.
- **ERR:** Stands for Error. When the span received an error status. A status description provides the error details. This can include errors such as:
  - **AI barge in:** The end-customer interrupted during AI reasoning or response generation, causing the model inference to stop before the AI agent completed its response.
  - **Timeout:** The system waited for a response or result from that operation, but it exceeded the maximum allowed time window.

Monitor AI agents using CloudWatch

To gain visibility into the real-time recommendations that AI agents provide to your agents, and the customer intents they detect through natural language understanding, you can query CloudWatch Logs. CloudWatch Logs give you visibility into the entire contact journey: the conversation, triggers, intents, recommendations. You can also use this information for debugging, or provide it to Support when you contact them for help.

This topic explains how to enable logging for AI agents.

Topics

- Required IAM permissions
- Enable logging for AI agents
- Supported log types
- Check for CloudWatch Logs quotas
- Documenting CloudWatch Events by using Interactive Handler
- Examples of common queries to debug assistant logs

Required IAM permissions

Before you enable logging for a Connect assistant, check that you have the following AWS Identity and Access Management permissions. They are required for the user account that is signed into the Connect Customer console:

- `wisdom:AllowVendedLogDeliveryForResource`: Required to allow logs to be delivered for the assistant resource.

To view an example IAM role with all the required permissions for your specific logging destination, see Logging that requires additional permissions [V2]. That topic contains examples for different logging destinations, such as logs sent to CloudWatch Logs and logs sent to Amazon S3 The examples show how to allow updates to your specific logging destination resource.

Enable logging for AI agents

To enable logging for AI agents, you use the CloudWatch API. Complete the following steps.

1. Get the ARN of your *assistant* (also known as its *domain*). After you create an assistant, you can obtain it's ARN from the Connect Customer console or by calling the GetAssistant API. The ARN follows this format:

   `arn:aws:wisdom:your-region:your-account-id:assistant/assistant-id`

2. Call PutDeliverySource: Use this CloudWatch API to create a delivery source for the assistant. Pass the ARN of the assistant as the `resourceArn`. For `logType`, specify `EVENT_LOGS` to collect logs from your assistant.

   ```
   {
   "logType": "EVENT_LOGS",
   "name": "your-assistant-delivery-source",
   "resourceArn": "arn:aws:wisdom:your-region:your-account-id:assistant/assistant_id"
   }
   ```

3. Call PutDeliveryDestination: Use this CloudWatch API to configure where the logs are to be stored. You can choose CloudWatch Logs, Amazon S3, or Amazon Data Firehose as the destination for storing logs. You must specify the ARN of one of the destination options for where your logs are to be stored. You can choose the `outputFormat` of the logs to be one of the following: `json`, `plain`, `w3c`, `raw`, `parquet`.

   The following example shows how to configure logs to be stored in an Amazon CloudWatch Logs Group and in JSON format.

   ```
   {
   "deliveryDestinationConfiguration": {
       "destinationResourceArn": "arn:aws:logs:your-region:your-account-id:log-
   group:your-log-group-name:*"
   },
   "name": "string",
   "outputFormat": "json",
   "tags": {
       "key": "value"
   }
   }
   ```

4. Call CreateDelivery: Use this CloudWatch API to link the delivery source to the delivery destination that you created in the previous steps. This API operation associates the delivery source with the end destination.

```
{
"deliveryDestinationArn": "string",
"deliverySourceName": "string",
"tags": {
    "string": "string"
}
}
```

The following example shows how to run the previous steps as a sequence of AWS CLI commands. This example enables event logging for an assistant and sends the logs to a Amazon CloudWatch Logs log group. Run the commands in order, and replace each *value* with your own resource names and ARNs.

1. Create a delivery source for the assistant. Use the assistant ARN as the resource ARN, and specify EVENT_LOGS as the log type.

```
aws logs put-delivery-source \
    --name your-assistant-delivery-source \
    --resource-arn arn:aws:wisdom:your-region:your-account-id:assistant/assistant-id \
    --log-type EVENT_LOGS
```

2. Create a delivery destination that points to your log group. To send logs to Amazon S3 or Amazon Data Firehose instead, specify that resource ARN.

```
aws logs put-delivery-destination \
    --name your-delivery-destination \
    --delivery-destination-configuration "destinationResourceArn=arn:aws:logs:your-region:your-account-id:log-group:your-log-group-name" \
    --output-format json
```

3. Link the delivery source to the delivery destination. Use the destination ARN that the previous command returns.

```
aws logs create-delivery \
    --delivery-source-name your-assistant-delivery-source \
    --delivery-destination-arn arn:aws:logs:your-region:your-account-id:delivery-destination:your-delivery-destination
```

After you create the delivery, you can view logged events in your log group. To confirm that logging works, generate assistant activity, and then query the log group as described in Examples of common queries to debug assistant logs.

Supported log types

AI agents support the following log type:

- `EVENT_LOGS`: Logs that track event of an Connect assistant during calls, chats, tasks, and emails.

Check for CloudWatch Logs quotas

We recommend checking Amazon CloudWatch Logs endpoints and quotas to see whether there are any quotas for making CloudWatch Logs delivery-related API calls. Quotas set a maximum number of times you can call an API or create a resource. Exceeding the limit results in a `ServiceQuotaExceededException` error.

Documenting CloudWatch Events by using Interactive Handler

Event Type Definitions

The following table describes each event type. Note that different event types contain different fields. Refer to the Field Definitions section for detailed information about each field.

EventType	Definition
TRANSCRIPT_CREATE_SESSION	Logged when a new AI agents session is created. This marks the beginning of a conversation.
TRANSCRIPT_INTENT_TRIGGERING_REFERENCE	Logged when a specific customer intent is detected in the conversation, which might trigger automated responses or workflows.
TRANSCRIPT_LARGE_LANGUAGE_MODEL_INVOCATION	Logged when a large language model (LLM) is invoked to generate responses or process conversation content. Records the inputs to and outputs from the LLM.

EventType	Definition
TRANSCRIPT_QUERY_ASSISTANT	Logged when one of the following AI agents is invoked: AnswerRecommendation, CaseSummarization, EmailGenerativeAnswer, EmailOverview, EmailResponse, ManualSearch, NoteTaking.
TRANSCRIPT_RECOMMENDATION	Logged when the system provides a recommendation to an agent or customer, which might include knowledge articles, generated responses, or suggested actions.
TRANSCRIPT_RESULT_FEEDBACK	Logged when feedback is provided about a search or query result's usefulness or relevance.
TRANSCRIPT_SELF_SERVICE_MESSAGE	Logged when a customer interacts with a SelfService AI agent
TRANSCRIPT_SESSION_POLLED	Logged when the system detects an agent is connected to a session (A session is polled when a GetRecommendations API call has been made)
TRANSCRIPT_TRIGGER_DETECTION_MODEL_INVOCATION	Logged when the trigger detection model is invoked to determine if a conversation has intents
TRANSCRIPT_UTTERANCE	Logged when a message is sent by any participant in the conversation, recording the actual conversation content.

EventType	Definition
TRANSCRIPT_ORCHESTRATION_MESSAGE	Logged for each step within an orchestration loop, including the initial customer message, bot text responses, reasoning, tool use requests, and tool results. Captures the full detail of multi-turn agentic reasoning performed by an Orchestration AI agent.
TRANSCRIPT_ORCHESTRATION_ERROR	Logged when an error occurs during orchestration, such as exceeding the maximum number of orchestration iterations, system capacity constraints, or a general orchestration failure.
TRANSCRIPT_AI_AGENT_TRACE	Logged for each execution span during AI agent orchestration, capturing detailed traces including LLM configuration, token usage, messages, and guardrail assessment results.

Field Definitions

The following table describes each field.

Field	Definition
ai_agent_id	Unique identifier for the AI agent resource.
assistant_id	Unique identifier for the Connect assistant resource.
completion	The raw completion text returned by the LLM or generated for the message.
connect_user_arn	Amazon Resource Name (ARN) of the Connect user accessing the session.
event_timestamp	Unix timestamp (in milliseconds) when the event occurred.

Field	Definition
event_type	Type of the event, indicating what action or process occurred in the system.
generation_id	Unique identifier for a specific AI-generated response.
intent	The intent text or description.
intent_clicked	Boolean indicating if the recommendation was triggered by a clicked intent.
intent_id	Unique identifier for the detected intent.
issue_probability	Numerical probability (0.0–1.0) that an issue was detected in the conversation (A probabili ty greater than 0.5 will invoke intent generatio n)
is_recommendation_useful	Boolean indicating whether the user found the result helpful.
is_valid_trigger	Boolean indicating whether the detection model analysis resulted in a valid trigger.
model_id	Identifier of the AI model used to invoke the LLM.
parsed_response	The processed/parsed version of the language model response, often in structured format.
prompt	The input prompt used to invoke the LLM.
prompt_type	Type of AI prompt used for processing the message or query.
recommendation	The actual recommendation text content provided to the user

Field	Definition
recommendation_id	Unique identifier for the recommendation.
response	The final response text generated for the user after processing.
session_event_id	Unique identifier for a specific event within the session.
session_event_ids	List of session event identifiers.
session_id	Unique identifier for the AI agents session.
session_message_id	Unique identifier for a self-service message within a session.
session_name	Name of the session.
utterance	The actual message text exchanged in the conversation.
orchestration_id	Unique identifier for the orchestration run. Corresponds to the initial customer message ID that triggered orchestration.
orchestration_iteration	The iteration number within the orchestration loop.
ai_agent_orchestration_use_case	The orchestrator use case, such as `CONNECT_AGENT_ASSISTANCE` or `CONNECT_SELF_SERVICE`.
participant	The participant role for the message, such as `CUSTOMER` or `BOT`.

Field	Definition
values	JSON-serialized list of message values. Each entry has a type: `text` (with a text value), `tool_use` (with toolUseId, toolId, name, and arguments), `tool_result` (with toolUseId, toolId, name, values, and error), or `reasoning` (with a text value).
guardrail_blocked	Boolean indicating whether the response was blocked by an AI guardrail.
orchestration_error	JSON-serialized error details containing `errorMessage` and an optional `errorDetails` object (with `estimatedInputTokens` and `estimatedOutputTokens`).
span	JSON-serialized map of the full span object. Each key is snake_case. Notable keys include `input_messages` (conversation history sent to the model), `output_messages` (model response messages), `guardrail_assessments` (list of guardrail evaluation results with `guardrailId`, `guardrailName`, `source`, `action`, and `policies`), and `input_messages_truncated` (`"true"` when input messages were truncated to fit the 256KB record limit). Present only when `event_type` is `TRANSCRIPT_AI_AGENT_TRACE`.

Examples of assistant logs

Below are examples of different event logs for each event type. Refer to the Event Type Definitions section for detailed explanations of each event type.

Examples of common queries to debug assistant logs

You can interact with logs by using queries. For example, you can query for all events within a session by using `SESSION_NAME`.

Following are two common queries to return all the logs generated for a specific session.

- `filter session_name = "SessionName"`
- `filter session_id = "SessionId"`

Agentic CX designer

Agentic CX designer is a service within Amazon Connect Customer and works with flows in Connect Customer for delivering AI-powered customer experiences.

You may hear these experiences described as "bots," but in agentic CX designer, we refer to them as conversational applications because they can do more than respond to simple user messages. A conversational application can guide structured workflows, answer questions from trusted knowledge, connect to APIs, reason through multi-step tasks, and escalate to human agents.

Agentic CX designer gives teams one workspace to create conversational experiences that are structured enough for business control and flexible enough for natural AI-powered interaction.

What you can build

With agentic CX designer, you can build conversational AI applications for experiences such as:

- Customer service automation
- Appointment scheduling
- Order lookup and updates
- Account support
- Knowledge base Q&A
- Troubleshooting flows
- Agentic task completion
- Human handoff and escalation

These applications can combine deterministic workflow logic with generative AI, integrations, knowledge bases, and guardrails.

How agentic CX designer works with Connect Customer flows

Connect Customer flows provide the customer entry point. Agentic CX designer provides the conversational AI application layer.

Connect Customer flows	Agentic CX designer
Manages the customer entry point into the experience.	Designs and runs the conversational AI experience.
Handles contact flows, routing, queues, and channel setup.	Handles applications, flows, nodes, prompts, integrations, knowledge bases, guardrails, and analytics.
Routes the customer into the selected agentic CX designer application and environment.	Executes the selected application logic and returns the next response or action.
Supports escalation into the contact center experience.	Determines when and how the conversat ion should escalate based on the application design.

In a typical setup, a customer enters through a Connect Customer flow. That flow uses an Agentic CX block to invoke the selected conversational AI application and deployed environment. Agentic CX designer then handles the conversation experience, including flow routing, user responses, API calls, knowledge retrieval, generative AI behavior, guardrails, and monitoring.

Build, deploy, observe, and improve

Agentic CX designer brings the full conversational AI lifecycle into one workspace.

Capability	What it helps you do
Build	Create applications, flows, nodes, prompts, slots, variables, integrations, knowledge bases, and guardrails.
Test	Validate routing, flow behavior, variables, state, tools, and troubleshooting details before deployment.
Deploy	Package application changes into builds and deploy them to the appropriate environment.

Capability	What it helps you do
Observe	Review conversation history, transcripts, evaluations, analytics, guardrails, and performance after deployment.
Optimize	Use analytics, tags, A/B tests, and conversation review to improve the experience over time.

Core capabilities

Agentic CX designer helps teams create conversational AI applications with:

Capability	Description
Visual workflow design	Build structured conversation paths using a no-code Canvas.
Deterministic logic	Guide users through predictable steps, decisions, user choices, API calls, and controlled handoffs.
Generative AI nodes	Generate dynamic responses, classify user intent, transform data, and support more flexible interactions.
Agentic experiences	Use agent nodes to reason through multi-step tasks, call tools, collect information, and complete goals.
Knowledge bases	Ground responses in trusted content.
Integrations and Data requests	Connect conversations to managed services, custom APIs, and external systems. A data request can also invoke a published Connect Customer flow module to reuse conversation logic you govern in Connect Customer. For more information, see Data requests.
Guardrails	Apply safety, brand, compliance, and policy controls to user inputs and application outputs.
Testing and debugging	Test applications and flows, inspect event logs, and troublesh oot variables, state, tools, and routing behavior.

Capability	Description
Analytics and monitoring	Observe live performance, review transcripts, track tags, analyze flow traversal, and improve deployed applications.

How conversations run

At runtime, agentic CX designer orchestrates the conversation between the user, the application, and any connected systems.

During a conversation, agentic CX designer can:

1. Receive a user message or event.
2. Determine the appropriate flow or next step.
3. Maintain conversation state across turns.
4. Collect user inputs through slots and variables.
5. Apply deterministic logic or generative AI behavior.
6. Retrieve information from knowledge bases.
7. Call APIs or managed integrations.
8. Apply guardrails to inputs and outputs.
9. Return the next response, action, or handoff.
10. Record activity for testing, troubleshooting, analytics, and monitoring.

This lets builders create experiences that feel natural to users while still giving teams control over business logic, compliance requirements, and operational behavior.

Built-in AI and model flexibility

Agentic CX designer includes built-in generative AI capabilities that can be used across different parts of a conversational application.

Examples include:

AI capability	Use
Text generation	Create dynamic responses, summaries, reformatted messages, or user-facing explanations.
Intent classification	Route user utterances to the right flow using AI descriptions.
Slot capture	Collect multiple pieces of information naturally, even when users provide details out of order.
Generative conditions	Route conversations based on semantic meaning instead of only exact values.
Data transformation	Filter, map, sort, or reshape information before presenting it to the user.
Agentic reasoning	Let an agent node use tools, knowledge, and user input to complete a multi-step task.
MCP-enabled flows	Allow flows to be used as tools by an agent when structured workflow execution is needed.

Teams may use native model capabilities or connect supported model providers through bring-your-own-key configurations, depending on workspace setup and organizational requirements.

Why use agentic CX designer

Agentic CX designer helps reduce the need to stitch together separate systems for conversation design, AI behavior, orchestration, testing, deployment, and monitoring.

Without agentic CX designer	With agentic CX designer
Conversational logic, APIs, AI prompts, testing, and analytics may be spread across several tools.	Builders manage applications, flows, tools, testing, deployment, and monitoring from one workspace.

Without agentic CX designer	With agentic CX designer
Changes may require updates across multiple systems.	Updates can be made in the application and deployed through the build and deployment process.
Debugging may require reviewing disconnec ted logs.	Test chat and debugger details help inspect conversation turns and state.
AI behavior may be difficult to govern consistently.	Guardrails, roles, permissions, audit, and versioning support governance and control.
Multi-step agentic logic may require custom engineering.	Agent nodes and tool-enabled flows support complex task completion.
Performance insights may be fragmented.	Observe, analytics dashboards, conversat ion history, and In-Canvas analytics support ongoing improvement.

In simple terms

Agentic CX designer is where you build and manage the conversational AI application.

Amazon Connect Customer is where the customer enters the experience and where contact center routing, channels, and escalation are handled.

Together, they let teams create conversational AI experiences that can be designed visually, powered by AI and business data, governed with guardrails, deployed into customer channels, and improved using real conversation performance.

Accessing an agentic CX designer workspace

Agentic CX designer is accessed through Amazon Connect Customer and organized into workspaces.

A workspace is a standalone environment where teams build and manage conversational AI applications. Each workspace has its own applications, flows, integrations, knowledge bases, guardrails, analytics, users, roles, and settings.

Because workspaces are separate, resources and permissions are not shared automatically across them. Changes made in one workspace do not affect another workspace.

Access from Connect Customer

Access to agentic CX designer starts from Connect Customer.

- Select your Connect Customer instance.
- From your instance, select agentic CX designer.

Users can launch agentic CX designer from the Connect Customer console. Account administrators can access the Admin Hub in agentic CX designer to create one or more workspaces and assign users to those workspaces.

When adding users, Account Administrators select from user profiles already available in the connected Connect Customer instance.

After a user profile is added to a workspace, the Account Administrator assigns that user a workspace role. The role determines what the user can view, create, edit, or manage inside that workspace.

To access agentic CX designer

1. Open the Amazon Connect Customer console.
2. Select agentic CX designer.

If a user cannot access the expected workspace, they should contact an Account Administrator to confirm that their Connect Customer user profile has been added to the workspace and assigned the correct role.

Workspace resources

Inside a workspace, users can create and manage resources such as:

Applications	The conversational AI experiences users interact with.
Agentic CX designer flows	The conversation paths that guide users through tasks.

Canvas	The visual builder used to create and connect flow nodes.
Integrations	Connections to external tools, APIs, and services.
Knowledge bases	Trusted content the AI can use to answer questions.
Variables and slots	Dynamic values captured, remembered, or referenced during a conversation.
Guardrails	Safety, brand, and compliance controls.
Analytics	Performance data used to monitor and improve experiences.
Users and roles	Access controls that determine what each person can view or manage within that workspace.

Switching workspaces

If you are an Account Administrator or have been assigned a role in more than one workspace, you can switch between workspaces from the workspace dropdown in the upper-left corner of an agentic CX designer workspace.

When you switch workspaces, you are changing which set of resources you are viewing and editing.

Only workspaces you have permission to access appear in the dropdown.

Each workspace is separate.

This means:

- Applications in one workspace do not appear in another workspace.
- Flows, integrations, knowledge bases, guardrails, and analytics are managed independently.
- Users must be assigned to each workspace where they need access.
- A role in one workspace does not automatically grant the same role in another workspace.
- Changes made in one workspace do not affect resources in another workspace.

Workspace separation helps teams organize work safely and keep resources permissioned appropriately.

Working with applications

An application is the control center for the conversational AI application your users interact with. You might think of it as your "bot."

From the agentic CX designer application page, you can:

- Organize the flows the application can handle
- Define default behavior for entry, unknown, fallback, or escalation scenarios
- Attach guardrails to user inputs and application outputs
- Create builds for testing and deployment

Creating an application

To create an application

1. Select **Applications** from the workspace menu.
2. Select **New application**.
3. Enter a clear application name.
4. Select **Create**.

Use a name that helps teammates quickly understand the purpose of the application.

Examples:

- Hotel Concierge
- Appointment Scheduler
- Retail Order Support
- Internet Troubleshooting Assistant
- Benefits Enrollment Support

Adding flows to an application

Once you've designed the workflows and necessary resources in your workspace, you can come back to the **Design** tab of your application and attach the flows your application should use, the default behavior, and any guardrails.

To start, flows define what your application can do.

To add flows

1. Open the application > Select the **Design** tab.
2. Choose one or more flows from the workspace to attach.
3. Save your changes.

Configuring default behavior

Default behavior determines which flow runs when the application needs a standard starting point, recovery path, or escalation path.

To configure default behavior

1. Open the application > Select the **Design** tab.
2. Select the Default behavior icon under the Flows section OR select the three-dot menu beside each attached flow to manage defaults.
3. Assign the appropriate flow for each behavior.
4. Save your changes.

You may choose to assign the same flow to one or more defaults, depending on the user experience.

Welcome	Runs when a new conversation session starts. Use this flow to greet the user, set expectations, and begin the experience.
Unknown	Runs when the application cannot match the user's message to a supported flow or choice AND no match pathways in your flow are not defined. Use this flow to recover, ask clarifying questions, or check a knowledge base.
Fallback	Runs when the application needs to recover from issues such as repeated incomprehension, timeout, integration failure, or state-related errors.

Escalation	Runs when the application should move the user toward human support or another controlled escalation path.

Attaching guardrails

Guardrails help control user inputs and application outputs during conversations.

Attach guardrails when the application needs safety, compliance, brand, privacy, or policy controls.

To add guardrails

1. Open the application > Select the **Design** tab.
2. Select **Add guardrail**.
3. Choose one or more guardrails from the workspace.
4. Save your changes.

Be mindful that guardrails and the number of rules within each can add latency to your application.

Once you have attached and configured flow behavior and guardrails, you can move to the next phase of builds and deployments for your application.

Topics

- Builds and deployments
- Testing your application

Builds and deployments

Builds and deployments are related but are not the same thing.

In agentic CX designer, a *build* packages the current version of your application into a deployable snapshot. A *deployment* makes a selected build available for use through a flow in Amazon Connect Customer.

Builds

A build assembles the current application configuration into a package.

This includes:

- Attached flows
- Routing descriptions
- Default behavior
- Guardrails
- Slots
- Language settings
- Application settings
- Other configuration available at the time the build is created

Because a build captures the application at a specific moment, edits made after the build are not included in a deployment until you create another build.

Builds are required before application changes can be tested or released through the application experience.

A build is especially important when you change anything that affects how the application understands, routes, or responds to users.

At least one build is also needed for test chats to work when testing from a Canvas flow or on the application's Test tab.

From your application's **Deploy** tab, you can create a new build, review build history, deploy a build or roll back to a previous build.

To create or manage builds

1. Open **Applications**.
2. Select the application you want to build.
3. Open the **Deploy** tab.
4. Choose whether the build is for a development or production environment.
5. Select **Build & deploy** to start the build process.

When you start a build, agentic CX designer walks you through the build process:

1. Review validation checks such as disconnected flow paths, incomplete configurations, etc. Critical errors appear in red and should be resolved before creating the build, as they are more likely to cause a failed build. Warnings appear in yellow and should also be reviewed, so you understand the possible impact on the user experience.
2. Add a build description as a simple changelog.
3. Select **Build**.

When the build completes, it appears in the builds table. From there, you can review the build version, description, status, and environment usage.

For failed builds, select the build from the table to review the full failure message.

Create a new build whenever you want to test or release meaningful application changes.

Examples:

- You added or removed a flow from the application.
- You updated the application's default flows.
- You changed custom slot configuration or values.
- You updated routing descriptions.
- You added languages or translations.
- You changed guardrails.

You can create builds as often as needed while developing. Creating a build does not automatically push changes to an external environment unless you continue through deployment or promotion.

After a build is created, you may use the test chat from a flow's Canvas or use the **Test** tab on the application.

Deployments

Once you are satisfied with testing in your agentic CX designer workspace, you can deploy your application for use in a flow in Amazon Connect Customer.

From the application's **Deploy** tab, use the builds table to manage which build becomes active. Only one build can be active in an environment at a time.

To deploy a build

1. Open an application and select the **Deploy** tab.
2. From the builds table, hover over the selected build's status.
3. Choose **Deploy**.

A deployment may take a few minutes. A successful deployment is indicated by a **Live** status.

After deployment, review the application's **Access** details in the application settings. Your frontend or implementation team may need connection values such as the application URL and API key when configuring the application for the intended frontend experience.

You can also return to a previous build version by hovering over a past build and choosing **Rollback**.

Select a build from the builds table to review additional details, such as the build ID, deployment key, and deployment management options. If needed, you can delete a deployment to take the application offline until another build is deployed.

Connecting to Amazon Connect Customer

After your agentic CX designer application has been deployed for the first time, configure Amazon Connect Customer to route conversations through it.

Create or choose a contact flow

In Connect Customer, create or choose the contact flow that will route incoming calls or chats to your agentic CX designer application.

This contact flow should include the routing logic needed to connect the customer entry point to your deployed application.

Choose a voice persona

For voice-enabled conversations, use a **Set voice** block in the Connect Customer flow.

To configure voice

1. Add a **Set voice** block.
2. Select the block.

3. Choose the voice provider.
4. Choose the language and voice persona.
5. Listen to available samples, if needed.
6. Confirm the selection.

Add the Agentic CX block

After your routing and voice setup is in place, add an **Agentic CX** block to the contact flow.

Configure the block by selecting:

1. The workspace where your application lives.
2. The name of the agentic CX designer application.
3. The deployed environment alias, such as `Development` or `Production`.
4. Any required block pathways, including escalation, error, or timeout handling.

The block tells Connect Customer which agentic CX designer application and environment to invoke during the conversation.

Depending on whether the contact is voice or chat, you may also configure additional settings on the **Agentic CX** block.

Speech recognition

For voice interactions, configure **Speech recognition**. This setting determines which engine transcribes the customer's voice input before it is processed by the agentic CX designer application.

You can set speech recognition in two ways:

Setting	Use when
Set manually	The flow should always use the same speech recognition engine.
Set dynamically	The flow should choose the speech recogniti on engine based on contact flow logic, contact attributes, language, region, or another available value.

Audio filler

For voice interactions, you can enable **Audio filler**. This can make voice conversations feel more natural when the application needs a moment to generate an output, retrieve or send data, or complete a tool call.

Idle chat timeout

For chat interactions, you can enable **Idle chat timeout**. This setting controls how long a chat contact can remain inactive before it is considered idle.

Use idle timeout when you want to handle abandoned or inactive chats consistently. For example, after a period of inactivity, the Connect Customer flow exits the **Agentic CX** block from the **Idle timeout** edge, where the conversation can provide a final message before ending the session.

When using timeout behavior, make sure all timeout paths from the **Agentic CX** block are connected to the appropriate next step in the Connect Customer flow.

Publish the contact flow

Publish the Connect Customer flow to make it active and available for use with the appropriate phone numbers or chat endpoints.

Once the contact flow has been published, you do not need to republish it every time you update the agentic CX designer application. The **Agentic CX** block continues to point to the selected application and environment. Any newly deployed build for that environment becomes the version used in live conversations.

If you change the contact flow itself, or any configuration on the **Agentic CX** block, publish the contact flow again.

Testing your application

Testing in agentic CX designer lets you validate how your conversational AI application behaves before it is used in a live customer experience.

Use testing to confirm that your application:

- Starts from the expected flow
- Routes user utterances to the correct flows
- Captures slots and variables correctly

- Applies state modifications as expected
- Uses Data requests, knowledge bases, and tools successfully

Agentic CX designer includes several testing tools for different stages of review:

Application test	Run an end-to-end test conversation from the application's starting point.
Flow test	Test a specific flow in isolation from the Canvas.
Routing tests	Validate whether different user utterances invoke the expected flows.
Flow logic tests	Save and replay a sequence of test inputs for repeatable flow testing.
Debugger	Inspect turn-by-turn events, variables, state, node traversal, and errors during test conversations.

A successful build is required before workspace testing features can run against your application package.

A build packages the current version of your application, including attached flows, routing descriptions, guardrails, slots, languages, and settings. Testing then lets you validate that packaged version before deploying it.

Application test

Use an application test when you want to validate the full end-to-end experience. The conversation starts from the flow assigned to the application's Welcome default behavior.

To run an application test

1. Open **Applications**.
2. Select the application you want to test.
3. Confirm the application has at least one successful build.
4. Select the **Test** tab.

5. Start a new conversation.
6. Type test user messages.
7. Review how the application responds by choosing the Debugger option in the upper right to see turn-by-turn events.

Use this test when you want to experience the application the way a user would from the beginning of a conversation.

Flow test

Use a flow test when you want to isolate and troubleshoot a specific flow.

Flow testing opens directly from the Canvas and begins from the first turn of the selected flow instead of the application's Welcome flow. This is useful when you are building or refining one flow and do not want to start from the full application every time.

To run a flow test

1. Open **Resources** from the workspace menu.
2. Select **Flows**.
3. Choose the flow you want to test.
4. Select the **Test** icon from the Canvas toolbar.
5. Enter test user responses in the test chat.
6. Refresh the test chat as needed.

The test panel in a flow test includes settings that let you adjust the test session.

Use the settings option (gear icon) when your test requires a specific starting point, context value, language, or environment.

Common settings include:

Starting flow	Change which flow the test initializes from.
Context variables	Enter values that would normally be set earlier in the conversat ion or passed from another system.

Language	Test language-specific behavior, if available.
Environment	Choose whether Data requests should use Development or Production endpoints, when configured.

For example, if a troubleshooting flow expects the user to already be authenticated, you can set an `authenticated` context variable before running the test.

After changing test settings, select **Save and refresh** so the updated settings apply to the session.

Routing tests

Routing tests validate whether user utterances invoke the expected flows.

Routing tests are located in the application's **Settings** area under **Testing**. They use the AI descriptions added to flows to evaluate whether a test utterance should match a specific flow.

Use routing tests when you want to confirm that different ways of asking for help route correctly.

Examples:

Test utterance	Expected flow
"I need to change my appointment."	Appointment rescheduling
"Can I talk to someone?"	Escalation
"What are your hours?"	Policy or knowledge base flow
"I need help with billing."	Billing support
"Can I check my order?"	Order status

To create a routing test

1. Open the application.
2. Select the application **Settings**.
3. Go to the **Testing** section.

4. Under **Routing**, select **New test**.
5. Enter a test name.
6. Add one or more test utterances.
7. Select the expected flow for each utterance.
8. Save the test.

To run a routing test

1. Open the saved routing test.
2. Select the test execution option.
3. Run the test.
4. Review the results.
5. Compare the expected flow against the actual matched flow.

A failed routing test means the utterance did not match the expected flow. Review the flow's AI description and routing coverage, then update and test again.

Flow logic tests

Flow logic tests let you save and replay a sequence of inputs for repeatable testing.

Use flow logic tests when you want to quickly validate the same path after making changes. This is helpful for regression testing, repeated QA, and confirming that known scenarios still work as expected.

To create a flow logic test

1. Open a flow from **Flows**.
2. Select the **Test** icon from the Canvas toolbar.
3. Enter the sequence of user inputs you want to test.
4. Save the input sequence as a new flow logic test by selecting the play icon on the bottom of the test panel:
    a. Enter a clear test name.
    b. Save the test.

After a flow logic test is saved, you can replay it to confirm the flow still behaves as expected after future changes. Replay a test by choosing the play button and the launch play icon on a saved named test.

Test chat controls

Test chats on an application or in a flow include controls that help you repeat or reset test sessions.

Replay	Reruns the last conversation using the same inputs.
Reset	Starts the test session over and clears previous inputs.
Debugger	Opens event details for troubleshooting a selected application message.

Use **Replay** when you want to quickly retest the same path. Use **Reset** when you need a clean session.

Debugger

The debugger helps you inspect what happened during a specific turn in a test conversation.

To open debugger details

1. Run a test conversation.
2. Select an application message in the transcript or choose the debugger icon on an application test.
3. Review the event list for that turn.
4. Expand events to inspect details.

Use the debugger when the application behaves unexpectedly, such as skipping a question, repeating a message, routing incorrectly, looping, triggering fallback, or failing after a Data request.

Many unexpected testing issues are related to state, slots, variables, or agentic or generative node prompts.

When troubleshooting, start with the last successful turn and inspect the events that followed.

If needed, simplify the flow path:

1. Start from the first node in the affected turn.
2. Temporarily disconnect later nodes.
3. Connect the first node to a simple Basic node with a success message.
4. Save and test.
5. If the turn succeeds, reconnect one additional node.
6. Test again.
7. Continue until the turn fails.

The last reconnected node is often where the issue begins.

Testing best practices

Follow these best practices when you test your applications and flows:

- Create a successful build before using application or flow testing.
- Use application tests for end-to-end behavior.
- Use flow tests for focused troubleshooting.
- Use routing tests to validate flow recognition across different utterances.
- Use flow logic tests for repeatable paths and regression testing.
- Set context variables before testing flows that depend on earlier conversation state.
- Test happy paths, unclear inputs, missing information, retries, No match paths, fallback paths, and escalation.
- Use the debugger to inspect unexpected behavior.

Working with flows

Flows define the structured paths your conversational AI application follows to help users complete a task, answer a question, or move toward the right next step.

Each flow contains the logic, messages, nodes, variables, and routing behavior needed to support a specific user intent or process. For example, one flow may help a user book a room, while another flow may answer policy questions, authenticate a user, utilize agentic AI to handle most tasks, or route the user to human support.

Flows are built visually in the agentic CX designer Canvas, where you add and connect nodes to map out each step of the experience.

A single application can include multiple flows, and a flow can also be reused across multiple applications in the same workspace.

After a flow is attached to an application and included in a deployed build, the application can execute that flow during conversations.

To access flows, select **Resources** from your workspace menu, then choose **Flows**.

User intent and flow routing

A user's intent is what they are trying to do.

The following example shows a user intent:

```
"I want to book a room."
```

The application can recognize that the user wants to book a room and route the conversation to a flow designed for that purpose, such as BookRoom.

Inside that flow, the application may ask for details such as check-in date, checkout date, number of guests, and room preference. The flow defines how those details are collected, what systems are called, and what happens next.

A flow can be triggered in several ways.

Use routing descriptions, default behavior, and Redirect nodes together to control when and how users move through flows.

Application default behavior	A flow runs when assigned as the application's Welcome, Unknown, Fallback, or Escalation behavior.
User input recognition	A User input node captures what the user says and attempts to match it to one of the flows attached to the application via provided routing data.
User choice recognition	A User choice node can route to another flow if the user's response does not match the expected choices but does match

	another flow attached to the application via provided routing data.
Redirect node	A flow deliberately sends the user to another flow or page.
MCP-enabled flow	A flow is exposed as a tool that an agent node can invoke.

Creating a flow

To create a flow

1. Open **Resources** from the workspace menu.
2. Select **Flows**.
3. Select **New flow**.
4. Enter a clear flow name (no spaces or special characters).
5. Select **Create flow**.

The Canvas

The Canvas is the visual builder where you create and maintain a flow.

Every flow has its own Canvas. The Canvas begins with a non-editable Start node. Connect the Start node to the first node in the flow so the conversation knows where to begin.

Use the Canvas to:

- Add nodes
- Connect paths
- Create branches
- Add pages
- Test the flow
- Validate flow issues
- Review in-canvas analytics after deployment
- Configure flow settings

The Canvas toolbar provides controls for building, testing, and managing a flow.

Toolbar options include:

Application	Switch between applications where the flow is attached.
Flow	Switch between flows attached to the selected application.
Pages	Create or navigate between pages within the current flow. Pages organize large flows into smaller sections, especially when a flow has many branches, repeated steps, or subproces ses. Use **Extract to new page** from the canvas shortcut menu to move selected nodes into a separate page and automatically create the Redirect nodes needed to connect the conversation path.
Analytics	View traffic data for deployed applications and review user paths.
Validation	Show issues such as disconnected paths, missing handling, or possible loops.
Settings	Configure routing, MCP, attached slots, languages, versions, and flow details.
Save	Save changes made on the Canvas.
Test	Open the test widget to test from the current flow.

Import and export

The **Advanced** tab in the flow's settings includes import and export options that help you move or reuse flow designs. Exporting a flow creates a JSON file that preserves the conversation path and Canvas structure so it can be imported later into a workspace.

Use export when you want to back up a flow, share a reusable flow pattern, or move a flow design into another workspace. Use import when you have a previously exported JSON file and want agentic CX designer to recreate that conversation path on the Canvas.

To import or export a flow

1. Open the flow.
2. Select **Settings** from the Canvas toolbar.
3. Select the **Advanced** tab.
4. Choose **Export** to download the flow as a JSON file, or choose **Import** to upload a previously exported JSON file.

You can also import a flow by dragging and dropping a supported exported JSON file directly onto the Canvas. After import, review the populated nodes, paths, and configuration before saving, testing, building, and deploying the application.

You may also duplicate a flow when you want to reuse an existing flow structure as a starting point.

To duplicate a flow

1. Open the flow.
2. Select **Settings** from the Canvas toolbar.
3. Select the **Advanced** tab.
4. Choose **Duplicate flow**.
5. Enter a name for the duplicated flow.

You can also find the option to delete a flow from the Advanced tab of the flow's settings.

If the flow is attached to an application, update the application, create a new build, and deploy the change so the deployed experience no longer references the deleted flow.

Canvas controls

Use Canvas controls to navigate and organize your flow.

Common controls include:

Zoom	Zoom in or out of the Canvas.
Pan	Move around the Canvas.

Magic layout	Align nodes into a cleaner layout.
Search	Find nodes or trigger quick commands.
Add note	Add internal notes for builders.
Undo/Redo	Reverse or restore recent Canvas changes.
Bookmark or highlight	Mark important nodes or areas for easier review.

You can also right-click the Canvas or an individual node to open shortcut menu options.

Flow settings

Flow settings define how a flow is recognized, reused, translated, and configured for use in an application or agentic experience.

To access flow settings

1. Open a flow.
2. Select **Settings** from the Canvas toolbar.
3. Choose the tab you want to configure.

Settings include:

- Routing
- MCP
- Attached slots
- Languages
- Versions
- Advanced settings

Routing

Routing helps agentic CX designer understand when a user's intent should match a flow.

The most important routing field is the *AI description*.

Use the AI description to explain what the flow does and when it should be used.

The following example shows a flow description:

```
Use this flow when the user wants to update, modify, or cancel an
existing hotel reservation.
```

A strong AI description should be:

- Concise
- Specific
- Action-oriented
- Written from the user's intent
- Distinct from other flow descriptions

The following examples show effective flow descriptions:

```
Use this flow when the user wants to check the status of an order.

Use this flow when the user wants to book, reschedule, or cancel an
appointment.

Use this flow when the user has a billing question or needs help
understanding a charge.
```

If a flow is only assigned as default behavior or only reached through a Redirect node, routing can be left blank.

MCP

MCP lets you make a flow available as a tool that an agent can invoke.

Use MCP when a Generative Journey or Live Sync agent should call the flow as part of completing a larger task.

To enable MCP on a flow

1. Open the flow.
2. Select **Settings** from the Canvas toolbar.

3. Open the **MCP** tab.
4. Enable the **MCP** toggle.
5. Add an input schema, if the flow requires values from the agent.
6. Save the flow.

MCP input schema defines the values the agent should collect or pass into the flow before invoking it.

Use an input schema when the flow needs specific information to run correctly.

Example:

A restaurant recommendation flow may need:

- cuisine
- location
- partySize

For each input field:

1. Use a short input name with no spaces or special characters.
2. Choose the appropriate property type.
3. Add a clear description.
4. Save the schema.

Example input schema descriptions:

cuisine	The type of food the user wants, such as Italian, Thai, or Mexican.
location	The area where the user wants to find a restaurant.

Inside the MCP-enabled flow, type { in supported fields to reference MCP input variables in messages, Data request payloads, Split conditions, and other node configurations.

The following example shows a message:

```
I'll look for {cuisine} restaurants near {location}.
```

Attached slots

Slots must be attached to a flow before the flow can use them.

Attach slots when the flow needs to collect or reference structured values from the user, such as a date, time, email, name, room type, or yes/no response.

To attach a slot

1. Open the flow.
2. Select **Settings** from the Canvas toolbar.
3. Open the **Attached slots** tab.
4. Select **Attach new slot**.
5. Choose a custom or built-in slot.
6. Enter the name that should be used for the slot in this flow.
7. Save the flow.

Only slots attached to the flow appear for selection in supported nodes, such as User choice and Generative Journey.

Use *custom slots* for business-specific values that you define.

Examples:

- Yes / No
- Small / Medium / Large
- Billing / Technical support / Account access

Use *built-in slots* for common input types that agentic CX designer already supports.

Examples:

- Date
- Time
- Email

- Name
- Number
- Phone number
- URL
- Freeform text

Custom slots are created from **Resources > Slots**. Built-in slots are selected when attaching slots to a flow.

Languages

The **Languages** tab lets you manage which languages are assigned to the flow.

Use flow-level languages when a flow needs specific localization support or when you need to override workspace-level language settings.

To add a language to a flow

1. Open the flow.
2. Select **Settings** from the Canvas toolbar.
3. Open the **Languages** tab.
4. Select **Add new language**.
5. Choose the language or locale.
6. Save the flow.

After adding languages, manage translations for flow messages and other translatable content.

Create a new application build after updating translations that should be included in testing or deployment.

Variables in flows

Variables let your flow use dynamic information instead of hardcoded text.

A variable may come from user input, a slot, a Data request, a context variable, a system variable, a generated output, a knowledge base response, or an MCP input.

To reference a variable, type { in a supported text field and choose from the placeholder menu.

Use variables in:

- Messages
- Data request payloads
- Split conditions
- Prompt fields
- Modality payloads
- Knowledge base questions
- Agent instructions

The following example shows a confirmation message:

```
Thanks, {firstName}. I found your reservation for {checkInDate}.
```

The following table describes the common variable types.

Variable type	Description	Color
Slot variables	Values captured from the user through attached slots.	Green
Data request variables	Values returned from a Data request node.	Orange
Context variables	Values available across flows during a conversation session.	Pink
Local variables	Values created inside a flow, such as Define, Loop, Generative text, or Knowledge base outputs.	Purple
System variables	Values tracked automatically by Agentic CX Designer, such as the latest utterance or conversation ID.	Blue
MCP input variables	Values passed into an MCP-enabled flow by an agent.	Pink

Variable type	Description	Color
Secrets	Reusable secure values that can be referenced in supported Data request fields.	Black

Slot variables

Slot variables store values captured from user responses.

Examples:

- `{CheckInDate}`
- `{CheckoutDate}`
- `{RoomType}`
- `{CustomerEmail}`

Slots are local to the flow where they are attached. If the same slot may be captured again later in the same session, clear or update the value using state modifications before asking again.

To make a captured slot available in other flows, set it as a context variable.

Data request variables

Data request variables are returned by a Data request node.

Use them after the Data request node has successfully run.

Examples:

- `{CustomerProfile.firstName}`
- `{OrderStatus.status}`
- `{AppointmentAvailability.times}`
- `{Reservation.confirmationNumber}`

If the Data request response contains a list, you may need to use a Loop or Transform node before referencing individual values or presenting them in a User choice node or modality.

If the data may change during the session, enable Always retrigger on the Data request node so the latest values are fetched when the node is revisited.

Context variables

Context variables are available across flows during a conversation session.

Use context variables when a value captured in one flow needs to be referenced later in another flow.

Examples:

- Authentication status
- Customer profile
- Selected reservation
- Preferred language
- Current task state

Context variables begin empty unless they are set by another process, such as a Data request, Connect Customer contact flow, or state modification.

Local variables

Local variables are created inside a flow and are available while the user is active in that flow.

Examples include outputs from:

- Define nodes
- Loop nodes
- Generative text nodes
- Knowledge base nodes
- Transform nodes

Use local variables when the value only matters inside the current flow. Use a context variable when the value needs to persist across flows.

System variables

System variables are tracked automatically by agentic CX designer.

These include:

System variable	Use
`{System.utterance}`	The latest message from the user.
`{System.conversationId}`	The unique ID for the current conversation.
`{System.userId}`	User identifier for the conversation. Voice interactions use the customer's phone number. Chat interactions can populate this value when `nlx_userId` is passed on the Agentic CX block in a Connect Customer flow.
`{System.transcript}`	The conversation transcript, with sensitive information redacted where supported.
`{System.channelType}`	The channel the user is using.
`{System.isVoice}`	Whether the user is communicating through voice.
`{System.language}`	The detected or configured language.
`{System.liveSyncTimeoutType}`	The reason for a Live Sync timeout (sessionStart = user did not engage; inactivity = user did not respond between steps)
`{System.locale}`	The detected or configured locale.
`{System.environment}`	The deployment environment.
`{System.applicationName}`	The application using the flow.

Use system variables in Split logic, messages, prompts, and Data request payloads when the flow needs conversation-level context.

Topics

- Working with nodes
- Using the Generative Journey agent node

- Using the Live Sync agent node
- Managing escalations

Working with nodes

Nodes are the building blocks of a flow in agentic CX designer.

Each node represents a specific action in the conversation, such as sending a message, collecting a user response, calling a Data request, generating AI output, routing to another flow, transforming data, escalating to a human agent, or ending the application session.

A flow is created by placing nodes on the Canvas and connecting them in the order the conversation should follow.

To add a node to the Canvas

1. Open a flow.
2. Select the **Add** option from the Canvas toolbar, or right-click the Canvas and choose **New node**.
3. Choose the node type you want to add.
4. Place the node on the Canvas.
5. Connect it to the appropriate previous or next node.
6. Save the flow.

Every flow includes a Start node. Connect the Start node to the first node in your flow so the conversation knows where to begin.

Connecting nodes

Nodes are connected through paths. A node may have one path or multiple paths depending on what can happen after the node runs.

To connect nodes

1. Select a node path.
2. Drag the connector line to the next node.
3. Release to connect the path.

Connected lines show the direction of the conversation. You can also stack nodes together by dragging one node above or below another. When stacked, the path turns into an arrow that shows the conversation direction.

To disconnect nodes, select the connecting line or move a stacked node away from the group.

Node side panel

Selecting a node opens its side panel.

The side panel lets you configure that node's messages, settings, paths, tools, variables, and added functionality. The available options depend on the node type.

Every node has a non-editable node ID that can be referenced across the workspace. To view the node ID, open the three-dot menu in the upper-right corner of the node side panel.

Node messages

Many nodes can send messages to the user.

To add a message

1. Select a node.
2. Choose **Add message** from the side panel.
3. Enter the message text.
4. Save the flow.

You can add multiple messages to a single node. This breaks longer responses into smaller messages, which can make the experience easier to read in chat or hear in voice.

To insert a variable or dynamic value into a message, type { in the message field and choose from the available placeholders.

Examples:

- {System.utterance}
- {CustomerProfile.firstName}
- {Reservation.confirmationNumber}
- {SelectedDate}

If a slot does not appear in the placeholder menu, confirm that the slot is attached to the flow. If a Data request value does not appear, confirm that the response model is configured and that list values are processed appropriately.

Node functionality

Select **Add functionality** from the node side panel to add supported enhancements.

Available functionality includes:

Analytics tags	Marks a node with system or custom tags to track user paths.
Live Sync	Triggers a Live Sync action for bidirectional web conversations.
Modality	Adds a rich interaction, such as a carousel or date input. Available for Basic, User choice, User input, Generative Journey, and Live Sync nodes. Works with the Touchpoint SDK to render.
Node payload	Triggers custom behaviors or passes custom data in the response using key-value pairs.
State modifications	Applies a state change to variables during the conversation.
Voice settings	Overrides the selected voice settings for that node. Read below for details.

Note that not every functionality option is available for every node type.

Use node-level Voice settings selectively. For example, you might enable interruption at the start of the conversation then disable interruption for an important compliance message downstream, or enable DTMF input when collecting a numeric value by keypad.

Voice settings include two groups: Speech and DTMF.

Speech setting	What it controls
Allow interruption	Lets the caller talk over the message. ON by default unless toggled OFF.

Speech setting	What it controls
Allow speech input	Lets the caller answer by speaking.
Voice start timeout	Controls how long the application waits for the user to start talking after the message.
Voice end timeout	Controls how long a pause must last before the application decides the user has finished talking.
Maximum utterance length	Controls the maximum amount of time the user can keep speaking.

DTMF setting	What it controls
Allow DTMF input	Lets the user answer using the keypad.
DTMF deletion key	Defines the key the user presses to clear all digits they entered.
DTMF end key	Defines the key the user presses to submit immediately instead of waiting for timeout.
DTMF end timeout	Controls how long to wait after the user's last key press.
DTMF maximum digits	Controls the maximum number of keys the user can press.

Each node defaults to the name of its node type. Rename nodes to make large flows easier to understand.

To rename a node

1. Select the node.
2. Click the node name in the side panel.
3. Enter a clear name.
4. Save the flow.

Color labels can help visually organize the Canvas.

To recolor a node

1. Right-click the node.
2. Select **Change color**.
3. Choose a color.
4. Save the flow.

Use color consistently across your workspace, such as one color for API calls, one for user inputs, one for error handling, and one for escalation.

Start node

The *Start* node is the beginning point of every flow or flow page.

It is created automatically and cannot be edited. Connect the Start node to the first node that should run when the flow begins.

Connects to the first node in the flow.

Basic node

A *Basic* node sends a message or acts as a state processing step between other nodes.

Use Basic nodes to:

- Greet the user
- Confirm an action
- Explain what happens next
- Add a progress message
- Clear or update variables with state modifications
- Create a simple recovery message before retrying a step

A Basic node is often used before or after nodes that do not send their own message.

Connects to the next node in the flow.

Exit application node

The *Exit application* node ends the conversation session.

Use this node when the application has completed its task and should stop the active chat or voice session. It provides a clear explicit ending point for the flow.

Use Exit application when:

- The user's task is complete
- The user chooses to end the conversation
- A voice or chat session should close after a final message

User input node

A *User input* node listens for an open-ended user response.

Use User input when the user should describe what they need in their own words. The application can then attempt to recognize the user's intent and route accordingly.

Use User input nodes to:

- Ask what the user needs help with
- Capture an open-ended response
- Collect freeform text that will be evaluated downstream
- Support broad navigation from a menu-like question

Common pattern:

1. Ask the user what they need help with.
2. Use User input to capture the user's response.
3. If a flow is recognized, connect to a Redirect node.
4. If no flow is recognized, connect to a clarification or Unknown path.

Flow recognition depends on the flows attached to the application and the routing descriptions configured for those flows. You can connect both pathways to the same node if simply using the system variable {System.utterance} downstream for evaluation.

Flow recognized	The user's utterance matched a flow attached to the applicati on.

No flow recognized	The user's utterance did not match a supported flow.

User choice node

A *User choice* node asks the user to provide or select a specific value.

Use User choice when the application needs a structured answer, such as a date, yes/no response, category, option, or value returned from a Data request.

Use User choice nodes to:

- Ask a yes/no question
- Ask the user to choose from custom slot values
- Capture a built-in slot such as date, time, email, or number
- Present options returned from a Data request
- Route based on the selected value

A User choice node can resolve values from:

- Custom slots attached to the flow
- Built-in slots attached to the flow
- Data request list responses

If the node uses values from a Data request, call the Data request before the User choice node.

Match	The user's response matched the assigned source.
No match	The user's response did not match the assigned source and did not match the routing description of another eligible flow.
Value paths	Optional paths that correspond to individual custom slot values.

A User choice node also participates in application-level flow routing.

When a user responds, agentic CX designer evaluates the response in the following order:

1. **Slot or source match.** The application first checks whether the response matches an available slot value or other configured source (via a data request) for the node.
2. **Flow routing.** If there is no match, the application checks flows that have routing enabled and an AI description configured. If the user's response matches one of those flow descriptions, the conversation automatically redirects to that flow.
3. **No match.** If the response matches neither the User choice source nor an eligible flow, the node follows its No match path.

Data request node

A *Data request* node calls a configured Data request during the conversation.

Use this node when the flow needs to send or retrieve data from an external system at a specific point in the conversation.

Use Data request nodes to:

- Retrieve customer profile details
- Check appointment availability
- Look up an order or ticket status
- Submit a form or request
- Send a confirmation message
- Update an external record

Place Data request nodes before any downstream nodes that need to use the returned data.

After the request succeeds, reference returned values by typing { in supported fields and choosing the Data request output.

Success	The request completed successfully.
Failure	The request failed or could not connect as configured.
Timeout	The request did not respond before the timeout.
In progress	Optional path used while the request is still resolving to deliver a message. Link path back to the data request.

The data request node has a **Mode** setting that controls whether the conversation waits for the request to finish before continuing. **Mode** has two options, **Synchronous** and **Asynchronous**, and is available on voice and chat.

In **Synchronous** mode, the conversation turn waits for the request to resolve, and the node routes the conversation on its result by using the **Success**, **Failure**, and **Timeout** paths.

In **Asynchronous** mode, the request runs on a background path and the conversation turn continues without waiting, so the result becomes available on a later turn. In this mode, the node replaces the **Success** and **Failure** paths with a single **Next** path. The **In progress** path still applies. Because there is no **Failure** path in asynchronous mode, plan how a later turn reads the result and how the conversation responds when the result is missing or indicates a failure.

Knowledge base node

A *Knowledge base* node retrieves an answer from a knowledge base.

Use this node when the flow should answer a user's question using trusted content from a Q&A or Documents knowledge base.

Use Knowledge base nodes to:

- Answer FAQs
- Provide policy information
- Share instructions or how-to guidance
- Support Unknown behavior
- Ground answers in approved content

Common pattern:

1. Send the user's question to the Knowledge base node.
2. Store the result in an output variable.
3. Connect the Match path to a Basic or User choice node.
4. Reference the answer in the message.
5. Connect No match to clarification, fallback, or escalation.

Match	Relevant knowledge base content was found.

No match	No confident answer was found.
Failure	The knowledge base request failed.
Timeout	The knowledge base request timed out.

Generative text node

A *Generative text* node uses a large language model to generate a text output during the flow.

Use Generative text when the application needs to create, rewrite, summarize, classify, or format information dynamically.

Use Generative text nodes to:

- Generate a personalized response
- Summarize prior information
- Rewrite text in a specific tone
- Format content for downstream use

The generated output is stored as an output variable and can be referenced downstream using {.

Success	The text was generated successfully.
Failure	The generation failed.
Timeout	The model did not respond before the timeout.

Define node

A *Define* node creates a local value that can be used later in the same flow.

Use Define nodes when you need to set, format, transform, or name a value without storing it globally as a context variable.

Use Define nodes to:

- Create a temporary value

- Rename a value for easier reference
- Extract part of a date
- Count or format a value
- Prepare a value for a message, condition, or payload

Defined values are local to the flow and do not persist beyond it.

Connects to the next node in the flow.

Transform node

A *Transform* node reshapes, filters, maps, or sorts data so it can be used later in the flow.

Use Transform nodes when data returned from a Data request, knowledge base, or variable does not match the structure you need.

Use Transform nodes to:

- Filter a list
- Sort items
- Reshape API data
- Map returned values into a modality schema
- Remove unavailable or irrelevant results
- Prepare data for User choice or downstream logic

Transform options include deterministic and generative methods, such as filter, map, generative filter, generative map, morph, and sort.

Connects to the next node in the flow.

Loop node

A *Loop* node repeats part of a flow or iterates over items in a list.

Use Loop nodes to:

- Limit retry attempts

- Prevent infinite loops
- Iterate over returned List results from a Data request

Loop modes include:

Range	Repeats a path a set number of times.
List	Iterates over values in a list.

Next	Continues through the looped path.
Completed	Runs when the loop has finished or the retry limit is reached.

Be sure to use state modifications with retry loops when a previous value needs to be cleared before the user tries again.

Split node

A *Split* node routes the conversation based on conditions or chance.

Use Split nodes when the flow should branch based on logic, variables, user responses, or traffic distribution.

Split modes include:

Conditions	Routes based on defined IF statements or generative condition s.
Chance	Randomly distributes users across paths by percentage. Useful for A/B testing.

Condition paths	Runs when a defined condition is met.
Else	Runs when none of the conditions are met.

Use Split nodes to:

- Route by customer type
- Check whether a variable exists
- Branch by channel type
- Evaluate a user's response
- Send users through A/B test paths
- Handle additional slot values after a User choice No match path

Redirect node

A *Redirect* node sends the user to another flow, another page in the current flow, a recognized flow, or another supported destination.

Use Redirect nodes to:

- Move from one flow to another
- Continue a task in a separate flow
- Route based on recognized intent
- Return to a previous redirect point
- Send control back to a parent application, when supported

If redirecting to another flow, make sure that flow is attached to the application before building and deployment.

Continuation	Optional path used when the redirected flow returns to the current point.

Escalate node

An *Escalate* node ejects the conversation out of the Escalation path on the Agentic CX block in your contact flow within Amazon Connect Customer.

Use Escalate nodes when:

- The user asks for a human agent

- A business rule requires human handling
- A task cannot be completed by the application
- An API failure requires a human recovery path

You can link to the same Escalate node from multiple places in your agentic CX designer flow.

Continuation	Runs if the conversation returns to the Agentic CX block after escalation in the Connect Customer flow.

Node type summary

Basic	Send a simple message
Exit application	End the conversation session
User choice	Ask the user to choose from options deterministically
User input	Capture intent or a user response deterministically
Data request	Call an external system
Knowledge base	Retrieve an answer from approved content
Generative text	Generate text output
Generative Journey	Complete a multi-step task with tools
Define	Set a temporary value
Transform	Reshape or filter data
Loop	Retry or iterate through items
Split	Branch based on logic or chance
Redirect	Move to another flow
Escalate	Transfer to human support

Agent nodes

Agent nodes use agentic AI to manage flexible goal-based experiences.

Generative Journey	Guide a multi-step conversation, collect information, and call tools such as Data requests, knowledge bases, modalities, or other flows. Learn how to configure a Generative Journey node.
Live Sync	Guide a hands-free web or mobile experience where the agent can converse with the user and coordinate supported frontend actions. Learn how to build a Live Sync experience.

Using the Generative Journey agent node

Generative Journey is an agent node that uses a large language model to complete a task through natural conversation, data capture, and tool use.

Use a Generative Journey node when a conversation needs more flexibility than a strictly deterministic path, but still needs clear instructions, controlled tools, and defined outcomes.

For example, a hotel application might use Generative Journey to collect travel dates, ask follow-up questions, check availability, present room options, and exit the node once the user has selected a room or needs help from an agent.

Use a Generative Journey node when the application needs to handle a multi-step task that may not happen in the exact same order every time.

Common use cases include:

- Scheduling or rescheduling an appointment
- Troubleshooting a customer issue
- Collecting several required details
- Searching a knowledge base during a broader task
- Calling Data requests as needed

- Presenting modalities such as cards or carousels
- Routing to another flow when a deterministic process is required
- Completing a task with several possible outcomes

Generative Journey is useful when the user may provide information out of order, ask clarifying questions, or need the AI to decide which tool to call next.

A Generative Journey node automatically:

1. Reads the user's latest utterance and the system transcript.
2. Follows the prompt instructions you provide.
3. Collects required or optional slot values defined.
4. Uses assigned tools, such as Data requests, flows, modalities, or knowledge bases.
5. Decides when the task has reached one of the defined exit conditions.
6. Continues the flow through the path linked to that outcome.

The node stays in control of the task until it exits through one of its configured exit paths, calls a handover flow tool, fails, or times out.

Pathways

Generative Journey uses pathways to determine where the conversation should go after the agent completes, fails, or times out.

Exit conditions	Outcomes you define that tell the agent when to leave the node and continue the flow.
Data capture completion	An automatic path triggered when required slots are collected and **Exit upon completion** is enabled.
Failure	Runs when the agent or one of its required tools fails.
Timeout	Runs when the agent does not respond within the configured timeout period.

Always connect each path to the next appropriate node so the flow can continue predictably.

Prompt

The prompt tells the agent what task it is responsible for completing.

A strong prompt should include:

- The agent's role
- The task it should complete
- Any runtime variables or critical information it should review every turn (e.g., context attributes, etc.)
- What information it must collect
- What tools it can use
- Rules or limitations it must follow
- Brand voice or tone guidance
- What counts as completion
- When to exit through each exit condition

Exit conditions

Exit conditions define the acceptable outcomes that can end the Generative Journey node.

Each exit condition should have:

- A short name
- A clear description
- A connected path to the next node in the flow

Examples:

Room selected	The guest selected a room and is ready to continue to confirmation.
No availability	No matching rooms were available for the requested dates.
Escalation requested	The guest asked to speak with a person.

User declined	The user decided not to continue.
Task complete	The requested task was completed successfully.

To add an exit condition

1. Select the Generative Journey node.
2. Choose **Add exit condition**.
3. Enter a clear name.
4. Add a brief description of when the agent should use it.
5. Connect the new path to the next node in the flow.

Use specific exit condition names so the flow is easy to understand on the Canvas.

Data capture

Data capture lets the agent collect slot values from the user during the task.

You can configure:

Required slots	Values the agent must collect before the task can complete.
Optional slots	Values the agent should collect or use if the user provides them.
Exit upon completion	Creates an automatic path that triggers after all required slots are collected.

Only slots attached to the current flow are available for selection.

Example required slots for a hotel booking task:

- Check-in date
- Checkout date
- Number of guests
- Number of rooms

Example optional slots:

- Preferred room type
- Accessibility needs
- Pet preference
- Loyalty number

Use **Exit upon completion** when the main purpose of the node is to collect a set of values, then continue to the next deterministic step.

In the main prompt, refer to slot names in plain language, as the placeholder syntax is empty until a value is given by the user.

The following examples show prompt instructions that refer to slot names in plain language:

```
Collect the checkInDate, checkoutDate, and preferred roomType. Only
collect one at a time.

If the user provides a different customerEmail, confirm it once before
using.
```

Use placeholders when you need to pass a resolved value into a tool input or field that supports variables.

Tools

Tools give the agent controlled capabilities it can use while completing the task.

Generative Journey can use tools such as:

Data requests	Call external systems to retrieve, send, or update data.
Knowledge bases	Search approved Q&A or document content for grounded answers.
Modalities	Present structured UI, such as a card, carousel, or date input.
Flows	Invoke another flow as a handover or structured tool via MCP.

Add only the tools the agent needs for the task. Too many tools can make the agent harder to control and test.

Each tool should include a short prompt that explains when and how the agent should use it.

A good tool prompt should explain:

- When to call the tool
- What information is required first
- What the tool returns or does
- Any rules for using the result
- What to do if the tool fails or returns no data

The following example shows a Data request tool prompt:

```
Use this tool only after the user has provided an appointment date and
location. It returns available appointment times. If no times are
returned, tell the user there are no available times for that date and
ask whether they want to try another date.
```

The following example shows a knowledge base tool prompt:

```
Use this knowledge base to answer questions about cancellation policy,
refund eligibility, and reservation changes. If the answer is not
found, do not guess. Exit through Escalation requested if the user
needs policy confirmation from an agent.
```

The following example shows a modality tool prompt:

```
Use this carousel to show available appointment times after the
availability Data request returns results. Each card should represent
one available time.
```

Some tools require input values.

For each input field, you can choose how the value should be provided. Simply switch the input option by selecting the icon to the right of the field:

LLM prompt	Let the agent infer or collect the value from the conversation.

Explicit text	Provide a fixed value that should always be sent.
Variable	Pass an existing value from the conversation, such as a slot, context variable, system variable, or Data request result.

Use *Variables* when a value already exists and should be passed directly into a tool.

Examples:

- {CustomerProfile.id}
- {CustomerEmail}
- {AppointmentDate}
- {SelectedLocation.id}
- {System.conversationId}
- {System.utterance}

Use the placeholder menu by typing { in supported fields, then select the value you want to pass.

Use variables in the prompt when the agent needs known context.

The following example shows a prompt that uses context variables:

```
#Important Customer Information
- Loyalty status: {customerTier}
- Authentication status: {authenticated}
```

The following example shows a prompt that uses a prior Data request result:

```
The customer has the following active reservations: {Reservations}.
Help them choose which reservation they want to modify.
```

Use variables when they provide useful context, but keep the prompt readable. The agent should still have clear instructions in plain language.

Using a Data request tool

Use a Data request tool when the agent needs to call an external system.

When adding a Data request tool

1. Add the Data request to the Generative Journey node.
2. Expand the tool.
3. Add a tool prompt.
4. Configure any required input schema fields.
5. Choose whether each field should come from the LLM prompt, explicit text, or a variable.
6. Add an optional interim message.
7. Save and test.

The following example shows an interim message:

```
One moment while I check your reservation.
```

Use interim messages for tool calls that may take more than a moment, especially in voice experiences.

Using a knowledge base tool

Use a knowledge base tool when the agent needs to answer questions from approved content during the task.

When adding a knowledge base tool

1. Add the knowledge base to the Generative Journey node.
2. Expand the tool.
3. Add a tool prompt that explains the tool is a knowledge base and what the knowledge base should be used for.
4. Tell the agent what to do if no answer is found.
5. Save and test.

The following example shows a knowledge base tool prompt:

```
Use this knowledge base for questions about refund policy and
cancellation rules. If no answer is found, say that you do not have
enough information and exit through Escalation requested.
```

Using a modality tool

Use a modality tool when the agent should present structured UI during the task.

When adding a modality tool

1. Add the modality to the Generative Journey node.
2. Expand the tool.
3. Add a tool prompt.
4. Map required payload fields.
5. Save and test.

The following example shows a modality tool prompt:

```
Use this card after the user selects an appointment time. Populate it
with the selected date, time, location, and appointment type.
```

Using flow tools

Generative Journey can use flows in two ways: *handover* or *MCP-enabled*.

Handover flows

Use a handover flow when you want the flow to take control of the conversation.

When the agent invokes a handover flow, the agent node is exited and the conversation follows that flow's nodes and messaging exactly as designed.

Use handover when:

- A deterministic process must run
- The user must complete a controlled workflow
- A flow already exists for the task
- The experience requires precise messaging or routing

To return from a handover flow to the Generative Journey node, add a Redirect node at the end of the handover flow and route it back to the agent flow and node using the Generative Journey's node ID (retrieved in the three-dot menu of a node).

MCP-enabled flows

Use an MCP-enabled flow when you want the agent to call a flow as a structured tool while the agent remains in control of the broader conversation.

Unlike a handover flow, an MCP-enabled flow does not fully take over the conversation. Instead, the Generative Journey node can invoke the flow as a tool, pass in any required inputs, use the flow's result, and continue managing the task.

Use MCP-enabled flows when:

- The agent should stay in control of the conversation
- You want deterministic flow logic available as an agent tool
- The flow needs structured inputs, such as location, date, account type

For example, a restaurant recommendation agent might call an MCP-enabled flow that takes cuisine and location as inputs, searches available recommendations, and returns matching results to the agent.

To make a flow available as an MCP tool

1. Open the flow you want the agent to use.
2. Select **Settings** from the flow toolbar.
3. Open the **MCP** tab.
4. Enable the **MCP** toggle.
5. Add optional input schema, if the flow requires information from the agent.
6. Save the flow.

Input schema defines the values the agent should collect or pass into the flow.

Use input schema when the flow needs specific information to run correctly.

Examples:

Use case	Input fields
Restaurant recommendations	cuisine, location, partySize

Use case	Input fields
Appointment lookup	appointmentDate, locationId, appointmentType
Eligibility check	customerId, planType, state
Order lookup	orderId, email

For each input field:

1. Use a short, unique input name with no spaces or special characters.
2. Choose the appropriate property type.
3. Add a clear description so the agent understands what the value means.
4. Save the schema.

Example input schema fields:

cuisine	The type of food the user wants, such as Italian, Thai, or Mexican.
location	The city, neighborhood, or area where the user wants recommendations.
partySize	The number of people included in the reservation or visit.

Clear descriptions help the agent collect the right information before calling the flow.

After you define the MCP input schema, the input values can be referenced inside the flow.

On any supported node field, type { and select the MCP input variable you want to use.

You can use MCP input variables in places such as:

- Messages
- Data request payload fields

- Split node conditions
- Define nodes
- Modality payload fields

The following example shows a message:

```
I'll look for {location} restaurants that match your interest in {cuisine}.
```

LLM model selection

The LLM model determines what model powers the agent's reasoning and tool use.

Choose the model based on the task, channel, latency needs, and complexity of the experience.

For simpler or voice-sensitive tasks, prioritize lower-latency models. For more complex tool use or reasoning-heavy chat experiences, a more capable model may be appropriate.

Settings

Generative Journey includes settings that control how the agent behaves.

Max steps	Limits how many times the agent can think, call a tool, reassess, and continue within one turn. Use this to prevent long loops and control latency or cost.
Zero-turn mode	Allows the agent to resolve required values from the latest user utterance and exit automatically when possible.
Timeout	Sets how long the agent has to respond before the timeout path is triggered.

Use conservative settings when latency, cost, or predictable behavior is important.

Using the Live Sync agent node

Live Sync enables bidirectional web or mobile conversations where the AI can respond to the user and coordinate actions on the frontend experience.

Use Live Sync when your application should do more than exchange messages. A Live Sync experience can help users navigate pages, fill forms, select options, trigger custom UI behavior, and understand what the user is currently viewing.

For example, a user might say "I'd like to check out on Saturday and pick the Ocean View room." With Live Sync, the agent can understand the request, use the current page context it's provided, fill the checkout date field, select the matching room option, and continue the conversation hands-free.

Live Sync is a bidirectional experience between your agentic CX designer application and your frontend.

It allows an AI-powered conversation to:

- Understand user speech or text
- Receive real-time frontend context
- Navigate pages
- Fill form fields
- Trigger custom frontend actions
- Return structured action payloads to your application

Live Sync is used with the Touchpoint SDK and Context API, which connects the conversational experience to your web or mobile frontend.

Live Sync components

A Live Sync experience usually includes:

Agent flow	Contains the Live Sync node that manages the conversation and tools.
Custom actions	Define what the agent can ask the frontend to do.
Touchpoint SDK	Renders the conversation and listens for bidirectional commands.
Command handlers	Execute actions such as navigating, selecting an item, opening a modal, or filling a form.

Context API	Sends current page and UI context back to the agent.

The frontend and the Live Sync agent work together. The agent decides what action should happen, and the frontend performs the action through registered command handlers.

Creating a Live Sync flow

To create a Live Sync flow

1. Open **Flows** from the workspace menu.
2. Select **Canvas**.
3. Create a new flow or open an existing flow.
4. Add the Live Sync node that will power the Live Sync experience.
5. Configure the node prompt, tools, actions, and paths.
6. Save the flow.

The agent node should be responsible for the Live Sync task, such as helping the user update a reservation, complete a form, or choose from available options.

Agent prompt

The agent prompt should clearly explain what the agent is responsible for and how it should behave.

A strong Live Sync prompt should include:

- The agent's role and persona
- The task or tasks the agent can complete
- What the agent should not do
- Tone and brevity expectations
- When to use tools
- When to trigger frontend actions
- How to handle multimodal or page-aware interactions
- Any context variables the agent should consider

Tools

Tools extend what the Live Sync agent can do.

Use tools when the agent needs to retrieve information, answer grounded questions, execute structured workflows, or collect data.

Supported tool patterns may include:

Data requests	Retrieve, send, or update data through a configured custom integration.
Knowledge bases	Answer questions from approved Q&A or document content.
Flows	Run a structured workflow as a handover or MCP-enabled tool.
Data capture	Collect required or optional slot values from the user.
Modalities	Present structured UI, such as cards, carousels, or date input, when supported.

Add only the tools the agent needs for the Live Sync task.

For example, do not create a Data request if the frontend already has the information and only needs the agent to pass a selected value. In that case, configure a Live Sync custom action and let the frontend handle the behavior.

Use a Data request when the agent needs to call an external system that the frontend does not already handle, such as checking availability, retrieving a customer profile, or submitting a backend update.

Each tool should include a short description that explains when and how the agent should use it.

A clear tool prompt helps the agent decide:

- Whether the tool is relevant
- What information to collect first
- What values to pass

- What the tool returns
- What to do if the tool fails or returns no results

The following example shows a knowledge base tool prompt:

```
Use this knowledge base to answer questions about hotel policies,
cancellation rules, check-in requirements, and room upgrade
eligibility. If no answer is found, do not guess.
```

Use **Data capture** when the agent needs to collect structured slot values from the user for use with other tools.

Examples:

- Name
- Email address
- Confirmation number
- Checkout date
- Room preference
- Appointment date
- Account identifier

Before adding slots to Data capture, attach the slots to the flow in the flow settings.

In the agent instructions, refer to slot names in plain text rather than placeholder syntax.

The following example shows an agent instruction that refers to a slot name in plain text:

```
Collect customerEmail before calling the newsletterSignup tool.
```

Avoid using placeholder syntax when simply telling the agent what to collect:

```
Collect {firstName}, {lastName}, and {customerEmail}.
```

Use placeholders when mapping resolved values into tool input fields.

Flow tools

Live Sync agents can use flows in two ways: *handover* or *MCP-enabled*.

Use an MCP-enabled flow when the agent should stay in control while calling a structured workflow.

This is often the preferred flow-tool pattern for Live Sync because the agent can call the flow, receive the result, and continue supporting page-aware actions, navigation, form fill, and custom frontend behavior.

Use MCP-enabled flows for tasks such as:

- Sending a confirmation message
- Reading legal language and collecting consent
- Retrieving disruption details
- Running a structured eligibility check

Use a handover flow when you intentionally want a deterministic flow to take over the conversation.

While the handover flow is running, the Live Sync agent is no longer orchestrating frontend actions or page-aware behavior. The conversation follows the handover flow's nodes and messages until it returns to the agent.

To return from a handover flow to the Live Sync node, add a Redirect node at the end of the handover flow and route it back to the agent flow and node using the Live Sync's node ID (retrieved in the three-dot menu of a node).

Live Sync actions

Live Sync actions tell the agent what it can understand about the user's current screen and what it can ask the frontend to do.

This is where Live Sync becomes bidirectional:

- The *input schema* gives the agent structured awareness of what the user is seeing or what options are available on the page.
- The *output schema* defines the structured command or value the agent can send back to the frontend.

- The frontend command handler receives that output and performs the UI action.

Without an input schema, the agent does not have structured awareness of the relevant screen content for that action, such as visible form fields, selectable products, or valid navigation destinations.

Without an output schema, the agent does not have a structured way to tell the frontend what action to take or what value to use.

This gives your business control over what the agent can see, decide, and trigger. Instead of giving the agent broad control over the entire frontend, you define specific approved actions, the exact data the agent can consider, and the exact response shape the frontend will accept.

Live Sync actions include:

- Navigate to a page
- Fill a form field
- Select an item
- Open or close a modal
- Highlight an option
- Apply a filter
- Update a visible UI state
- Trigger a custom frontend behavior

When configuring a custom action, provide:

Action name	A stable identifier your frontend listens for, such as `select_room .`
Description	A clear description of when the agent should use the action.
Input schema	The structured screen context or available options the agent can consider before taking action.
Output schema	The structured value or command the agent sends back to the frontend.

Scope tags	Optional tags that limit when the action is available based on the current page or UI state.

The action name and schema must match what your frontend command handler expects.

Example: Use this action when the guest asks to select a room from available options shown on the page.

Field	Value
Action name	`select_room`
Description	Use this action to select the room ID from the available options based on what the user said.
Scope	`room_selection`

The following example shows an input schema:

```
{
  "rooms": [
    {
      "id": 1,
      "roomName": "Garden Suite"
    },
    {
      "id": 2,
      "roomName": "Ocean View"
    },
    {
      "id": 3,
      "roomName": "Executive Suite"
    }
  ]
}
```

The following example shows an output schema:

```
{
```

```
  "type": "number",
  "description": "The ID of the selected room."
}
```

If the user says "I'd like the Ocean View," the agent can return:

```
2
```

The frontend can then use that value to highlight or select the correct room.

Scope tags help prevent actions from being used in the wrong place.

For example, a `select_room` action should only be available when the user is on the room selection page. A `modify_checkout_date` action may only apply when the user is on a checkout or stay modification screen.

The following example shows a scope tag:

```
{
  "scopes": ["room_selection"]
}
```

Use scope tags when different pages or UI states support different actions.

Navigation actions

Touchpoint can provide automatic handling for supported navigation and input actions.

Navigation actions let the agent move the user through supported destinations in the digital experience.

For example, the user might say "Go back." or "Take me to checkout."

When the appropriate destination is available in the current frontend context, the Live Sync agent can send a navigation action and Touchpoint can perform the corresponding navigation.

Custom navigation behavior can also be implemented when the frontend requires different routing logic.

Input actions

Input actions allow Live Sync to update supported form controls.

For example, the user might say "Change my checkout date to Friday."

The Live Sync agent can identify the applicable field from the current frontend context and send an input action containing the new value.

Touchpoint can apply the value to the matching form control and trigger the corresponding frontend input and change events.

Register custom action handlers

Your frontend should register application-specific actions using the same action names configured on the Live Sync node.

A custom action that does not need a returned value can simply execute its configured behavior:

```
setCustomLiveSyncActions([
  {
    action: "disable_features",
    handler: () => {
      FEATURE_DEFS.forEach((f) => toggleFeature(f.id, false));
    },
  },
]);
```

If a custom action returns a structured value, its handler can receive the value as a payload:

```
setCustomLiveSyncActions([
  {
    action: "select_room",
    handler: (payload) => {
      selectRoomById(payload);
    },
  },
]);
```

For example:

- Action: `select_room`
- Payload: 2
- Frontend behavior: Select the room associated with ID 2.

Whether the handler needs a payload depends on the action.

Custom action	Handler pattern	Use
`disable_features`	`handler: () => { ... }`	The action itself determines what the frontend should do.
`open_help_modal`	`handler: () => { ... }`	No additional value is required.
`select_room`	`handler: (payload) => { ... }`	The frontend needs the selected room ID.
`apply_filter`	`handler: (payload) => { ... }`	The frontend needs the selected filter value.

When an action includes an output schema, make sure the handler expects the corresponding value type.

Use automatic frontend context

A Live Sync agent needs information about the current digital experience before it can reliably navigate, update fields, or trigger frontend actions.

With the Touchpoint SDK, you can automatically gather this context and send it to the active Live Sync conversation. Automatic context is enabled by default.

For supported web experiences, automatic context can include:

- Current page or route
- Supported form controls
- Current field values
- Available selections
- Navigation destinations
- Registered custom actions

This means most implementations do not need to manually construct and send Context API requests whenever the page changes.

Automatic form context

For supported web experiences, Touchpoint can inspect common form controls including:

- Text inputs
- Text areas
- Select menus
- Checkboxes

Context can include information such as:

- Accessible field name
- Description
- Input type
- Current value
- Placeholder
- Available options

For example, suppose a checkout page contains:

- Checkout date
- Room type
- Email address
- Newsletter consent

The user can say "Change my checkout date to Friday and choose the Garden Suite."

The Live Sync agent can use the current form context to determine which controls should change and send the appropriate input actions.

Use meaningful labels, accessible names, descriptions, and option text to help Touchpoint represent frontend controls accurately.

Automatic navigation context

For supported web experiences, Touchpoint can inspect available links and expose their accessible names as navigation destinations.

For example, if the current page contains:

- Rooms
- Checkout
- Spa

the user can say "Take me to checkout."

The Live Sync agent can determine that Checkout is an available destination and send the appropriate navigation action.

Automatic context updates

Touchpoint monitors the digital experience for relevant changes.

Updated context can be sent when:

- The user navigates
- A form appears
- Available options change
- Page elements are added or removed
- Registered custom actions change

Touchpoint compares newly gathered context with the previous context and updates the active Live Sync conversation when the relevant information changes.

Automatic handling can be customized or disabled when an implementation requires more control.

Paths and exit conditions

A Live Sync agent node can route to different paths depending on how the agent session ends.

Common paths include:

Exit conditions	Routes the user when the conversation reaches a defined outcome.
Timeout	Runs when the agent does not respond within the configured timeout period.

Failure	Runs when the agent or its tools cannot complete as configure d.
Return	Used when scripted or predefined steps continue back into the flow, if supported.
Escalation	Used when the experience should route to a human handoff or escalation path.

Exit conditions define meaningful outcomes that allow the agent to leave the node and continue through the flow.

Examples:

Goodbye	The user clearly indicates they are done or wants to end the conversation.
Escalation requested	The user asks to speak with a human agent.
Task complete	The requested frontend task was completed successfully.
Unable to help	The agent cannot complete the requested action.

For each exit condition:

1. Add the exit condition to the agent node.
2. Give it a short, clear name.
3. Add a description that tells the agent when to use it.
4. Connect the exit path to the next node in the flow.

A Goodbye exit condition might route to an Exit application node that says:

```
Thanks for contacting us. Have a great day.
```

Set up the application

After configuring the Live Sync flow:

To set up the application

1. Open **Applications**.
2. Create an application or open an existing one.
3. Attach the flow containing the Live Sync node.
4. Configure the appropriate default behavior.
5. Configure required guardrails.
6. Save the application.

Create and deploy a build before connecting the deployed application to the Live Sync frontend implementation.

See Builds and deployments for detailed instructions.

Invoke the application from Connect Customer

Configure an Agentic CX block in a Connect Customer flow to invoke the deployed agentic CX designer application.

Select:

- The agentic CX designer workspace
- The application
- The appropriate deployed environment

Configure the downstream paths and publish the Connect Customer flow.

For an active Live Sync interaction, the frontend connection must also correspond to the correct Connect Customer contact.

The active Connect Customer contact ID identifies the interaction and associates Live Sync frontend actions with the corresponding conversation.

Touchpoint and frontend setup

Touchpoint is the frontend layer that enables voice input, bidirectional Live Sync behavior, and command handling in your web or mobile application.

In your frontend setup, configure Touchpoint using the connection details from your deployed application. You can find these values in the application's settings under the Access section. Your frontend team will need details such as the application URL and API key to initialize Touchpoint and connect the frontend experience to the deployed agentic CX designer application.

A Live Sync connection uses information associated with the deployed application and active interaction, including:

- Host
- Deployment key
- API key
- Language code
- Connect Customer contact ID

Common handler categories include:

Custom command handler	Handles custom actions, such as selecting a room or opening a modal.
Navigation handler	Handles page or route changes.
Form fill handler	Handles field updates in visible forms.

Your frontend team should map each action returned by the Live Sync agent to the correct UI behavior.

For Live Sync actions to work, the frontend must listen for the commands the agent may send.

The command names and schemas configured in the agent node should match the frontend code.

The following example shows a setup pattern:

```
function handleCustomCommand(action, payload) {
  if (action === "select_room") {
    selectRoomById(payload);
  }
  if (action === "open_modal") {
    openModal(payload.modalName);
```

```
  }
}

function handleNavigationCommand(command) {
  if (command.destination) {
    navigateTo(command.destination);
  }
}

function handleFormFillCommand(formData) {
  Object.entries(formData).forEach(([fieldId, value]) => {
    updateFieldValue(fieldId, value);
  });
}
```

If the names or schemas do not match, the agent may send the right intent, but the frontend may not know how to execute it.

Agent configuration	Frontend expectation
Action name: `select_room`	Handler listens for `select_room` .
Output schema: room ID as a number	Handler expects a number.
Action name: `open_modal`	Handler listens for `open_modal` .
Output schema: modal name	Handler expects a modal name.

Advanced: manual Context API

Most Live Sync implementations rely on automatic frontend context, which is enabled by default and gathers page, form, and navigation context for you. For more information, see Use automatic frontend context.

Use the manual Context API for advanced or custom control, when your implementation needs to construct and send context to the active Live Sync conversation directly, or when automatic handling does not cover a specific case.

The Context API lets your frontend send real-time page context to the active Live Sync conversation.

Context size limit

The context you send to a Live Sync conversation through the Context API is limited to 8 KB per update. Keep the context focused. Advertise only the actions, fields, and destinations relevant to the current page. Trim large or unnecessary values to stay within the limit.

This helps the agent understand:

- Current page or route
- Available form fields
- Current field values
- Valid navigation destinations
- Available frontend actions
- Active scope tags

Send updated context whenever the page or UI state changes.

Examples:

- The user navigates to a new page
- A form appears
- Field values change
- New actions become available
- Scope tags change

In this example, the frontend tells the agent that the user is on the room selection page and that three rooms are available:

```
{
  "conversationId": "ACTIVE_CONVERSATION_ID",
  "context": {
    "nlx:vpContext": {
      "uri": "https://example.com/rooms",
      "scopes": ["room_selection"],
      "destinations": [
```

```
        "/rooms",
        "/checkout",
        "/spa"
      ],
      "actions": [
        {
          "action": "select_room",
          "description": "Selects one of the available rooms shown on the room
 selection screen.",
          "input": {
            "rooms": [
              {
                "id": 1,
                "roomName": "Garden Suite"
              },
              {
                "id": 2,
                "roomName": "Ocean View"
              },
              {
                "id": 3,
                "roomName": "Executive Suite"
              }
            ]
          },
          "schema": {
            "type": "number",
            "description": "The ID of the selected room."
          }
        }
      ]
    }
  }
}
```

When this context is active, the user can say "I'd like the Ocean View" and the agent can identify the matching room and send the correct action result to the frontend.

In this example, the frontend tells the agent which checkout form fields are available:

```
{
  "conversationId": "ACTIVE_CONVERSATION_ID",
  "context": {
```

```
    "nlx:vpContext": {
      "uri": "https://example.com/checkout",
      "scopes": ["checkout"],
      "fields": [
        {
          "id": "checkoutDate",
          "name": "Checkout Date",
          "type": "date",
          "description": "The guest's requested checkout date",
          "placeholder": "Select checkout date"
        },
        {
          "id": "roomType",
          "name": "Room Type",
          "type": "select",
          "description": "The selected hotel room type",
          "options": [
            {
              "value": "garden_suite",
              "text": "Garden Suite"
            },
            {
              "value": "ocean_view",
              "text": "Ocean View"
            }
          ]
        }
      ]
    }
  }
}
```

When this context is active, the user can say "Set checkout to Saturday and pick the Garden Suite" and the agent can use the field context to understand which values should be filled or selected.

Managing escalations

Escalations let an agentic CX designer conversation hand control back to a flow in Amazon Connect Customer when the user needs human support or the application should leave the conversational AI experience.

Use escalations when a task requires an agent, a business rule prevents automation, the user asks for a person, or the flow needs to transfer the conversation into a Connect Customer queue.

When an Escalate node is reached in an agentic CX designer flow, the conversation exits through the Escalation path on the Agentic CX block in the Connect Customer flow.

From there, the Connect Customer flow controls what happens next.

A common escalation pattern is:

1. The user reaches an Escalate node in agentic CX designer.
2. The conversation returns to the flow in Connect Customer through the Escalation path on the Agentic CX block.
3. A **Set contact attributes** block stores any context returned from agentic CX designer.
4. A **Set working queue** block selects the queue.
5. A **Transfer to queue** block transfers the customer to an agent.

Add an Escalate node

To add an escalation to a flow

1. Open the flow in the Canvas.
2. Add an Escalate node where the conversation should transfer out of agentic CX designer.
3. Add a message, if needed.
4. Optionally add a State modification to set a context variable to pass context back to a flow in Connect Customer.
5. Connect any available failure, timeout, or continuation paths.
6. Save the flow.
7. Create a new application build and deploy it to the environment used by the Connect Customer flow.

Example escalation message:

```
Connecting you to an agent now.
```

Pass context during escalation

You can pass context back to a Connect Customer flow from the Escalate node using a context variable.

Use this when you want the human agent or Connect Customer flow to receive information collected or generated during the AI conversation.

Examples of escalation context:

- Transfer summary
- Customer intent
- Sentiment
- Authentication status
- Callback number
- Claim number
- Selected product or reservation
- Reason for escalation

State modification format

To pass data, add one or more State modifications to the Escalate node in your agentic CX designer flow that set one or more context variables.

For example, you may set a context variable `{summary}` to a variable generated upstream by a Generative text node that summarized the system transcript.

Set returned context as contact attributes

After the Agentic CX block's Escalation path, add a **Set contact attributes** block in a flow in Connect Customer.

Use this block to store the values returned from agentic CX designer so they can be used later in the Connect Customer flow or surfaced to an agent.

To set returned context

1. In the Connect Customer flow, connect the Escalation path from the Agentic CX block to a **Set contact attributes** block.
2. Add a new contact attribute.
3. Enter the attribute key you want to create, such as `transferSummary`.
4. Choose **Set dynamically**.

5. Select the **Agentic CX** namespace.
6. Select the returned context value, such as `summary`.
7. Confirm the block.

Example mapping:

Contact attribute key	Returned value from agentic CX designer
transferSummary	summary
customerIntent	customerIntent
callbackNumber	callbackNumber

Use clear attribute names so the values are easy to reference later in the Connect Customer flow or agent workspace.

After setting contact attributes, continue the Connect Customer flow by routing the customer to the appropriate queue.

A typical queue transfer sequence is:

1. **Set contact attributes** — Stores context returned from agentic CX designer.
2. **Set working queue** — Selects the queue the contact should use.
3. **Transfer to queue** — Transfers the customer to the selected queue.

For example, if the AI determines that the user needs billing support, the escalation path can pass `customerIntent=billingSupport`. The Connect Customer flow can then use that value to route the customer to the correct queue.

Use escalation context for the agent experience

Escalation context helps the human agent understand what happened before the transfer.

Use returned context to provide:

- A short summary of the AI conversation
- The reason for escalation

- Values the customer already provided
- Relevant IDs or selections
- Authentication or eligibility status
- Failed automation details

This reduces repeat questions and helps the agent continue the conversation with more context.

Example transfer summary:

```
The customer wants to update their billing address but the request
requires agent verification. The customer provided their account email
and confirmed they are the account holder.
```

Recommended flow pattern

Use this pattern when designing escalation from agentic CX designer to Connect Customer:

1. In agentic CX designer, collect or generate the context you want to preserve.
2. Store important values as context variables, slots, Define outputs, or Generative text outputs.
3. Add an Escalate node.
4. Add a user-facing escalation message.
5. Add a State modification to the Escalate node that sets a context variable, such as `{summary}`.
6. Build and deploy the application.
7. In a flow of Connect Customer, connect the Agentic CX block's Escalation path to **Set contact attributes**.
8. Store returned values from the Agentic CX namespace.
9. Route the contact with **Set working queue** and **Transfer to queue**.

Common issues

Issue	Likely cause	Fix
Escalation does not leave agentic CX designer	The flow did not reach an Escalate node or the deployed build is outdated.	Confirm the Escalate node is connected, then create and deploy a new build.

Issue	Likely cause	Fix
Returned context is missing in Connect Customer flow	State modification was not used to set a context variable.	Use a State modification to Set a context variable in the flow of agentic CX designer when the Escalate or Exit application nodes are reached.
Returned value is empty	The referenced variable was not in scope at the Escalate node.	Store the value as a context variable, Define output, Generative text output, or captured slot before escalatio n.
Agent receives no summary	The Set contact attributes block was not added after the Agentic CX escalation path.	Add Set contact attributes before Set working queue or Transfer to queue.
Wrong queue is selected	Queue routing logic does not use the returned context.	Use returned attributes to determine the correct queue before transfer.
Recent escalation changes are not active	The application was edited but not redeployed.	Create a new build and deploy it to the environme nt used by the Connect Customer flow.

Working with resources

Resources are reusable building blocks that help you create, manage, and scale experiences in agentic CX designer.

Instead of configuring the same content, data, or settings repeatedly, you can create resources once and reuse them wherever they're needed in the workspace. This keeps things easier to manage and helps teams build more consistent conversational AI applications.

Use Resources to manage shared items such as:

- *Context variables* for session-wide memory
- *Data requests* for connecting to external data
- *Knowledge bases* for trusted answer content
- *Modalities* for rich UI interactions
- *Secrets* for secure reusable values
- *Custom slots* for structured user selections
- *Resource tags* for organization and search
- *Translations* for multilingual content

To access Resources, select it from your workspace navigation and select the resource type you want to create or manage.

Topics

- Context variables
- Data requests
- Knowledge bases
- Live Sync Scripts
- Modalities
- Secrets
- Custom slots
- Resource tags

Context variables

Context variables store information that should remain available throughout a conversation session.

Use context variables when your application needs to remember information across flows, personalize responses, route users, avoid repeat questions, or pass context between the flow in Amazon Connect Customer and agentic CX designer.

For example, after a user is authenticated, you can set a context variable called `isAuthenticated` to `true`. Any flow in the same session can then check that value instead of asking the user to authenticate again.

To access context variables, select **Resources** from your workspace menu, then choose **Context variables**.

A context variable is a session-scoped value that can be referenced across flows.

Context variables are useful for information such as:

- Customer name
- Email address
- Account ID
- Claim number
- Authentication status
- Member or rewards tier
- Issue type
- Transfer summary
- Callback number
- Sentiment or intent
- Retry counters
- Selected product, reservation, appointment, or case

Context variables persist for the duration of the conversation session. They are different from local variables, which are intended for use within a single flow.

Use a Define node for temporary values that do not need to be shared across flows or passed during escalation.

Create a context variable

To create a context variable

1. Open **Resources** from the workspace menu.
2. Select **Context variables**.
3. Select **Add context variable**.
4. Enter a variable name.
5. Choose the data type or define a schema.

6. Optionally add a description.
7. Confirm whether **Allow frontend updates** should remain enabled.
8. Save the context variable.

Use clear, predictable names.

Examples:

- customerName
- claimNumber
- isAuthenticated
- transferSummary
- callbackNumber
- customerIntent
- selectedReservation

Context variable names should match exactly wherever they are referenced. Names are case-sensitive.

Each context variable has a schema that defines the type of value it can store.

Common types include:

String	Text values, such as name, email, claim number, or summary.
Number	Numeric values, such as retry count or score.
Boolean	True or false values, such as authentication status.
Object	Structured data, such as a customer profile or reservation.
List	Multiple values, such as selected items or available options.

For complex structures, use auto-generate schema when available to create a schema from sample JSON.

Allow frontend updates

The **Allow frontend updates** setting controls whether values from outside agentic CX designer can update the context variable.

Keep this setting enabled when the value should be populated from:

- Connect Customer flow
- A frontend client
- Touchpoint

Disable this setting when the value should only be set or modified inside agentic CX designer flows.

This setting is especially important when passing data from a flow in Connect Customer into agentic CX designer.

The exception is `nlx_userId`. When `nlx_userId` is passed on the Agentic CX block in a Connect Customer flow, it sets the built-in {System.userId} variable in agentic CX designer. You do not need to create a context variable named `nlx_userId`.

Use a context variable in a flow

After a context variable is created, you can reference it in supported fields across flows.

To reference a context variable, type { in a supported text field, then select the context variable from the placeholder menu.

The following examples show how to use context variables in messages:

```
Thanks, {customerName}. I found your claim: {claimNumber}.
The customer's authentication status is {isAuthenticated}.
Here is the summary I'll pass to the agent: {transferSummary}.
```

Context variables can be used in:

- Messages
- Split conditions
- Data request payloads
- Agent prompts

- Knowledge base questions
- Node payloads
- Modality payloads
- State modifications

Passing context from Connect Customer flows

Connect Customer flows can send context into an agentic CX designer application session.

Use this when the contact flow already knows information that the conversational AI should use, such as a phone number, customer ID, claim number, language, account status, or previously collected intent.

In the Connect Customer flow, configure the Agentic CX block to send context variables into the agentic CX designer session.

In the block's **Context variables** section, add key-value pairs.

Each key should match a context variable created in agentic CX designer. The exception is `nlx_userId`. Passing `nlx_userId` on the Agentic CX block automatically sets {System.userId} in agentic CX designer. No matching context variable is required.

For context variables your team creates in agentic CX designer, you can set values in two ways in the Connect Customer flow:

Option	Use
Set manually	Enter a fixed value directly in the Agentic CX block.
Set dynamically	Pull a value from the contact flow, contact attributes, or another supported Connect Customer namespace.

Example:

Agentic CX context key	Dynamic value from Connect Customer
claimNumber	Existing contact variable for the user's claim number

Agentic CX context key	Dynamic value from Connect Customer
customerName	Existing customer name value from Profiles
customerIntent	Intent or reason collected earlier in the contact flow

When the conversation reaches the Agentic CX block, the configured key-value pairs are passed into agentic CX designer and populate matching context variables for the session.

When passing context from Connect Customer flow into agentic CX designer:

- For standard context variables, the context variable must exist in agentic CX designer.
- The key name must match exactly.
- Names are case-sensitive.
- **Allow frontend updates** must be enabled for the context variable.
- You do not need to add a system-internal prefix to the context variable name.
- The special key `nlx_userId` does not need to be created as a context variable. When passed on the Agentic CX block, it sets {System.userId}.

For example, use the following variable name:

```
claimNumber
```

Do not use the following:

```
acxd_claimNumber
```

To set {System.userId} from a Connect Customer flow, use:

```
nlx_userId
```

Setting context variables with state modifications

Context variables can also be set or updated inside agentic CX designer flows.

Use **State modifications** when you want to copy a value into a context variable so it can be used later in the same session.

Examples:

- Set `isAuthenticated` after a successful authentication Data request.
- Set `selectedReservation` after the user chooses a reservation.
- Set `customerIntent` after a User input or Split node identifies the issue.
- Set `transferSummary` after a Generative text node creates a summary.

Common pattern:

1. Capture or retrieve a value.
2. Add a node with State modifications (be sure to do that downstream from a successful capture/retrieval).
3. Set the context variable to the captured or generated value.
4. Reference the context variable in later flows.

Use this pattern when values need to persist across multiple flows.

Passing context to Connect Customer flows

Agentic CX designer can send context back to Connect Customer flows when Escalation or Exit Application nodes are reached in an agentic CX designer flow.

Use this when a conversation exits from the Agentic CX block in the Connect Customer flow, and the downstream process requires a summary, intent, callback number, customer selection, or other context collected.

To pass data back, add one or more State modifications to the Escalate node in your agentic CX designer flow that Sets one or more context variables.

For example, you may set a context variable {summary} to a variable generated upstream by a Generative text node that summarized the system transcript.

Receive returned context in Connect Customer flow

After the agentic CX designer escalation occurs, returned values can be used in the Connect Customer flow.

Use a **Set contact attributes** block after the Agentic CX block to store or remap the returned values.

For example:

1. Add a **Set contact attributes** block after the Agentic CX block.
2. Create an output attribute, such as Key: `summary`.
3. Set the value dynamically from the agentic CX designer returned context.
4. Select the Agentic CX namespace shown in the Connect Customer block.
5. Select the returned key, such as `summary`.
6. Confirm the block.

Example mapping:

Contact attribute key	Dynamic value from Agentic CX
transferSummary	summary
customerIntent	customerIntent
callbackNumber	callbackNumber

Troubleshooting

Issue	Cause	Fix
Context variable is not populated in agentic CX designer	Name mismatch or frontend updates disabled	Confirm exact name match and enable **Allow frontend updates** in the context variables Settings.
{System.userId} is not populated for a chat interacti on	`nlx_userId` was not passed on the Agentic CX block, or the value was not available in the Connect	In the Agentic CX block's context variables section, pass `nlx_userId` and map it to the correct Connect Customer value, such as a

Issue	Cause	Fix
	Customer flow at the time the block was invoked.	contact attribute containin g the customer ID. Do not create `nlx_userId` as a context variable in agentic CX designer. Simply reference {System.userId} in agentic CX designer.
Value from Connect Customer flow is missing	Value was not set on Agentic CX block or not mapped into context variables	Map the value in the Agentic CX block.
Returned attribute is not available in Connect Customer flow	Context variable not set	Use a state modification to Set a context variable in the flow of agentic CX designer when Escalate or Exit application nodes are reached.
Context variable value is empty or null	Variable is not in scope at the Escalate node	Use a context variable, Define output, Generative text output, or captured slot available downstream.
Generative Journey value is not available later	Value was collected internally but not captured as a slot	Add the value as a required or optional slot in Data capture.
Value is needed in multiple flows	Slot or local variable is flow-scoped	Copy the value into a context variable with state modificat ions.
Returned value is hard to find in Connect Customer flow	Namespace or key is mismatched	Use the Agentic CX namespace and confirm the exact key spelling.

Data requests

Data requests are custom integrations that let agentic CX designer send data to, or retrieve data from, external systems during a conversation.

Use data requests when your conversational AI application needs real-time information or needs to trigger an action in another system. For example, a data request can retrieve appointment availability, look up a customer profile, check order status, or send a confirmation message.

Data requests can be used in two main ways:

Data request node	Trigger the data request at a specific point in a deterministic flow, then use the returned data in later nodes.
Agentic tool	Attach the data request as a tool to an agent node so the agent can call it when needed to complete a user task.

To access data requests, select **Resources** from your workspace menu, then choose **Data requests**.

Use data requests to connect conversations to systems such as scheduling tools, ticketing systems, order systems, account databases, and messaging services.

Common examples include:

- Providing available appointment times
- Authenticating a user
- Retrieving customer profile or account details
- Checking order, claim, or ticket status
- Looking up products
- Sending confirmation emails
- Updating a reservation or appointment

How data requests work

A data request defines how agentic CX designer communicates with an external system.

When a data request is triggered, agentic CX designer can:

1. Send a request to an external endpoint.
2. Pass values from the conversation into the request.
3. Receive a structured response.
4. Make returned values available to the flow or agent.
5. Use those values in messages, conditions, user choices, prompts, or downstream logic.

For example, a scheduling flow may collect a user's preferred date, send it to an appointment API, receive available time slots, and present those options back to the user.

Creating a data request

To create a data request

1. Open **Resources** from the workspace menu.
2. Select **Data requests**.
3. Select **New data request**.
4. Enter a clear name.
5. Add a description.
6. For **Implementation**, select the implementation type (static, external, Model Context Protocol (MCP), or Connect flow module).
7. Define the request/response model, or MCP tools.
8. Save and test the data request.

Use a name and description that make the purpose easy for teammates to understand.

Examples:

- GetAppointmentAvailability
- AuthenticateCustomer
- GetOrderStatus
- UpdateReservation
- SendConfirmationEmail

Implementation types

The **Implementation** tab defines what happens when the data request is called.

The following table describes the four implementation types.

Static	Returns a fixed response. Use this for prototyping, testing flow logic, or building before an endpoint is ready.
External	Calls a configured external endpoint using an HTTP method, URL, headers, parameters, and request/response models. Use this for traditional API or webhook calls.
MCP	Connects to an MCP server endpoint and syncs available tools so they can be reviewed, enabled, and used from the data request resource. Use this when the external service exposes tool-based capabilities through MCP.
Connect flow module	Invokes a published flow module in your Connect Customer instance and returns its output to the conversation. Use this type to reuse conversation logic you already built and govern in Connect Customer, instead of building and maintaining an external endpoint.

Use a *Static* implementation when you want the data request to return sample data without calling an external system.

Static responses are useful when:

- The real endpoint is not ready yet
- You want to test flow logic first
- You need predictable sample data
- You are prototyping a new experience

For example, you might return a sample list of appointment times so you can build and test a scheduling flow before connecting to the real scheduling system.

Use an *External* implementation when the data request should call a real API or webhook.

When configuring an external implementation, define details such as:

- HTTP method
- Endpoint URL
- URL parameters
- Headers
- Request payload
- Response structure

External implementations can support separate Production and Development endpoint configurations. This lets you test safely against a development endpoint before using production systems.

If the endpoint requires authentication, use Secrets instead of hardcoding API keys, tokens, or credentials directly into headers or payloads.

Use an *MCP* implementation when the external service exposes one or more tools through an MCP server.

When configuring an MCP implementation, you provide the MCP endpoint details, such as:

- HTTP method
- Production endpoint URL
- Headers, such as an authorization header
- Dynamic header behavior, if needed

After the MCP implementation is configured, use **Sync** to retrieve the available tools from the MCP server. Synced tools appear in the **Tools** section of the data request.

From the **Tools** section, you can:

- Review available MCP tools
- Enable or disable individual tools
- Expand a tool to review its description
- Inspect expected arguments

- Review available input schema details
- See whether the tool declares an output schema

Each tool can include a description and an argument schema that explains what information the tool expects.

MCP implementations can support separate Production and Development endpoint configurations. This lets you test safely against a development endpoint before using production systems.

If the endpoint requires authentication, use Secrets instead of hardcoding API keys, tokens, or credentials directly into headers or payloads.

For external or MCP implementations, dynamic headers can let you adjust header values when the data request is used.

Use dynamic headers when a header value may change based on the flow, environment, or context.

For sensitive or reusable values, such as API keys, bearer tokens, or authorization headers, use Secrets instead of entering the value directly.

Use a *Connect flow module* implementation when a data request should call a published flow module in your Connect Customer instance. A flow module packages conversation logic that you author, version, and govern in Connect Customer. With this implementation type, agentic CX designer invokes that logic during a conversation and returns its output to your application. You reuse governed logic instead of standing up and maintaining an external endpoint.

When you configure a *Connect flow module* implementation, you select and review the following items:

- The published flow module to invoke
- The module version
- The read-only request and response models
- An optional mock response used for testing

Important

Before a flow module appears in agentic CX designer, an administrator must publish the module and enable external invocation for it in Connect Customer. You can select only

modules that an administrator has published and enabled for external invocation. For instructions on preparing a module, see Create module as tools.

When you configure the implementation, you choose a module version. Choose **Latest** to always use the current published version of the module. When you republish the module, the data request uses the new current version. Choose a specific version number to pin the data request to that exact version. The data request keeps using that version even after you republish the module.

For a *Connect flow module* data request, the request and response models are read-only. These models derive from the module's input and output parameters, which you edit in Connect Customer. You cannot change the fields of these models in agentic CX designer. The only setting you can edit here is each field's sensitivity.

To configure a Connect flow module data request

1. For the implementation method, choose **Connect flow module**.
2. For the module, choose **Select Connect flow module**, then choose a module from the list.

   Only modules that are published and externally invocable appear in the list. A module that is not published, or that is not externally invocable, does not appear in the list. If you expect a module and cannot find it, prepare it as described in the prerequisites, then reopen the list.
3. For the version, choose **Select version**, then choose **Latest** or a specific version number.
4. Review the read-only request and response models.
5. (Optional) For **Mock response**, enter valid JSON. The data request uses the mock response only when you test it.

   When you test the data request in the resource editor, on the canvas, or on the application page, agentic CX designer returns this mock response and never invokes the live module. A flow module runs only in a real conversation. Author a mock response that matches the shape of the module's response model so that your tests exercise realistic data.

After you configure the implementation, add the data request to a flow so your conversation can call the module and use its results. This procedure adds a data request node that calls the module and makes the returned data available to later nodes.

Before you start, configure the *Connect flow module* implementation for the data request, including the module, version, and models. For instructions on preparing a module in Connect Customer, see Create module as tools.

The **Payload** editor is bound to the module's declared input schema. It marks required fields.

To use the data request in a data request node

1. Add a data request node and select the *Connect flow module* data request you configured.
2. In the **Payload** editor, map the values to send to the module. Provide a value for each required field, either a literal value or a reference to conversation data.
3. For **Output variable**, enter a name for the variable that receives the module's result.
4. Reference the fields of the output variable in later nodes to use the returned data downstream in the conversation.

> **Important**
>
> Saving a *Connect flow module* data request validates only the shape of the request. For example, it checks that the mock response is valid JSON and that field values are within their limits. Saving does not verify that the referenced module exists, is published, or is externally invocable.
> Saving accepts a reference to a module that is missing or ineligible. The reference fails during a live conversation, when the module cannot be invoked. Confirm that the module is published and externally invocable before you rely on the data request in production.

The following limits apply to a *Connect flow module* data request.

Field	Constraint
Connect flow module	Required. The module identifier is 1 to 256 characters.
Version	Optional. Defaults to **Latest**. A specific version is an integer of 1 or greater.
Mock response	Optional. Up to 200,000 characters. Must be valid JSON. Used only when you test the data request.

Field	Constraint
Payload	Optional. Bound to the module's input schema. The serialized request payload is 1 to 60,000 characters.
Output variable	Required. A local variable name that receives the module's result.

The module's response is limited to 1 MiB (1,048,576 bytes). If a response is larger than this limit, agentic CX designer rejects it instead of truncating it, and the data request takes the failure path. Because the limit is measured in bytes, a response that contains multi-byte characters reaches the limit with fewer characters.

Use a mock response that matches the shape of the module's response model so that your tests behave like a real invocation. The following JSON mock response returns an order status:

```
{
  "orderStatus": "SHIPPED",
  "estimatedDelivery": "2026-10-02",
  "carrier": "ExampleCarrier"
}
```

When you test the data request, agentic CX designer returns this response instead of invoking the module. To reference a field of this result downstream, use the output variable name. For example, if the output variable is named `orderLookup`, reference `orderLookup.orderStatus`.

In the **Payload** editor, map each required input field to a literal value or to conversation data. In the following example, replace `A12345` and `C67890` with your own order and customer identifiers.

The following JSON payload maps two values to the module's declared input fields:

```
{
  "orderId": "A12345",
  "customerId": "C67890"
}
```

Request model

The request model defines the optional payload that agentic CX designer sends to the external system.

Use a request model when the API needs values from the conversation.

You may select the Auto-generate option (star icon) to input sample JSON for easily constructing a complex schema structure.

Examples:

Request field	Example use
`email`	Send the user's email to retrieve a profile.
`appointmentDate`	Send a selected date to retrieve available times.
`orderId`	Send an order number to retrieve order status.
`reservationId`	Send a reservation ID to update a booking.
`message`	Send a confirmation message to an external notification service.

Fields in the request model can be populated dynamically from values captured in the conversation, such as slots, context variables, system variables, or prior data request results.

Response model

The response model defines the structure of the data returned from the external system.

Use the response model to shape returned data so it can be referenced in the conversation.

You may select the Auto-generate option (star icon) to input sample JSON for easily constructing a complex schema structure.

Examples:

Response data	How it might be used
`firstName`	Personalize a greeting or confirmation.
`availableTimes`	Present appointment options to the user.
`orderStatus`	Tell the user where their order stands.
`confirmationNumber`	Confirm a completed action.
`eligibleItems`	Show selectable return or exchange options.

A clear response model makes it easier to use returned values in later nodes, prompts, user choices, conditions, and messages.

When defining request and response models, choose the property type that matches the value.

String	A text value, such as a name, email, status, or confirmation message.
Number	A numeric value, such as age, quantity, price, or count.
Boolean	A true or false value, such as whether a customer is authentic ated or eligible.
List	A list of values, such as available times, products, orders, or options.
Object	A structured group of related values, such as a customer profile or reservation record.

Use Array when the response returns multiple values that may need to be presented as options. Use Object when the response returns a structured item with multiple properties.

List responses are useful when a user needs to choose from returned options.

Examples:

- Available appointment times

- Open reservations
- Eligible return items
- Nearby store locations
- Support ticket results

A list can be used with a User choice node when the user should select from returned options.

If the response contains a list of objects, use a Loop node to iterate over the nested values, or a Transform node or Generative text node to change the schema to a desired output and reference the correct nested properties depending on how you want to display or process the returned values.

Sensitive fields

You can mark fields as **Sensitive** to help prevent values from appearing in conversation logs where supported.

Use sensitive fields for values such as:

- Personally identifiable information
- Account identifiers
- Tokens or credentials
- Payment-related data
- Authentication responses
- Protected customer details

To mark a field as sensitive, open the field settings and enable the **Sensitive** toggle.

You may also use the data request-level sensitive setting if the entire data request should be treated as sensitive.

Data request settings

Description	Explains the purpose of the data request. Helpful for builders and for agent tool use.

Sensitive	Prevents values for the data request from appearing in logs where supported. Useful for concealing sensitive or personally identifiable information.
Send context	Sends available conversation context variables when the webhook is called. This is enabled by default when supported.

Testing a data request

Use the test feature to confirm that a data request is configured correctly before using it in a flow or agent node.

To test a data request

1. Open **Resources**.
2. Select **Data requests**.
3. Choose the data request you want to test.
4. Select **Test**.
5. Enter any required test values.
6. Choose the environment to test, if applicable.
7. Run the test.
8. Review the response.

A successful test should return the expected response structure based on your response model.

If the test fails, review:

- Endpoint URL
- HTTP method
- Headers
- Secrets or authentication values
- URL parameters
- Request payload
- Request model

- Response model
- Environment selection

Using a data request in a flow

To use a data request in a deterministic flow

1. Open the flow in the Canvas.
2. Add a Data request node.
3. Select the data request.
4. Map required request fields to values collected upstream from the conversation.
5. Connect the success path to the next node.
6. Configure failure, timeout, or in-progress paths.
7. Save and test the flow.

After the data request returns successfully, use the returned values in downstream messages, conditions, user choices, or other nodes.

Example:

"I found three available times: {AvailableTimes}. Which one works best for you?"

Using a data request as an agent tool

To use a data request as an agentic tool

1. Open the flow that contains the agent node.
2. Select the agent node.
3. Add a custom data request tool.
4. Choose the data request.
5. Provide a clear tool prompt or description.
6. Define when the agent should call the tool.
7. Map any required inputs to values collected upstream or allow the agent to collect them.
8. Save and test the agent behavior.

Use this pattern when the agent should decide when to call the integration as part of completing a task.

Example:

A rescheduling agent may collect the user's preferred date, call a data request to retrieve availability, ask the user to choose a time, then call another data request to update the appointment.

Synchronous and asynchronous data requests

On the data request node, the **Mode** control sets whether the conversation waits for the data request to finish. **Mode** has two options: **Synchronous** and **Asynchronous**. This setting is available on voice and chat.

In **Synchronous** mode, the conversation turn waits for the data request to resolve before it continues. The node routes the conversation on its result. For example, it can route along a success, failure, or timeout path.

In **Asynchronous** mode, the data request runs on a background path and the conversation turn continues without waiting. The result becomes available on a later turn.

Asynchronous mode removes the success and failure edges from the node. Because there is no failure edge in asynchronous mode, you must design failure handling differently. Plan how a later turn reads the result, and how the conversation responds when the result is missing or indicates a failure.

You can add an **In progress** edge to deliver a message while the request is still resolving. When you use the **In progress** edge, set a **Wait time** from 0 to 30,000 milliseconds. The conversation follows the **In progress** edge to deliver your message, then returns to the data request.

Resolve flow module data request errors

Use the following table to resolve the messages you might see when you configure a *Connect flow module* data request in agentic CX designer, or when a data request fails during a conversation. Some messages appear in the designer while you build. Others reach you as the failure reason on a data request that failed during a live conversation. The symptom column shows the message text where a message exists. The cause and remediation help you correct the underlying configuration.

Symptom	Cause	What to do
Save error: **You must select a compatible flow module**	The selected module is not published, or it is not enabled for external invocation.	In Connect Customer, publish the module and enable it as a tool. Then return to the data request and select the module again.
Notice: **Connect flow module not published**	The referenced module has no published version.	Publish a version of the module in Connect Customer.
Notice: **External invocation disabled**, with the link **How to enable external invocatio n**	The module is not saved and published as a tool, so it cannot be invoked from outside a flow.	Enable external invocation on the module in Connect Customer. For instructions, see Create module as tools.
Drift banner: **Out of date**, with text about parameters that have changed since the models were last synced, and a **Re-sync** button	The module's input or output parameters changed in Connect Customer after the request and response models were last synced.	Choose **Re-sync**. Then review your mapped inputs and outputs, because a parameter might have been added, removed, or renamed.
Mock editor error: **Invalid response**	The mock response does not match the response model.	Edit the mock response so that it matches the fields and types in the response model.
Save or test error: **Invalid JSON mock response.** or **The mock response of this flow module data request is not valid JSON.**	The mock response is not valid JSON.	Enter valid JSON for the mock response.
Empty state: **No Connect flow modules available** or **There are no Connect flow modules in your Connect Customer instance yet...**	Your instance has no modules that qualify, or no modules at all.	In Connect Customer, create a module, publish it, and enable it as a tool.

Symptom	Cause	What to do
A module you expect is missing from the module list	The module is not published , or it is not enabled for external invocation. Modules that do not qualify do not appear in the list.	In Connect Customer, publish the module and enable it as a tool. After the module qualifies, it appears in the list.
Canvas warning: **Data request not found.**	The data request that the node references was deleted or is missing.	Recreate the data request, or select a different data request on the node.
A data request saves without error but fails only during a live conversation	Saving validates the shape of your configuration. It does not check that the module exists, that your instance owns it, that it is published, or that it is enabled for external invocation.	Confirm that the module exists in your instance, is published, and is enabled as a tool.
Failure reason: **Flow module request could not be built**	The request payload is outside the allowed size, or an input mapping is missing required context.	Reduce or correct the request payload, and check your input mapping against the module's required inputs.
Failure reason: **flow module response exceeds the 1,048,576-byte limit**	The module returned a response larger than 1 MiB. The response is rejected, not truncated.	Reduce the size of the data that the module returns.
Failure reason: **flow module response did not match its declared schema**	The module's output does not match the declared response model.	Change the module so that its output matches the declared response model.

Symptom	Cause	What to do
Failure reason: **flow module orchestration** followed by a status (for example, `TIMED_OUT` or `FAILED`), or the module's own error details	The module did not finish successfully.	Handle the failure edge on the data request node, and review the module's own error handling.
Failure reason: **Flow module invocation throttled: request rate exceeded**	The synchronous request rate for the instance was exceeded.	Reduce the request rate, then retry.
Failure reason: **Flow module invocation throttled: too many concurrent requests**	Too many asynchronous requests ran at the same time.	Reduce the number of concurrent requests, then retry.
Failure reason: **Flow module endpoint could not be resolved**	The module's endpoint could not be resolved. This can happen after your Connect Customer account is migrated.	Contact AWS Support. This condition can persist, so retrying does not resolve it.
Failure reason: **Flow module invocation failed** or **Failed to trigger async flow module invocation**	The invocation, or the asynchronous dispatch, failed.	Handle the failure edge on the data request node, then retry.

Note

A data request can report success while its output variable holds unexpected or empty content. This can happen when a module signals a failure in a way that the data request node does not recognize as a failure. If a downstream step behaves as though the data succeeded when it did not, check the module's own error handling and confirm how the module reports failures in its output.

Best practices

- Use clear data request names and descriptions.
- Use static implementations for prototyping before the real endpoint is ready.
- Use external implementations for real API calls.
- Use Secrets for API keys, tokens, and credentials.
- Define request and response models clearly.
- Mark sensitive fields appropriately.
- Send only the data the external system needs.
- Test the data request before using it in a flow or agent node.
- Use a data request node for controlled deterministic calls.
- Keep chained data request nodes shallow. Each data request node that runs in sequence across conversation turns adds to the time a customer waits. When you need several results, prefer adding several data requests to one node over chaining separate nodes across turns.

Important

Make modules with side effects idempotent. A module that changes state, such as one that takes a payment, can run more than once for a single customer intent. A retried conversation turn can invoke the module again, and a deliberate repeat invocation of the same module on the same node might return the earlier result instead of running again. Design modules that have side effects to be idempotent, or add a guard that prevents a repeated action from taking effect twice.

Important

Author failure-edge handling. When a data request fails, the customer hears nothing from this node unless you handle the failure. Authoring failure-edge handling is required, not optional. On the data request node, connect the failure edge to a step that responds to the customer or recovers the conversation.

> **Note**
>
> Treat module output as untrusted. A flow module's output can be bound to a variable that a generative node later references. Validate or sanitize the module's output before you reference it from a generative node.

Knowledge bases

Knowledge bases are reusable libraries of trusted content that your agentic CX designer applications can use to answer user questions.

Use a knowledge base when you want your conversational AI application to provide grounded answers without creating a dedicated flow for every possible question. Knowledge bases are useful for FAQs, policies, product information, troubleshooting guidance, support instructions, and other content users may ask about during a conversation.

To access knowledge bases, select **Resources** from your workspace menu, then choose **Knowledge bases**.

A knowledge base is an on-demand content source that helps your application answer questions using approved information.

When a user asks a question, agentic CX designer can search the knowledge base for relevant content and return an answer based on the best match. This helps the application respond to common questions while keeping answers grounded in the content your team provides.

Knowledge bases can be used in:

Knowledge base node	Retrieves an answer at a specific point in a deterministic flow.
Agent tool	Lets an agent use the knowledge base as a tool when answering questions or completing a task.

Agentic CX designer supports these knowledge base content types:

Q&A	Stores question-and-answer pairs entered manually or uploaded through a supported file format.

Documents	Ingests uploaded files, such as PDFs, images, or text files, so the application can retrieve relevant information from the document content.

Knowledge base settings

Knowledge base settings control how content is matched and returned.

Minimum confidence score	Determines how confident the match must be before the knowledge base returns an answer.
Summarize	Allows the application to rephrase retrieved content into a more natural response.
Temperature	Controls how much flexibility the model has when summarizi ng or rephrasing an answer. Lower values are more conservat ive; higher values allow more variation.
Top P	Controls how many word choices are considered when generating a summarized response. Lower values generally produce more conventional responses.

Use conservative settings when accuracy and consistency are more important than dynamic creative phrasing.

Q&A knowledge bases

A Q&A knowledge base stores structured question-and-answer pairs.

Use Q&A when your content is already organized as clear questions and approved answers, such as FAQs, policy responses, support scripts, or short troubleshooting guidance.

To create a Q&A knowledge base

1. Open **Resources** from the workspace menu.
2. Select **Knowledge bases**.
3. Select **New knowledge base**.

4. Enter a name.
5. Choose **Q&A** as the content type.
6. Create the knowledge base.
7. Add content manually or upload supported Q&A content.
8. Save your changes.

You can add Q&A content by manually creating articles or uploading supported structured content.

Each Q&A entry should include:

- A user-facing question or phrase
- One or more approved responses
- Optional payload or metadata, if supported

Example JSON format:

```
[
  {
    "question": {
      "text": "What are your business hours?"
    },
    "responses": [
      {
        "type": "text",
        "body": "We are open Monday through Friday from 9 AM to 6 PM."
      }
    ]
  }
]
```

You can also upload Q&A content as a comma-separated values (CSV) file. Each row is one article: The first column is the question, and the second column is the response.

```
question,answer
What is your refund policy?,We send you money.
```

You can name the response column either `answer` or `responses`. Both names produce the same result:

```
question,responses
What is your refund policy?,We send you money.
```

Use one response per row. To provide multiple responses for a single question, use the JSON format.

Metadata can be used to filter which Q&A content should be searched during retrieval, when supported.

Use metadata when a Q&A knowledge base contains a large amount of content and you only want to search a specific subset.

For example, an insurance support application may include policy questions for multiple states. Metadata can help filter answers by state, coverage type, or document type so the user receives a more relevant response.

Example metadata schema:

```
{
  "documentId": "",
  "policyholderId": "",
  "documentType": "",
  "coverageType": "",
  "language": "",
  "state": "",
  "sensitive": true
}
```

To configure metadata

1. Open the Q&A knowledge base.
2. Select the **Metadata** tab.
3. Add or generate the metadata schema.
4. Save the schema.
5. Open the **Q&A content** tab.
6. Expand the relevant Q&A article.
7. Add metadata values.

8. Save your changes.
9. Publish a new version of the knowledge base.

After metadata is configured, you can apply metadata filters when the knowledge base is called from a flow, if supported by the node configuration.

After creating or updating Q&A content, publish the knowledge base so the changes become available.

To publish

1. Open the Q&A knowledge base.
2. Select the **Publish** tab.
3. Enter an optional deployment description.
4. Select **Publish knowledge base**.

Publishing creates a new version of the Q&A knowledge base content. After the initial application deployment, publishing Q&A updates can make content changes available without requiring a new application deployment.

If needed, you can roll back a Q&A knowledge base to a previous published version.

To roll back

1. Open the Q&A knowledge base.
2. Select the **Publish** tab.
3. Locate the previous version.
4. Select **Rollback** for the version you want to restore.

Use rollback when a recent content update introduced incorrect or unintended answers.

Documents knowledge bases

A Documents knowledge base lets you upload files and use their content for retrieval.

Use Documents when your source material exists as policies, manuals, PDFs, guides, articles, or other documentation that would be difficult to convert into individual Q&A pairs.

Document ingestion processes your uploaded files so the application can search and retrieve relevant content when a user asks a question.

To create a Documents knowledge base

1. Open **Resources** from the workspace menu.
2. Select **Knowledge bases**.
3. Select **New knowledge base**.
4. Enter a name.
5. Choose **Documents** as the content type.
6. Create the knowledge base.
7. Select **Add documents**.
8. Upload files from your computer (pdf, txt, jpg, png, doc, docx).
9. Save your changes.
10. Wait for the files to finish processing.

When processing is complete, the document status should show that the content has been ingested.

How retrieval works

Knowledge bases use semantic retrieval to find relevant content.

At a high level:

1. A user asks a question.
2. Agentic CX designer compares the user's question against knowledge base content.
3. The most relevant matching content is retrieved.
4. The application returns or summarizes an answer based on the retrieved content.
5. If no confident match is found, the flow can follow a no-match, fallback, or escalation path.

This helps the application answer questions based on approved content rather than relying only on a prompt.

Using a knowledge base in a flow

To use a knowledge base in a deterministic flow

1. Open a flow.
2. Add a Knowledge base node.
3. Select the knowledge base to query.
4. Choose the user question or variable that should be sent to the knowledge base (default is {System.utterance}).
5. Configure the output variable that will store the answer.
6. Connect the match path to the next message or action where the output variable is referenced.
7. Connect the no-match path to a recovery, fallback, or escalation experience.
8. Save and test the flow.

For example, an Unknown flow might send the user's latest utterance to a knowledge base. If a match is found, the application returns the answer. If no match is found, the application can ask a clarifying question, link to a different knowledge base node, or route to escalation.

Using a knowledge base as an agent tool

A knowledge base can also be attached as a tool to an agent node.

Use this when the AI agent should decide when to search the knowledge base as part of a broader task.

For example, an AI agent may use a knowledge base to answer policy questions while also collecting user details and calling Data requests.

When attaching a knowledge base as a tool, provide clear instructions so the agent understands:

- Identify the tool as a knowledge base and when to use
- What to do if no answer is found
- Whether it should summarize or quote content

Live Sync Scripts

Live Sync Scripts let you pair controlled, predefined voice lines with interactions in a web or mobile experience.

Use a Live Sync Script when the wording or sequence should be determined in advance rather than generated dynamically by the Live Sync agent.

For example, while a user completes a checkout experience, a script might say:

"Review your order details, then select **Confirm** to continue."

When the user completes that step in the digital experience, the experience can move to the next scripted voice line or return control to the Live Sync agent.

Live Sync Scripts work alongside Live Sync, Touchpoint, and your agentic CX designer application to create experiences that combine conversational AI with deterministic voice guidance.

Live Sync agents and Live Sync Scripts serve different purposes.

When to use a Live Sync Script

Capability	Use it when
Live Sync agent	The experience requires flexible conversation, reasoning, tool use, dynamic responses, or decisions based on the user's request.
Live Sync Script	The experience requires predefined wording or a controlled sequence associated with frontend behavior.

Live Sync Scripts are useful when you need:

- Exact messaging
- Consistent instructions
- Controlled legal or compliance language
- Guided step-by-step experiences
- Voice prompts synchronized with specific frontend events
- Predictable transitions back into agentic or deterministic flow behavior

You can combine both approaches in the same experience.

For example, a Live Sync agent can help a customer choose a service plan conversationally. When the customer reaches a required consent step, a Live Sync Script can provide the approved disclosure before the experience continues.

How Live Sync Scripts work

A Live Sync Script contains a series of predefined voice messages called steps. Each step can be associated with part of your frontend experience so that the appropriate voice line plays when the corresponding event occurs.

A typical experience includes:

Component	Responsibility
Live Sync Script	Contains the predefined voice lines and step behavior.
Live Sync node	Provides the conversational Live Sync experience and handles script continuation or escalation paths.
Touchpoint SDK	Connects the digital experience to the active Live Sync interacti on.
Frontend	Presents the UI and coordinates relevant script behavior with frontend events.
Connect Customer Flow	Provides the active customer interaction and invokes the agentic CX designer application.

A simplified experience might look like:

Live Sync conversation → frontend event → scripted voice step → frontend interaction → next scripted step or return to Live Sync

Unlike standard Live Sync agent responses, the wording of a script step is defined by you rather than generated by the LLM.

Requirements

Before using a Live Sync Script, configure the broader Live Sync experience.

You typically need:

- An application
- A flow containing a Live Sync node
- A deployed application
- A Connect Customer flow that invokes the application through the Agentic CX block
- The Touchpoint SDK integrated with the supported digital experience
- A Live Sync Script containing the required voice steps
- A deployed Live Sync Script

Your implementation can determine how users enter the digital experience. For example, a Connect Customer flow might send a link to the customer, but SMS delivery is not inherently required by Live Sync Scripts.

Create a Live Sync Script

To create a script

1. Open **Resources** from the workspace menu.
2. Select **Live Sync Scripts**.
3. Create a new script or open an existing script.
4. Select **Add step**.
5. Enter the voice message for the step.
6. Repeat for each predefined step in the experience.
7. Save the script.

Each step represents an authored voice line that can be synchronized with the corresponding frontend experience.

Write effective script steps

Live Sync Scripts work best when each message clearly tells the user what is happening or what they should do next.

Avoid open-ended prompts when the digital experience expects a specific action.

Instead of:

"Would you like to use the card on file?"

Use:

"We can use the card on file. Select **Confirm** to authorize it, or choose another payment method."

The second version tells the user exactly how to interact with the digital experience.

Keep script messages:

- Short enough to sound natural when spoken
- Specific to the current UI state
- Clear about the next expected action
- Consistent with the controls shown on screen
- Free of unnecessary conversational filler

Because the wording is predefined, Live Sync Scripts are especially useful when exact phrasing matters.

Configure step actions

Optional actions can be configured for a Script step that provides additional behaviors.

Simply expand a Script step and select **Enable** under **Actions**. Only one action is permitted per step.

Continue

Use **Continue** when the experience should leave the scripted sequence through the Continuation path of the Live Sync node in a flow.

This lets you transition from controlled scripted behavior back into the appropriate flow or agentic experience.

Escalate

Use **Escalate** when the scripted experience should leave through the Escalation path of the Live Sync node.

For example, a scripted disclosure or verification step might escalate when the experience requires support from a human agent.

The Continuation and Escalation paths on the Live Sync node are specifically used to support Live Sync Script behavior.

End

Use **End** when the scripted experience should end the interaction with the agentic CX designer application.

When the experience triggers a step with **End** action enabled, the contact progresses from the Default path of the Agentic CX block on the Connect Customer flow.

Use Context variables in script messages

You can use Context variables to personalize predefined script messages with information already available in the conversation.

For example:

"Thanks, `{customerName}`. Review your updated reservation before continuing."

To insert a Context variable

1. Open or add a script step.
2. Select the message field.
3. Enter an opening curly brace {.
4. Select the appropriate Context variable.
5. Save the script.

Make sure the variable is populated in a flow before the script step that references it.

Use Context variables for values such as:

- Customer name
- Appointment date
- Reservation information

- Account information
- Previously selected options

This allows the wording to remain controlled while still incorporating relevant customer or session information.

Add analytics tags

Assign Analytics tags to important script steps when you want to measure how users progress through the scripted experience.

For example, you might tag:

- A disclosure step
- A confirmation step
- A payment step
- A successful completion step
- An escalation step

Use meaningful names that describe the event being measured.

For example:

`payment_confirmation_presented`

or:

`consent_completed`

Analytics tags can help identify where users continue, abandon, or escalate during a guided experience.

Connect the script to your Live Sync experience

Live Sync Scripts are designed to work as part of an active Live Sync experience.

Configure your agentic CX designer flow with a Live Sync node and connect its relevant paths to the behavior your script requires.

In particular:

- Use the Continuation path when a script step should transition back into the flow.
- Use the Escalation path when a script step should trigger escalation behavior.

Your frontend implementation should associate the applicable script steps with the digital events or UI states that should trigger them.

For example:

Frontend event	Script step
Checkout page opens	"Review your order details before continuing."
Consent panel appears	"Please review the authorization statement shown on screen."
Confirmation succeeds	"Your changes are confirmed."
Additional assistance is required	Escalate from the Live Sync node.

This lets the digital experience control when an authored line is appropriate while agentic CX designer controls the surrounding conversational flow.

Use Live Sync Scripts with Touchpoint

The Touchpoint SDK connects the digital experience to the active Live Sync interaction.

For Live Sync Scripts, your frontend implementation uses Touchpoint as part of the same Live Sync connection used for the broader digital experience.

Touchpoint connection information includes values associated with the deployed application and active customer interaction, such as:

- Host
- Deployment key
- API key
- Language code

- Connect Customer contact ID

The Connect Customer contact ID associates the digital experience with the correct active interaction.

Use the current Touchpoint implementation for the Live Sync connection and associate your scripted behavior with the relevant frontend events.

Refer to the Touchpoint SDK documentation for implementation details.

Combine scripts with agentic Live Sync

Live Sync Scripts do not replace the Live Sync agent. They give you a deterministic option for specific moments within the broader experience.

For example:

The customer says:

"I want to upgrade my internet plan."

The Live Sync agent discusses available options, answers questions, and helps the customer choose a plan.

When the user reaches the final order screen, a Live Sync Script delivers:

"Your new monthly price will be $75. Review the terms shown on screen and select **Accept** to continue."

The wording is fixed rather than generated.

The customer selects **Accept**.

The script uses its continuation behavior and returns control to the appropriate Live Sync flow.

The agent confirms the completed change and continues helping the customer.

1. Agentic conversation
2. Scripted disclosure
3. Frontend confirmation

4. Continue
5. Agentic conversation resumes

This pattern allows you to use generative AI where flexibility is valuable and deterministic messaging where control is more important.

Deploy a Live Sync Script

Create and deploy the script before using it in a production Live Sync experience.

From the script's deployment area:

To deploy a script

1. Create a build.
2. Review the build status.
3. Resolve any validation or build errors.
4. Deploy the successful build to the appropriate environment.

Script changes should be deployed from the Live Sync Script resource.

Changes to the agentic CX designer application or its flows follow the normal application build and deployment process.

This separation allows you to update scripted messaging without unnecessarily changing unrelated conversational logic.

Modalities

Modalities are reusable structured UI components that bring richer interaction into agentic CX designer conversations.

A modality complements a text response by sending structured data that your frontend can render as an interactive experience. For example, a modality can display a carousel of options, show a confirmation card, open a date picker, render an image, or support a custom UI pattern built for your application.

Modalities are rendered by the application frontend via the Touchpoint SDK.

To access modalities, select **Resources** from your workspace menu, then choose **Modalities**.

A modality is a structured payload that helps the user take action or view richer content during a conversation.

Instead of sending only a message, the application can send data that the frontend knows how to display.

For example:

- A hotel assistant can show resort options in a carousel.
- A banking assistant can show a card summary for a selected transaction.
- A scheduling assistant can show a date picker.
- A shopping assistant can show product cards with images and labels.
- A support assistant can show a custom troubleshooting interface.

Modalities are useful when the user needs to select, confirm, compare, review, or interact with information visually.

Use modalities when text alone is not the best way to guide the user.

Modalities can be added to supported node types, including:

- Basic nodes
- User choice nodes
- User input nodes
- Agent nodes, such as Generative Journey and Live Sync nodes

For Basic, User choice, and User input nodes, modalities are added from the node's functionality options.

For agent nodes, modalities can be attached as tools so the agent can choose when to use them during a task.

Predefined modalities

Agentic CX designer includes predefined modalities that can be reused across flows.

Predefined modalities are designed to work with the agentic CX designer Touchpoint SDK, without requiring you to create a custom frontend component. They behave like reusable UI blocks and can be attached to supported nodes.

The predefined modalities include:

Carousel	Shows multiple options in a horizontally browsable card layout.
Card	Shows a single focused item, summary, confirmation, or preview.
Date input	Lets users select a date through a date picker.
Video	Shows an inline video player that the user can play, with an optional preview image.

Carousel

Use a Carousel modality when users need to browse or select from multiple options.

Best for:

- Product selections
- Resort or hotel options
- Appointment times
- Credit card or plan options
- Search results
- Return or exchange options

The following example shows a carousel schema:

```
[
  {
    "id": "uuid",
    "thumbnail": "imageUrl",
    "label": "Label text",
    "value": "Value text"
```

```
  }
]
```

A carousel can be powered by static values, values entered directly in the node, or dynamic data returned from a Data request.

Card

Use a Card modality when users need to review one focused item.

Best for:

- Confirmation summaries
- Selected item previews
- Reservation details
- Payment or billing summaries
- Account or profile previews
- Important next-step information

The following example shows a card schema:

```
{
  "id": "uuid",
  "thumbnail": "imageUrl",
  "label": "Label text",
  "value": "Value text"
}
```

A card is useful when you want to visually reinforce the information the user is about to confirm or act on.

Date input

Use a Date input modality when users need to select a date.

Best for:

- Scheduling appointments

- Choosing a reservation date
- Selecting a service date
- Confirming an existing date
- Capturing a date for a downstream Data request

The Date input modality does not require a custom schema. It opens a date selector and returns the selected date to the conversation.

Video

Use a Video modality when a short video helps the user more than text alone.

Best for:

- Product demos
- How-to or troubleshooting clips
- Onboarding or welcome messages
- Visual confirmations or walkthroughs

The Video modality takes two payload values.

Field	Required	Description
`url`	Yes	The URL of the video file to play, such as an MP4.
`previewImageUrl`	No	The URL of an image shown in the player as a preview (poster) frame before the user plays the video.

The following example shows a video payload:

```
{
  "url": "https://example.com/demo.mp4",
  "previewImageUrl": "https://example.com/demo-preview.jpg"
}
```

In the Canvas, this modality appears as **DefaultVideo**.

Custom modalities

Create a custom modality when your use case requires a visual or interaction pattern beyond the predefined options.

A custom modality is a reusable resource with its own schema and frontend rendering behavior.

When the conversation reaches a supported node with a custom modality attached, agentic CX designer sends the structured payload to the frontend for rendering.

Schema	Defines the structure of data the modality accepts, such as text, image URLs, links, IDs, or metadata.
Component	Defines how the frontend displays that data through Touchpoint SDK or your own custom UI.

To create a custom modality

1. Open **Resources**.
2. Select **Modalities**.
3. Select **New modality**.
4. Enter a clear name.
5. Open the **Schema** tab.
6. Add the schema manually or use auto-generate from sample JSON, if available.
7. Add descriptions for schema properties (if intended to be used by an agent node).
8. Save the modality.

Add property descriptions when the modality may be used by an agent node. Descriptions help the agent understand what each field means and how the modality should be populated.

Custom modality properties may include a **Sensitive** setting.

Enable **Sensitive** for fields that may contain:

- Personally identifiable information

- Account details
- Protected customer data
- Payment-related information
- Any value your organization treats as private

Sensitive fields help prevent those values from appearing in conversation logs where supported.

The **Code generation** tab lets you retrieve schema output for use in your frontend codebase.

Depending on what is available in your workspace, this may include formats such as:

- JSON schema
- TypeScript schema

Use generated code to help validate modality payloads and support type-safe rendering in your frontend.

Using a predefined modality

To use a predefined modality

1. Open a flow in the Canvas.
2. Add or select a supported node, such as a Basic, User choice, User input, Generative Journey, or Live Sync node.
3. Select Add functionality on the node.
4. Select **Modality**.
5. Choose the predefined modality.
6. Map or enter any required values.
7. Save the flow.
8. Create a new build before testing or deployment, if the change should be included in the application experience.

For agent nodes, attach the modality as a tool and provide instructions for when the agent should use it.

Using a custom modality

To use a custom modality

1. Open a flow in the Canvas.
2. Add or select a supported node, such as a Basic, User choice, User input, Generative Journey, or Live Sync node.
3. Open the node's functionality options.
4. Select **Modality**.
5. Choose the custom modality.
6. Enter payload values manually or use dynamic placeholders.
7. Save the flow.

You can populate modality fields with values from:

- Slots
- Context variables
- System variables
- Data request outputs
- Other values already available in the conversation

Type { in supported fields to select available placeholders.

For agent nodes, attach the custom modality as a tool and provide clear instructions for when the agent should use it. You can provide explicit variables to the fields or provide agent instructions on what fields it should populate.

Modalities with dynamic data

Modalities are often powered by dynamic data returned from a Data request.

For example:

1. A user asks to book an appointment.
2. A Data request retrieves available appointment times.
3. A Transform, Loop, or Define step reshapes the returned data.

4. A carousel modality displays the available times.
5. The user selects one.
6. The selected value is used in the next step of the flow.

This pattern helps turn real-time API responses into interactive UI elements.

A Data request response may not match the schema a modality expects.

When that happens, use transformation tools to reshape the data before sending it to the modality.

Transform node with Morph	Uses generative AI to reshape the data into the target schema. Helpful for prototyping or variable response structures.
Transform node with Generative map	Maps each item in a list into the expected list-item schema. Useful for carousels and repeated cards.
Loop node with Define node	Deterministically builds the structure from complex or nested data. Useful when you need precise control.

Use generative transformation when speed and flexibility are important. Use deterministic transformation when structure, predictability, or compliance matters more.

Secrets

Secrets let you securely store reusable values that may be needed when configuring Data requests in agentic CX designer.

Use Secrets for values that should not be hardcoded directly into URLs, headers, or request payloads, such as API keys, tokens, passwords, authorization headers, or other sensitive configuration values.

Secrets can also help teams manage commonly reused values more efficiently because the value can be stored once and referenced where needed.

To access Secrets, select **Resources** from your workspace menu, then choose **Secrets**.

A Secret is a workspace resource that stores a value for later use.

Secrets are commonly used when configuring Data requests that call external systems or MCP servers. Instead of typing a sensitive value directly into a Data request, you can reference the Secret as a placeholder.

Use Secrets for values such as:

- API keys
- Bearer tokens
- Authorization headers
- Passwords
- Webhook secrets
- Reusable endpoint values
- Environment-specific configuration values

Secrets help reduce exposure of sensitive information and make it easier to update values in one place when credentials or shared configuration values change.

Creating a Secret

To create a Secret

1. Open **Resources** from the workspace menu.
2. Select **Secrets**.
3. Select **Add secret**.
4. Enter a clear name.
5. Enter the Secret value.
6. Add an optional description.
7. Keep **Sensitive** enabled if the value should be hidden and redacted.
8. Select **Create secret**.

Use a clear name that helps teammates understand what the Secret is used for.

Examples:

- `prod_api_key`

- `dev_api_key`
- `authorization_token`
- `mcp_server_token`
- `webhook_secret`
- `customer_profile_base_url`

Sensitive setting

When the **Sensitive** setting is enabled, the Secret value is hidden and redacted where supported.

Keep **Sensitive** enabled for values such as:

- API keys
- Tokens
- Passwords
- Authorization headers
- Customer identifiers
- Credentials
- Any value your organization considers private or restricted

Only disable **Sensitive** for values that are safe for teammates to view and that do not need to be redacted.

Referencing Secrets

After a Secret is created, you can reference it when configuring a Data request.

Secrets may be used in places such as:

- Endpoint URLs
- Headers
- Authorization values
- Request payload fields
- Dynamic configuration values

To reference a Secret, type an open curly brace { in a supported field, then select the Secret from the available placeholder options.

Using Secrets in an External implementation

Use Secrets in an External Data request implementation when calling an API or webhook that requires secure values.

To use a Secret in an External implementation

1. Open **Resources**.
2. Select **Data requests**.
3. Create a new Data request or open an existing one.
4. Go to the **Implementation** tab.
5. Select **External**.
6. Add the endpoint URL.
7. Add any required headers.
8. In a supported URL, header, or payload field, type {.
9. Select the Secret you want to reference.
10. Save the Data request.

For example, if an API requires an authorization header, store the token as a Secret and reference it in the header value instead of entering the token directly.

Using Secrets in an MCP implementation

Use Secrets in an MCP Data request implementation when the MCP server requires authentication or other protected configuration values.

To use a Secret with an MCP implementation

1. Open **Resources**.
2. Select **Data requests**.
3. Create a new Data request or open an existing one.
4. Go to the **Implementation** tab.
5. Select **MCP**.

6. Enter the MCP server endpoint.
7. Add required headers, such as Authorization.
8. In the header value field, type {.
9. Select the Secret that stores the required token or credential.
10. Save the Data request.
11. Sync the MCP server to retrieve available tools.

Secrets are especially useful for MCP implementations because MCP servers often require authorization values that should not be typed directly into the Data request configuration.

Using Secrets in a Data request node

You can also reference Secrets when configuring a Data request node in a flow, if the selected Data request includes fields that can accept dynamic values.

To use a Secret in a Data request node

1. Select a flow.
2. Add or select a Data request node.
3. Choose the Data request you want to call.
4. Locate the payload field where the Secret should be used.
5. Type {.
6. Select the Secret from the available placeholder options.
7. Save the node and test the flow.

Use this when a specific Data request call needs a secure or reusable value at runtime.

Testing

After adding or updating a Secret, test the Data request that uses it.

To test

1. Open the Data request.
2. Select the **Test** option.
3. Run the test.

4. Confirm that the request succeeds.
5. Review whether the expected response is returned.

If the test fails, check:

- The Secret value
- Header name and format
- Endpoint URL
- Request method
- Request payload
- Whether the correct environment is being tested
- Whether the external service expects a prefix such as Bearer

Custom slots

Custom slots define structured values your application can capture during a conversation.

In agentic CX designer, slots help collect information from users so a flow can continue with the right data. A custom slot is a slot type you create for values specific to your business, such as room types, product sizes, support categories, appointment reasons, or yes/no choices.

For example, if a user says "I'd like a large," the application can capture "large" as the selected value for a custom Size slot.

To access custom slots, select **Resources** from your workspace menu, then choose **Slots**.

Use a custom slot when the user should choose from a defined set of values. Common examples include:

- Yes / No
- Small / Medium / Large
- Standard / Deluxe / Suite
- Billing / Technical support / Account access
- Pickup / Delivery
- Email / SMS / Phone

- "I want to sign up" / "I want something else"

Custom slots are especially useful with User choice nodes or agent nodes because they help the application capture a structured value and route the conversation based on that value.

Use custom slots for business-specific values that you define.

Use built-in slots for common input types that agentic CX designer already supports, such as:

- Date
- Time
- Email
- Phone number
- Freeform text

You do not create built-in slots from the custom Slots resource. Instead, select the appropriate built-in slot when attaching slots to a flow.

Creating a custom slot

To create a custom slot

1. Open **Resources** from the workspace menu.
2. Select **Slots**.
3. Select **New slot** or **Add slot**.
4. Enter a clear slot name.
5. Add one or more values.
6. Save the slot.

Use a name that describes what the slot captures.

Examples:

- RoomType
- AppointmentReason
- SupportCategory

- ShirtSize
- CommunicationPreference

Adding values

Values are the allowed options for the custom slot.

To add values

1. Open the custom slot.
2. Select **Add new value**.
3. Enter the value.
4. Repeat for each option.
5. Save your changes.

Example values for a RoomType slot:

- standard
- deluxe
- suite

Avoid values that are too similar, such as Yes and Yes, please, because closely named values can make matching less clear. In that case, use Yes as the main value and add Yes, please as a synonym.

Synonyms

Synonyms let you define alternate phrases that should resolve to the same slot value.

For example, a "Yes" value may include synonyms such as:

- Sure
- OK
- Yep
- That works
- Sounds good

To add synonyms

1. Open the custom slot.
2. Expand a value.
3. Select **Add synonym**.
4. Enter one or more alternate phrases.
5. Save your changes.

Synonyms help users respond naturally while still letting the application capture a controlled value.

Choice payload

A choice payload defines additional information for how a value should be displayed or handled when shown as a user selection.

Use a choice payload when you need to:

- Customize how a choice appears
- Include supporting display information
- Reference context variables in a displayed choice
- Control ordering or sorting behavior
- Add metadata that helps the frontend or flow handle the selected value

To add a choice payload

1. Open the custom slot.
2. Expand the value.
3. Locate the **Choice payload** field.
4. Enter the payload details.
5. Save your changes.

You can use the placeholder menu by typing { in supported fields to insert available variables.

Attaching a custom slot to a flow

After creating a custom slot, attach it to the flow where it will be used.

To attach a slot

1. Open the flow.
2. Open the flow settings from the Canvas toolbar.
3. Go to **Attached slots**.
4. Add the custom slot.
5. Give the attached slot a clear name, if prompted.
6. Save the flow.

Once attached, the slot can be used in nodes that collect or reference user responses.

Using custom slots in a User choice node

Custom slots are commonly used with User choice nodes.

To use a custom slot in a User choice node

1. Open the flow in the Canvas.
2. Add or select a User choice node.
3. Choose the attached custom slot as the response source.
4. Configure paths for matched values.
5. Add a No match path for unclear or unsupported responses.
6. Save and test the flow.

For example, a User choice node may ask: "What type of room would you like to book?"

The custom RoomType slot captures whether the user selected standard, deluxe, or suite.

Translations

If your application supports multiple languages, translate custom slot values and synonyms using Translations in the workspace.

Custom slots used in multilingual flows should be translated for each language your application supports.

Review translated slot values carefully, especially when values affect routing, compliance, or customer-facing choices.

Sensitive setting

Enable **Sensitive** when slot values should not appear in conversation transcripts.

Use this setting for values that may include:

- Personal information
- Account details
- Protected user attributes
- Sensitive selections
- Any value your organization treats as confidential

Only mark a slot as non-sensitive when the captured value is safe to store and review in conversation transcripts.

Resource tags

Resource tags help you organize, search, and identify resources in an agentic CX designer workspace.

A resource tag is a custom keyword or label that can be applied to workspace resources. Tags are useful when you want to group resources by purpose, team, environment, audience, status, or any other category that helps builders quickly find and understand them.

For example, you might use tags such as:

- production
- development
- customer
- internal
- billing
- support
- needs_review
- approved

Resource tags are especially helpful in larger workspaces where many applications, flows, knowledge bases, guardrails, Data requests, or other resources may exist.

To access Resource tags, select your username from your workspace menu, choose **Workspace settings**, then select **Resource tags**.

Reviewing resource tags

The Resource tags page helps you review which tags exist and where they are being used.

For each tag, you can:

- View the tag name
- Review its color, if one has been assigned
- Expand the tag to see which resources use it
- Identify where tags may need to be updated or removed

Resource tags only appear in this list when they are currently assigned to at least one resource in the workspace.

Color coding tags

You can assign colors to resource tags to make them easier to visually identify.

To color code a tag

1. Open **Workspace settings**.
2. Select **Resource tags**.
3. Expand the tag you want to update.
4. Select the color indicator.
5. Choose a color.
6. Save your changes.

Use colors to help distinguish tags by category, such as environment, team, status, or priority.

Viewing tag usage

To see where a tag is used

1. Open **Workspace settings**.
2. Select **Resource tags**.

3. Expand the tag.

The expanded view lists resources where that tag is applied.

Use this when you want to understand which resources belong to a category, find resources tied to a project, or confirm whether a tag is still in use.

You can also use global workspace Search to find resources associated with a tag.

Search by the tag keyword to locate matching resources more quickly.

This is useful when you need to find resources by business unit, environment, status, or feature area.

If a tag is removed from all resources, it no longer appears in the Resource tags list.

This helps keep the Resource tags page focused on tags that are actively used in the workspace.

Before removing a tag from multiple resources, confirm that it is no longer needed for search, organization, review, or governance workflows.

Best practices

Follow these best practices when you tag resources:

- Use clear tag names that are easy for teammates to understand.
- Keep tag naming consistent across the workspace.
- Use tags to distinguish resources by environment, team, project, audience, or status.
- Avoid creating multiple tags with similar meanings.
- Use colors to make important categories easier to identify (e.g., "Prod" in red).
- Use global Search to quickly find resources by tag.

Translations

Translations help you create multilingual conversational AI applications in agentic CX designer.

Use Translations to manage localized content across your workspace so users can interact with your application in supported languages and regional dialects. This includes:

- Predefined flow messages
- Custom slot values
- Knowledge base content invoked via knowledge base node
- Live Sync scripts (script step messages)

Translations help keep multilingual experiences easier to manage because localized content can be reviewed from one place instead of editing every resource individually.

To access Translations, select **Translations** from your workspace menu.

Agentic CX designer supports multilingual application development across supported languages and locales.

For voice-enabled experiences, language may also depend on the voice provider configured in the contact flow in Amazon Connect Customer.

Adding a language

Before translating content, add the languages your workspace should support.

To add a language

1. Open **Translations**.
2. Select the **Languages** tab.
3. Choose **Add language**.
4. Select the language or locale you want to support.
5. Save your selection.
6. Choose **Apply languages** to make the language available across the workspace.

After a language is added, it can be used for translatable resources such as flows, slots, application messages, and supported knowledge base content.

Manual translation

You can add or edit translations directly in the workspace.

Use manual translation when:

- Exact wording is important
- Legal, compliance, or brand language must be approved
- A human translator needs to review AI-generated content
- Certain terms should not be translated literally
- Regional or dialect-specific phrasing matters

When reviewing translations, check that the localized content preserves the original intent, tone, and required business meaning.

Translations can be managed offline by downloading and uploading translation files, when supported.

Use this workflow when:

- A localization team needs to translate content outside the workspace
- Translations require legal, brand, or regional review
- You want to bulk edit many translation values at once
- Your team uses an external translation management process

After uploading translated content, review it in the workspace before building and deploying the application.

Auto-translate

Auto-translate helps generate localized content for selected resources.

Use auto-translation as a starting point, especially when you need to quickly prepare draft translations across many resources. Review auto-translated content before using it in a live customer experience.

To request auto-translation

1. Open **Translations**.
2. Select the **Auto-translate** tab.
3. Choose **Request auto-translation**.
4. Select whether to translate specific resources or filter by application.

5. Choose one or more target languages.
6. Select **Request translation**.

Optional settings may include:

Exclude translations already marked	Keeps existing translated content from being overwritten.
Mark as translated when finished	Marks generated translations as completed after the job finishes.

Each auto-translation job displays status details so you can track progress.

Status	Whether the translation job is completed or still in progress.
Languages	The target language or languages included in the job.
Succeeded	How many resources were translated successfully out of the total checked.
Created	When the translation job was created.

Review job results after completion and check any resources that did not translate successfully.

After adding or updating translations, create a new application build so the latest language content is included in the application package.

If translated content belongs to a Q&A knowledge base, publish the updated knowledge base content as needed so the latest translated entries are available.

Testing multilingual changes

Before deploying multilingual changes, test the application in each target language to confirm:

- The correct language appears
- Flow messages are translated
- Slot values and choices work as expected

- Knowledge base answers return appropriately

Analytics

Analytics helps you understand how users move through your agentic CX designer applications, where conversations succeed, and where experiences may need improvement.

Use the various analytics features in agentic CX designer to monitor application performance, review conversation behavior, inspect flow paths, and identify patterns that can help your team refine prompts, routing, recovery paths, and deterministic logic over time.

- Review application and flow performance
- Understand how often users reach specific paths
- Track important business or conversation events
- Review conversation transcripts
- Identify repeated fallback, no-match, or escalation patterns
- Find opportunities to improve routing, prompts, knowledge content, and user response handling

Dashboards	View high-level performance metrics and trends across your applications and conversations.
Analytics tags	Mark important points in a flow so you can track custom events, outcomes, or user paths.
Flow traffic	Understand how users move through flows and where they continue, drop off, retry, or escalate.
Conversation transcripts	Review individual conversation records to troubleshoot behavior and understand the user experience.

Topics

- Analytics dashboards
- Analytics tags
- Flow traffic

- Conversation transcripts

Analytics dashboards

Analytics dashboards help you view, organize, and monitor performance data for deployed agentic CX designer applications.

Review dashboards to understand how users are interacting with your conversational AI applications, whether flows are performing as expected, where users may be dropping off, and whether integrations or response times may be affecting the experience.

Analytics dashboards can help you:

- Monitor application health and user behavior
- Review conversation volume and traffic trends
- Evaluate flow recognition and user experience
- Track Data request performance and response time
- Monitor analytics tags tied to key milestones
- Identify drop-off points or opportunities for improvement
- Compare performance before and after flow changes or A/B tests

Analytics dashboards can be reviewed from a deployed application's **Observe** tab.

After an application has been deployed for the first time, the **Observe** tab becomes available. From there, you can review predefined dashboard views that surface common performance metrics for that application.

You can also create custom analytics dashboards for metrics, panels, filters, and views that matter most to your team.

Predefined dashboard views

The **Observe** tab includes predefined analytics dashboard views to help you begin monitoring immediately after deployment.

Use the dropdown at the top of the Observe page to switch between dashboard views.

The default views include:

Default	General application usage, conversation volume, traffic, and high-level outcomes.
User experience	How well the application understands users, invokes flows, and responds to common phrases.
Performance	Data request usage, success rates, response times, and technical performance indicators.

These dashboards provide a quick starting point for understanding deployed application health.

Custom dashboards

Predefined dashboards provide a useful starting point, but you can also create custom analytics dashboards for your team's specific reporting needs.

Custom dashboards let you choose:

- Metrics
- Chart types
- Filters
- Aggregations
- Date ranges
- Analytics tags
- Visibility settings

Use custom dashboards when your team needs to track specific milestones, flow outcomes, integration health, or business KPIs that are not fully covered by the predefined Observe views.

To create a custom analytics dashboard

1. Open **Resources**.
2. Select **Dashboards > Add dashboard**.
3. Enter a dashboard name > choose visibility.
4. Choose a predefined template or start from a blank dashboard.

5. Add or edit chart panels.
6. Configure each panel with a chart type, metric, aggregation, and filters.
7. Save the dashboard.

A dashboard can contain one or more panels. Each panel tracks a specific metric or visualization.

Dashboards include two visibility settings.

Private	Visible only to the dashboard creator.
Public	Visible to other users who have access to the workspace.

Use private dashboards for personal analysis or draft reporting. Use public dashboards for shared team monitoring.

> **Important**
>
> If a dashboard is made public, it cannot be reverted to private later.

Charts

A chart is an individual visualization inside a dashboard.

Each chart can be configured to show a metric in a specific format. For example, one chart may show total conversations over time, while another may show Data request response time or the number of conversations that reached a tagged node.

When configuring a chart, you may define:

Panel name	The title shown on the dashboard.
Description	A short explanation of what the panel tracks.
Chart type	The visual format used to display the metric.
Metric	The data being measured.

Aggregation	How the data is calculated, such as sum, average, minimum, or maximum.
Filters	Conditions used to include or exclude specific data.
Time interval	How data is grouped over time, when applicable.

Different chart types are useful for different kinds of data.

Value	Shows a single number, such as total conversations.
Gauge	Shows a value against a defined range.
Pie chart	Shows proportions across a group.
Bar chart	Compares values across categories or time intervals.
Line chart	Shows trends over time.
Box plot	Shows distribution, such as minimum, maximum, and median values.
Table	Shows one or more metrics in rows and columns.
Funnel	Shows how users move through staged steps or filtered conditions.

Some metrics are only compatible with certain chart types. If the metric you want is unavailable, try selecting a different chart type.

Metrics

Analytics dashboards can surface many types of metrics.

Common examples include:

Conversation activity	Conversations, users, messages, messages per conversation, time spent per conversation.

Flow recognition	Flows invoked, flows detected, confidence score, phrase occurrences, phrase trends.
User experience	Time spent per flow, time spent per node, tagged milestones, completion or drop-off indicators.
Integrations	Data requests invoked, percentage of successful Data requests, Data request response time.
Knowledge bases	Knowledge base invoked, knowledge base confidence score, knowledge base response time.

Use the metric that most directly answers the question you are trying to investigate.

Aggregations determine how a metric is calculated.

For example, use Sum to count total conversations and Average to review average response time.

Sum	Total value.
Average	Mean value.
Minimum	Lowest value.
Maximum	Highest value.
Median	Middle value, when supported.

Filters

Filters help include or exclude specific data from a chart.

Use filters to focus on a subset of conversations, such as:

- One application
- One channel
- One flow
- One language

- One region
- One Data request
- One analytics tag
- One date range
- One status, such as successful or failed requests

When adding multiple filter values, settings such as **Any** or **All** may be available.

Any	Data is included if at least one selected filter value is present.
All	Data is included only if every selected filter value is present.

Filters are useful when you want to compare specific experiences or remove unrelated data from a chart.

Formulas

Analytics dashboards can do more than display one metric at a time. For more advanced reporting, you can use formulas, multi-metric panels, and external analytics to calculate custom values, compare related trends, or bring in data from another system.

Use these options when a single metric does not fully answer the question you are trying to investigate.

Formulas let you transform or combine existing metrics into a new calculated metric.

Use formulas when you need to:

- Convert values, such as seconds to milliseconds
- Calculate percentages or rates
- Compare two filtered metrics
- Combine multiple datasets into one value
- Create a custom KPI for your team

For example, you could calculate a completion rate by comparing conversations that reached a "booking_completed" analytics tag against conversations that reached a "booking_started" tag.

To add a formula

1. Create or edit a dashboard.
2. Add or edit a chart.
3. Choose a supported chart type, such as Value, Line, or Bar.
4. Add one or more datasets or data columns.
5. Select **Add formula**.
6. Enter a name for the calculated metric.
7. In the **Formula** field, enter the expression you want to calculate.
8. To reference an existing metric, type an opening curly bracket { and choose from the available metrics.
9. Choose a **Formula unit**, such as percentage, seconds, or another available display unit.
10. Save the panel.

Supported formula operations may include basic arithmetic, such as addition, subtraction, multiplication, and division, as well as common math functions such as absolute value, square root, ceiling, floor, and power.

> **Important**
>
> A calculated metric cannot be referenced inside another formula.

Multi-metric panels

Multi-metric panels let you compare more than one dataset in the same chart.

Use multi-metric panels when you want to compare related trends side by side instead of creating separate panels for each metric.

Examples include:

- Chat conversations vs. voice conversations
- Successful Data requests vs. failed Data requests
- Booking started vs. booking completed

- Escalation requested vs. escalation completed

To create a multi-metric panel

1. Create or edit a dashboard.
2. Add or edit a chart.
3. Choose a supported chart type, such as Line, Bar, or Table.
4. Select **Add dataset** > Name the first dataset.
5. Choose the metric, aggregation, time interval, and filters for that dataset.
6. Select **Add dataset** again > Name the second dataset.
7. Choose the metric, aggregation, time interval, and filters for the second dataset.
8. Repeat as needed for additional datasets.
9. Save the panel.

External analytics

External analytics lets you display data from an external source inside an analytics dashboard.

Use external analytics when your team needs to compare agentic CX designer conversation metrics with data from another system, such as business reporting, operational data, or an internal service.

External data is available through the Table chart type.

To add external analytics data

1. Create or edit a dashboard.
2. Add or edit a chart.
3. Set the chart type to **Table**.
4. Choose **External** as the data source.
5. Select **URL** as the type.
6. Enter the endpoint URL.
7. Add any required headers.
8. Mark sensitive values appropriately so they are redacted where supported.

9. Save the panel.

The external endpoint must return a status code and a string body containing the data.

Example response:

```
{
  statusCode: 200,
  body: JSON.stringify("one,two\n1,2\n3,4\n5,6")
}
```

You can also use placeholders in the URL field to pass the dashboard's selected time range to your endpoint:

- {startTimestampExtended}
- {endTimestampExtended}

Use these placeholders when the external data source should return results for the same time window selected in the dashboard.

When using external analytics, follow your organization's security requirements for endpoint access, authentication, headers, and sensitive values.

Analytics tags

Analytics tags help you mark important moments in a conversation flow so you can track how users move through your agentic CX designer application.

A tag can be applied to a specific node in a flow. When a user reaches that node during a deployed conversation, the tag is recorded. You can then use tags to review flow traversal, filter conversation history, or create analytics dashboard charts around milestones that matter to your team.

Use analytics tags to track moments such as:

- Task started or completed
- User reached fallback or escalation
- Booking completed
- Offer accepted or declined

- Knowledge base answer shown
- Payment handoff started
- User reached a key decision point

Analytics tags do not automatically determine whether a conversation was successful, helpful, or automated. They mark the points you choose so you can measure and review them later.

To access analytics tags, select **Resources** from your workspace menu then choose **Analytics tags**.

Strategic tag placement

Users may not always complete a conversation in the way you expect. They may abandon a flow, loop through a retry path, escalate to a human agent, or complete a task successfully.

By placing analytics tags at strategic points in a flow, you can better understand where users are going and what outcomes they are reaching.

For example:

Tag	Where you might place it	What it helps track
booking_started	First node in a booking flow	How many users begin the booking process.
booking_completed	Confirmation node	How many users complete the booking.
fallback_reached	Fallback or recovery path	How often users hit an error or unsupported path.
escalation_requested	Human handoff node	How often users request or require escalation.
offer_declined	Decline path after an offer	How often users reject an offer.

These tags can help you identify completion rates, drop-off points, repeated issues, and opportunities to improve the experience.

Default system tags

Agentic CX designer includes default system tags that can be used in flows:

- automated
- helpful
- not_helpful

These tags are available by default, but they do not automatically classify a conversation. You decide where to place them based on what each point in your flow represents.

For example, you might place automated on a node reached after the application completes a task without human handoff, or not_helpful on a path where the user indicates the answer did not solve their issue.

Custom analytics tags

You can create custom analytics tags for the milestones, outcomes, or events that matter to your application.

To add a custom analytics tag

1. Open **Resources**.
2. Select **Analytics tags**.
3. Choose **Add tag**.
4. Enter the tag details.
5. Save the tag.

Custom tag fields include:

Label	The name of the tag that appears when tagging nodes in a flow. Use a clear, descriptive name.
Type	Categorizes the tag for analytics reporting, if available.
Description	Explains what the tag is intended to track. This description is visible from the Analytics tags resource page.

Tag labels should be easy to understand and consistent across the workspace. Use names that describe the event clearly, such as booking_completed, escalation_requested, or payment_started.

Applying tags to nodes

After a tag is created, you can apply it to nodes in a flow.

To add an analytics tag to a node

1. Open the flow in the Canvas.
2. Select the node you want to track.
3. Open the node's **Functionality** menu.
4. Choose **Analytics tags**.
5. Select one or more tags.
6. Save the flow.

Once the updated flow is included in a deployed build, future conversations that reach the tagged node will record the tag.

You can review tag activity in several places:

In-Canvas analytics	Filter the flow view to conversations that reached tagged nodes.
Conversation transcripts	Filter transcripts by selected tags to review sessions where a milestone occurred.
Analytics dashboards	Create dashboard charts that track tag activity over time.

Use tags when you want to move beyond general conversation volume and monitor specific outcomes or checkpoints inside the experience.

Deleting a tag

To delete a custom tag

1. Open **Resources**.

2. Select **Analytics tags**.
3. Expand the tag details.
4. Choose **Delete tag**.

Before deleting a tag, confirm that it is no longer needed for active reporting or flow analysis.

Best practices

Follow these best practices when you use analytics tags:

- Analytics tags only apply to conversations that occur after the tag is added to a node and deployed.
- Tags are not applied retroactively to previous conversations.
- A node can have more than one tag, but using one tag per node is often easier to interpret and helps avoid confusing counts.
- Tags mark that a node was reached; they do not automatically explain why the user reached that node.
- Use clear tag names and descriptions so teammates understand what each tag is intended to measure.

Flow traffic

Flow traffic shows how conversations move through a deployed flow — where users continue, drop off, retry, or escalate — with usage displayed on each node directly in the flow's Canvas.

When analytics mode is enabled, each node displays traffic data showing how many unique conversations reached that node. This helps you identify common paths, underused branches, drop-off points, A/B testing results, and whether users are reaching the intended completion steps.

Use In-Canvas analytics to answer questions like:

- Which nodes are users reaching most often?
- Where are users dropping off?
- Are users reaching the expected success path?
- Are fallback or escalation paths being used more than expected?

- Did a specific conversation follow the path you expected?
- Does the flow behave as expected after deployment?

> **Important**
>
> A build that includes the flow must be deployed before In-Canvas analytics can display conversation traffic.

Viewing In-Canvas analytics

To view In-Canvas analytics

1. Open **Resources** from the workspace menu.
2. Select **Flows**.
3. Choose the flow you want to review.
4. Select the **Analytics** icon from the Canvas toolbar.
5. Review the traffic indicators displayed on each node.

To turn off In-Canvas analytics, select the Analytics icon again.

You can continue editing a flow while analytics mode is enabled. If you make changes that should affect live behavior, create a new build and deploy it before expecting updated deployed traffic to reflect the new flow version.

Traffic indicators

When In-Canvas analytics is enabled, each node displays a number that represents how many unique conversations reached that node during the selected filter period.

Use these indicators to quickly compare:

High traffic on a node	Many users are reaching this point in the flow.
Low traffic on an expected path	Users may not be reaching the intended route.

High traffic on fallback or escalation paths	Users may be confused, unsupported, or encountering errors.
Drop-off before a completio n node	The flow may be too long, unclear, or blocked by missing information.
Unexpected traffic on a branch	Routing, conditions, or state may need review.

In-Canvas analytics is especially useful when you want to connect a performance signal to the exact path users took inside a flow.

Filters

Use filters to refine the analytics view and focus on the conversations that matter most.

Application	Review data for a specific application, especially when a flow is attached to more than one application.
Conversation ID	View the path taken during one specific conversation retrieved from conversation history.
Start time	Set the beginning of the date and time range.
End time	Set the end of the date and time range.
Tag	Focus on conversations that reached nodes with selected analytics tags.

Filters help you narrow your review when investigating a release window, a specific user session, a known issue, or a tagged milestone.

Using a Conversation ID

You can use a Conversation ID to inspect the exact path from one conversation:

1. Open the deployed application.
2. Go to **Observe**.

3. Open a conversation from the **Transcripts** table.
4. Copy the **Conversation ID**.
5. Open the flow involved in that conversation.
6. Enable **In-Canvas analytics**.
7. Paste the Conversation ID into the filter field.
8. Review the path the user took through the flow.

This is helpful when a transcript shows unexpected fallback behavior, repeated questions, missed routing, a failed integration, or user drop-off.

Conversation transcripts

Conversation transcripts let you review the exact exchanges from past sessions with a deployed application — what the user asked, how the application responded, and where a conversation succeeded or broke down. You open these past conversations from the **Observe** tab.

Use these historical transcripts to review what happened during real user interactions, troubleshoot unexpected behavior, inspect transcripts, and identify opportunities to improve flows, routing, prompts, integrations, or escalation paths.

Each conversation record can help you understand:

- What the user asked
- How long the session lasted and latency of the system
- Whether the user engaged or abandoned the experience
- Whether analytics tags were reached
- What the full transcript looked like

Use conversation transcripts when you need to move from high-level performance data into the details of a specific user session.

Accessing conversation transcripts

To access conversation transcripts for an application

1. Open **Applications**.

2. Select a deployed application.
3. Open the **Observe** tab.
4. Select **History**.
5. Review the Transcripts table.

The **Observe** tab appears after an application has been deployed for the first time.

Filters

Use filters to narrow the conversation transcripts to the sessions you want to inspect.

Start/End time	Filter conversations within a specific date and time range.
User engagement	Filter for conversations where the user did or did not respond.
Tags	Review conversations where selected analytics tags were reached.
Search	Find conversations containing specific user utterances or keywords.

Filters are useful when investigating a known issue, reviewing behavior from a specific release window, or finding examples of repeated user friction.

Each row in the transcripts table represents a unique conversation session.

Select a conversation row to view more details.

Conversation details

When you open a conversation, you can review the full transcript and supporting session details.

Conversation details include:

- Conversation ID (select the Information icon)
- User ID (select the Information icon)
- Full message transcript

- User messages
- Application responses

- Debugger/event log (select a message in the transcript to review all events in the selected turn)

First message	The first user utterance in the conversation. If a user started a session and did not engage, this appears as N/A.
Time	When the conversation session started.
Duration	How long the conversation lasted.
Confidence	Confidence or AI-related scoring details available for the session.
Average response time	How long the application took to respond on average.
Flows	Flows invoked during the conversation.
Tags	Analytics tags reached during the session, when available.
Transcript	The full exchange between the user and the application.

Copy options are available for conversation and user IDs. These IDs can be useful when investigating a specific session or reviewing that same path in In-Canvas analytics.

Troubleshooting workflow

Conversation transcripts explain what happened in a session. In-Canvas analytics helps you see where that conversation traveled inside a flow.

A common troubleshooting workflow is:

1. Find the relevant conversation in the transcripts list.
2. Open the conversation and review the transcript.
3. Select the information icon > Copy the Conversation ID.
4. Open the flow involved in the conversation.
5. Use In-Canvas analytics to filter by that Conversation ID.

6. Review the path the user took through the flow.

This is useful when a conversation shows unexpected fallback behavior, missed routing, repeated questions, drop-off, or escalation.

Common use cases

A user says the application did not help	Review the transcript to see what the user asked and how the application responded.
Escalations increased	Filter by escalation-related flows or tags and inspect the conversations leading up to escalation.
Users are dropping off	Review transcripts near drop-off points and compare with In-Canvas analytics.
A flow is being invoked unexpectedly	Search for user utterances and review whether routing matched the intended flow.
A Data request appears slow or unsuccessful	Review affected conversations and compare timing or failure behavior.
A new user need is emerging	Search repeated phrases and identify whether a new flow, prompt, or knowledge base content is needed.

Governance

Agentic CX designer helps protect your workspace and deployed conversational AI applications through access control, sensitive data handling, secure integrations, runtime guardrails, and auditability.

Governance in agentic CX designer is supported through:

Security area	What it helps control
Access control	Who can access a workspace and what they can view, create, edit, or manage.

Security area	What it helps control
Data protection	What sensitive information is stored, logged, masked, or redacted.
Secure integrations	How applications connect to external systems, APIs, credentia ls, and environments.
Runtime protections	How user inputs and application outputs are checked during conversations.
Auditability	What changed, when it changed, and which user performed the action.

Together, these controls help teams build conversational AI applications that are safer, more governed, and easier to monitor across development and production environments.

Access control

Access in agentic CX designer is managed through Amazon Connect Customer and controlled at the workspace level.

Account Administrators can add users from the available Connect Customer user profiles, assign those users to one or more workspaces, and grant workspace roles based on what each person needs to do.

Use roles and permissions to control who can:

- View workspace resources
- Create or edit applications and flows
- Configure integrations and Data requests
- Manage guardrails
- Review analytics and conversation history
- Create builds or deploy applications
- Manage users, roles, and workspace settings

Common governance goals include the following:

- Limit who can deploy to Production
- Restrict who can configure integrations and secrets
- Allow read-only access for reviewers and stakeholders
- Separate access by business unit, team, environment, or project
- Review workspace access regularly

Sensitive data handling

Agentic CX designer provides controls that help reduce exposure of sensitive information in conversations, logs, transcripts, and connected systems.

Use sensitive data controls to help prevent protected or restricted values from appearing where they should not.

- Mark fields as Sensitive in Data request schemas and slots so values are redacted where supported.
- Use Guardrails to detect and mask sensitive patterns, such as credit card numbers, IDs, email addresses, or other restricted values.
- Avoid storing sensitive data in conversation messages unless it is required for the experience.
- Review transcripts and logs to confirm sensitive values are handled according to your organization's policies.
- Use state modifications carefully when storing or clearing sensitive context.

Secure integrations and secrets

Integrations are a critical security boundary between a conversational AI application and external systems.

Agentic CX designer supports secure integration patterns through structured Data requests, schemas, secrets, and environment-specific configuration.

Follow these best practices when you configure external integrations:

- Store API keys, tokens, and credentials as Secrets instead of hardcoding them in headers or payloads.
- Use separate Development and Production endpoints when possible.

- Validate request and response payloads with clear schemas.
- Only send the data required for the external system to complete the task.
- Mark sensitive request or response fields appropriately.
- Test integrations in a non-production environment before deployment.
- Confirm failure, timeout, and fallback paths are handled safely.

Runtime protections

Security is not only about workspace access. It also includes what happens while users interact with your conversational AI application.

Guardrails evaluate conversation messages at runtime and can check user inputs before they are processed or application outputs before they are returned to the user.

Guardrails can help with:

Protection	Guardrail type
Prompt injection or jailbreak detection	Input
Sensitive data detection or masking	Input or Output
Brand, legal, or compliance checks	Output
Hallucination or unsupported claim detection	Output
Redirecting risky conversations to a controlled flow	Input or Output
Logging policy violations for review	Input or Output

Guardrails can enforce behavior using actions such as Override, Mask, Redirect, or Flag, depending on how the application should respond when a rule is triggered.

Auditability and governance review

Agentic CX designer includes governance features that help teams review workspace changes and maintain a traceable history of activity.

Use Audit to review write and delete events across workspace resources, including who made a change, when it happened, and where it occurred.

Use Versioning to review previous configurations of supported resources and restore earlier versions when needed.

These features help teams:

- Investigate unexpected workspace changes
- Confirm who updated or removed a resource
- Review activity around production-impacting resources
- Support internal change-management processes
- Recover from breaking changes
- Preserve a record of workspace activity over time

Topics

- User roles and permissions
- Versioning
- Audit
- Guardrails

User roles and permissions

Access in agentic CX designer is managed through Amazon Connect Customer and controlled at the workspace level.

This means users do not create standalone agentic CX designer accounts manually. Instead, Account Administrators select from the user profiles already available in the connected Connect Customer instance, add those users to the appropriate agentic CX designer workspace, and assign each user a workspace role.

Workspace roles determine what a person can view, create, edit, or manage inside that workspace.

Access model

Agentic CX designer uses a workspace-based access model.

Connect Customer access	Determines whether a user can access Connect Customer and, depending on their permissions, launch or administer agentic CX designer.
Agentic CX designer workspace access	Determines which workspace or workspaces a user can open.
Workspace role	Determines what the user can do inside a specific workspace.

A user may have access to one workspace, multiple workspaces, or no workspaces, depending on how an Account Administrator has configured their access.

Resources and permissions are not shared automatically across workspaces. This means:

- Applications in one workspace do not appear in another workspace.
- Flows and resources are managed independently by workspace.
- User roles are assigned per workspace.
- Access to one workspace does not automatically grant access to others.

If you are an Account Administrator or have been assigned a role in more than one workspace, you can switch between workspaces from the workspace dropdown in the upper-left corner of agentic CX designer.

Account Administrators

Account Administrators manage workspace setup and user access for agentic CX designer.

Account Administrators can:

- Launch agentic CX designer from the Connect Customer console
- Access the Admin Hub
- Create workspaces
- Select users from available Connect Customer user profiles
- Add users to one or more workspaces
- Assign workspace roles & create custom roles

- Manage workspace access over time

Users are selected from the profiles already available in the connected Connect Customer instance.

Workspace users

Workspace users are people who have been added to one or more agentic CX designer workspaces by an Account Administrator.

Workspace users can access the workspace or workspaces assigned to them. What they can do inside each workspace depends on their assigned role.

For example, one user may have edit access in a development workspace but read-only access in another workspace used for production review.

To give a user access to agentic CX designer

1. Open agentic CX designer from Connect Customer.
2. Go to the Admin Hub.
3. Select **Users**.
4. Add users from the available Connect Customer user profiles.
5. Assign each user a workspace role.
6. Save the changes.

Only users with the appropriate account-level permissions can manage workspace access.

Workspace roles

Roles determine what users can do inside a workspace.

Account Administrator	Manages account-level setup, workspaces, user access, and role assignments through the Admin Hub.
Workspace Administrator	Manages resources inside an assigned workspace, depending on the permissions granted.
Builder	Creates and edits conversational AI resources such as applicati ons, flows, prompts, slots, and knowledge bases.

Developer	Configures technical resources such as integrations, Data requests, APIs, secrets, and environment-specific settings.
Analyst	Reviews analytics, conversation history, dashboards, evaluatio ns, and performance data.
Read-only	Views workspace resources without making changes.

Versioning

Versioning helps you review and recover previous configurations for key resources in agentic CX designer.

Each time you save a supported resource, agentic CX designer captures a snapshot of that resource. This gives your team a historical record of changes so you can understand how a resource evolved, troubleshoot regressions, and restore a previous configuration when needed.

Versioning is useful when multiple builders are collaborating, when a recent change caused unexpected behavior, or when you want to experiment while keeping a recovery path available.

Versioning is available for key workspace resources:

What can be versioned?

Resource	What the version can include
Flows	Canvas structure, node configuration, conversation logic, prompts, paths, and flow settings.
Applications	Via application builds.
Custom slots	Slot values, synonyms, and translations.
Data requests	Custom API configuration, endpoints, request and response schemas, headers, and settings.

Each version includes details such as the timestamp and author depending on the resource type.

Viewing versions

To view versions for a resource

1. Open the resource you want to review.
2. Select its **Versions** tab.
3. Browse the available historical snapshots.
4. Select a version to preview its previous configuration.

For flows, version history is accessed from the flow **Settings** area in the Canvas.

For applications, build history is managed from the deployment or builds area. Application builds act as packaged versions of the application that can be rolled back, deployed, or promoted to an environment.

Restoring a version

When you restore a previous version, agentic CX designer makes that configuration current again.

Restoring does not erase the version history. Instead, it creates a new saved version based on the restored configuration, preserving the full history of changes over time.

Use restore when you need to:

- Roll back after an unintended change
- Recover a previous working configuration
- Compare a current issue against an earlier setup
- Revert after testing a change that did not work as expected.

Audit

Audit gives governance and administrator teams a centralized place to review change activity inside an agentic CX designer workspace.

Audit logs capture write and delete events across workspace resources such as applications, flows, integrations, guardrails, and more. This makes it easier to reconstruct change history, investigate unexpected configuration changes, and support internal review or compliance processes.

Use Audit to:

- Trace configuration changes that may affect application behavior
- Confirm who created, updated, or removed a resource
- Review activity around sensitive or production-impacting assets
- Support security or governance investigations
- Monitor adherence to internal change-management processes
- Provide evidence of workspace activity for audit or compliance reviews

To access Audit, select your username from your workspace menu, choose **Workspace settings**, then select **Audit**.

Audit events

Each row in the Audit table provides details about a workspace event.

Event	A short description of the change, such as updating a flow or deleting an integration.
Event source	The workspace area or system component where the change occurred, such as Canvas, Integrations, or Workspace settings.
Event type	The type of action, such as Write or Delete.
Time	When the event occurred.
User	The user who performed the action.

Filtering audit logs

Use filters at the top of the Audit page to narrow the log to the activity you want to review.

Filtering helps you quickly find the most relevant events when investigating a change, reviewing user activity, or confirming when a resource was updated.

Start/End time	Limit results to a specific date and time range.

Principal email	View events performed by a specific user.
Event type	Filter by action type, such as Write or Delete.
Event name	Focus on a specific kind of change, such as a deployment event or resource update.

Guardrails

Guardrails help evaluate and control conversational behavior in agentic CX designer applications.

They act as a safety, compliance, and brand-control layer for conversations by checking user inputs and application outputs against rules you define. Guardrails can help prevent unsafe requests, off-brand responses, sensitive data exposure, prompt injection attempts, hallucinated claims, or other behavior that does not align with your business requirements.

Once created in your workspace, guardrails can be attached to one or more applications.

To access guardrails, select **Resources** from your workspace menu, then choose **Guardrails**.

A guardrail is a reusable resource that evaluates conversation messages at runtime.

Guardrails can check:

- *User inputs* before they are processed by the application
- *Application outputs* before they are returned to the user

This makes guardrails useful for controlling both sides of the conversation. For example, an input guardrail might detect a prompt injection attempt from a user, while an output guardrail might prevent the application from returning a response that includes unsupported claims or restricted language.

Guardrails run independently from flow logic and prompts. They provide an additional layer of control so safety, compliance, and brand expectations are not handled only inside individual flows or LLM instructions.

Input and output guardrails

Guardrails can be configured as either Input or Output guardrails.

Input guardrails	Messages from the user before they are processed by the application. Use cases include detecting prompt injection attempts, masking or flagging sensitive information, blocking unsupported or risky requests.
Output guardrails	Messages from the application before they are returned to the user. Use cases include preventing hallucinated claims, enforcing brand tone, meeting compliance requirements, masking sensitive information, or redirecting unsafe responses.

Detection methods

Each guardrail rule uses a detection method to determine whether a message violates the rule.

Regex	Matches precise text patterns. Best for structured or predictab le cases, such as account numbers, email addresses, or other formatted values.
Keyword	Triggers when specific words or phrases appear. Best for simple inclusion checks, such as blocked terms, competitor names, or restricted phrases.
LLM Judge	Uses an LLM to evaluate whether the message violates the rule based on instructions you provide. Best for nuanced, contextua l, or semantic checks.

Use an LLM Judge when a rule requires interpretation rather than an exact match.

Examples:

- The user is attempting to override instructions or manipulate the application.
- The application output makes a claim that is not supported by available information.
- The response does not follow brand tone or compliance requirements.
- The message includes sensitive information that should not be disclosed.
- The user request asks for private account details that should not be shared.

When using an LLM Judge, you may select the model used in the guardrail's setting.

Guardrails can include multiple rules, so clear naming is important.

Use descriptive rule names that make the purpose easy to understand at a glance.

Examples:

- Prompt injection detection
- PII masking
- Unsupported financial advice
- Brand voice compliance
- Hallucinated claim detection
- Private account data disclosure

Clear rule names make guardrails easier to review, test, troubleshoot, and maintain over time.

Enforcement actions

When a guardrail rule is triggered, choose how the application should respond.

Choose the enforcement action based on how serious the violation is and what the user experience should be.

Override	Replaces the original message with a safe alternative. May use static messaging or use an LLM to generate a new response.
Mask	Allows the message through but redacts sensitive or restricted content.
Redirect	Routes the conversation to a specific flow, such as escalation, recovery, or a compliance-safe path.
Flag	Logs the violation but allows the message to pass unchanged.

For example, a prompt injection attempt may require an override or redirect, while a lower-risk brand style issue may only need to be flagged for review.

In addition to detection and enforcement, a guardrail rule can trigger optional actions when it is activated.

Optional actions include:

Analytics tags	Apply one or more analytics tags so triggered guardrails can be tracked in reporting.
State modifications	Set, clear, or update variables when a guardrail rule is triggered .

Use analytics tags when you want to monitor how often a specific rule is triggered. Use state modifications when the conversation needs to remember that a safety, compliance, or policy event occurred.

Testing guardrails

Test guardrails before attaching them to a live application.

Testing helps confirm whether rules detect the correct messages and apply the expected enforcement behavior.

To test a guardrail

1. Open **Resources**.
2. Select **Guardrails**.
3. Choose an existing guardrail.
4. Select the **Test** option.
5. Enter a sample message.
6. Run the test.
7. Review the result for each rule.

Test results help show whether each rule was clear or triggered.

Clear	The message did not violate that rule.

Violation	The rule was triggered for the test message.

Use a range of sample messages when testing. Include messages that should trigger the rule and messages that should not trigger it.

Guardrail activity logs

Each guardrail includes activity or log details that help you review when rules were triggered.

Use guardrail logs to:

- View when a rule was triggered
- Review the original message
- Inspect the final enforced output
- Confirm which enforcement action occurred
- Monitor patterns of misuse, sensitive disclosures, or policy violations
- Decide whether a rule needs tuning

Guardrail activity is useful after deployment because it helps confirm that safety and compliance controls are working as expected in real conversations.

When exploring tracked events in the conversation transcripts or using the test chat, the debugger also lists all guardrail events.

Attaching guardrails to an application

After a guardrail is created, attach it to an application so it can run during conversations.

To use a guardrail

1. Open **Applications**.
2. Select the application.
3. Open the application configuration area.
4. Add one or more guardrails from the workspace.
5. Save the application.
6. Create a new build.

7. Deploy the build to the appropriate environment.

Once assigned and deployed, guardrails run automatically during conversations where they apply. Input guardrails check incoming user messages, while output guardrails check application responses before they are returned to the user.

Evaluation order

When multiple guardrails and rules are attached to an application, agentic CX designer evaluates them in a predictable order.

1. Guardrails attached to the application run in the order they appear in the application's guardrail list.
2. Rules within each guardrail run from top to bottom.
3. All triggered rules are evaluated and logged.
4. Only one corrective action is applied.
5. The corrective action comes from the first triggered rule in the evaluation order.

This means order matters. Place the most important or restrictive rules higher in the list so they take priority when multiple rules are triggered during the same turn.

Deactivating a rule

You can deactivate a guardrail rule without deleting it.

This is useful for testing, temporary policy changes, troubleshooting, or preserving a rule for later use.

To deactivate a rule

1. Open **Resources**.
2. Select **Guardrails**.
3. Choose the guardrail.
4. Locate the rule.
5. Open the rule menu (three-dot menu).
6. Select **Deactivate**.

Deactivated rules remain saved in the guardrail, but they are not evaluated at runtime until they are reactivated.

Connect Customer Cases

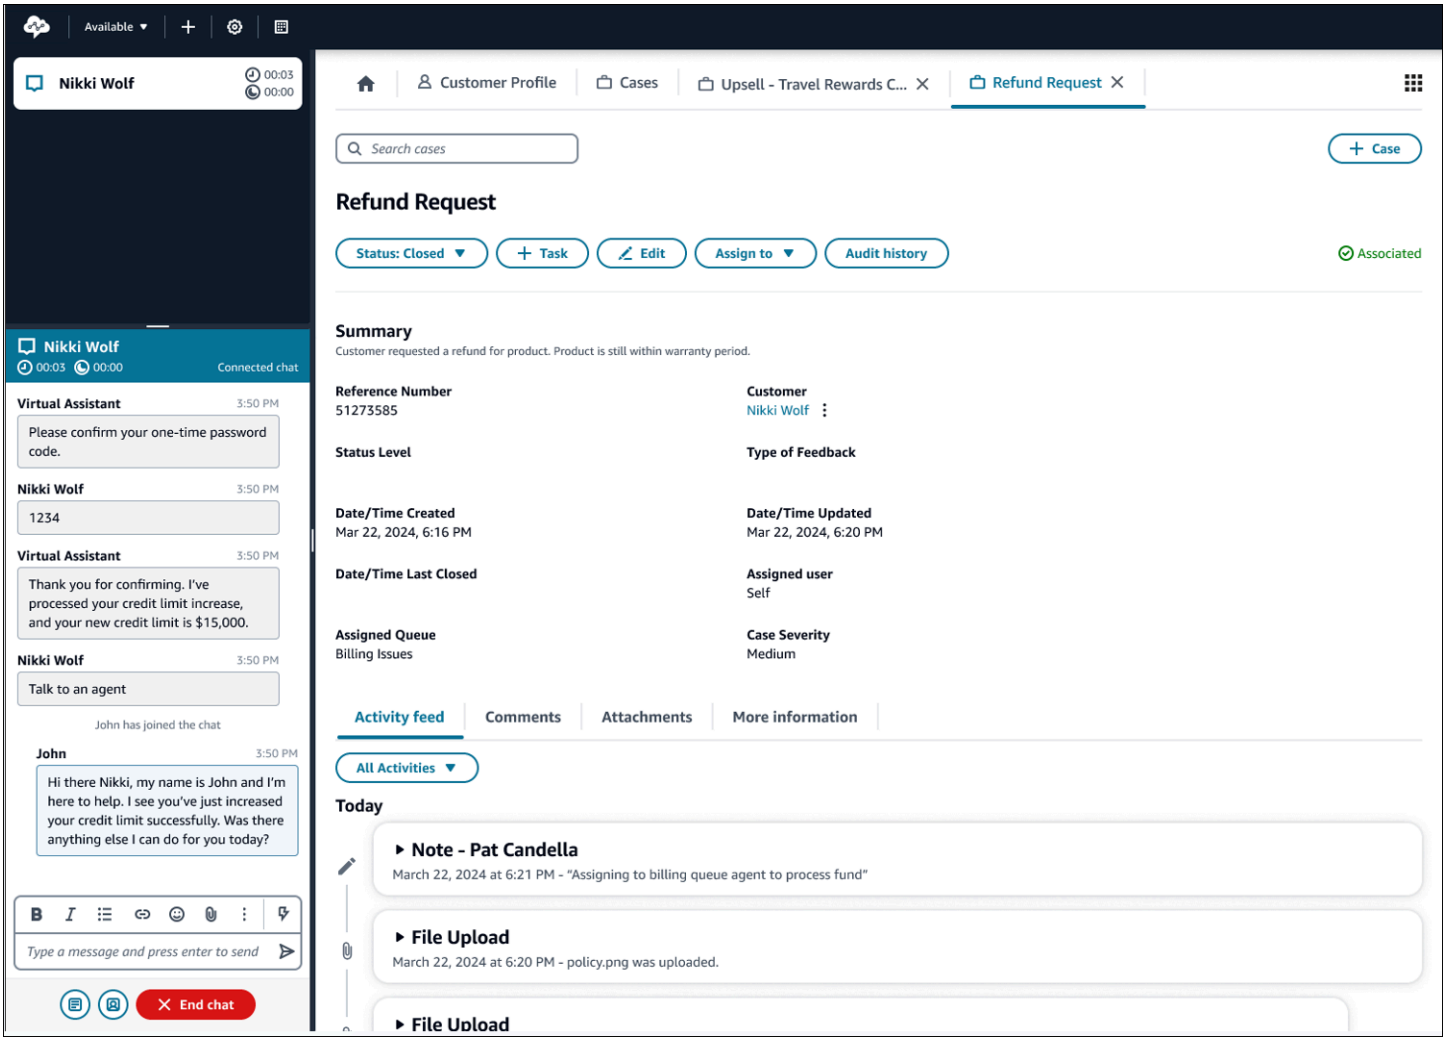
> **Tip**
>
> **New user?** Check out the Connect Customer Cases Workshop. This online course guides you through setting up and using Connect Customer Cases.

Connect Customer Cases enables your customer service organization to track, collaborate, and resolve customer cases.

A *case* represents a customer's issue. It is created to record the customer's issue, the steps and interactions taken to resolve the customer's issue, and the outcome.

Without doing any integration work, you can enable Cases for your contact center. You can set up cases to be created when contacts come in, and collect information from the customer to display on the case. Alternatively, agents can manually create cases. When an agent accepts a contact, they have context about an issue and can immediately start solving it. You can create tasks to track and route follow up steps to resolve the case.

The following image shows an example case as it appears in the agent workspace.



Getting started with Cases

We recommend reviewing these topics to help you get started.

Contact center manager or Admin actions on the Connect Customer admin website

- Enable Cases
- Assign permissions
- Create case fields and case templates
- Set up a case assignment in Connect Customer Cases
- Automatically monitor and update cases in Connect Customer Cases
- Connect Customer Cases metrics
- Cases block

- Case event streams
- Cases quotas
- Tag-based access controls

Agent actions in the agent workspace

- Search cases in Connect Customer to view customer contact details
- Edit an existing case
- Add comments to a case
- Associate a contact with a case
- Create a task from a case
- Export cases to CSV
- Merge cases
- Link related cases

Enable Cases using the Connect Customer console

This topic explains how to enable Connect Customer Cases using the Connect Customer console. To use the API, see Connect Customer Cases API Reference.

> **Tip**
>
> You must have Customer Profiles enabled. Make sure that you check your instance settings in the Connect Customer console, and if a Customer Profiles domain does not yet exist, see Enable Customer Profiles for your Connect Customer instance.

Requirements

If you're using custom IAM policies to manage access to the Connect Customer Cases, your users need the following IAM permissions to onboard to Cases using the Connect Customer console:

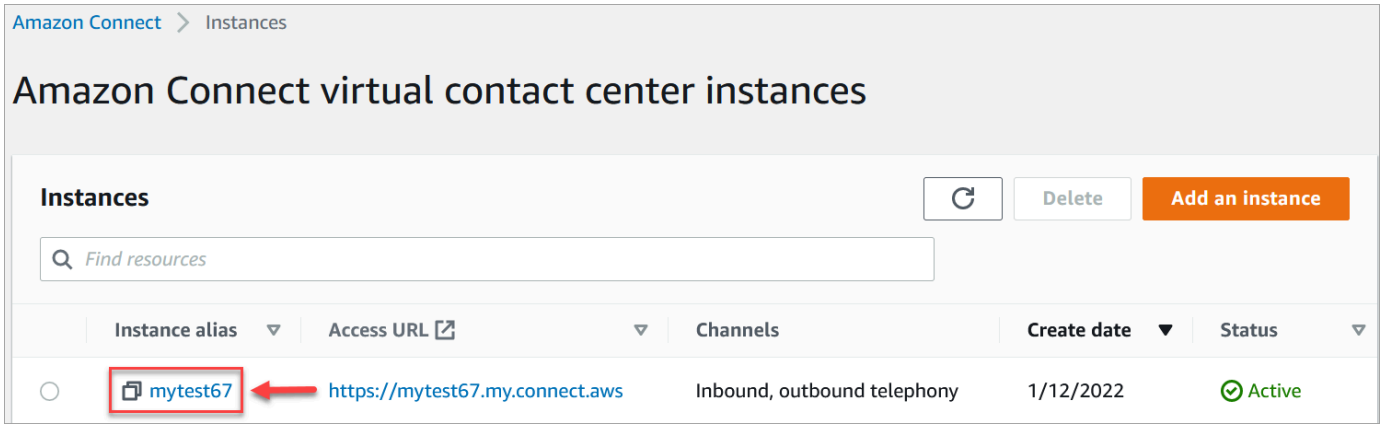
- `connect:ListInstances`
- `ds:DescribeDirectories`
- `connect:ListIntegrationAssociations`

- `cases:GetDomain`
- `cases:CreateDomain`
- `connect:CreateIntegrationAssociation`
- `connect:DescribeInstance`
- `iam:PutRolePolicy`

For more information, see Required permissions for using custom IAM policies to manage Connect Customer Cases.

How to enable Connect Customer Cases

1. Open the Connect Customer console at https://console.aws.amazon.com/connect/.
2. On the instances page, choose the instance alias. The instance alias is also your **instance name**, which appears in your Connect Customer URL. The following image shows the **Connect Customer virtual contact center instances** page, with a box around the instance alias.



3. On the left navigation menu, choose **Cases** under the **Applications** section. If you don't see this option, it might not be available in your Region. For information about where Cases is available, see Cases availability by Region.
4. Choose **Enable cases** to get started.
5. On the **Cases** page, choose **Add domain**.
6. On the **Add domain** page, enter a unique, friendly name that's meaningful to you, such as your organization name.
7. Choose **Add domain**. The domain is created.

   If the domain is not created, choose **Try again**. If that doesn't work, contact Support.

> **Tip**
>
> To delete a Cases domain, use the DeleteDomain API.

Next steps

After your cases domain is created, do the following:

1. Assign security profile permissions to agents and call center managers.
2. Create case fields. Fields are the building blocks of your case templates.
3. Create case templates. Case templates are forms that agents complete and reference in the agent workspace. Templates ensure the right information is collected and referenced for different types of customer issues.
4. Optionally, enable attachments across your Connect Customer instance. This step allows your agents to upload files to cases. For more information on the Files API, see the StartAttachedFileUpload API documentation.

   > **Note**
   >
   > Make sure that you have the `cases:CreateRelatedItem` permission for your IAM entity. For more information on Cases permissions, see Actions, resources, and condition keys for Connect Customer Cases.

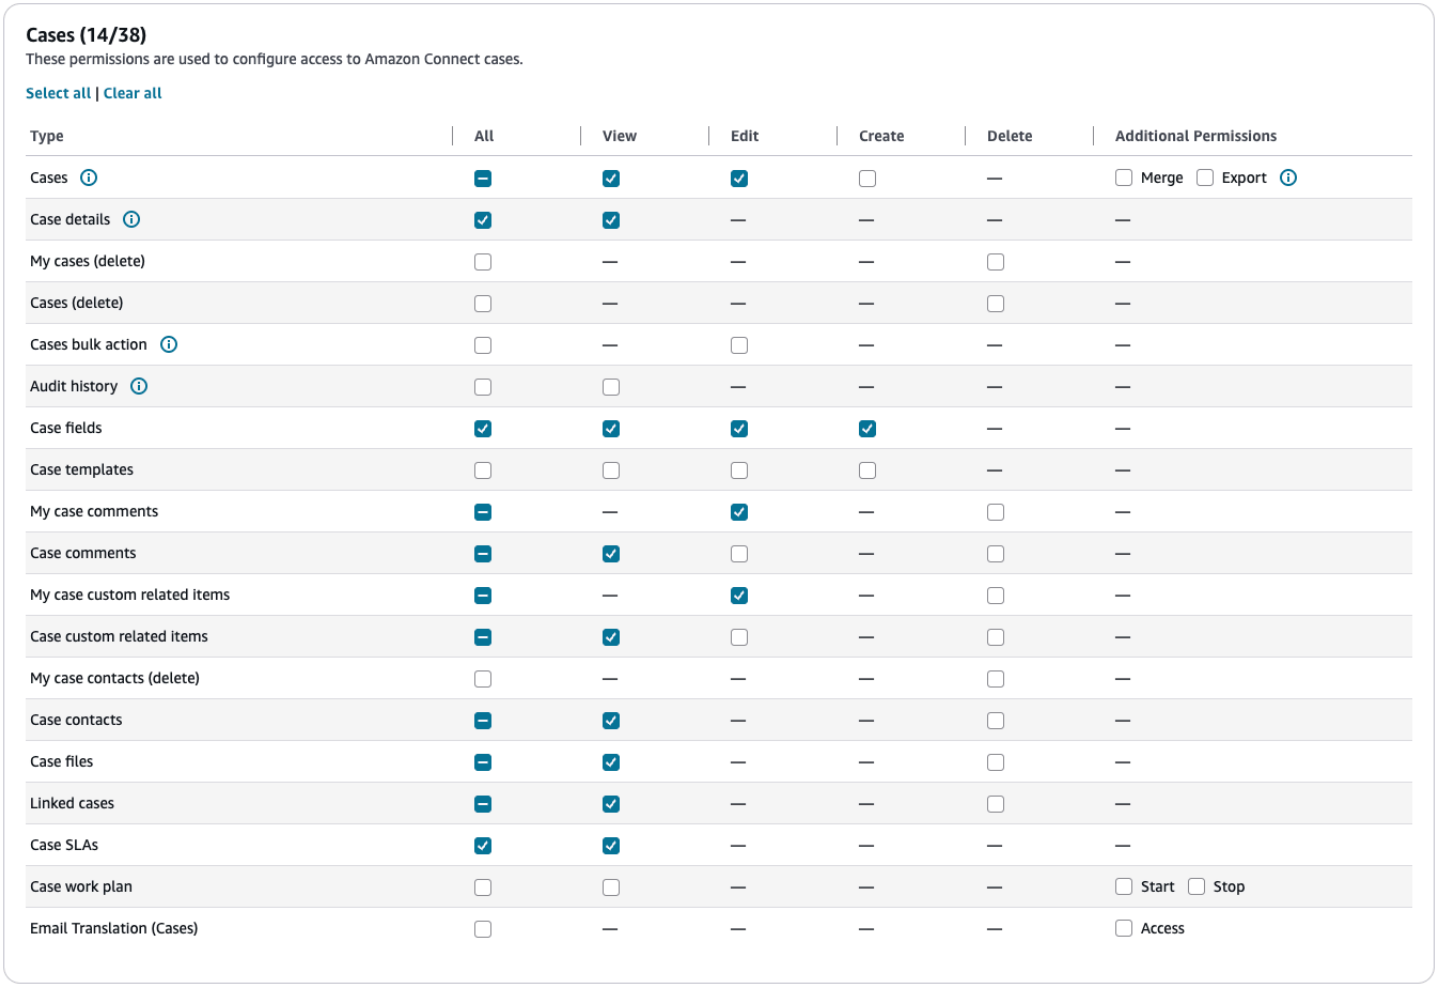
5. Optionally, add the Cases block to your flows. With this block, you can get, update, or create cases automatically.
6. Optionally, set up case event streams to get near real-time updates when cases are created or modified.
7. Optionally, set up a AI agents domain and Configure your flow to generate AI-powered Case Summaries in the agent workspace
8. Optionally, set up tag-based access controls for cases.

Security profile permissions for Cases

This topic describes the security profiles permissions that are required to access and use Connect Customer Cases. For a list of Cases permissions and their API name, see List of security profile permissions in Connect Customer.

Required Cases permissions

The following image shows the security permissions used to manage access to Connect Customer Cases functionality:



Cases (14/38)

These permissions are used to configure access to Amazon Connect cases.

Select all | Clear all

Type	All	View	Edit	Create	Delete	Additional Permissions

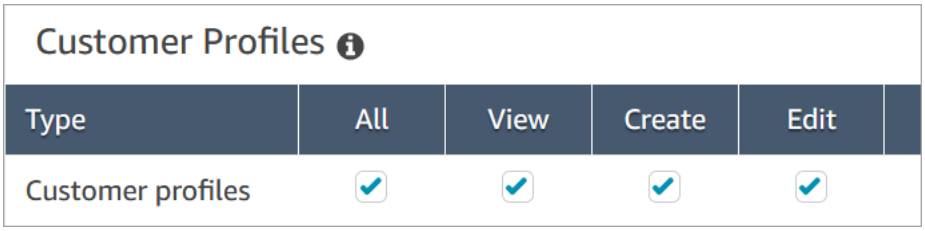
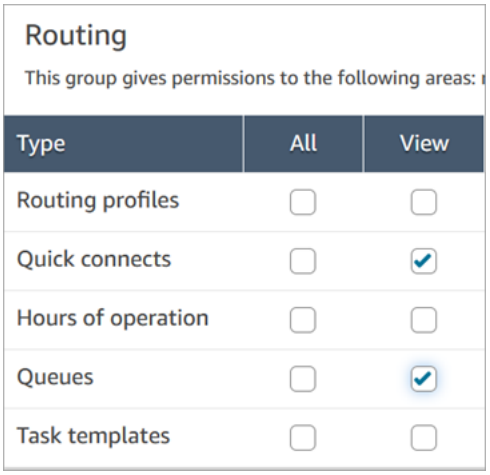
Required Customer Profiles permissions

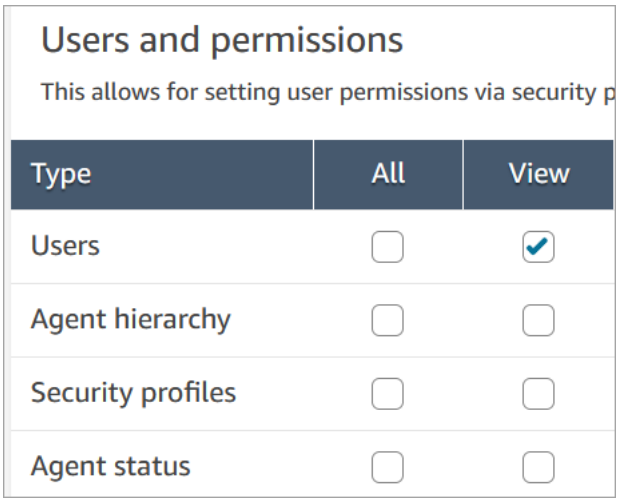
To use Connect Customer Cases, your users also need permissions to Customer Profiles permissions, as shown in the following image.



Required queue, quick connect, and user view permissions

To be able to assign case ownership to users or queues, agents need permissions to view queues, quick connects, and users. To be able to view the author name on comments, agents need permission to view users. These permissions are shown in the following two images.





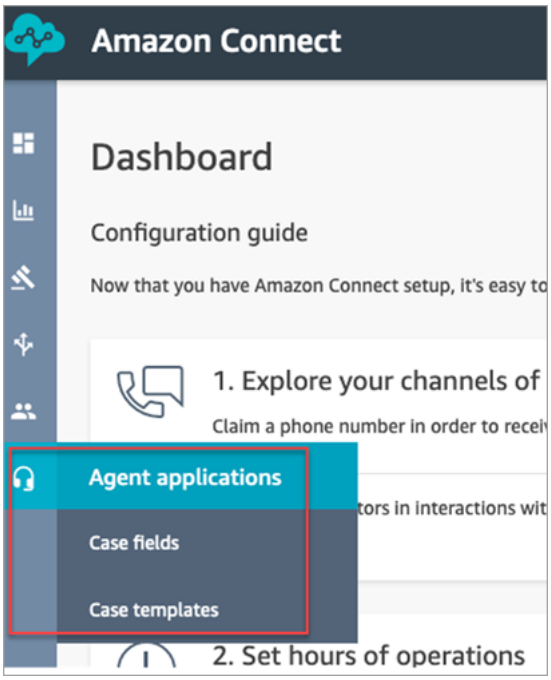
Description of Cases permissions

- **Audit History**: Manage who can access the audit history of cases in the agent workspace.
  - **View Audit History**: Allows the user to view the audit history of cases in the agent workspace.

- **Cases**: Manage who can access cases by using the agent workspace.
  - **View case**: Allows the user to view and search cases in the agent workspace. This includes viewing case data (for example, status, title, summary), contact history (for example, calls, chats, tasks with information such as start time, end time, duration), and comments.
  - **Edit case**: Allows the user to edit cases, which includes editing case data (for example, update case status), add comments, and associate contacts to cases.
  - **Create case**: Allows the user to create new cases, and associate contacts to cases.
  - **Delete case**: Allows the user to delete any case in the domain.
- **Cases bulk action**: Manage who can perform actions on multiple cases at once in the agent workspace.
  - **Edit bulk cases**: Allows the user to select multiple cases in the Cases search view and assign them, update their status, or add a comment to them in a single action, for up to 100 cases.
- **My Cases**: Manage if the user can delete cases that they created.
  - **Delete case**: Allows the user to delete cases that they created.
- **Case Fields**: Manage who can configure case fields by using the Connect Customer admin website.
  - **View Case Fields**: Allows users to view the case fields page and all of the existing case fields (could be system or custom).
  - **Edit Case Fields**: Allows users to edit any of the case fields (for example, change title, description, single-select options).
  - **Create Case Fields**: Allows users to create new case fields.
- **Case Templates**: Manage who can configure case templates by using the Connect Customer admin website.
  - **View Case Templates**: Allows users to view the case templates page and all of the existing case templates.
  - **Edit Case Templates**: Allows users to edit any of the case templates.
  - **Create Case Templates**: Allows users to create new case templates.
- **Case Comments**: Manage who can edit or delete comments on any case, regardless of who authored them.
  - **Edit Case Comment**: Allows the user to edit any comment on a case.
  - **Delete Case Comment**: Allows the user to delete any comment on a case.
- **My Case Comments**: Manage if the user can edit or delete comments that they authored.

  - **Edit Case Comment**: Allows the user to edit comments that they authored.
  - **Delete Case Comment**: Allows the user to delete comments that they authored.
- **Case Custom Related Items**: Manage who can edit or delete custom related items on any case, regardless of who created them.
  - **Edit Case Custom Related Item**: Allows the user to edit any custom related item on a case.
  - **Delete Case Custom Related Item**: Allows the user to delete any custom related item from a case.
- **My Case Custom Related Items**: Manage if the user can edit or delete custom related items that they created.
  - **Edit Case Custom Related Item**: Allows the user to edit custom related items that they created.
  - **Delete Case Custom Related Item**: Allows the user to delete custom related items that they created.
- **Case Contacts**: Manage who can remove contact associations (calls, chats, tasks, emails) from any case, regardless of who associated the contact.
  - **Delete Case Contact**: Allows the user to remove any contact associated with a case.
- **My Case Contacts**: Manage if the user can remove contact associations that they created.
  - **Delete Case Contact**: Allows the user to remove contact associations that they created.
- **Cases Export**: Manage who can export cases from the agent workspace.
  - **Export** (`Cases.Export`): Allows the user to select cases in the case search view and download them as a CSV file. Enabling this permission automatically grants **View case** if it is not already granted.
- **Cases Merge**: Manage who can merge cases in the agent workspace.
  - **Merge** (`Cases.Merge`): Allows the user to merge a case into another case. The merged case is closed and linked to the case it was merged into. You can't undo a merge. This permission doesn't require **Edit case**. Enabling this permission automatically grants **View case** if it is not already granted.
- **Case Files**: Manage who can remove files attached to cases.
  - **Delete Case File**: Allows the user to delete any file attached to a case.
- **Linked Cases**: Manage who can remove links between cases.
  - **Delete** (`CaseLinkedCases.Delete`): Allows the user to unlink any linked case from the **Linked Cases** tab of a case.

When users have permissions to **View Case Fields** and **View Case Templates**, they will see the **Case fields** and **Case templates** options in their left navigation menu, as shown in the following image:



Required Agent Application permissions

To be able to generate a summary for a case in the agent workspace, agents need permission to view AI agents in the agent workspace, as shown in the following image.

Agent Applications

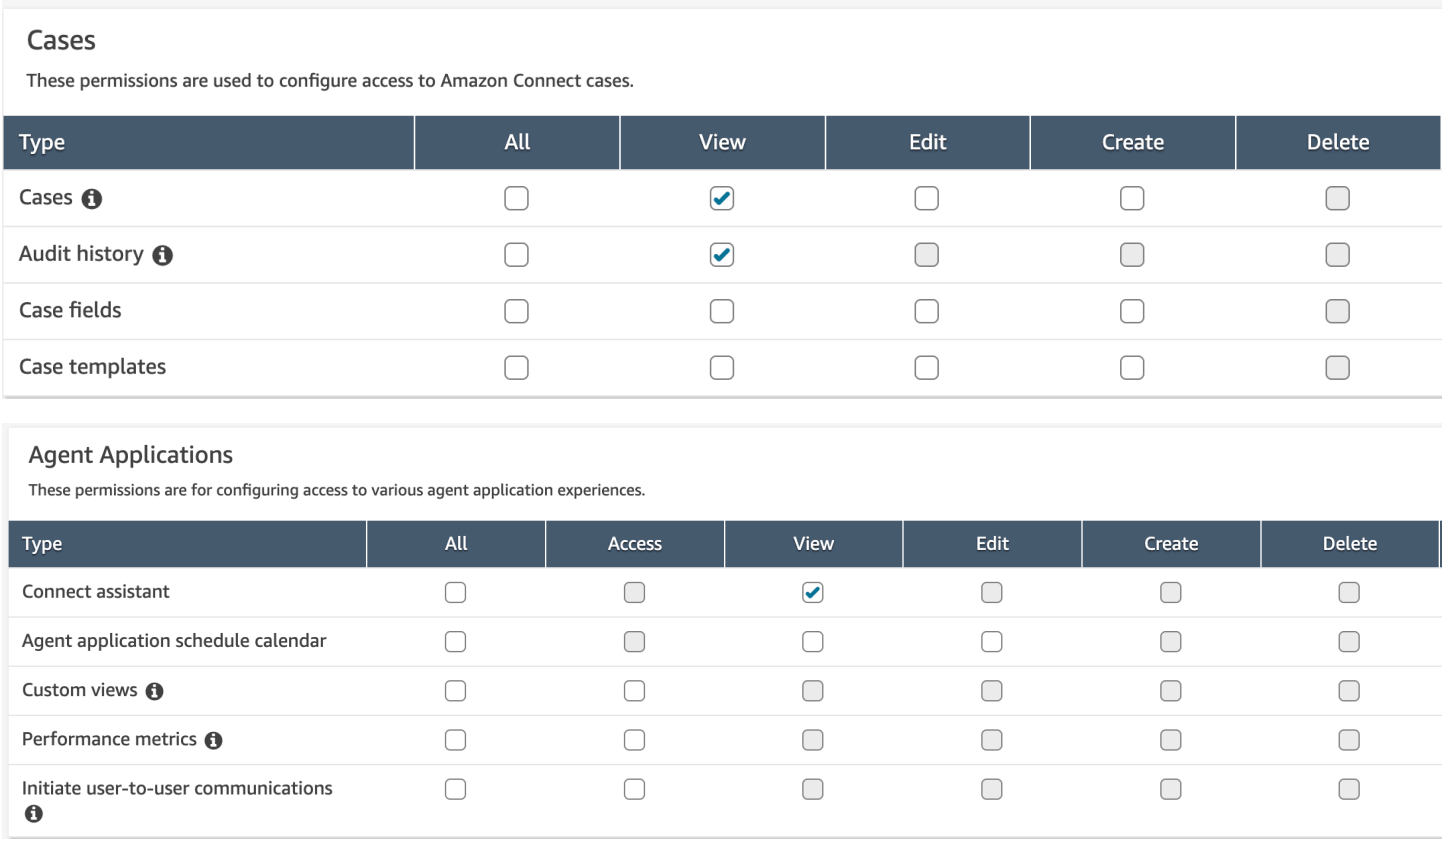
These permissions are for configuring access to various agent application experiences.

Type	All	Access	View	Edit	Create	Delete
Amazon Q Connect	☐	☐	☑	☐	☐	☐

Required Cases and Agent Applications permissions to generate AI-powered case summarization

To generate an AI-powered case summary, agents need View permissions on Cases and Audit History, and View permissions on Connect Assistant under Agent Applications.

To save an AI-powered case summary, agents additionally need Edit permission on Cases.



Cases

These permissions are used to configure access to Amazon Connect cases.

Type	All	View	Edit	Create	Delete
Cases	☐	☑	☐	☐	☐
Audit history	☐	☑	☐	☐	☐
Case fields	☐	☐	☐	☐	☐
Case templates	☐	☐	☐	☐	☐

Agent Applications

These permissions are for configuring access to various agent application experiences.

Type	All	Access	View	Edit	Create	Delete
Connect assistant	☐	☐	☑	☐	☐	☐
Agent application schedule calendar	☐	☐	☐	☐	☐	☐
Custom views	☐	☐	☐	☐	☐	☐
Performance metrics	☐	☐	☐	☐	☐	☐
Initiate user-to-user communications	☐	☐	☐	☐	☐	☐

Required permissions for using custom IAM policies to manage Connect Customer Cases

If you're using custom IAM policies to manage access to the Connect Customer Cases, your users need some or all of the permissions listed in this article, depending on the tasks they need to do.

View Cases domain details

There are two options for granting users IAM permissions to view Cases domain details on the Connect Customer console.

Option 1: Minimum required IAM permissions

To view Cases domain details in the Connect Customer console, users must have the following IAM permissions:

- `connect:ListInstances`
- `ds:DescribeDirectories`

- connect:ListIntegrationAssociations
- cases:GetDomain

Following is a sample IAM policy with these permissions:

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Sid": "AllowsViewingConnectConsole",
            "Effect": "Allow",
            "Action": [
                "connect:ListInstances",
                "ds:DescribeDirectories"
            ],
            "Resource": "*"
        },
        {
            "Sid": "ListIntegrationAssociations",
            "Effect": "Allow",
            "Action": [
                "connect:ListIntegrationAssociations"
            ],
            "Resource": "*"
        },
        {
            "Sid": "CasesGetDomain",
            "Effect": "Allow",
            "Action": [
                "cases:GetDomain"
            ],
            "Resource": "*"
        }
    ]
}
```

Note the following:

- `cases:GetDomain` Action is required on Resource *
- `connect:ListIntegrationAssociations` action supports the `instance` resource type. See the table in Actions defined by Connect Customer.

Option 2: Update the existing Connect Customer policy with `cases:GetDomain` and `profile:SearchProfiles`

Include the AmazonConnectReadOnlyAccess policy, and add `cases:GetDomain`, as shown in the following example.

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Sid": "CasesGetDomain",
            "Effect": "Allow",
            "Action": [
                "cases:GetDomain"
            ],
            "Resource": "*"
        }
    ]
}
```

Onboard to Cases

There are two options for granting users IAM permissions to onboard to Cases using the Connect Customer console.

Option 1: Minimum required permissions

To onboard to Cases by using the Connect Customer console, users must have the following IAM permissions:

- `connect:ListInstances`
- `ds:DescribeDirectories`

- connect:ListIntegrationAssociations
- cases:GetDomain
- cases:CreateDomain
- connect:CreateIntegrationAssociation
- connect:DescribeInstance
- iam:PutRolePolicy
- profile:SearchProfiles

Following is a sample IAM policy with these permissions:

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Sid": "AllowsViewingConnectConsole",
            "Effect": "Allow",
            "Action": [
                "connect:ListInstances",
                "ds:DescribeDirectories"
            ],
            "Resource": "*"
        },
        {
            "Sid": "ListIntegrationAssociations",
            "Effect": "Allow",
            "Action": [
                "connect:ListIntegrationAssociations"
            ],
            "Resource": "*"
        },
        {
            "Sid": "CasesGetDomain",
            "Effect": "Allow",
            "Action": [
                "cases:GetDomain"
            ],
            "Resource": "*"
```

```
        },
        {
            "Sid": "CasesCreateDomain",
            "Effect": "Allow",
            "Action": [
                "cases:CreateDomain"
            ],
            "Resource": "*"
        },
        {
            "Sid": "CreateIntegrationAssociationsAndDependencies",
            "Effect": "Allow",
            "Action": [
                "connect:CreateIntegrationAssociation",
                "connect:DescribeInstance"
            ],
            "Resource": "*"
        },
        {
            "Sid": "AttachAnyPolicyToAmazonConnectRole",
            "Effect": "Allow",
            "Action": "iam:PutRolePolicy",
            "Resource": "arn:aws:iam::*:role/aws-service-role/
connect.amazonaws.com/AWSServiceRoleForAmazonConnect*"
        },
        {
            "Sid": "ProfileSearchProfiles",
            "Effect": "Allow",
            "Action": [
                "profile:SearchProfiles"
            ],
            "Resource": "*"
        }
    ]
}
```

Note the following:

- `cases:GetDomain` Action is required on Resource *
- You can scope the permissions to specific Connect Customer tasks by using the information in Actions, resources, and condition keys for Connect Customer.

- `profile:SearchProfiles` Action is required because the `CreateCase` API calls the `SearchProfiles` API to search for customer profiles to validate against, and then associate the profile with the case.

Option 2: Use a combination of existing policies

The following combination of policies will also work:

- **AmazonConnect_FullAccess** policy
- `iam:PutRolePolicy` to modify the service-linked role. For an example, see AWS managed policy: AmazonConnect_FullAccess policy.
- The following IAM policy:

  JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Sid": "CasesGetDomain",
            "Effect": "Allow",
            "Action": [
                "cases:GetDomain",
                "cases:CreateDomain"
            ],
            "Resource": "*"
        },
        {
            "Sid": "ProfileSearchProfiles",
            "Effect": "Allow",
            "Action": [
                "profile:SearchProfiles"
            ],
            "Resource": "*"
        }
    ]
}
```

Create case fields in Connect Customer Cases

Case fields are the building blocks for *case templates*. You create all of the possible fields of information (for example, VIN number, policy number, make/model of car) that you want agents to collect for a given customer issue.

After you create case fields, you can create case templates.

There are two types of case fields:

- System case fields: Connect Customer provides system fields. You cannot change the name or description.
- Custom case fields: You can create custom case fields that are specific for your business. You must name the case field, and optionally provide a description. Note that the description appears only in the Connect Customer admin website. It doesn't appear to agents.

How to create case fields

1. Log in to the Connect Customer admin website with an **Admin** account, or an account assigned to a security profile that has permissions to create fields. For a list of required permissions, see Security profile permissions for Cases.
2. Verify the quota for case fields and request an increase if needed. For more information, see Connect Customer Cases service quotas.
3. On the left navigation menu, choose **Agent applications**, **Case fields**.
4. The first time you create new fields, you'll notice several system fields are already present. You cannot change the name of these fields, but in some cases you can edit them.

   For example, **Case Id** is a system field. When a case is created, Connect Customer adds a case ID automatically, and you cannot change it. **Case reason** is also a system field but you can edit it and enter reasons that are specific to your contact center.
5. Choose **+ New field**.
6. Select the type of field you want to create. For example, you might choose **Text** if you want agents to be able to enter free form notes.
7. Assign a name to the field. It will appear to agents in the agent workspace.
8. Optionally, provide a description. It appears only to admins on the Connect Customer admin website. It does not appear to agents in the agent workspace.

9. Choose **Save**.
10. When you're done adding fields, you're ready to create a template.

System case fields

Connect Customer provides system fields. You cannot change the name or description of a system field.

The following table lists the system case fields:

Field name	Field ID (how you call the field in the API)	Field type	Description	Where the data comes from
Assigned queue	assigned_queue	text	The Connect Customer queue that is assigned to a case	Agent
Assigned user	assigned_user	text	The Connect Customer user who is assigned to a case	Agent
Case ID	case_id	text	Unique Identifier of the case in UUID format (for example, 689b0bea-aa29-4340-896d-4ca3ce9b6226)	Connect Customer
Case Reason	case_reason	single-select	The reason for opening the case	Agent

Field name	Field ID (how you call the field in the API)	Field type	Description	Where the data comes from
Created By	created_by	user	The identity of the user who created the case.	Connect Customer

Field name	Field ID (how you call the field in the API)	Field type	Description	Where the data comes from
Customer	customer_id	text	Enter the full ARN of the customer profile associated with the case. The `requiredFields` configuration in the case template controls whether this field is required. If `customer_id` is included in `requiredFields`, you must provide a customer profile ARN when you create a case. Otherwise, the customer profile is optional. You can add, change, or remove the customer profile after you create the case. When using the API, provide the ARN in this format:	Connect Customer

Field name	Field ID (how you call the field in the API)	Field type	Description	Where the data comes from
			arn:aws:profile: *region-id* :domains/ *domain-name* /profiles/ *profile-id* .	
Date/Time Closed	last_closed_datetime	date-time	The date and time the case was last closed. It does not guarantee that a case is closed. If a case is reopened, this field contains the date/time stamp of the last time the status was changed to closed.	Connect Customer
Date/Time Opened	created_datetime	date-time	The date and time the case was opened.	Connect Customer
Date/Time Updated	last_updated_datetime	date-time	The date and time the case was last updated.	Connect Customer

Field name	Field ID (how you call the field in the API)	Field type	Description	Where the data comes from
Last Updated User	last_updated_user	user	The identity of the user who performed the last update on the case.	Connect Customer

Field name	Field ID (how you call the field in the API)	Field type	Description	Where the data comes from
Reference number	reference _number	text	A friendly identifier for the case. By default, Cases automatically generates an 8-digit numeric reference number. However, you should treat this value as a string, since you can override the reference number through API to pass in a value with 1–50 alphanumeric characters, for example to carry over an existing identifier from an upstream system. Reference numbers (unlike the Case ID) are not guarantee d to be unique. We recommend that you identify	Connect Customer

Field name	Field ID (how you call the field in the API)	Field type	Description	Where the data comes from
			the customer and then collect the reference number to correctly find the right case.	

Field name	Field ID (how you call the field in the API)	Field type	Description	Where the data comes from
Reference ID	reference_id	text	An identifier for the case that is unique within a Cases domain, so you can use it to look up a case directly. By default, Cases automatically generates a 9-character alphanumeric reference ID. However, you can override the reference ID through API to pass in a value with 1–50 alphanumeric characters, for example to carry over an existing identifier from an upstream system. Reference IDs are not case-sensitive.	Connect Customer
Status	status	single-select	Current status of the case	Agent

Field name	Field ID (how you call the field in the API)	Field type	Description	Where the data comes from
Summary	summary	text	Summary of the case	Agent
Title	title	text	Title of the case	Agent

Custom case fields

You can create custom case fields that are specific for your business. You must name the case field, and optionally provide a description. Note that the description appears only in the Connect Customer admin website. It doesn't appear to agents.

You can create fields that are type: number, text, single-select, true/false, datetime, and URL.

Text fields

Text fields allow agents to capture and store textual information related to customer cases. These fields are flexible and can accommodate various types of text-based data, from brief notes to detailed descriptions.

When creating a text field in the Connect Customer admin website, you can select from two input display options under the **Input display** section to best suit your data collection needs:

Single line text fields: Single line text fields display text in a single horizontal line and have a character limit of 500 characters. They are ideal for capturing concise information such as customer reference numbers, product names, brief case summaries, and contact names.

Multi-line text fields: Multi-line text fields expand vertically to accommodate multiple lines of text and have a character limit of 4,100 characters. They are suitable for capturing detailed information such as case descriptions, customer feedback, resolution steps, and agent observations.

Single-select fields

For single-select case fields, whether system or custom, you can add value options that the field can take. For example, you can add options to the single-select system field Case reason such as

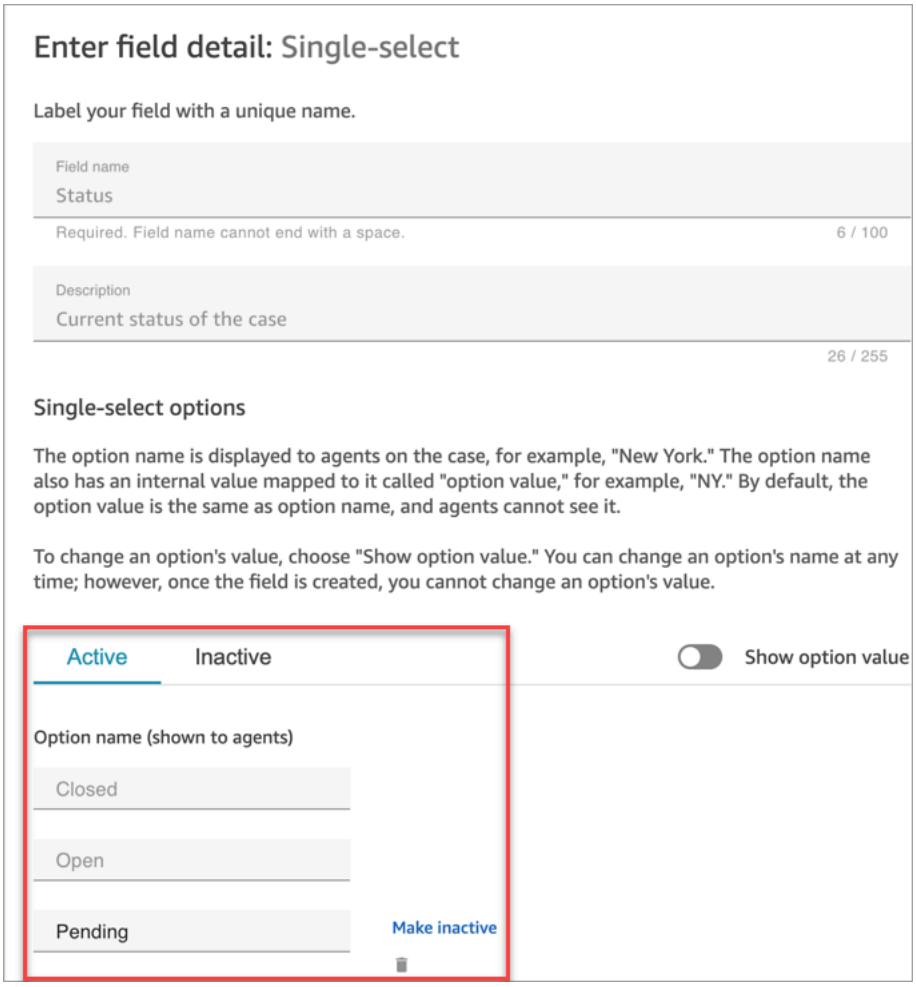
General inquiry, **Billing issue**, or **Product defect**, that reflect the types of issues in your contact center.

About the Status field

You can add options to the single-select **Status** field, such as **Investigating** or **Escalated to manager**. The field comes with two options, **Open** and **Closed**, which cannot be changed.

Active/inactive field options

Single-select case fields can be active or inactive.

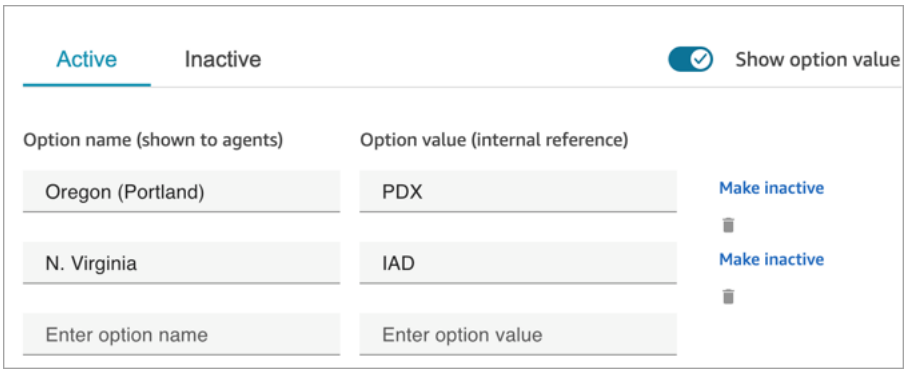


- **Active**: If a field option is active, it means that the field can be given that option. For example, based on the following image, the Status field can be set to **Closed**, **Open**, or **Pending**, as these are the only active options.
- **Inactive**: If you make the **Pending** option inactive, then the field can no longer be given that option. Any existing cases remain unchanged and can still have the status as **Pending**.

Single-select options have two parts:

1. Option name (shown to agents): The label that is displayed to agents in the agent workspace.
2. Option value (internal reference): The data that's collected. For example, for AWS Region, you might want to display **US West (Oregon)** but collect the data as **PDX**.

   Field options appear to the agent in alphabetical order.



Add case field conditions to a case template in Connect Customer

Case field conditions in Connect Customer make your case templates more dynamic and user-friendly. There are three types of case field conditions: Conditionally required, Hidden field conditions, and Dependent field options. With conditionally required fields, you can enforce field completion based on specific criteria. With hidden field conditions, you can show or hide fields based on other field values. Dependent field options create cascading dropdown menus where available choices depend on previous selections. These features help streamline agent workflows, reduce data entry errors, and ensure agents see only relevant information when managing cases.

Conditionally required

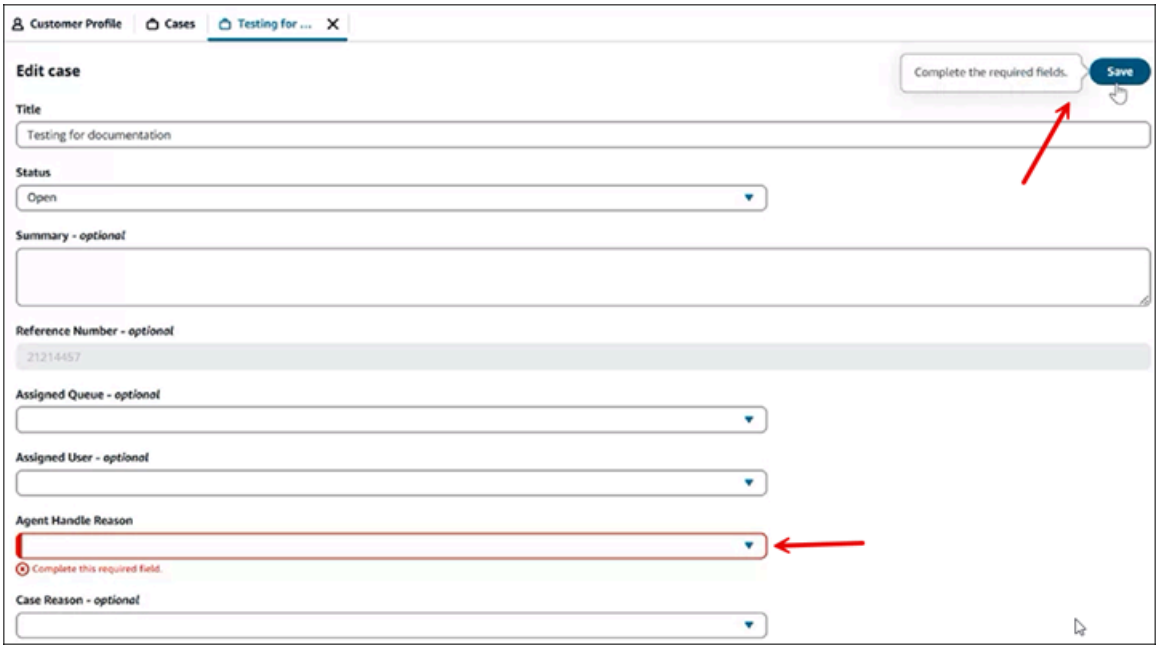
You can streamline how agents populate case fields, and reduce data entry errors, by conditionally requiring specific fields.

To make a field conditionally required, you first set up a field condition. Then, on a case template, choose which field the case field condition should apply to.

For example, you might want to enforce that **Agent Handle Reason** is required if a case is updated after it was created. To achieve this you would:

1. Create a case field condition based on whether the Date/Time Opened field is not blank.
2. Apply the case field condition to the **Agent Handle Reason** field on the case template.

The following image shows an example **Edit case** page where this requirement is being enforced.



This feature provides a lot of flexibility. Following are few other examples you can set up:

- If Status = Closed, then the Close Reason field must be populated.
- If Case Reason = Refund, then the Amount field is required.
- If Country = USA, the State field is required.

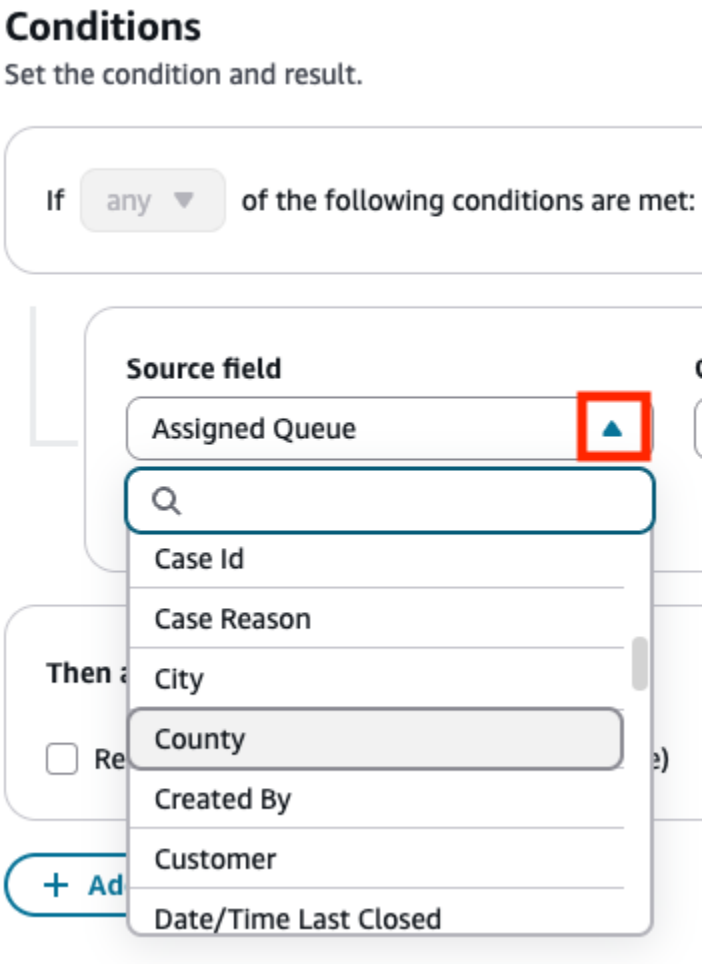
You can apply case field conditions to multiple fields on a template.

Topics

- Step 1: Create case field conditions
- Step 2: Add case field conditions to a template
- Example case field conditions
- APIs to create case field conditions

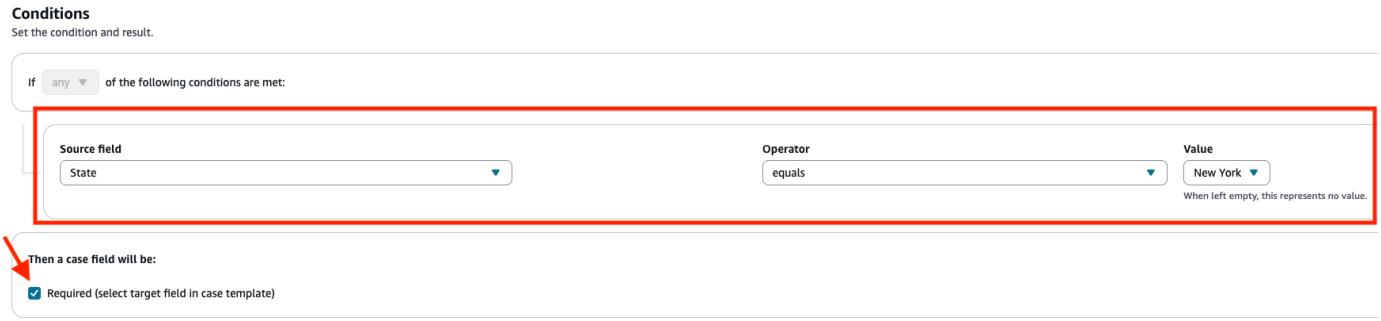
Step 1: Create case field conditions

1. Log in to the Connect Customer admin website with an **Admin** account, or an account assigned to a security profile that has the following permission in it's security profile: **Cases** - **Case Templates** - **Create**.
2. On the left navigation menu, choose **Agent applications**, **Case field conditions**.
3. Choose **New Field Condition**.
4. On the **Create new field condition** page, use the **Source field** dropdown list to choose the field you want to validate, as shown in the following image:



5. Choose the operator and the value to check.

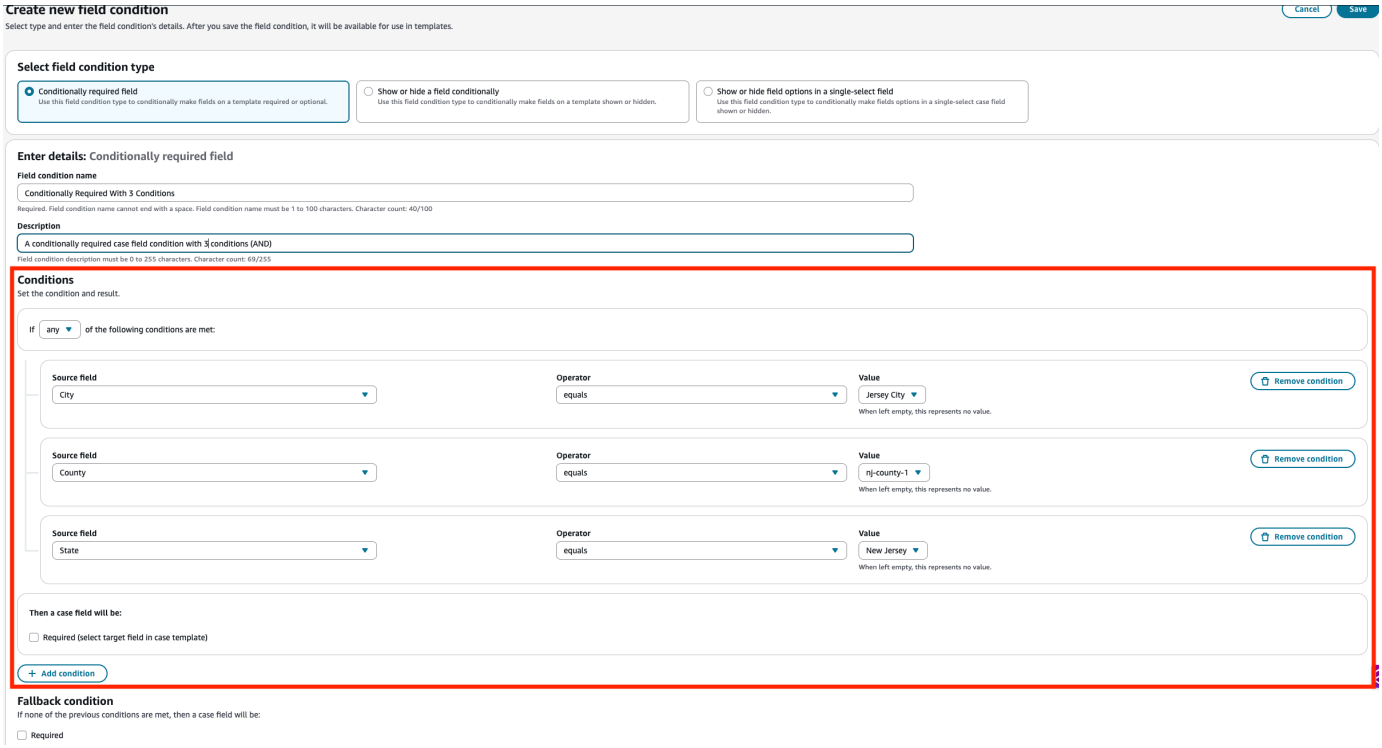
   For example, the following image shows when the **State** field equals **New York**, a case field will be required.



The condition is configured as follows:

- **Source** = **State**
- **Operator** = **equals**
- **Value** = **New York**
- **Required** is selected. A case field that you specify in Step 2 will be required when this condition is met.

6. You can add up to 5 field conditions and choose whether they are fulfilled by AND or OR conditions, by choosing the Add Condition button.



7. For **Fallback condition**, if the condition is not met, choose this field to set the default experience.

For example, if you leave **Fallback condition** unselected, when **Country** does not equal **USA**, then the field this condition is applied to won't be required. So, if you apply the condition to **State**, but the **Country = France**, the **State** field won't be required.

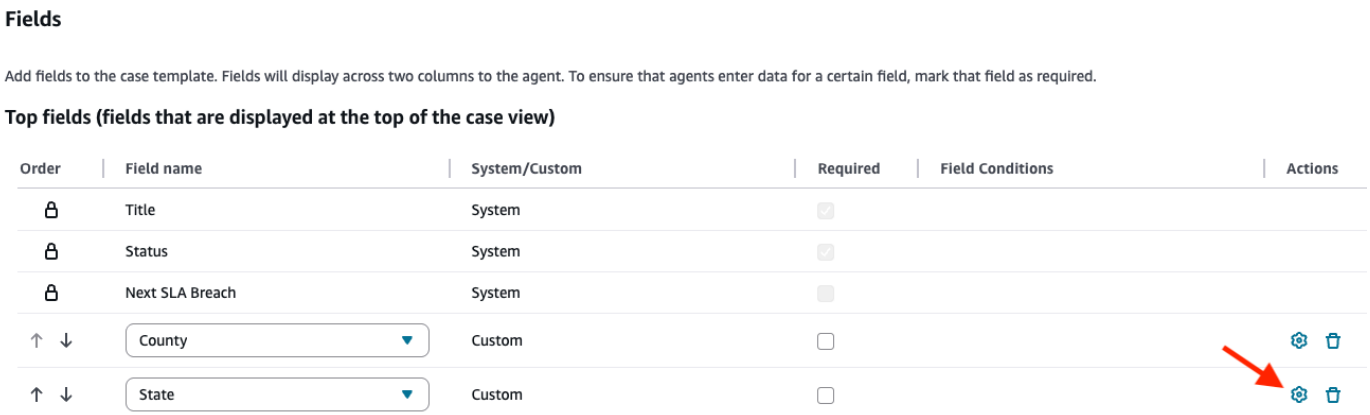
8. Choose **Save**, and then proceed to the next step to add the condition to your template.

Step 2: Add case field conditions to a template

In this step, you specify which case fields the condition will apply to.

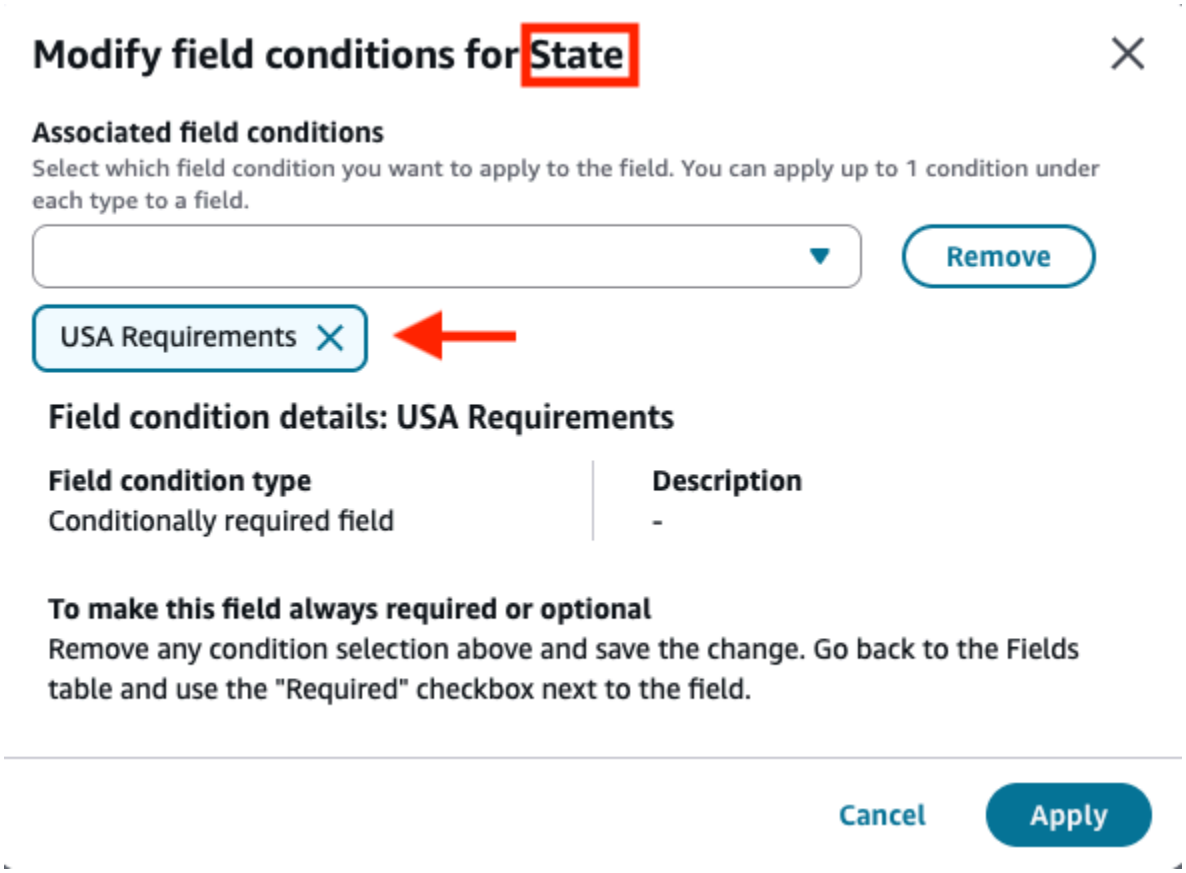
1. Log in to the Connect Customer admin website with an **Admin** account, or an account assigned to a security profile that has the following permission in it's security profile: **Cases - Case Templates - Create** or **Edit**.
2. On the left navigation menu, choose **Agent applications**, **Case templates**.
3. Choose the case template you want to apply the condition to.

   You might want the condition to apply to one template but not others. For example, you might want a **Close reason** condition to apply to escalations, but not to general inquires.
4. In the **Fields** section, choose the settings icon next to the field you want to apply the condition to. The following image shows the settings icon for the **State** field.



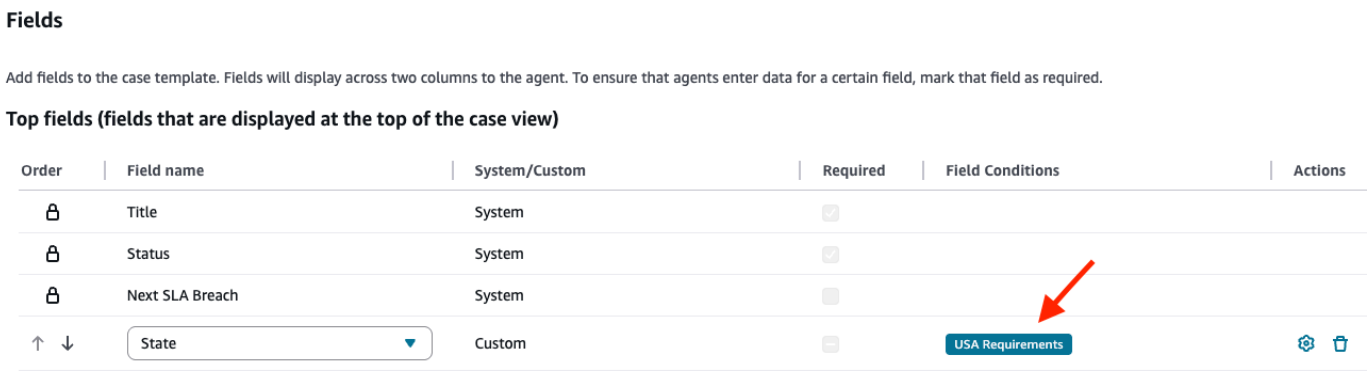
5. In the **Modify field conditions for** [*field*] use the dropdown box to choose the condition you want to apply to the field.

   In the following image, the **USA requirements** condition is going to be applied to the **State** field.



6. Choose **Apply**, and then choose **Save** to save the change to the template.

   The status page indicates which conditions have been applied to a field. The following image shows the **USA requirements** condition is applied to the **State** field.



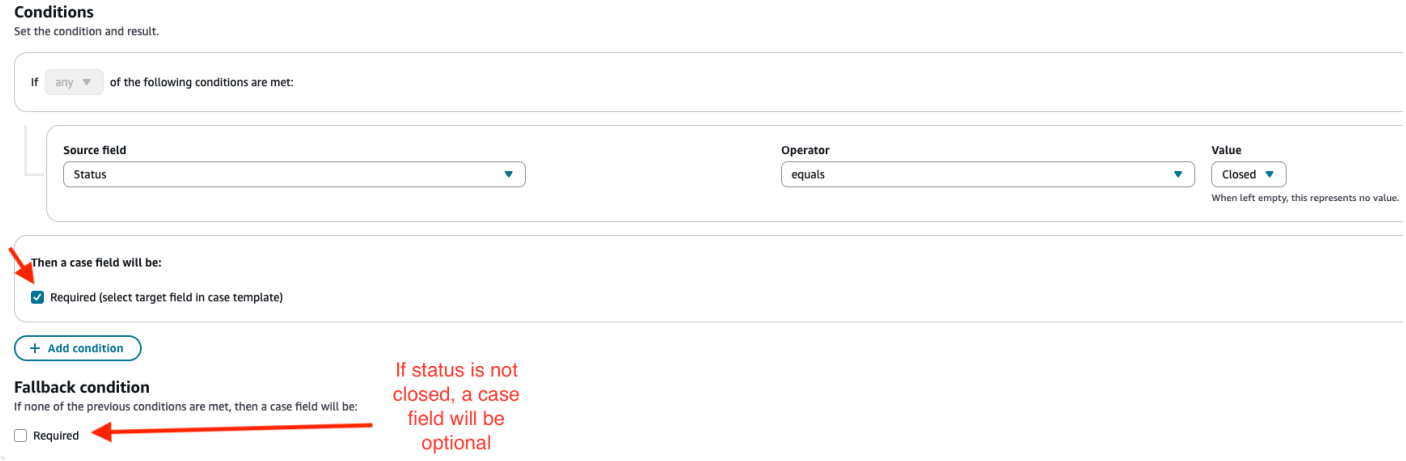
Example case field conditions

Example 1: Require agents to enter a reason for closing a case

1. Create the following condition:

- If **Status** is **Closed**, then a case field will be required. If **Status** is not **Closed**, then a case field will be optional.

The following image shows how to set up this condition.

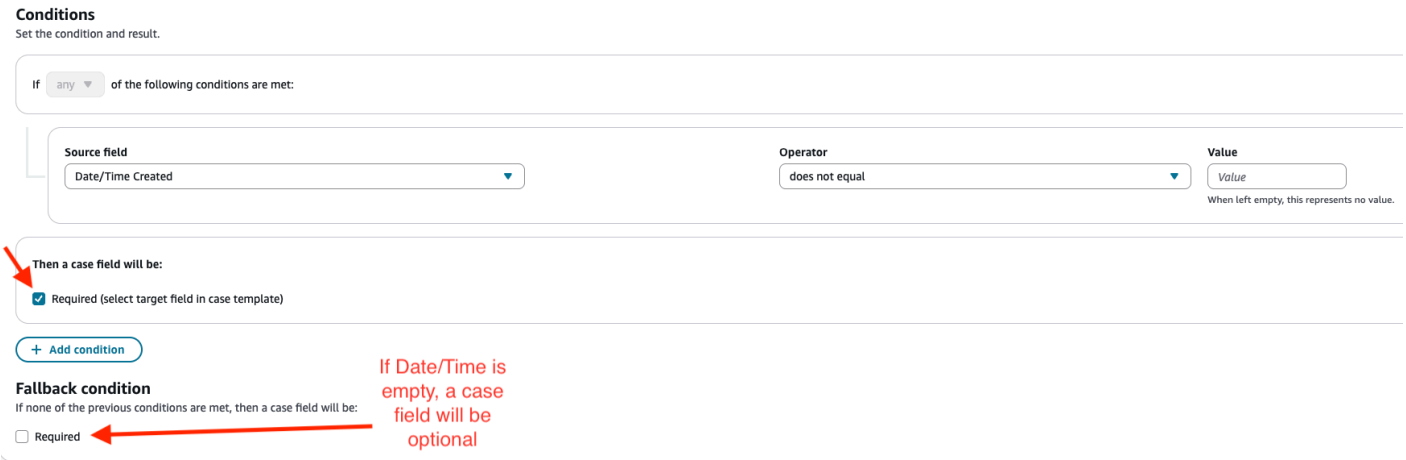


2. Assign this condition to the **Closed Reason** field on the cases template.
3. Result: When agents save a case and the **Closed Reason** field is blank, they will be prompted to enter a value.

Example 2: Require agents to provide a reason every time they update a case

1. Create the following condition:

   If the **Date/Time Created** field does not equal blank, then a case field will be required. If the **Date/Time Created** field is empty, then that case field is optional. The following image shows how to set up this condition.



2. Assign this condition to the **Agent Handle Reason** field on the cases template.

3. Result: When agents save a case and the **Agent Handle Reason** is blank, they will be prompted to enter a value.

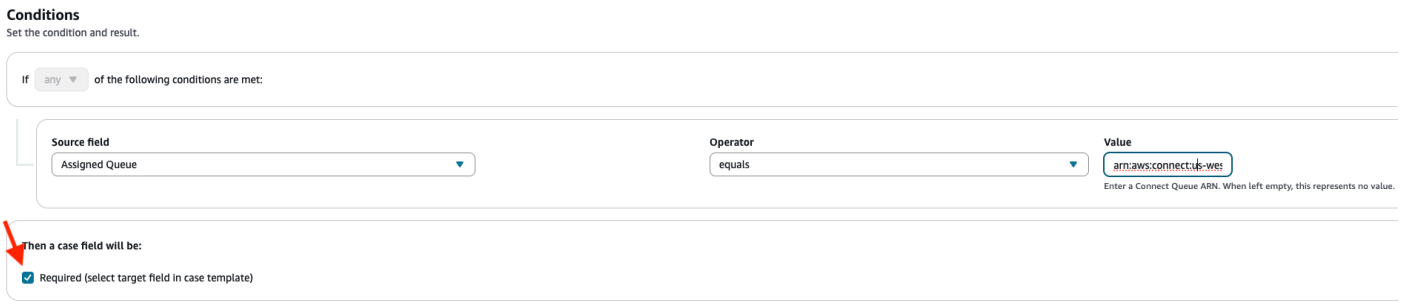
Example 3: Require agents to provide a reason when they assign a case to the Escalation queue

1. Create the following condition:

   If the **Assigned Queue** field equals the **Escalation queue** Amazon Resource Name (ARN), then a case field will be required. If the **Assigned Queue** field does not equal the **Escalation queue** ARN, then that case field is optional.

   > **Tip**
   >
   > You can copy the ARN of a queue from the **Queues** page.

   The following image shows how to set up this condition.



2. Assign this condition to the **Escalation reason** field on the cases template.
3. Result: When agents assign a case to the **Escalation queue**, and the **Escalation reason** field is blank, they will be prompted to enter a value.

APIs to create case field conditions

Use the following APIs to programmatically create case field conditions and associate them to a template:

- CreateCaseRule: Creates the case field condition.
- CreateTemplate or UpdateTemplate: Associate the case field condition with the case template.

Hidden field conditions

You can create dynamic case templates that show or hide fields based on other field values, improving the user experience and reducing complexity for agents.

To make a field conditionally hidden, you first set up a hidden field condition. Then, on a case template, choose which field the hidden field condition should apply to.

For example, you might want to hide the **Advanced Configuration** field unless the user selects **Advanced** as the **User Level**. To achieve this you would:

1. Create a hidden field condition based on whether the **User Level** field equals **Advanced**.
2. Apply the hidden field condition to the **Advanced Configuration** field on the case template.

This feature provides a lot of flexibility. Here are a few other examples you can set up:

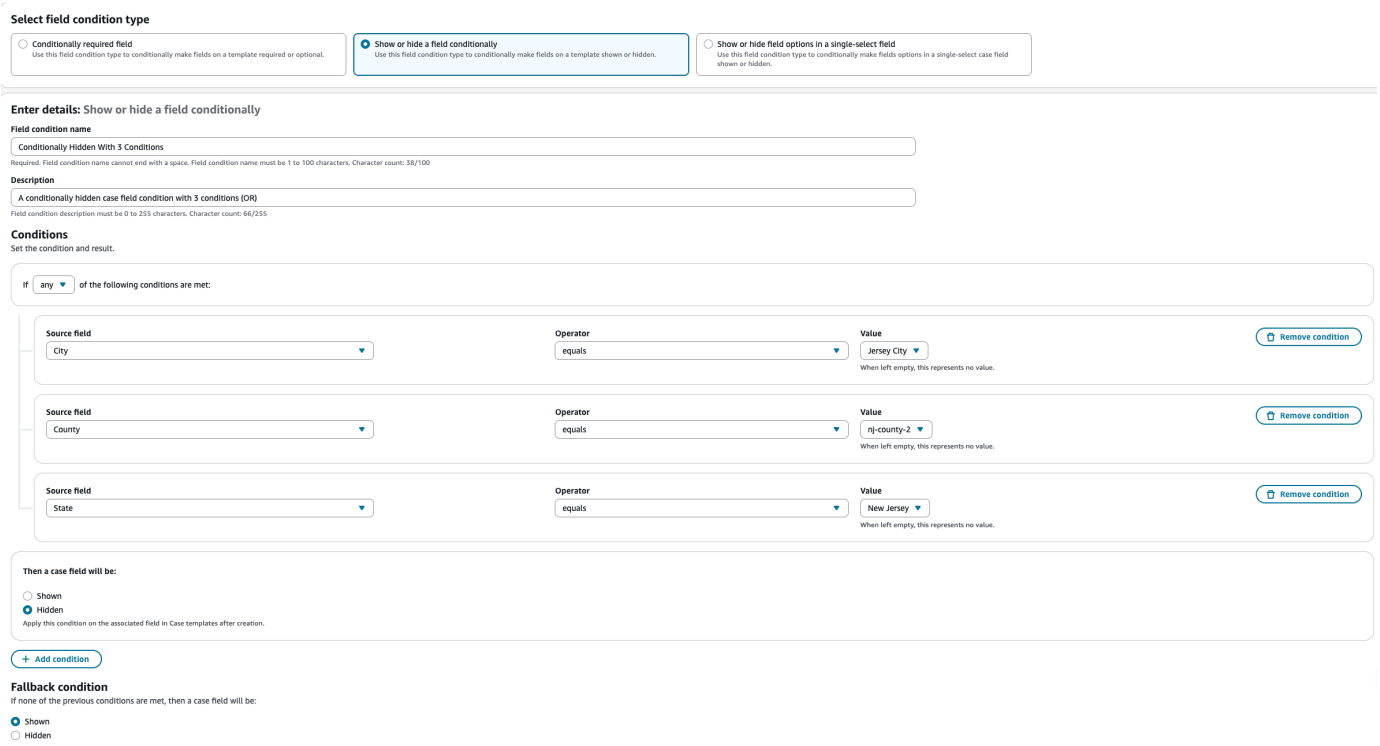
- If Case Type = Basic, hide the Priority field.
- If Customer Type = Internal, hide the Billing Address fields.
- If Status = Draft, hide the Approval fields.

You can apply hidden field conditions to multiple fields on a template.

Step 1: Create hidden field conditions

1. Log in to the Amazon Connect admin website with an **Admin** account, or an account assigned to a security profile that has the following permission in it's security profile: **Cases** - **Case Templates** - **Create**.
2. On the left navigation menu, choose **Agent applications**, **Case field conditions**.
3. Choose **New Field Condition**.
4. On the **Create new field condition** page, select **Hidden** as the condition type.
5. Use the **Source field** dropdown list to choose the field you want to evaluate for the condition.
6. You can add up to 5 field conditions and choose whether they are fulfilled by AND or OR conditions, by choosing the Add Condition button.
7. Configure the visibility settings:
    - **Default visibility**: Choose whether the field is hidden or shown when no conditions match
    - **Show field when**: Define the conditions that will show the field

8. Choose the operator and the value to check.
9. You can add up to 5 field conditions and choose whether they are fulfilled by AND or OR conditions, by choosing the Add Condition button.



10. Choose **Save**, and then proceed to the next step to add the condition to your template.

Step 2: Add hidden field conditions to a template

In this step, you specify which case fields the hidden condition will apply to.

1. Log in to the Amazon Connect admin website with an **Admin** account, or an account assigned to a security profile that has the following permission in it's security profile: **Cases - Case Templates - Create** or **Edit**.
2. On the left navigation menu, choose **Agent applications**, **Case templates**.
3. Choose the case template you want to apply the condition to.
4. In the **Fields** section, choose the settings icon next to the field you want to apply the condition to.
5. In the **Modify field conditions for** [field] use the dropdown box to choose the hidden condition you want to apply to the field.
6. Choose **Apply**, and then choose **Save** to save the change to the template.

Example hidden field conditions

Example 1: Hide advanced options unless user selects advanced mode

1. Create the following condition: If **User Level** equals **Advanced**, then show the field. Otherwise, hide the field by default.
2. Assign this condition to the **Advanced Configuration** field on the cases template.
3. Result: **Advanced Configuration** will only be visible when agents select **Advanced** in the **User Level**.

Example 2: Hide billing fields for internal customers

1. Create the following condition: If **Customer Type** does not equal **Internal**, then show the field. If **Customer Type** equals **Internal**, hide the field.
2. Assign this condition to the **Billing Address** field on the cases template.
3. Result: **Billing Address** will be hidden when the **Customer Type** is set to **Internal**.

Example 3: Hide approval fields for draft cases

1. Create the following condition: If **Status** does not equal **Draft**, then show the field. If **Status** equals **Draft**, hide the field.
2. Assign this condition to the **Approval** field on the cases template.
3. Result: **Approval** will be hidden until the case **Status** changes from **Draft**.

APIs for hidden field conditions

Use the following APIs to programmatically create hidden field conditions:

- CreateCaseRule: Creates the hidden field condition using the "hidden" rule type.
- CreateTemplate or UpdateTemplate: Associate the hidden field condition with the case template.

Dependent field options

You can create cascading dropdown fields where the options in a single-select field (target) depend on the selection made in another field (source), providing a more intuitive and organized experience for agents.

To set up dependent field relationships, you first create a field options condition that defines the relationship between a source field and a target field. Then, on a case template, apply this condition to control the available options.

For example, you might want the **State/Province** field options to change based on the selected **Country**. To achieve this you would:

1. Create a field options condition that maps country selections to their respective states/provinces.
2. Apply the field options condition to the **State/Province** field on the case template.

This feature provides a lot of flexibility. Here are a few other examples you can set up:

- If Product Category = Electronics, show subcategories: Computers, Phones, Tablets, Accessories.
- If Department = IT, show relevant issue types: Hardware, Software, Network, Security.
- If Service Type = Premium, show premium-specific options in the Service Level field.

You can apply field options conditions to multiple dependent field pairs on a template.

Step 1: Create field options conditions

1. Log in to the Amazon Connect admin website with an **Admin** account, or an account assigned to a security profile that has the following permission in it's security profile: **Cases** - **Case Templates** - **Create**.
2. On the left navigation menu, choose **Agent applications**, **Case field conditions**.
3. Choose **New Field Condition**.
4. On the **Create new field condition** page, select **Field Options** as the condition type.
5. Configure the relationship:
   - **Source field**: Choose the field that will control the options
   - **Target field**: Choose the field whose options will be controlled
6. Set up the option mappings by defining which source field values correspond to which target field options.

   For example, the following configuration shows when **Country** equals **United States**, the state field will show US states:

- **Source field** = **Country**
- **Target field** = **State/Province**
- Mapping: "United States" → ["California", "New York", "Texas", "Florida"]

7. Add additional mappings for other source field values as needed.
8. Choose **Save**, and then proceed to the next step to add the condition to your template.

Step 2: Add field options conditions to a template

In this step, you specify which target field the options condition will apply to.

1. Log in to the Amazon Connect admin website with an **Admin** account, or an account assigned to a security profile that has the following permission in it's security profile: **Cases** - **Case Templates** - **Create** or **Edit**.
2. On the left navigation menu, choose **Agent applications**, **Case templates**.
3. Choose the case template you want to apply the condition to.
4. In the **Fields** section, choose the settings icon next to the target field you want to apply the condition to.
5. In the **Modify field conditions for** [field] use the dropdown box to choose the field options condition you want to apply to the field.
6. Choose **Apply**, and then choose **Save** to save the change to the template.

Example field options conditions

Example 1: Show states/provinces based on country selection

1. Create the following condition:
   - **Source field**: **Country**
   - **Target field**: **State/Province**
   - Mappings:
     - "United States" → ["California", "New York", "Texas", "Florida"]
     - "Canada" → ["Ontario", "Quebec", "British Columbia"]
2. Assign this condition to the **State/Province** field on the cases template.
3. Result: When agents select a **Country**, only the relevant states or provinces will be shown.

Example 2: Show product subcategories based on main category

1. Create the following condition:
   - **Source field**: **Product Category**
   - **Target field**: **Subcategory**
   - Mappings:
     - "Electronics" → ["Computers", "Phones", "Tablets", "Accessories"]
     - "Clothing" → ["Shirts", "Pants", "Shoes", "Accessories"]
     - "Books" → ["Fiction", "Non-Fiction", "Technical", "Children"]
2. Assign this condition to the **Subcategory** field on the cases template.
3. Result: When agents select a **Product Category**, only relevant subcategories will be shown.

Example 3: Show department-specific issue types

1. Create the following condition:
   - **Source field**: **Department**
   - **Target field**: **Issue Type**
   - Mappings:
     - "IT" → ["Hardware", "Software", "Network", "Security"]
     - "HR" → ["Benefits", "Payroll", "Policy", "Training"]
     - "Finance" → ["Invoicing", "Expenses", "Budget", "Reporting"]
2. Assign this condition to the **Issue Type** field on the cases template.
3. Result: When agents select a **Department**, only issue types relevant to that department will be available.

APIs for field options conditions

Use the following APIs to programmatically create field options conditions:

- CreateCaseRule: Creates the field options condition using the "fieldOptions" rule type.
- CreateTemplate or UpdateTemplate: Associate the field options condition with the case template.

CSV upload for dependent field options

When you configure dependent field options for case templates, you can upload a CSV file. The file contains your field option mappings. This approach saves time compared to manually entering each relationship through the Amazon Connect admin website. This capability is useful when you have large datasets of hierarchical relationships. Examples include geographic hierarchies (Country → State → City) or product categorizations (Category → Subcategory).

What is CSV upload for dependent field options?

CSV upload is a bulk configuration method for dependent field options in Connect Customer Cases. Dependent field options create cascading dropdown menus. The available choices in one field (the target field) depend on the value selected in another field (the source field).

You can prepare your mappings in a CSV file and upload it. This saves time compared to manually configuring each source-target value relationship through the Amazon Connect admin website. The system parses your CSV file and validates the field names and values against your case template. The system then pre-populates the rule creation form with your data. You create the rule using the standard workflow.

How CSV upload works?

CSV file structure

The CSV file uses a four-column format with the following headers:

- **Parent Field Name** - The name of the source field that controls the relationship
- **Child Field Name** - The name of the target field whose options depend on the source field
- **Parent Value** - A specific value from the source field
- **Child Value** - An option that appears in the target field when the parent value is selected

Each row in your CSV represents one source-target value relationship. You can include multiple field pairs in a single CSV file by using different parent-child field name combinations. For example, you can include both Country-State relationships and Product Category-Subcategory relationships in the same file. The number of entries you can save depends on your account's quota limits.

You can download a CSV template from the Amazon Connect admin website. The template provides the correct format with placeholder headers.

Upload and validation process

When you upload a CSV file, the system performs several validation checks:

- **File format validation** - Verifies the CSV structure and required columns
- **Field existence** - Confirms that the field names in your CSV match fields in your selected case template
- **Field type validation** - Ensures both source and target fields are single-select type fields
- **Value validation** - Checks that source field values exist in your template and identifies any child field values that don't exist

The system displays an error if source field values in your CSV do not exist in the template. If child field values do not exist, the system skips those values and shows an informational message.

After validation, the system groups your CSV rows by unique field pairs. The system displays each detected pair as a selectable option. If your CSV contains multiple field pairs, you select which pair to configure.

Creating rules from CSV data

After you select a field pair from your uploaded CSV, the rule creation form automatically populates with the field names and value mappings from your file.

You must explicitly create the rule after the form is populated. The upload process does not automatically create rules. If you upload a new CSV file before creating the rule, the new file's data overwrites the previously populated options.

Each CSV upload creates one rule at a time. If your CSV contains multiple field pairs, you create rules for each pair separately. Select different pairs and complete the rule creation workflow for each.

Limits and requirements

CSV upload has the following limits and requirements:

- **Single-select fields only** - Both source and target fields must be single-select type fields
- **Existing fields required** - All field names in your CSV must match fields that already exist

Additional resources

Use the following APIs to programmatically create field options conditions:

- CreateCaseRule: Creates the field options condition using the "fieldOptions" rule type.
- CreateTemplate or UpdateTemplate: Associate the field options condition with the case template.

Create case templates to document customer issues in Connect Customer Cases

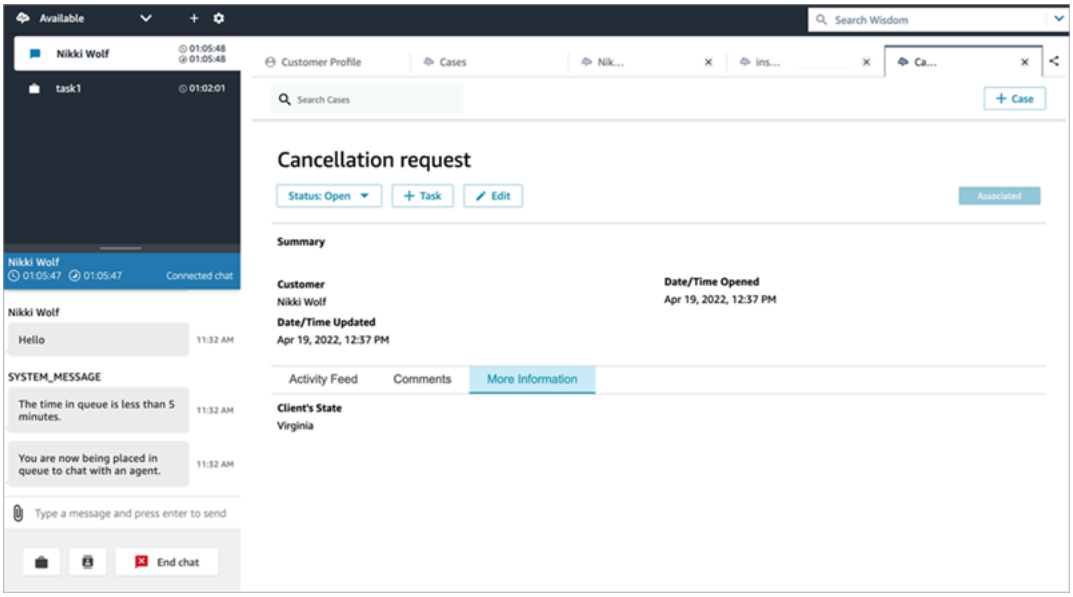
Case templates are forms that ensure agents collect and reference the right information for different types of customer issues. For example, you can create a case template for vehicle damage issues, and require agents complete certain fields when they talk to a customer filing an insurance claim.

When you create a case template, you choose the name that appears to agents, the fields on the form, and the order of the fields.

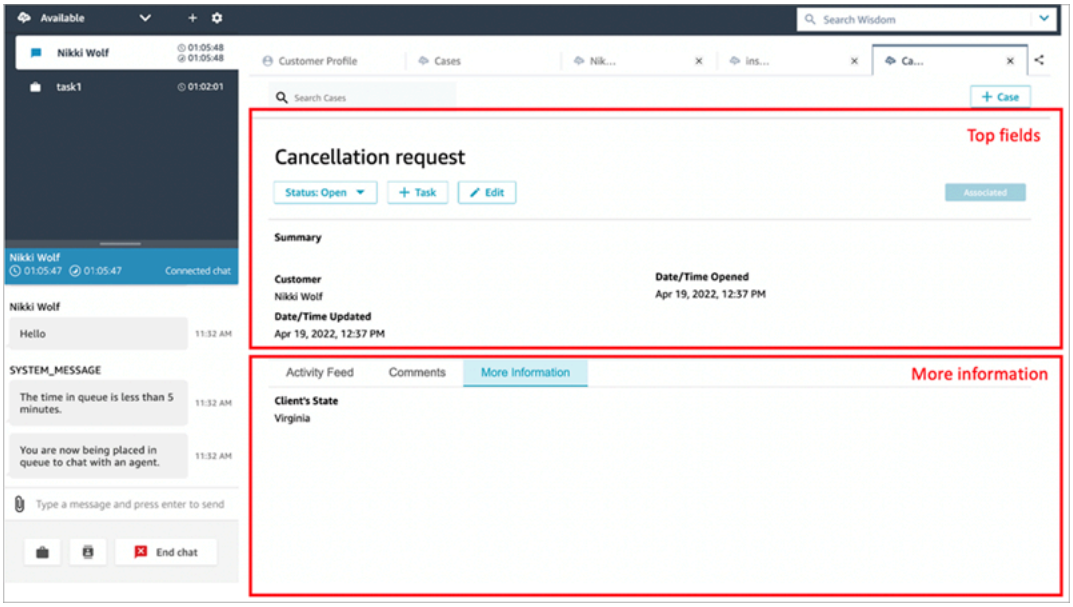
> **Important**
>
> Cases are always created based on a template.

How case templates look in the agent workspace

In the agent workspace, the agent sees the case fields in a Z-formation: case fields are displayed in two columns from left to right, top to bottom.



When you're building a case template, think of the information in the agent workspace as being is divided into two sections where case fields are displayed to the agent:



- Top fields: This section is always visible on the case, even when agent is viewing sub-sections of the case (for example, **Activity Feed** or **Comments**).
- More information: This is a tabbed subsection of the case. It is visible when agent is viewing another subsection, such as **Activity Feed** or **Comments**.

When you create and edit a template, you can do the following in each section:

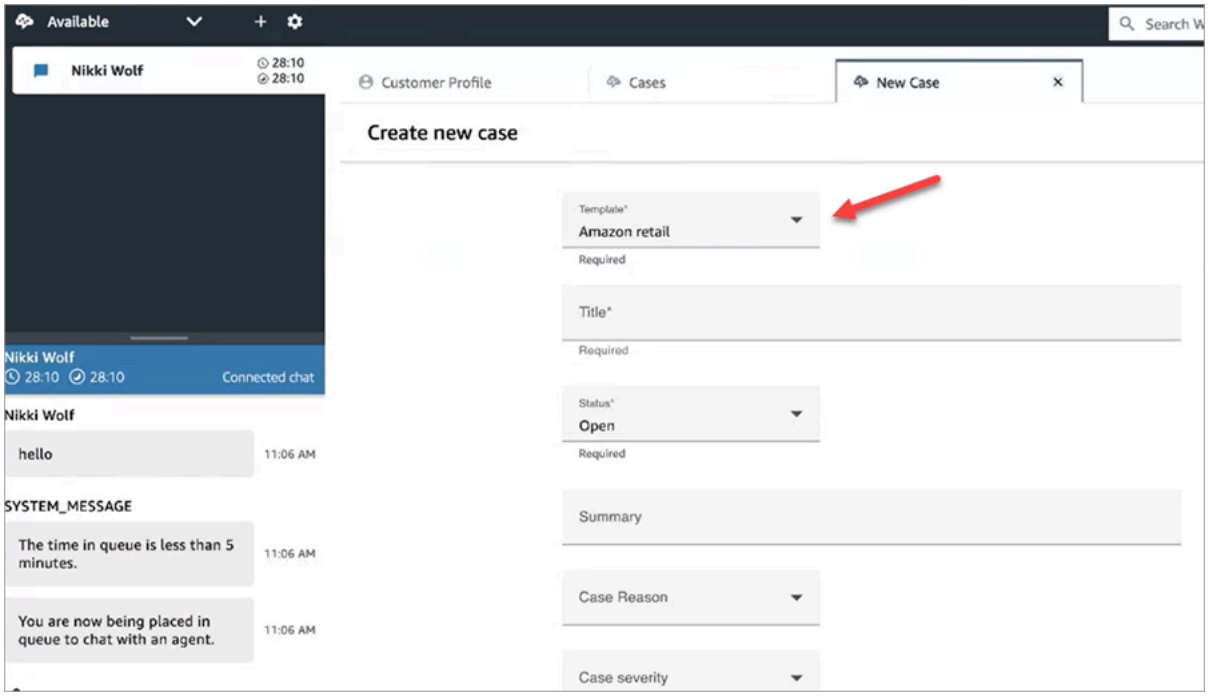
- Change the order of the fields.
- Indicate if fields are required.

Some system fields, such as **Title** and **Status**, appear on all cases and are required. Other system fields, such as **Customer**, **Summary**, and **Reference number**, appear by default on the case details page. You can remove or rearrange these fields.

Each case that is created is connected to a customer profile from your Connect Customer instance. On new case templates, the customer name appears by default on the case details page. You can remove or rearrange this field from your templates from the Connect Customer admin website.

How to create a template

1. Log in to the Connect Customer admin website with an **Admin** account, or an account assigned to a security profile that has permissions to create templates. For a list of required permissions, see Security profile permissions for Cases.
2. Verify the quota for case templates and request an increase if needed. For more information, see Connect Customer Cases service quotas.
3. Verify the case fields you want to add to your case template have already been created.
4. On the left navigation menu, choose **Agent applications**, **Case templates**.
5. Choose **+ New Template**.
6. Assign a name to the template. It will appear to agents in the agent workspace. The following image shows an example of how templates appear, by default in alphabetical order:



7. In the **Top fields** section, you'll see some system fields already there. Choose **Add fields**, and use the dropdown to choose the field. Fields that are gray-out are already a part of the template. If you want agents to complete the field to save the form, choose **Required**.
8. In the **More information** section, choose the fields you want to appear.
9. Optionally, add **Case tags** to automatically propagate tags to cases created from this template. See Tag-based access controls for more information.
10. When you're done, choose **Save**. The template is immediately made available to agents in the agent workspace.

Case layouts for developers using Connect Customer Cases APIs

This topic is intended for developers who are using the Connect Customer Cases APIs.

There is an underlying resource called a *case layout* that is linked to the case template. Technically, it is the case layout that holds the display elements for a case, such as:

- Which fields to display.
- The section, either Top panel or More information.
- The order within a section to display these fields

Whereas it's the case template that mandates a particular schema, such as required case fields.

The case layout is linked to a case template.

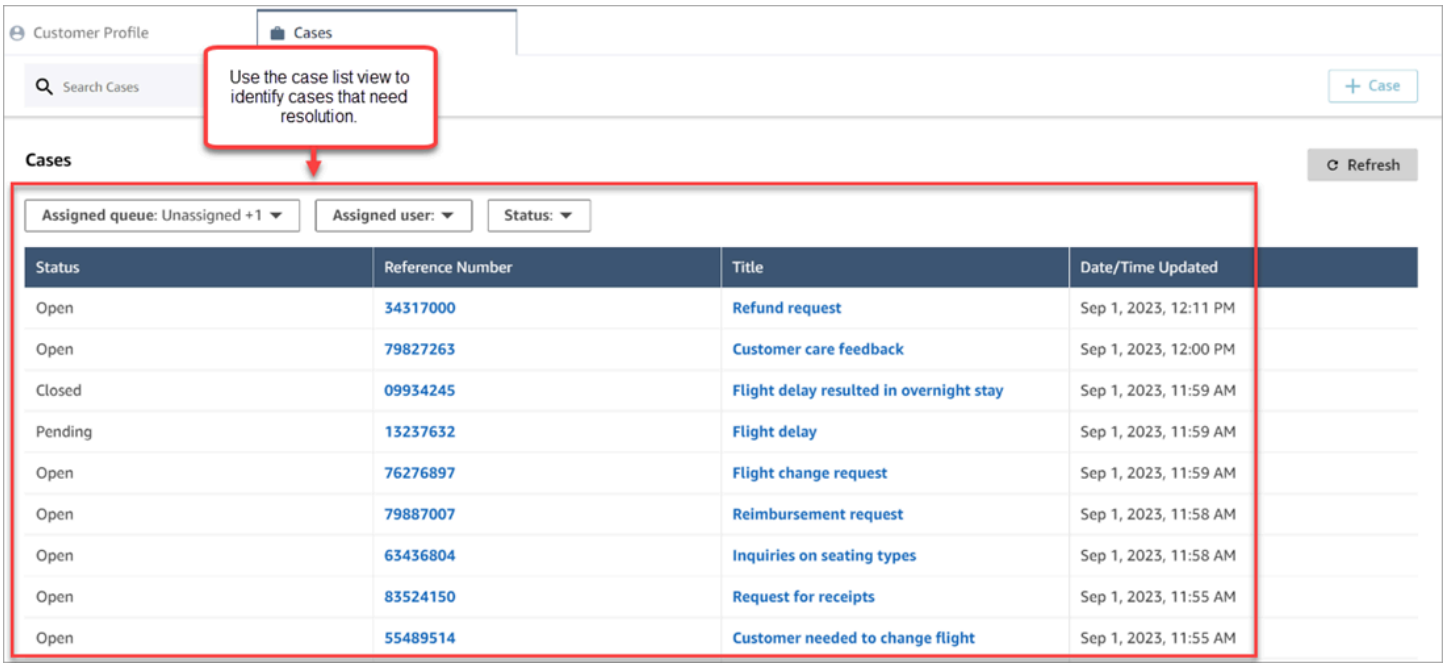
> **Note**
>
> You can create a case template and not link it to a case layout. Any case created with a case template that is not linked to a case layout will display system fields in a default order.

Set up a case assignment in Connect Customer Cases

To help your organization clearly track ownership of cases and resolve them faster, you can ensure every case has an assigned owner who is responsible for case resolution. The owner can be a queue or an individual user.

> **Note**
>
> Assigning a case owner does not route the case to the queue or the individual.

The following image shows the **Case list** view in the agent workspace. You can filter by unassigned cases, for example, and assign ownership as needed. The default view is set to cases assigned to the agent who is viewing the list.



Topics

- Set up agents and flows case assignment
- How agents assign case ownership
- How to configure the Cases block to assign case ownership in a flow

Set up agents and flows case assignment

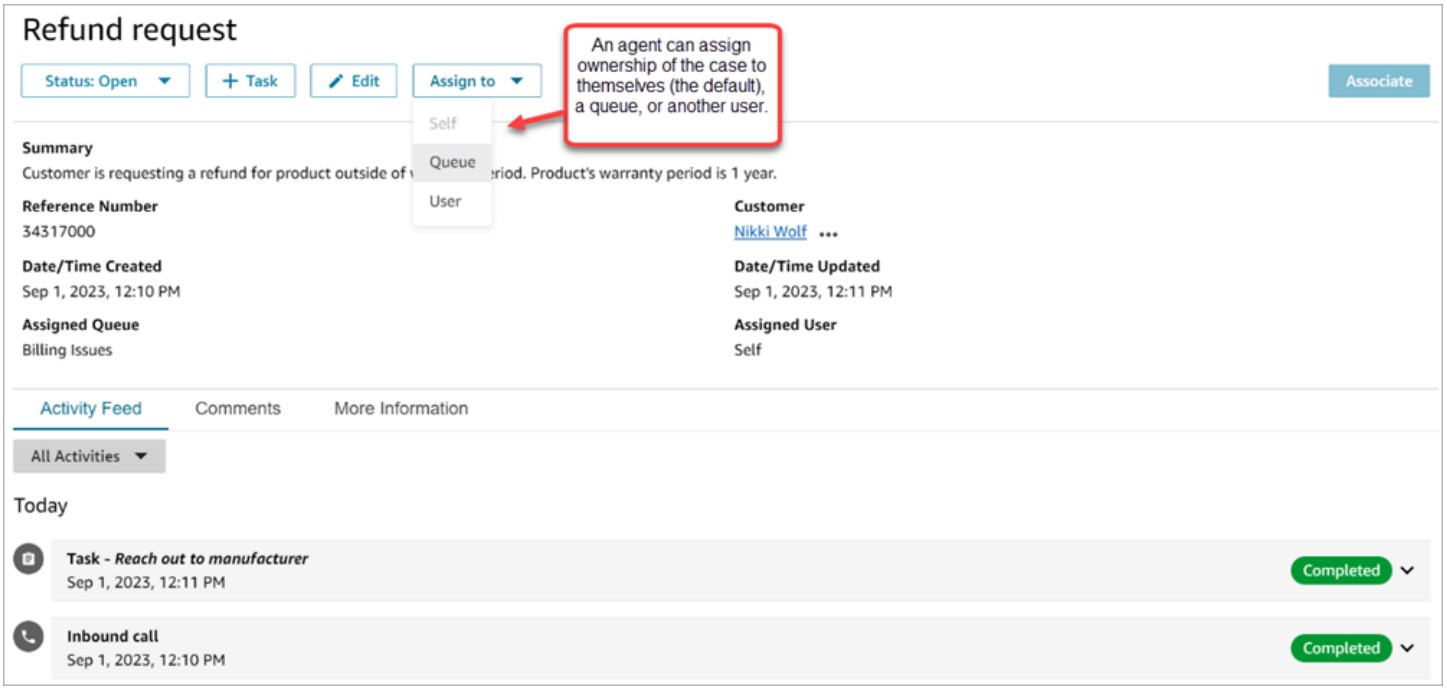
To enable case assignment in your Connect Customer instance, configure the following resources:

1. **Case template**. Add the following system case fields to a new or existing case template:
   - Assigned queue
   - Assigned user
2. To enable agents to assign case ownership in the agent workspace:
   - **Security profile**. Grant agents permission to view the queues, users, and quick connects that are going to appear in the dropdown lists in the agent workspace. For more information, see Required queue, quick connect, and user view permissions.
   - **Quick connects**. Create user and queue quick connects for each user and queue that you want to appear in the dropdown lists. For instructions, see Create quick connects in Connect Customer.
   - **Queues**. Add the quick connects to the agent's queue. For instructions, see Create a queue using the Connect Customer admin website.
   - **Routing profile**. Add the queue to the agent's routing profile. For instructions, see Create a routing profile in Connect Customer to link queues to agents.

     Agents see only those quick connects that are added to the queues assigned to their routing profile.
3. To configure the Cases block to assign case ownership automatically during a flow, set the **Request Fields** section to **Assigned Queue** or **Assigned User**. For an image and more instructions, see How to configure the Cases block to assign case ownership in a flow.

How agents assign case ownership

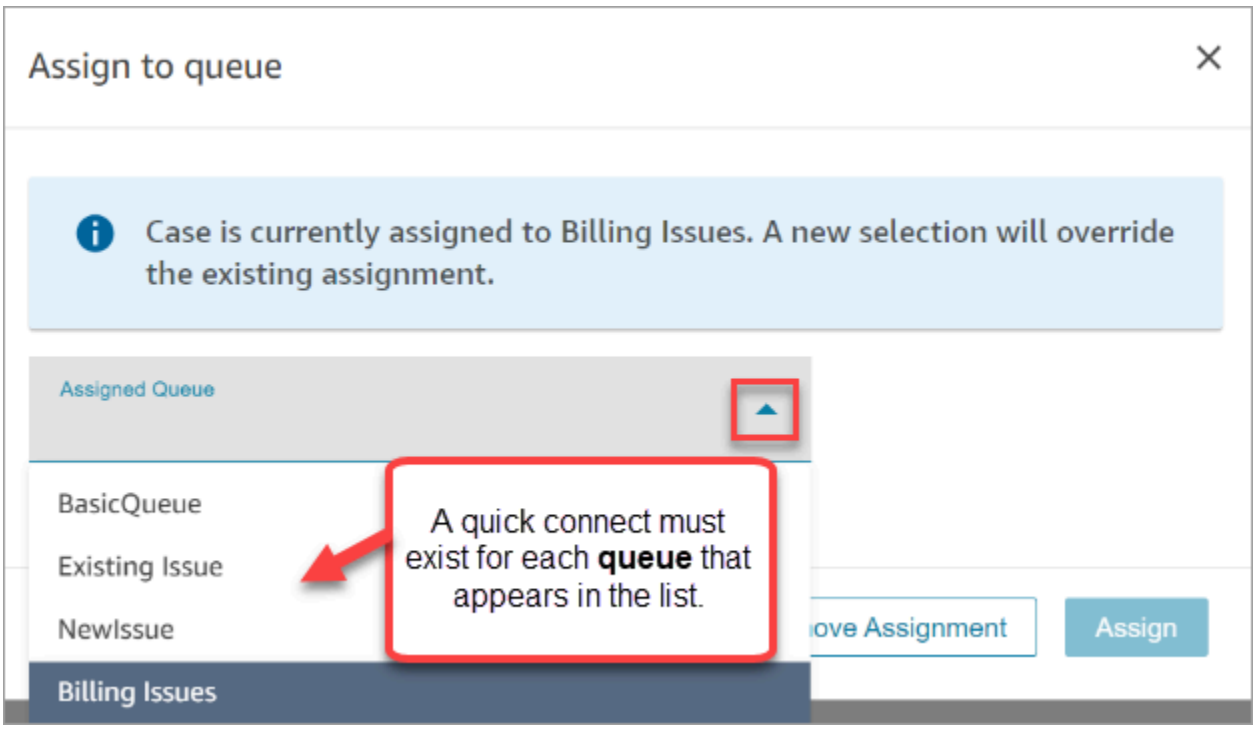
The following image shows the agent workspace. Agents choose the **Assign to** dropdown box to assign ownership of a case to themselves (the default option), a queue, or another user.



If agents assign ownership of a case to a queue or another user, they are presented with a prompt to choose from a filtered list of queues or users. The filtered list of available queues or users is based on the quick connects in the agent's routing profile.

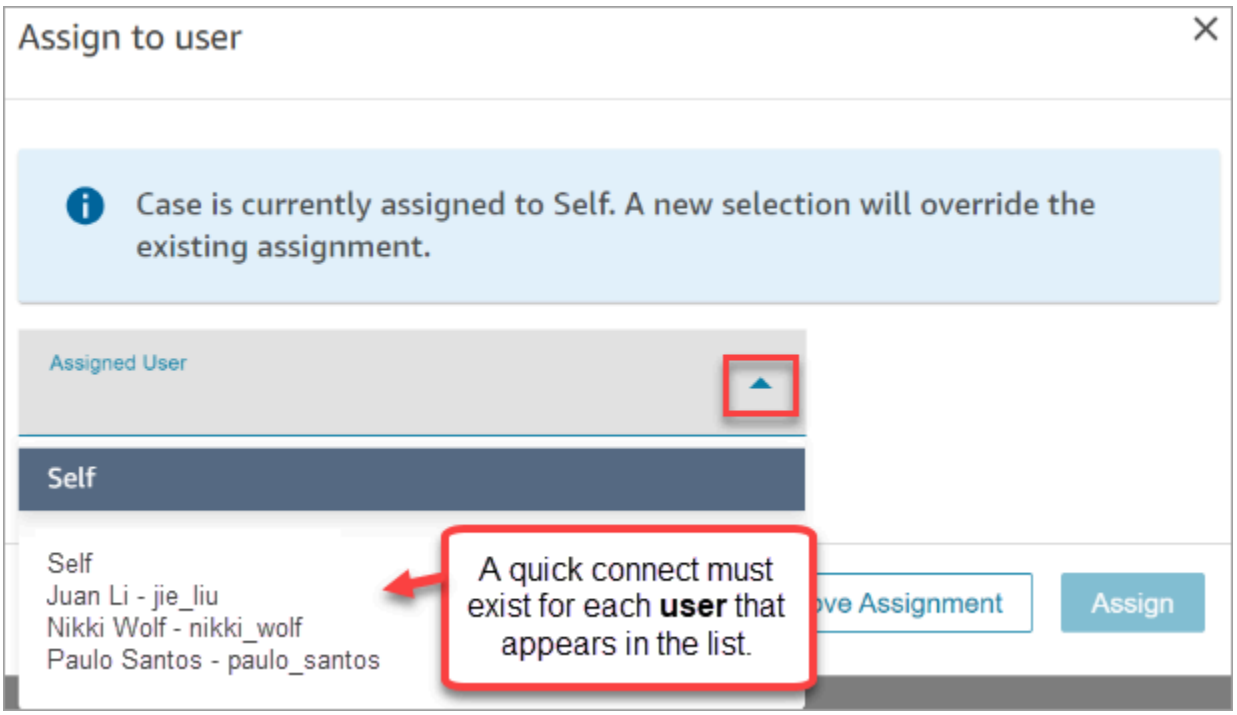
Assign to queue

The following image shows an example dropdown list of queues in the agent workspace. For this list of queues to be displayed to an agent: create a quick connect for each queue, and then add the queue to the agent's routing profile.



Assign to user

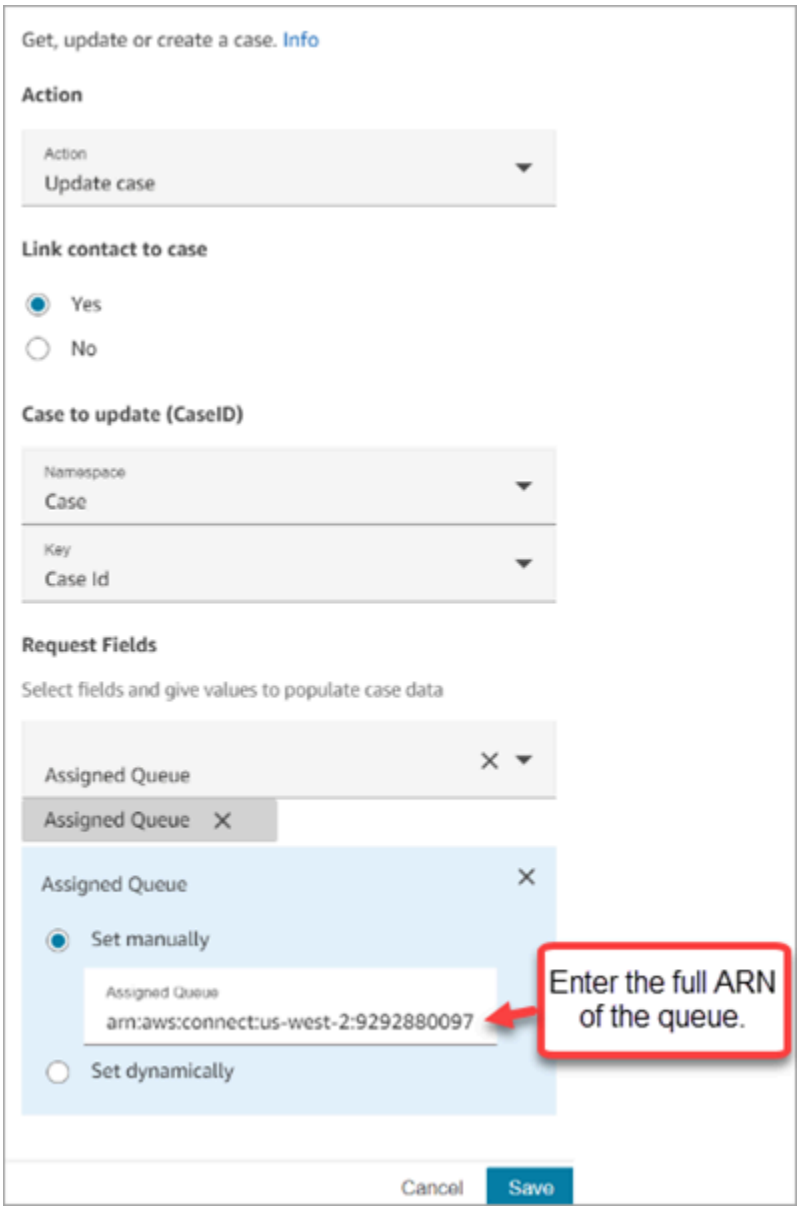
The following image shows an example dropdown list of users in the agent workspace. For this list of users to be displayed to an agent: create a quick connect for each user, assign the quick connects to the queue, add the queue to the agent's routing profile.



How to configure the Cases block to assign case ownership in a flow

You can configure the Cases block to automatically populate the **Assigned queue** or **Assigned user** ownership fields. When agents view the case in the agent workspace, the case ownership is already set. Agents can override the assignment as needed, but are restricted to the queues and users that are available in their routing profile.

The following image shows an example of the Properties page for the **Cases** block. The **Request Fields** section is configured to **Set manually**, **Assigned queue**. You must enter the full ARN of the queue.



There are situations where you might want to set the assigned queue or assigned user dynamically. For example, when the customer enters a DTMF number for a fraud issue, you can create cases where the Fraud department is automatically set as the case owner.

Access Connect Customer Cases in the agent workspace

After you enable Connect Customer Cases, you need to take steps to make the functionality available through the agent workspace. This topic explains your options.

> **Tip**
>
> Make sure your agents have **Cases** permissions in their security profile so they can access Cases. For more information, see Security profile permissions for Cases.

Option 1: Use Cases with the CCP out-of-the-box

Cases is already embedded alongside the Contact Control Panel (CCP). Your agents will access the CCP and Cases in the same browser window using a link that looks like this:

- `https://instance-name.my.connect.aws/agent/`

If you access your instance using the **awsapps.com** domain, use the following URL:

- `https://instance-name.awsapps.com/connect/agent/`

For help finding your instance name, see Find your Connect Customer instance name.

Option 2: Embed Cases into a custom agent application

When you embed your Contact Control Panel (CCP), you have the option of showing or hiding the pre-built CCP user interface. For example, you might want to develop a custom agent application that has a user interface you design, with customized buttons to accept and reject calls. Or, you might want to embed the pre-built CCP that's included with Connect Customer into another custom app.

You can display the pre-built CCP user interface, or hide it and build your own. In both scenarios, you can incorporate Cases into your custom agent application by using public APIs provided by

Connect Customer. These APIs are built to provide you the flexibility to create the functionality and user experience that you want. For more information, see the Cases API documentation.

> **Tip**
>
> When you customize the agent's application, you determine what URL agents will use to access your custom agent application. This might be very different from the one provided by Connect Customer. For example, your URL could be https://example-corp.com/agent-support-app.

Export cases to CSV in Connect Customer Cases

When you search for cases in the agent workspace, you can select one or more cases and export them to a CSV file. The exported file contains the case field values you choose, formatted for use in spreadsheet applications such as Microsoft Excel or Google Sheets. This is useful for generating reports, sharing case data with stakeholders, or performing offline analysis.

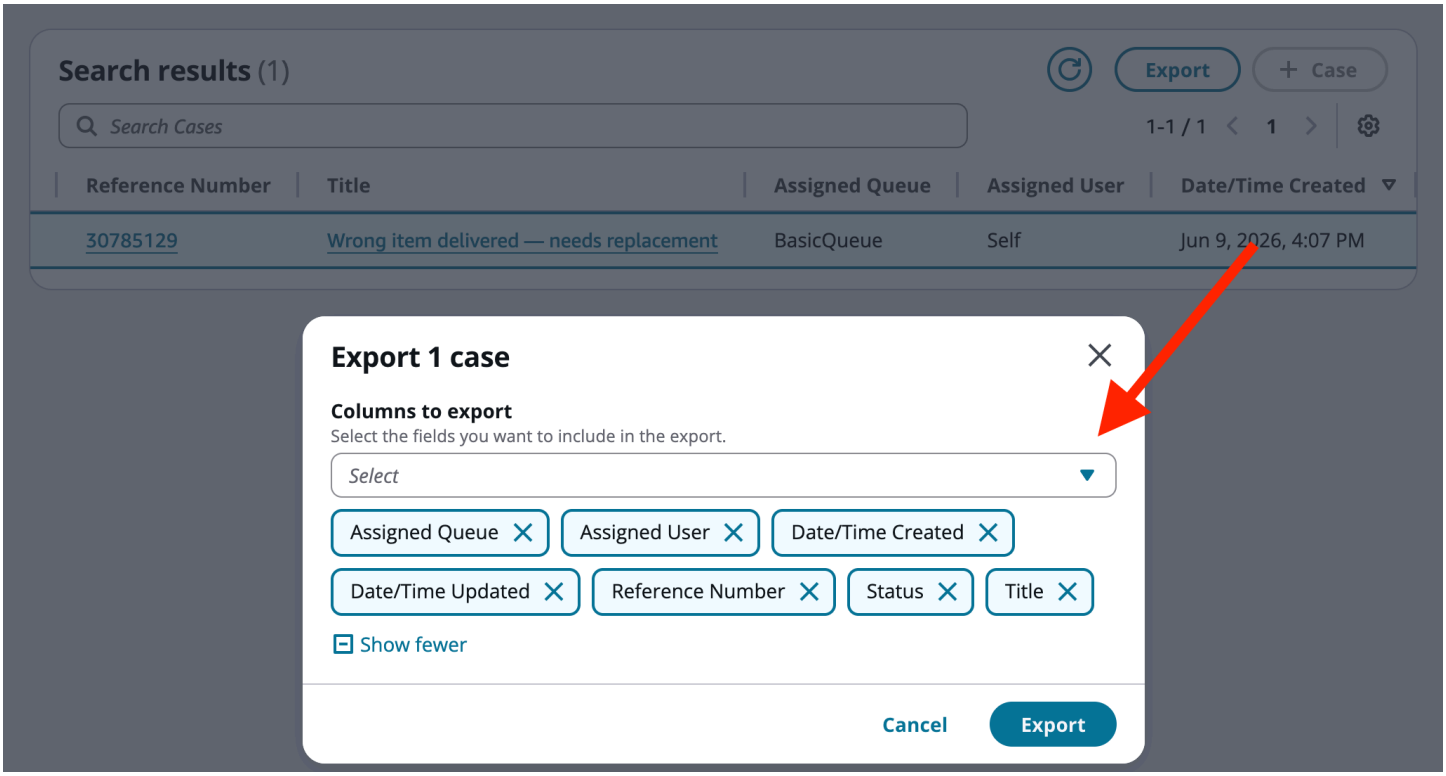
Prerequisites

To export cases, the agent's security profile must include the **Cases** - **Export** permission. Without this permission, the **Export** button is not displayed in the case search view. Enabling **Export** automatically grants the **View** permission for Cases if it is not already granted. For information about configuring security profiles, see Security profile permissions for Cases.

How to export cases

1. In the agent workspace, navigate to the case search view.
2. Use search filters to find the cases you want to export.
3. Select one or more cases using the checkboxes in the search results table.
4. Choose the **Export** button. The export modal opens and shows the number of cases selected.
5. In the export modal, choose the columns to include and then choose **Export**. For details, see Choose columns.

Choose columns to export



In the export modal, you can select which columns to include in the CSV file:

- By default, all columns currently displayed in the search results table are pre-selected.
- Use the **Columns to export** multiselect dropdown to add or remove fields. You can type to filter the list.
- You must select at least one column. The **Export** button is disabled when no columns are selected.

Choose **Export** to generate and download the CSV file, or choose **Cancel** to close the modal without exporting.

CSV file format

The exported CSV file has the following characteristics:

- **File name** — The file is named `Cases-export-YYYY-MM-DD.csv`, where the date reflects when the export was initiated.

- **Encoding** — UTF-8 with a byte order mark (BOM), which ensures correct character rendering when opening the file in spreadsheet applications.
- **Headers** — The first row contains the display name of each selected field as a column header.
- **Column order** — Columns appear in the same order as they are displayed in the search results table.

How field values appear in the CSV

The export supports all case field types. The following table describes how each type is formatted in the CSV output.

Field type	How it appears in the CSV
Text	Exported as-is.
Number	Formatted according to the agent's locale settings.
Date/time	Formatted using medium date style and short time style based on the agent's locale.
Boolean	Displayed as **True** or **False**.
Single-select	The option's display name is shown, not the internal value.
User	The user's display name is resolved and shown.
Queue	The queue's display name is shown.
Tags	All tags are joined with commas.

Fields with no value are exported as an empty cell.

Download and confirmation

After you choose **Export**, the CSV file downloads immediately to your browser's default downloads folder. A success banner confirms the export and displays the file name.

If the export fails, an error banner is shown. Choose **Export** again to retry.

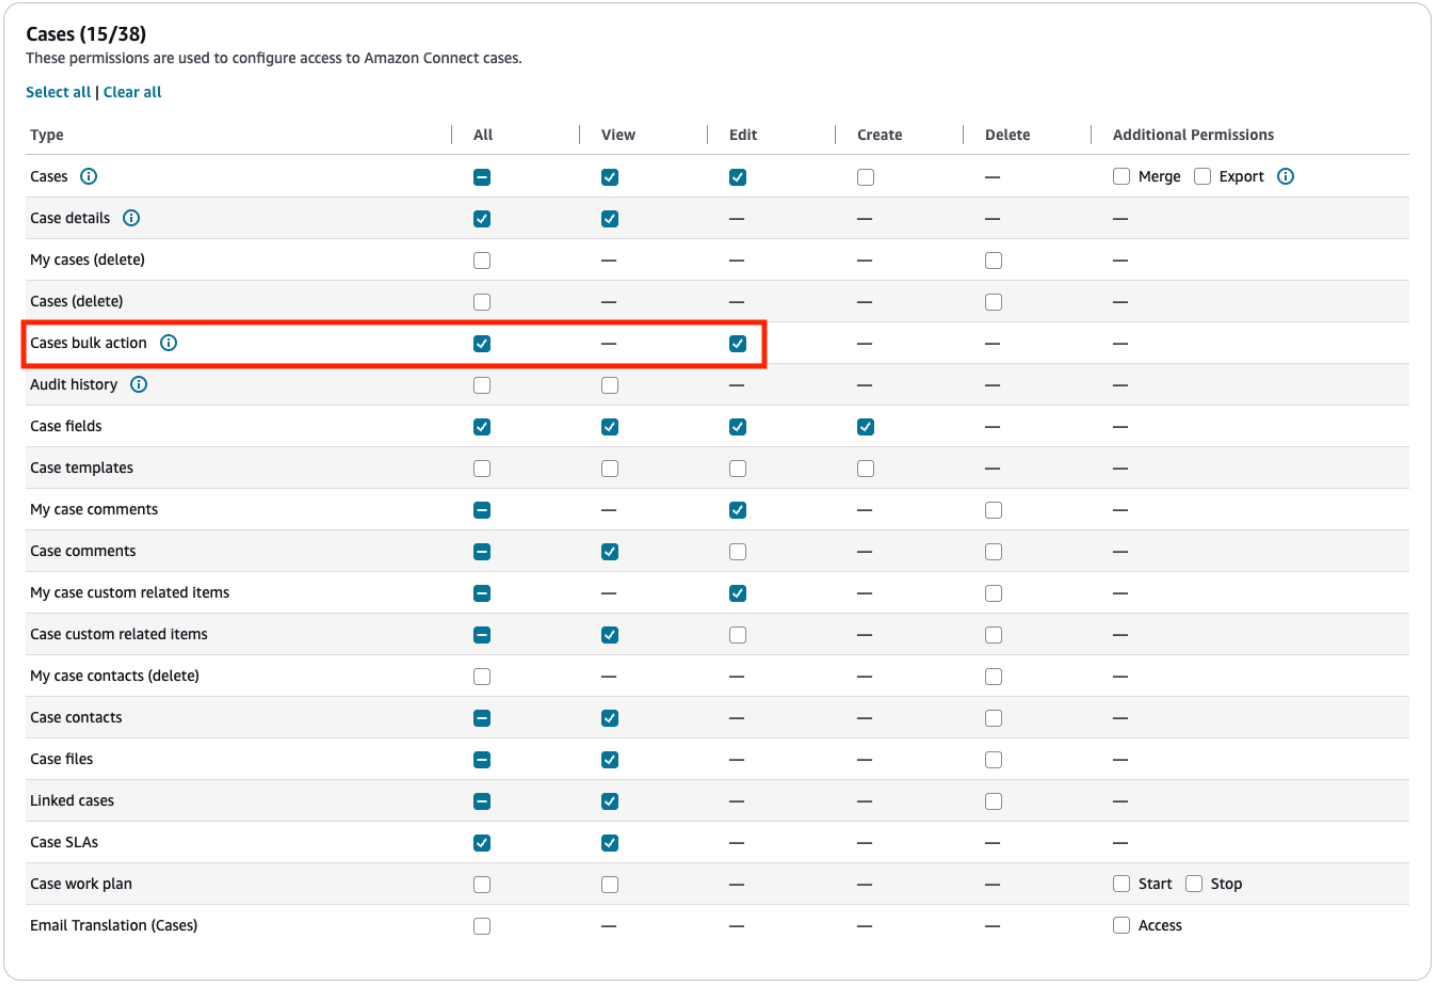
Batch actions on Cases

You can apply an action to multiple cases at the same time by using batch case actions, without opening and updating each case individually. You can assign cases, update their status, add a comment, or export selected cases as CSV. The actions available to you depend on your security profile permissions.

Prerequisites

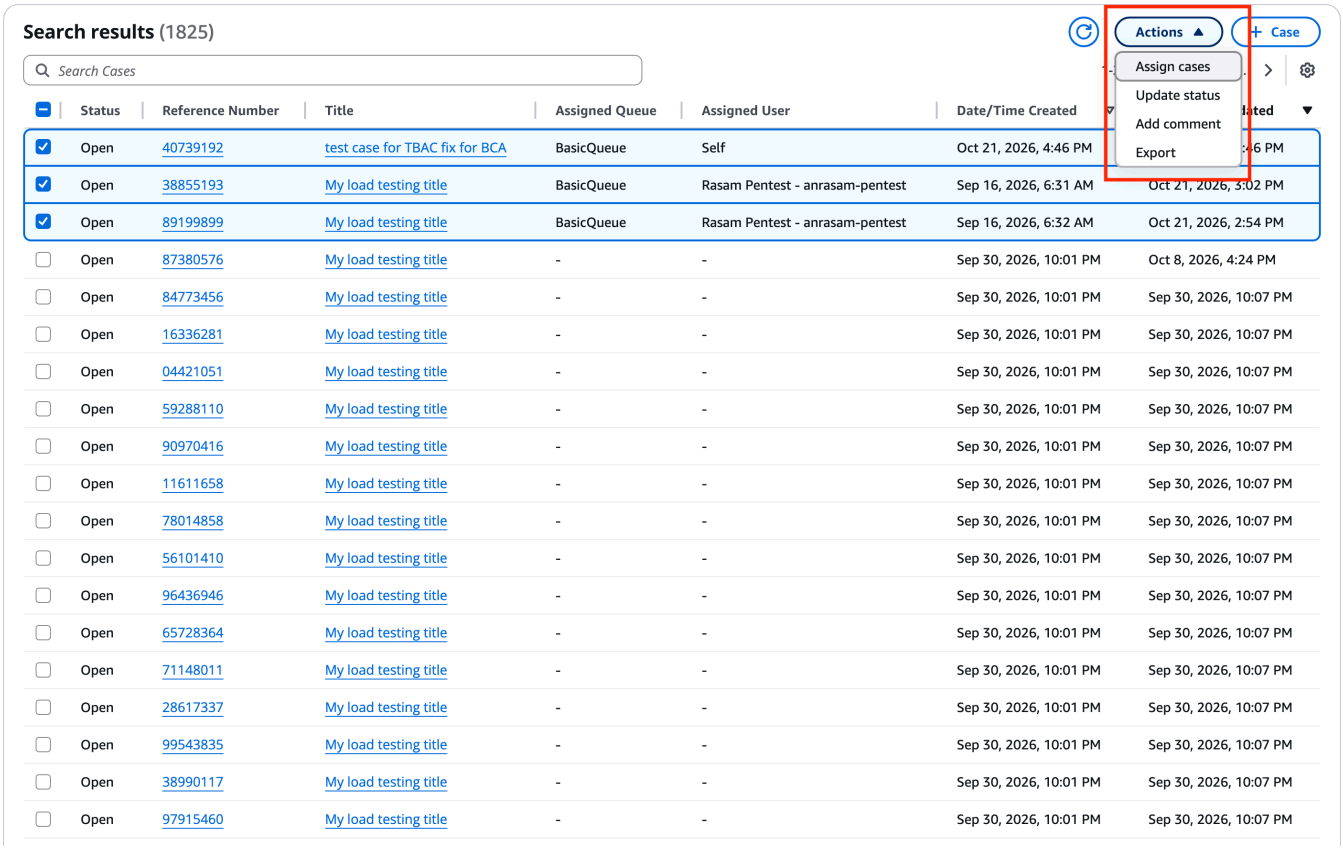
To use batch case actions, your security profile must include the **Cases** - **Cases bulk action** permission. Without this permission, the **Actions** dropdown is not available in the Cases search view. For information about configuring security profiles, see Security profile permissions for Cases.

The following image shows the **Cases bulk action** permission selected in a security profile.

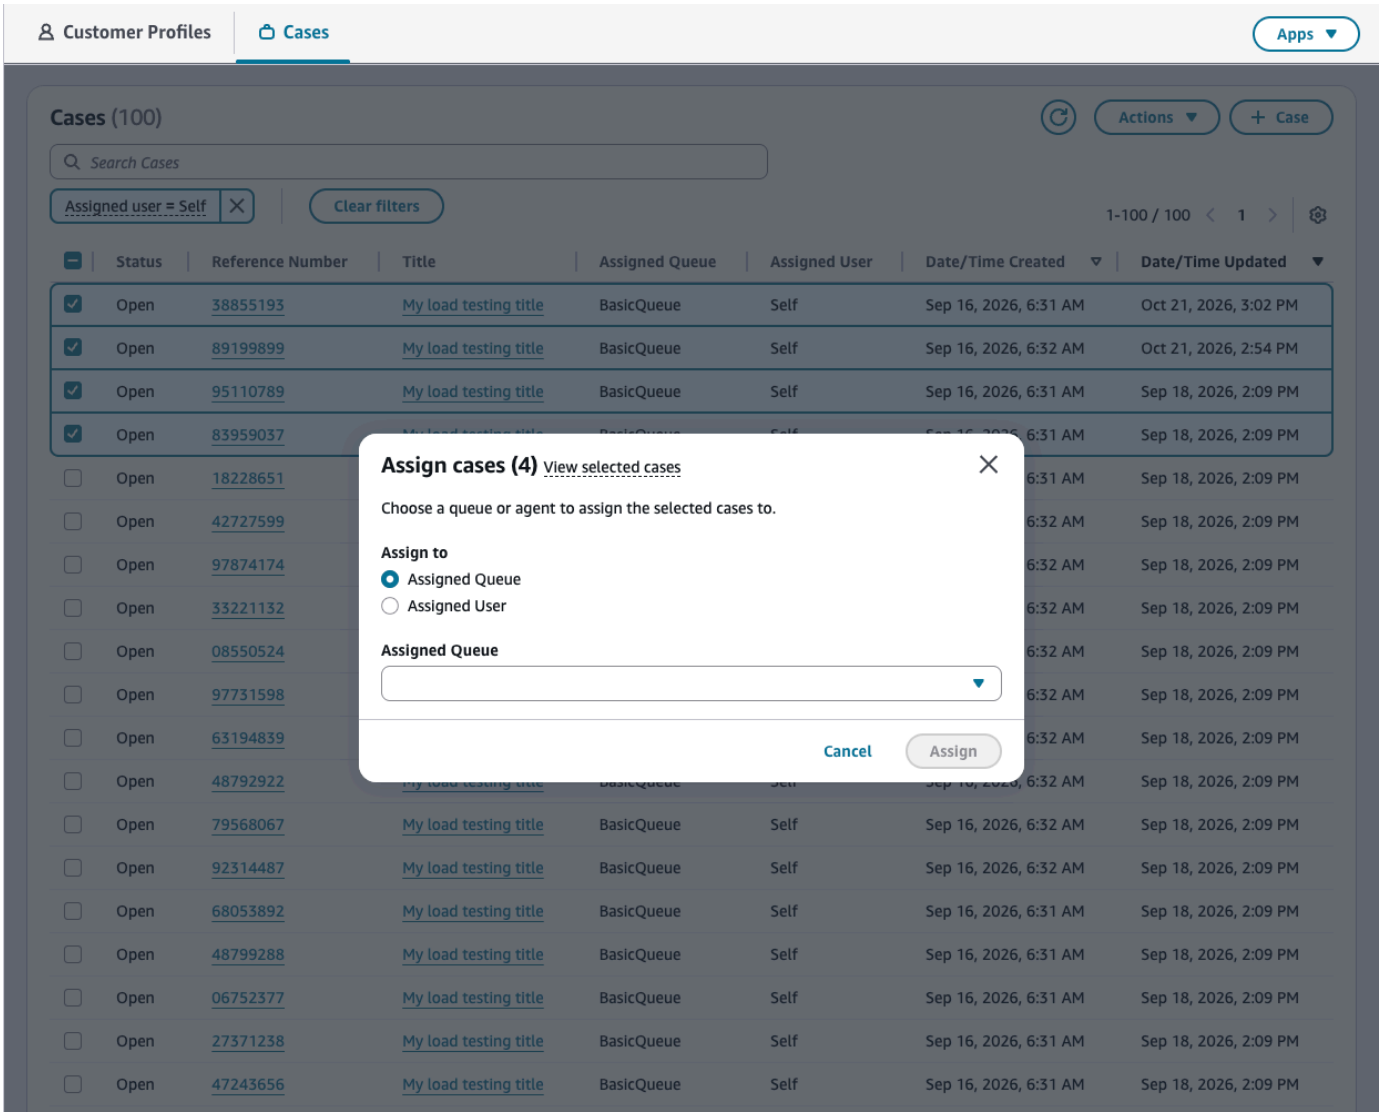


Batch case actions in the agent workspace

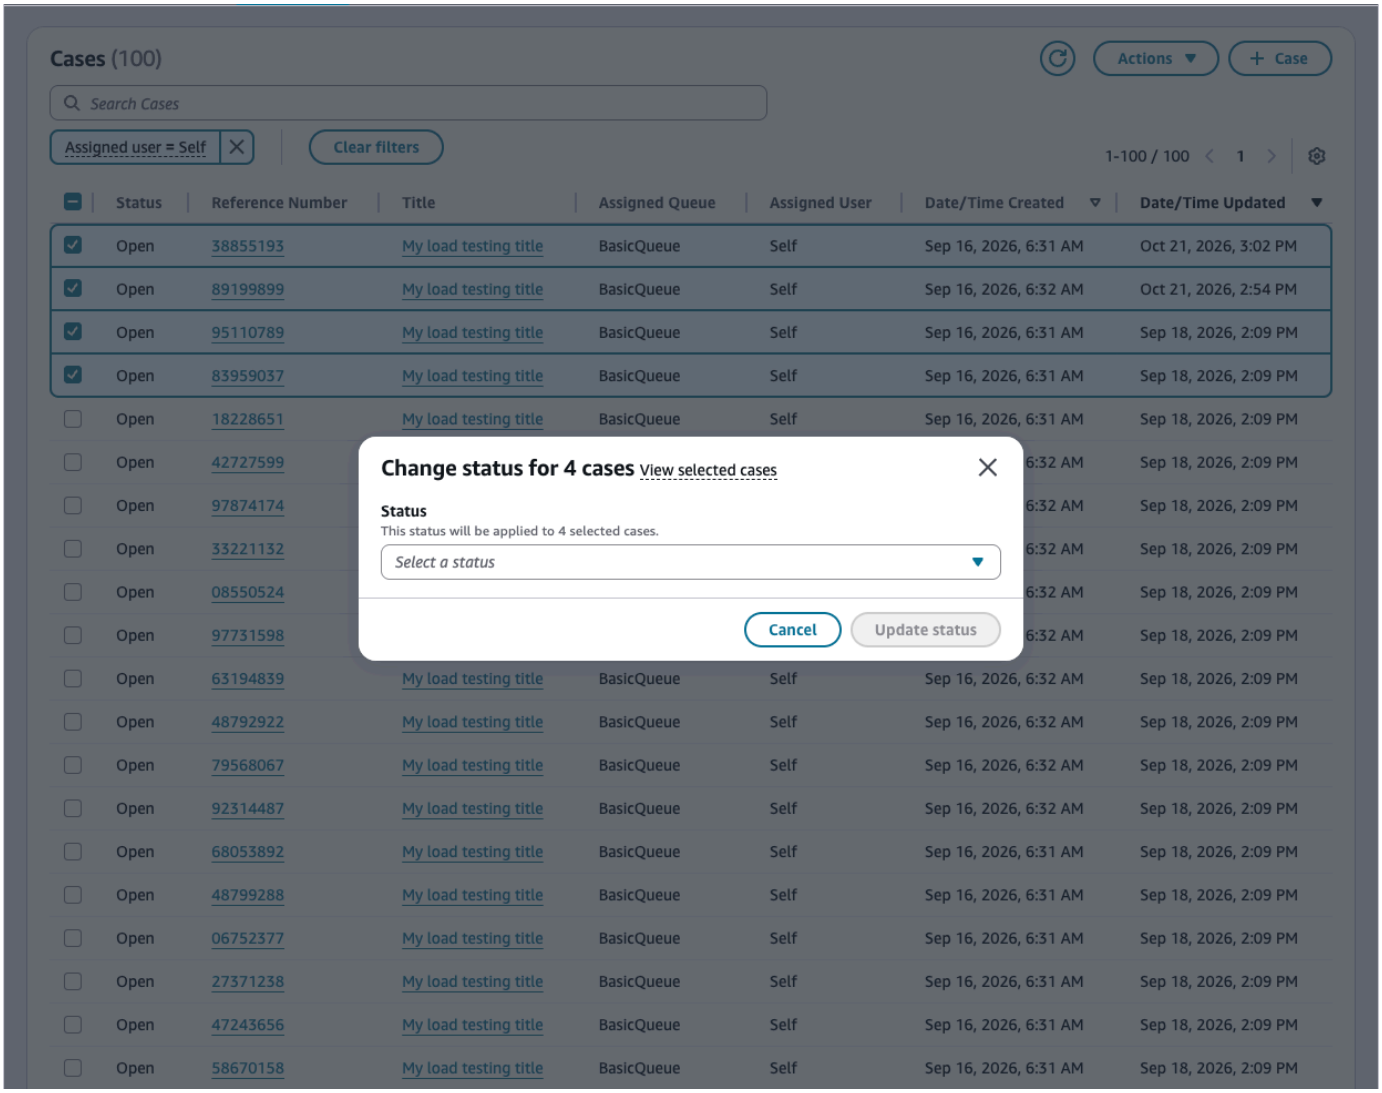
1. In the Cases search view, confirm that the **Actions** dropdown appears. You can assign cases, update status, or add comments. Search for the cases you want to act on.



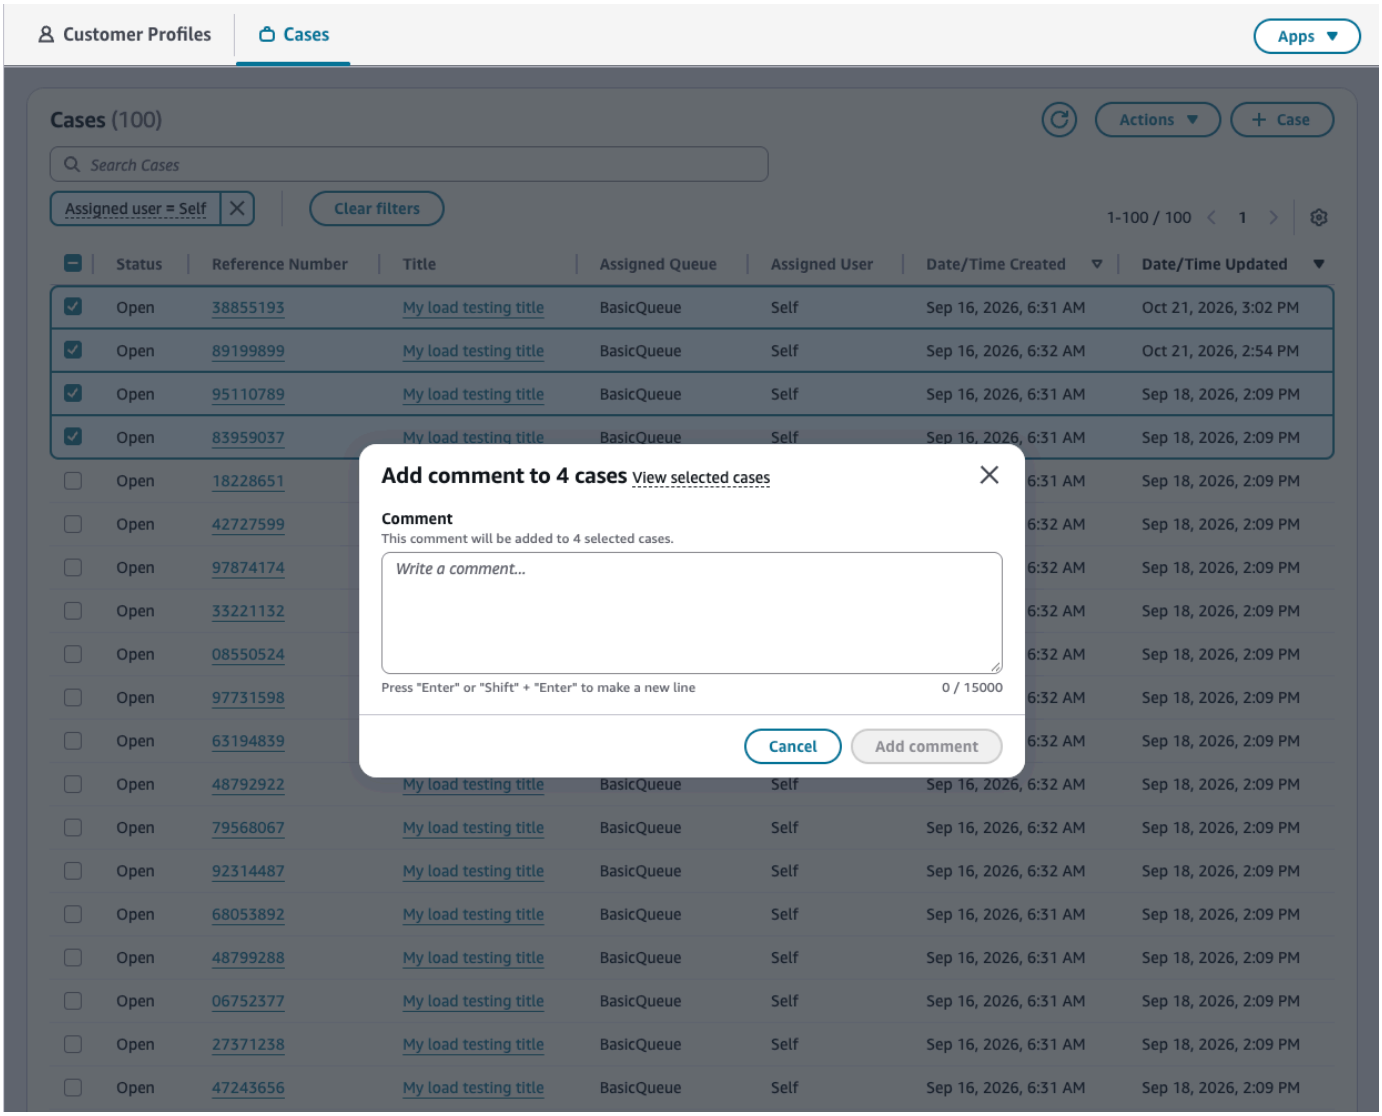
2. From the **Actions** dropdown, choose **Assign cases** to assign the selected cases to a user or queue.



3. From the **Actions** dropdown, choose **Update status** to change the status of the selected cases.



4. From the **Actions** dropdown, choose **Add comment** to add a comment to the selected cases.



Merge cases in Cases

Agents can merge cases in the agent workspace. You choose a *primary case*, which stays open, and a *secondary case*, which is merged into the primary case and then closed. The merge copies field values to the primary case, moves related items such as comments and contacts, links the two cases to each other, and records the merge in the audit history of both cases.

> **Important**
>
> You can't undo a merge. After a case is merged into another case, it can't be merged again.

Prerequisites

To merge cases, the agent's security profile must include the **Cases** - **Merge** permission. Without this permission, the **Merge** button is not displayed on the case details page. Enabling **Merge** automatically grants the **View** permission for Cases if it is not already granted. Agents don't need the **Edit** permission to merge cases. For information about configuring security profiles, see Security profile permissions for Cases.

If you use tag-based access control for cases, the agent must have access to both the primary case and the secondary case. For more information, see Set up tag-based access controls on cases.

Which cases can be merged

You can merge two cases when all of the following are true:

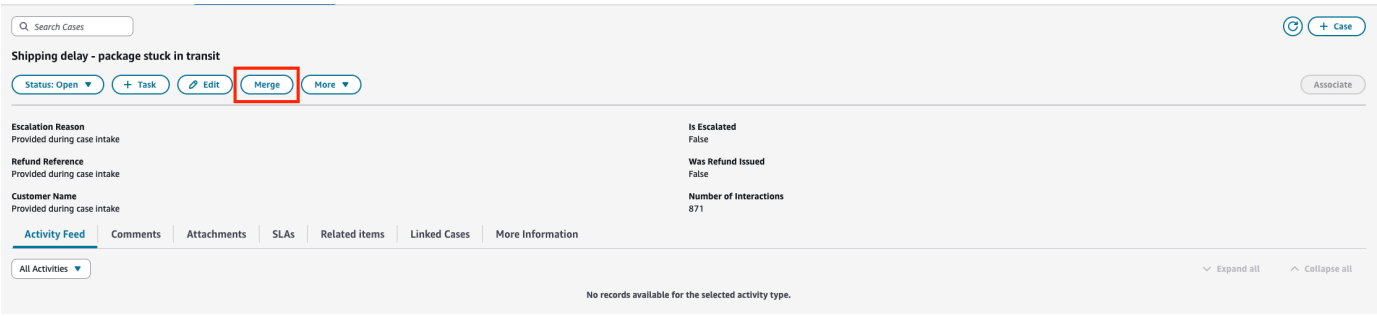
- Neither case is **Closed**.
- Both cases have the same customer, or at least one of the cases has no customer.
- Neither case is part of a merge that is still in progress.
- Neither case was previously merged into another case. A case that was the primary case in an earlier merge can be merged again.
- After the merge, the primary case doesn't have more than 500 field values and doesn't exceed the maximum case size.
- After the merge, the related items on the primary case, including the related items moved from the secondary case and the new link to the secondary case, don't exceed the quota for related items that can be attached to a case. For more information, see Connect Customer Cases service quotas.

The cases can use different case templates. The primary case keeps its case template.

You merge one secondary case into a primary case at a time.

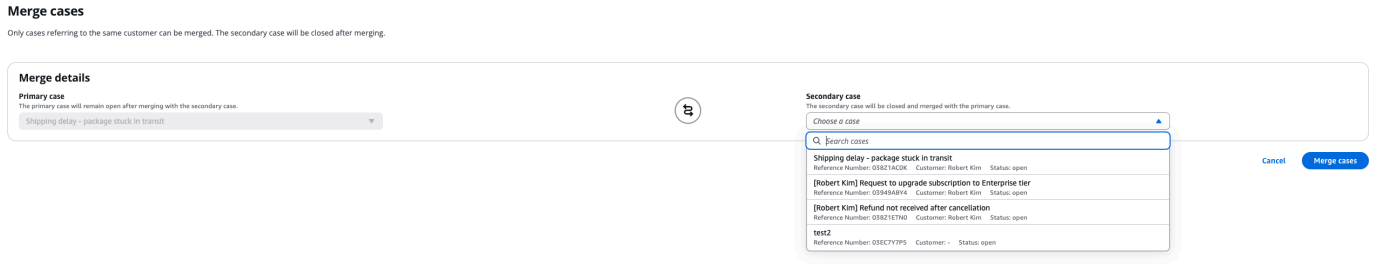
How to merge cases

1. In the agent workspace, open one of the cases that you want to merge.
2. On the case details page, choose **Merge**. If the button isn't displayed, choose **More**, and then choose **Merge**.



The **Merge cases** page opens in a new tab. The case that you started from is the **Primary case**.

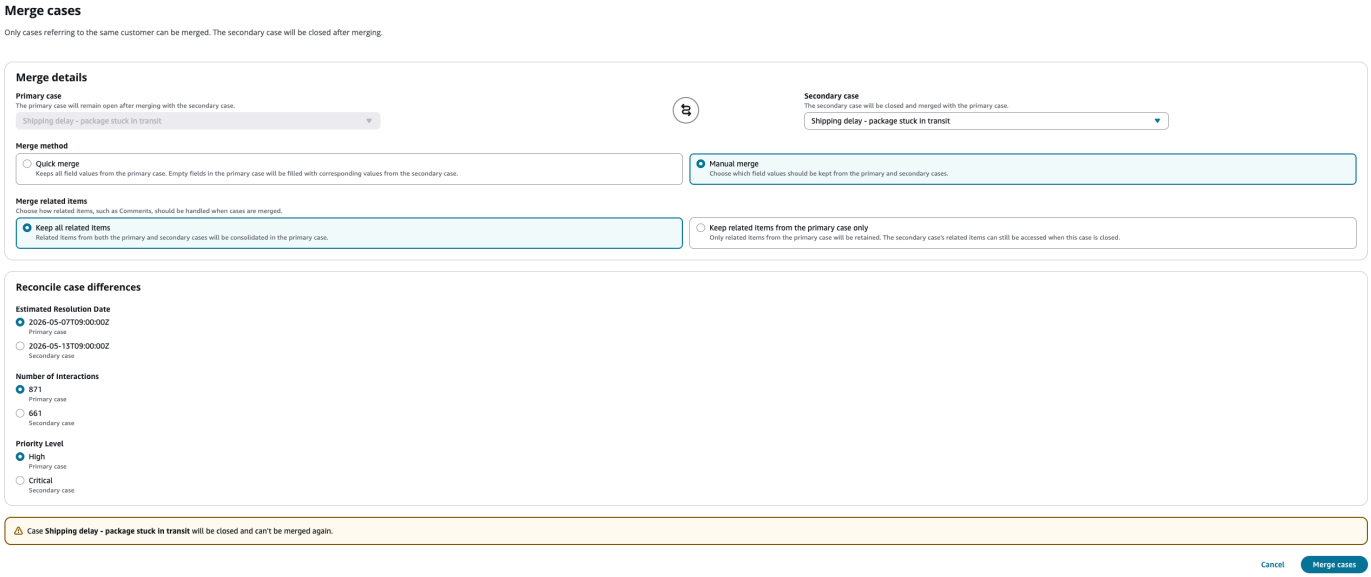
3. For **Secondary case**, choose **Choose a case**, and then search for and select the case to merge. The list shows only cases that are not closed and that have the same customer as the case you started from, or no customer.



To make the selected case the primary case instead, choose the swap icon (**Swap primary and secondary cases**).

4. For **Merge method**, choose one of the following:

   - **Quick merge** (default): Keeps all field values from the primary case. Empty fields on the primary case are filled with the values from the secondary case.
   - **Manual merge**: Under **Reconcile case differences**, for each field where the two cases have different values, choose whether to keep the value from the **Primary case** or the **Secondary case**. Each field defaults to the primary case's value. Empty fields on the primary case are filled with the values from the secondary case.



5. For **Merge related items**, choose one of the following:

   - **Keep all related items** (default): Moves supported related items from the secondary case to the primary case. For details, see What is merged.
   - **Keep related items from the primary case only**: No related items are moved. The related items of the secondary case stay on the secondary case after it's closed.

6. Review the warning that the secondary case will be closed and can't be merged again, and then choose **Merge cases**.

   The **Merge cases** tab closes and the merge runs in the background.

What is merged into the primary case

Fields

- The merge applies to custom fields and to the following system fields: assigned queue, assigned user, summary, and case reason. Other system fields, such as status, title, customer, and reference number, keep the primary case's values.
- For each of these fields, the primary case keeps its value unless you chose the secondary case's value in a manual merge. If the field is empty on the primary case, it's filled with the value from the secondary case.

- Field values are read from both cases when the merge runs, so changes made to the primary case after the merge starts are taken into account.

Related items

The following table describes what happens to the related items of the secondary case when you choose **Keep all related items**.

Related item	What the merge does
Comments, contacts, custom related items, and linked cases	Moved from the secondary case to the primary case. Tags on these items are kept, except tags whose keys start with `aws:`.
A contact that is on both cases	Kept once, on the primary case. Tags that exist only on the secondary case's copy are added to it.
A linked case that the primary case is already linked to	Removed from the secondary case. The primary case keeps its existing link.
Files, SLAs, and other related item types	Not moved. They stay on the secondary case.

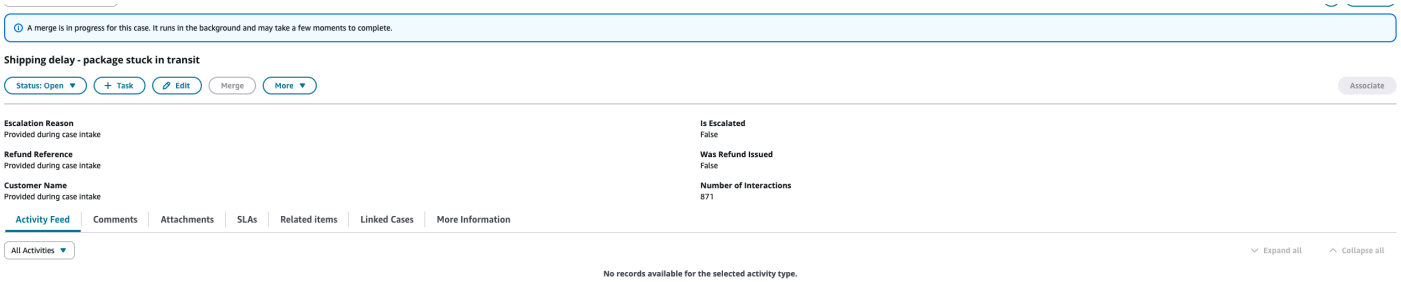
Case links and status

- The primary and secondary cases are linked to each other. Each case shows the other case on its **Linked Cases** tab.
- The secondary case is closed.
- The merge doesn't change the tags on either case.

Primary and secondary cases during and after a merge

A merge runs in the background. It can take a few moments, and longer for cases with many related items. While a merge is in progress:

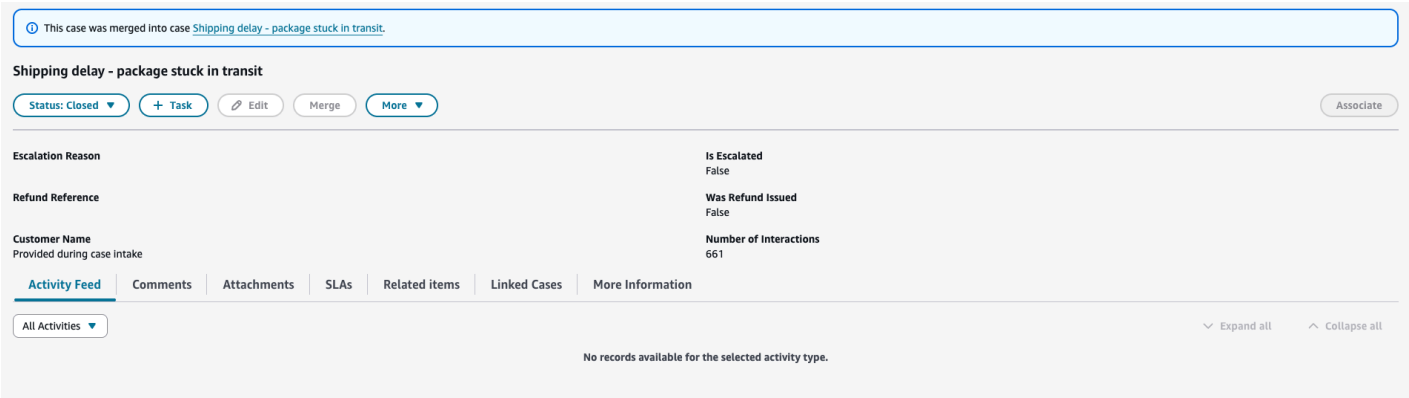
- The primary case shows the banner **A merge is in progress for this case**. Agents can continue to edit the primary case, but they can't delete it or include it in another merge.



- The secondary case shows the banner **This case is currently being merged**. Agents can't edit, delete, or take any other action on the secondary case until the merge is complete.

After the merge completes:

- The primary case can be edited, deleted, and merged like any other case.
- The secondary case is closed and shows a banner that links to the case it was merged into. Agents can reopen, edit, or delete the secondary case like any other case, but they can't merge it again, either as a primary case or as a secondary case.



Merges in case audit history

Each case keeps its own audit history. The merge adds entries to the audit history of both cases for the changes it makes, such as the field updates on the primary case and the closed status on the secondary case. Both cases also get a summary entry for the merge.

In the GetCaseAuditEvents API, the summary entry has the type `Case.Merged`. Audit events created by a merge include a `mergeMetadata` object with a `mergeEventId`, the `primaryCaseId`, and the `secondaryCaseId`. Use the `mergeEventId` to group all the audit events from the same merge.

APIs to merge cases

You can also merge cases by using the Connect Customer Cases API:

- StartMergeCases: Starts merging a secondary case into a primary case. The merge runs asynchronously. The request is rejected with a `ConflictException` if either case is part of a merge that is in progress or was previously merged into another case.
- GetMergeCasesStatus: Returns `IN_PROGRESS` for both cases while a merge runs, and `COMPLETED` for the secondary case after the merge finishes. For any other case, including the primary case after the merge finishes, it returns a `ResourceNotFoundException`.

How SLAs work in Connect Customer Cases

Service Level Agreements (SLAs) in Amazon Connect Cases are a type of related item that can be associated with a case. With SLAs, you can track service goals for your contact center, specifying that particular types of cases should reach certain milestones within set timeframes.

Understanding SLAs in Cases

Case SLAs in Amazon Connect consist of the following components:

- **SLA name**: The identifier for the SLA in the UI and API responses.
- **Target date and time**: The deadline by which the case needs to progress to the target status. This can be configured up to 90 days.
- **Target value**: The field value that the case needs to be updated to for the SLA to be considered fulfilled.
- **SLA status**: The current fulfillment status of the SLA. Possible statuses include:
  - Active: SLA not yet fulfilled, but target time not reached
  - Met: SLA fulfilled before target time
  - Not met: SLA fulfilled after target time exceeded
  - Due soon: SLA not fulfilled, target time less than 24 hours away
  - Overdue: SLA not fulfilled, target time already exceeded
- **Time to breach**: For unfulfilled SLAs, the time remaining until the target date and time is exceeded. For overdue cases, this continues to run negative until the target value is achieved.

Adding SLAs to Cases

You can associate SLAs with cases in two ways:

- **Automatically**: Use conversational analytics rules to add SLAs to cases that meet specified conditions (case template and field values) for Case Creation and Update rules. For more information, see Automatically monitor and update cases in Connect Customer Cases.
- **Manually**: Use the CreateRelatedItem API to add an SLA related item to a case.

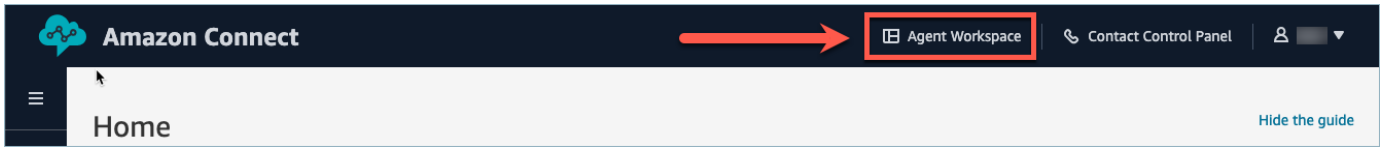
Viewing SLAs on Cases

Managers and agents can view case SLAs in the agent workspace to prioritize cases and identify those at risk of missing service goals.

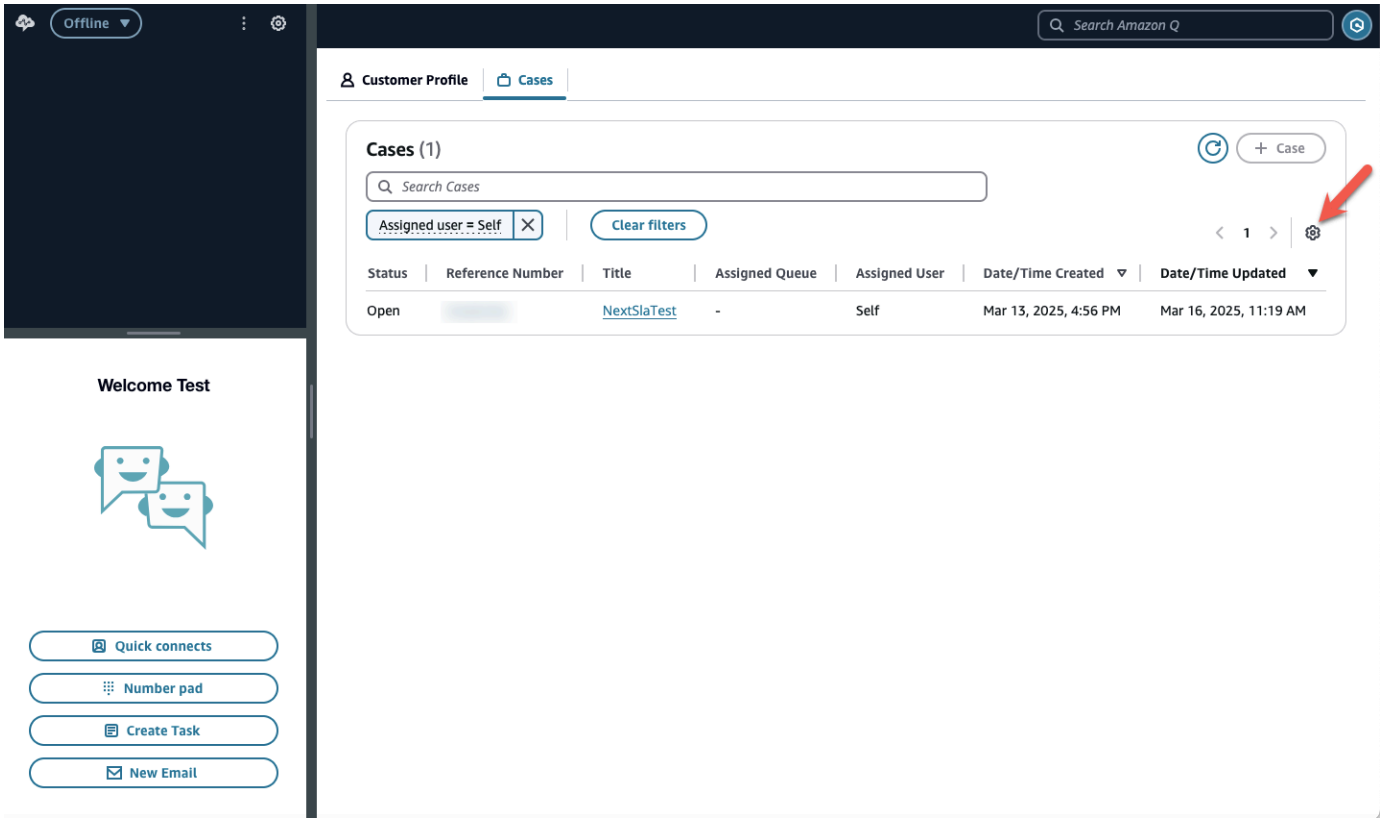
Case summary page

To add SLA information to the case list view:

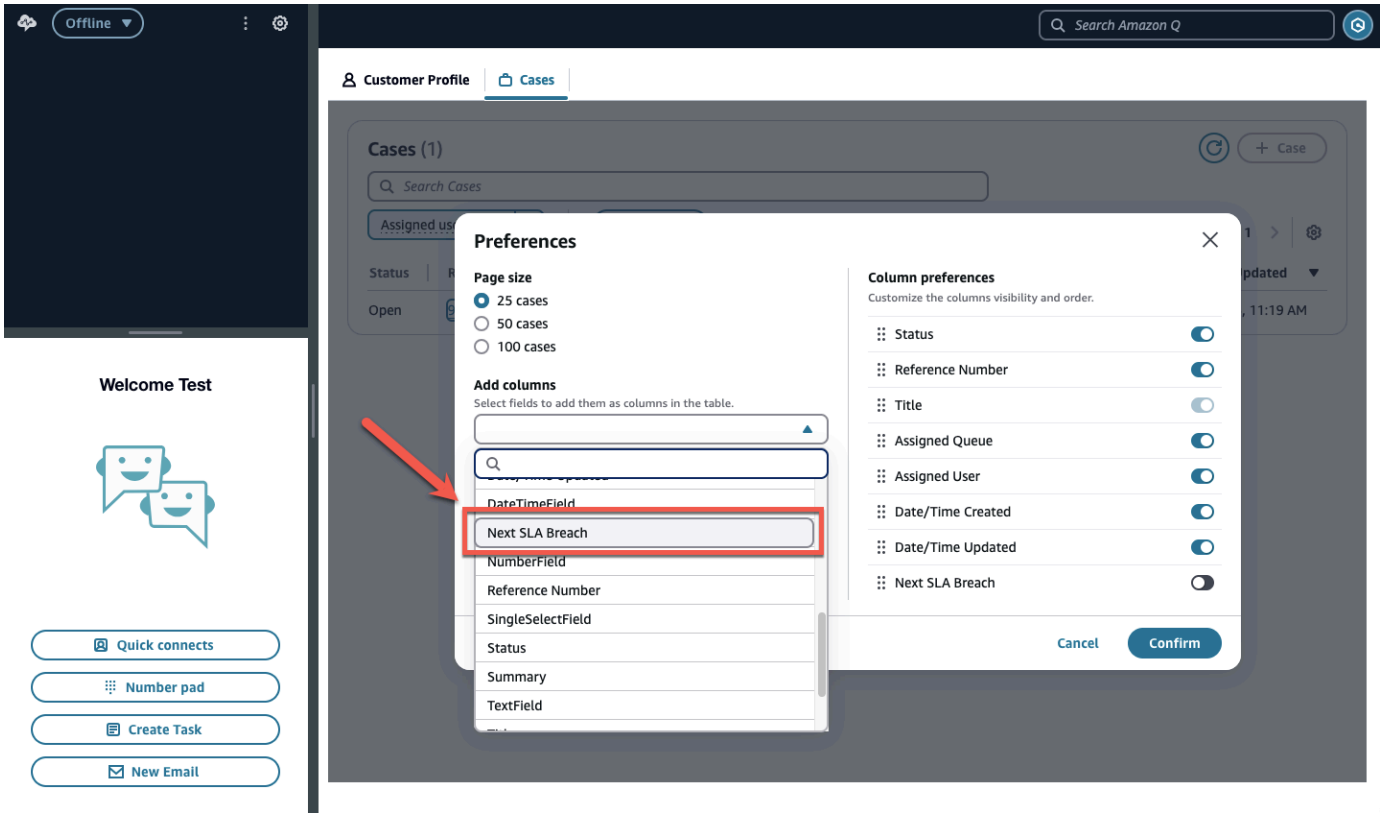
1. Log in to the Connect Customer admin website at https://*instance name*.my.connect.aws/.
2. Open the **Agent Workspace**.



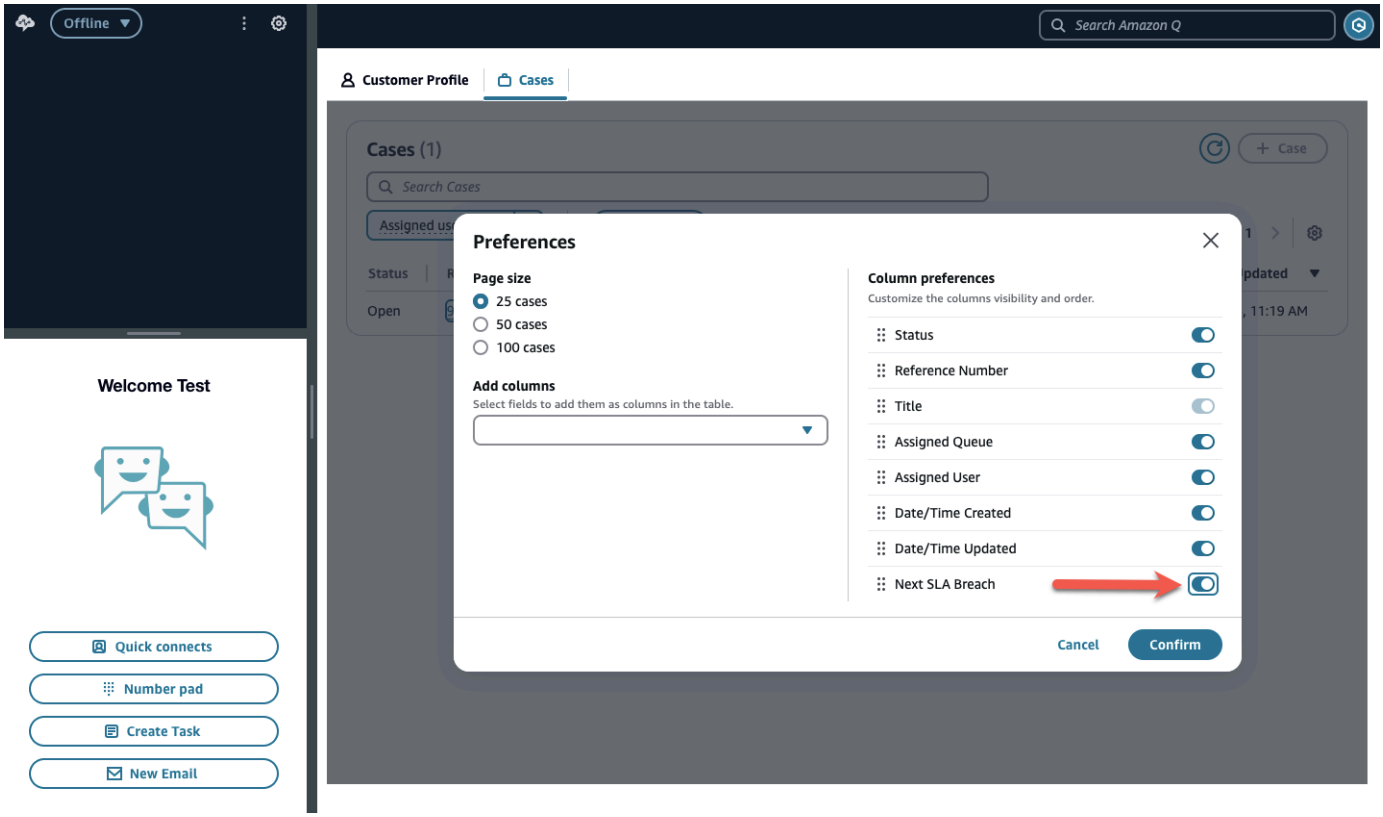
3. Choose the gear icon in the top right of the table.



4. Add the **Next SLA Breach** field to the active list.



5. Toggle the field from inactive to active.



> **Note**
>
> These settings persist unless you clear your cookies.

Case detail page

For cases with active SLAs:

- A badge notification appears next to the case title, showing the time until the next active SLA will breach.
- An SLAs section below the case details lists all active and completed SLAs associated with the case, including:
  - SLA name
  - Status
  - Target date and time
  - Completion date and time (if applicable)

- Time to breach (if applicable)

Automating Actions for Breached SLAs

You can use conversational analytics rules to trigger automated actions when SLAs reach their target completion time without being met:

1. In the conversational analytics rules interface, add a new rule with the trigger based on **Case SLA Breach**.
2. Specify which SLA names the **Breach rule** should apply to.

For more information, see Automatically monitor and update cases in Connect Customer Cases in the Amazon Connect documentation.

Automatically monitor and update cases in Connect Customer Cases

You can easily set up case notifications and automation. You can create rules that automatically run whenever a case is created or updated. You can create rules that:

- Assign service level agreements to cases
- Create tasks
- End associated tasks
- Update cases
- Send email alerts to Connect Customer users

For example, you can set up an alert that automatically sends an email to a manager when a high-priority case is created or updated.

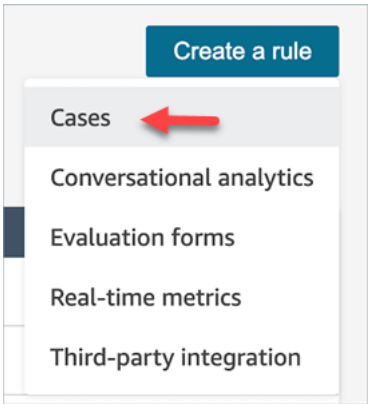
> **Tip**
>
> A developer needs to enable this feature. For instructions, see Allow Connect Customer Cases to send updates to conversational analytics rules.

Topics

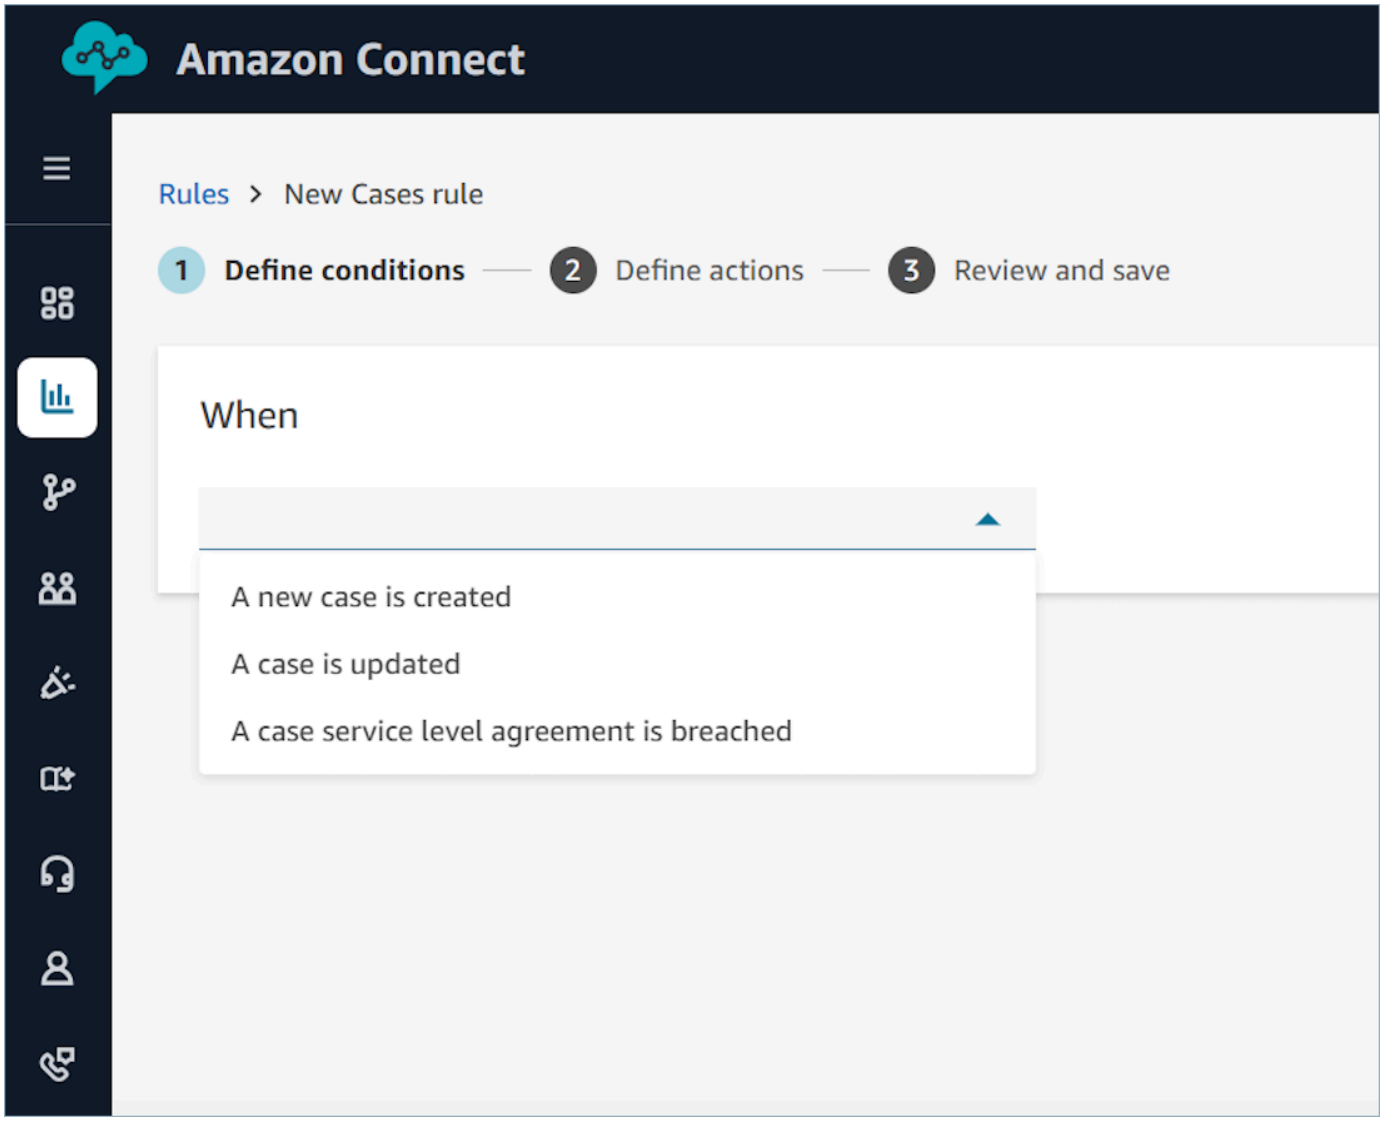
- Step 1: Define rule conditions
- Step 2: Define rule actions

Step 1: Define rule conditions

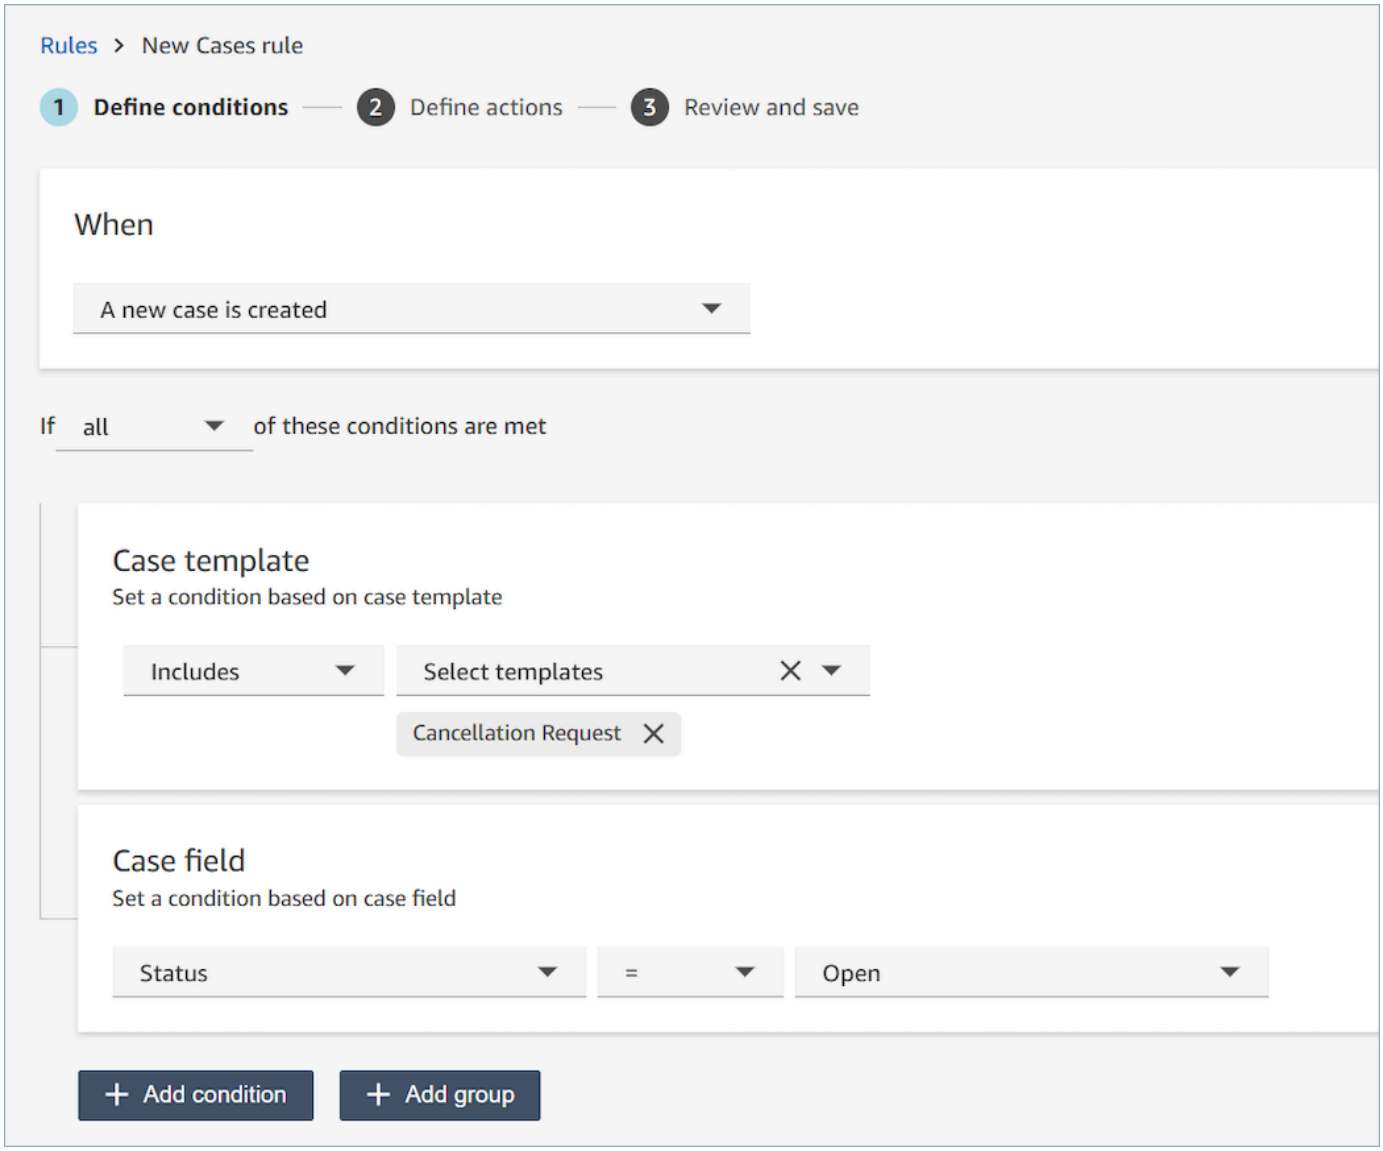
1. On the navigation menu, choose **Analytics and optimization**, **Rules**.
2. Select **Create a rule**, **Cases**.



3. Under **When**, use the dropdown list to choose from two event sources: **A new case is created**, **A case is updated**, or **A case service level agreement is breached**. These options are shown in the following image.

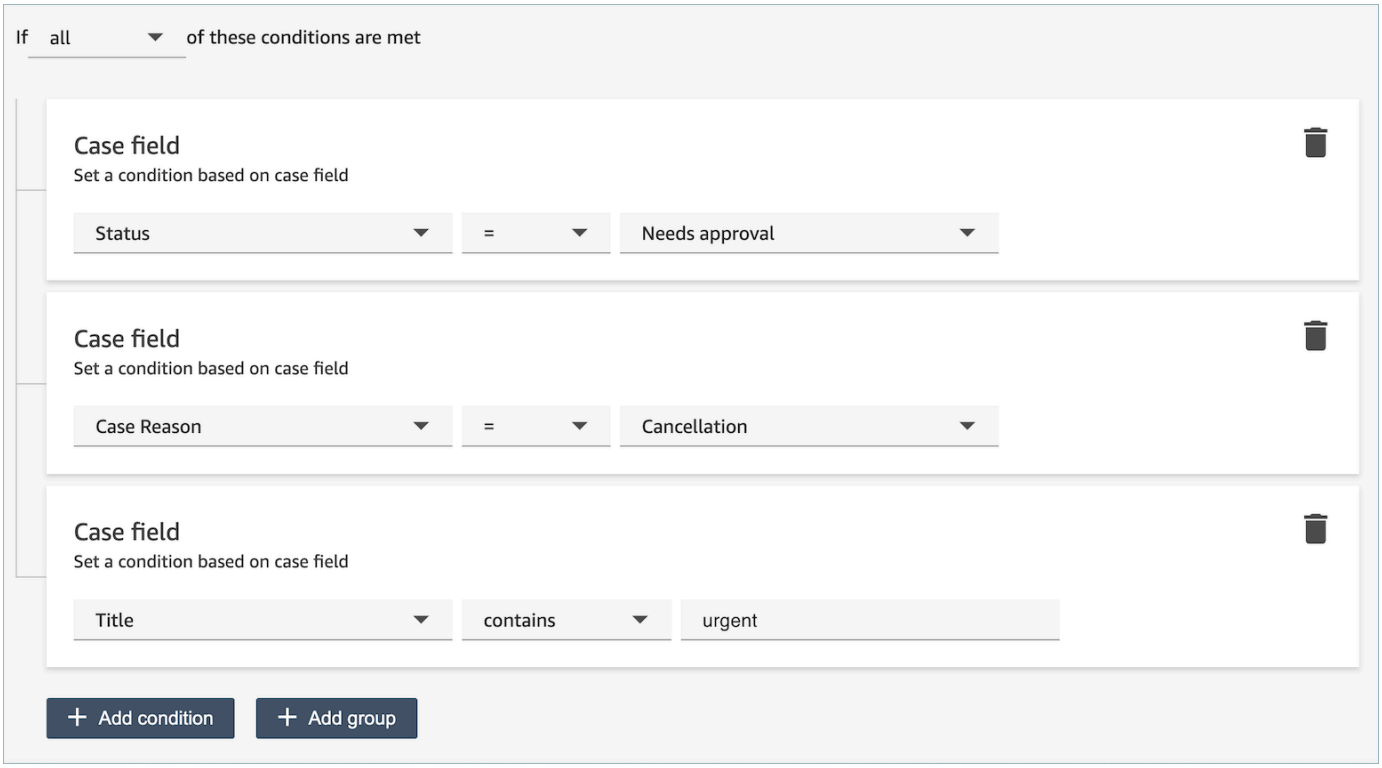


4. Choose **Add condition**. You can define conditions based on the case template value, such as when the case template equals **Billing**, or based on case field values, such as when Priority equals **high**.



You can combine multiple conditions to build very specific rules.

The following image shows a sample rule with multiple conditions:

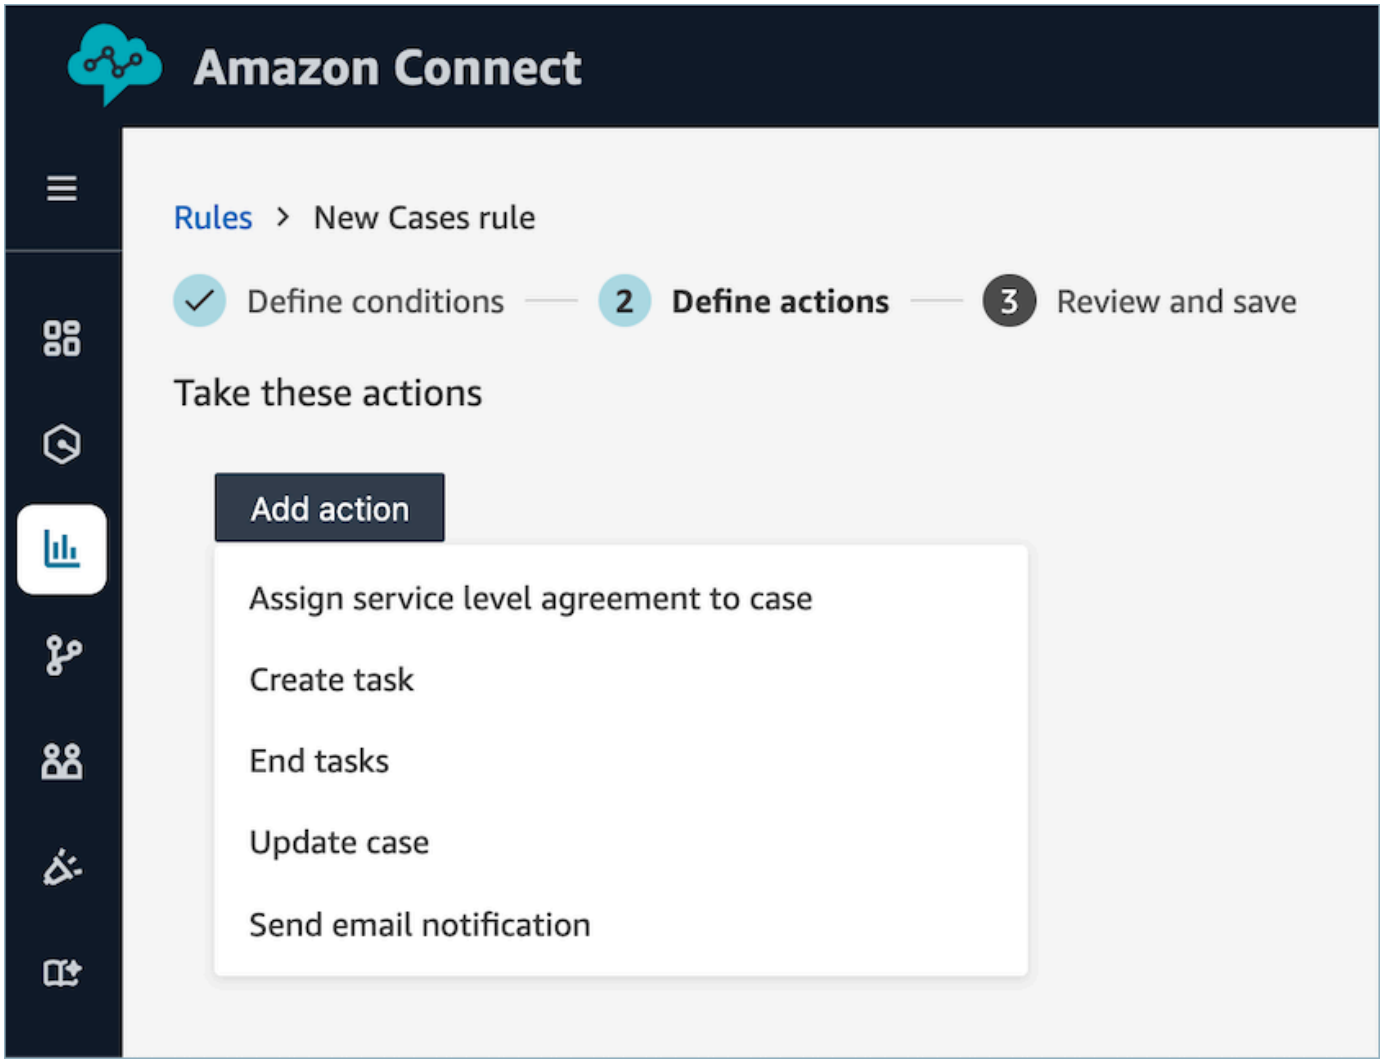


5. Choose **Next**.

Step 2: Define rule actions

1. Choose **Add action**. You can choose the following actions:

   - Assign service level agreement to case
   - Create task
   - End tasks
   - Update case
   - Send email notification



2. Choose **Next**.
3. Review and make any edits, then choose **Save**.

Connect Customer Cases metrics

The following case driven metrics are available on the Historical metrics reports. To access these metrics on a report, Cases needs to be enabled for your instance, and at least one case template is created.

Average case resolution time

This metric measures the average amount of time spent to resolve a case during the provided time interval.

Metric type: String (*hh:mm:ss*)

Metric category: Case driven metric

How to access using the Connect Customer API:

- GetMetricDataV2 API metric identifier: `AVG_CASE_RESOLUTION_TIME`

How to access using the Connect Customer admin website:

- Historical metrics reports: Average Case Resolution Time

Average contacts per case

This metric measures the average number of contacts (calls, chat, tasks, and email) for cases created during the provided time interval.

Metric type: String

Metric category: Case driven metric

How to access using the Connect Customer API:

- GetMetricDataV2 API metric identifier: `AVG_CASE_RELATED_CONTACTS`

How to access using the Connect Customer admin website:

- Historical metrics reports: Average Case Related Contacts

Cases created

This metric counts all the cases created.

Metric type: Integer

Metric category: Case driven metric

How to access using the Connect Customer API:

- GetMetricDataV2 API metric identifier: `CASES_CREATED`

How to access using the Connect Customer admin website:

- Historical metrics reports: Cases Created

Calculation logic:

- Check case_create_time createdDataTime present?
- Return count = 1 for each case, or null if not present.

Notes:

- Uses SUM statistic for aggregation.
- Counts each case creation event.
- Returns null if creation timestamp is not present.
- Can be filtered by case template and status.
- Data for this metric is available starting from January 26, 2024 0:00:00 GMT.

Cases reopened

This metric measures the number of times cases have been reopened.

Metric type: Integer

Metric category: Case driven metric

How to access using the Connect Customer API:

- GetMetricDataV2 API metric identifier: `REOPENED_CASE_ACTIONS`

How to access using the Connect Customer admin website:

- Historical metrics reports: Reopen Case Actions Performed

Calculation logic:

- Check case_reopened_time lastReopenedDateTime present?
- Return count = 1 for each reopened case.

Notes:

- Uses SUM statistic for aggregation.
- Counts each reopen action.
- Returns null if reopen timestamp is not present.
- Can be filtered by case template and status.
- Data for this metric is available starting from January 26, 2024 0:00:00 GMT.

Cases resolved

This metric measures the number of times cases have been resolved.

Metric type: Integer

Metric category: Case driven metric

How to access using the Connect Customer API:

- GetMetricDataV2 API metric identifier: `RESOLVED_CASE_ACTIONS`

How to access using the Connect Customer admin website:

- Historical metrics reports: Resolve Case Actions Performed

Calculation logic:

- Check case_resolved_time lastCloseDateTime present?
- Return count = 1 for each resolved case.

Notes:

- Uses SUM statistic for aggregation.

- Counts each resolution action.
- Returns null if resolution timestamp is not present.
- Can be filtered by case template and status.
- Data for this metric is available starting from January 26, 2024 0:00:00 GMT.

Cases resolved on first contact

This metric measures the percent of cases that were resolved on the first contact (only including calls, chats, or email). Cases that have been reopened and subsequently closed in the specified interval will contribute to this metric. If cases are reopened but not closed in the specified interval it will not contribute to this metric.

Metric type: String

- Min value: 0.00%
- Max value: 100.00%

Metric category: Case driven metric

How to access using the Connect Customer API:

- GetMetricDataV2 API metric identifier: `PERCENT_CASES_FIRST_CONTACT_RESOLVED`

How to access using the Connect Customer admin website:

- Historical metrics reports: Case First Contact Resolution Rate

Calculation logic:

- Check if Case Status is closed?
- Count contacts (CHAT/VOICE/EMAIL) for the case.
- Calculate first contact resolution: Return true (1.0) if exactly one contact. Else false (0.0).

Notes:

- Uses AVG statistic for final percentage.

- Only considers closed cases.
- Counts only CHAT, VOICE, and EMAIL contacts.
- Returns null if case is not closed or has no contacts.
- True (1.0) if resolved in single contact.
- Data for this metric is available starting from December 4, 2023 0:00:00 GMT.

Current cases

This metric counts the total cases existing in a given domain for a specific point in time.

Metric type: Integer

Metric category: Case driven metric

How to access using the Connect Customer API:

- GetMetricDataV2 API metric identifier: CURRENT_CASES

How to access using the Connect Customer admin website:

- Historical metrics reports: Current cases

Calculation logic:

- Get statusesNested.count for current time period.
- Sum counts across all matching status records.

Notes:

- We recommend limiting the queried time window to 5 minutes. Otherwise the returned data may be inaccurate.
- Uses SUM statistic for aggregation.
- Provides point-in-time case count.
- Can be filtered by status and template.
- Based on case snapshot timestamp.
- Data for this metric is available starting from January 26, 2024 0:00:00 GMT.

Set up tag-based access controls on cases

You can use resource tags and access control tags to apply granular access to cases in Amazon Connect Cases. For example, you can control who has access to view, create, or edit cases containing sensitive customer information based on department, case type, or security classification.

With tag-based access controls, you can configure granular access to specific cases based on assigned resource tags. Cases inherit tags from their associated case templates, ensuring consistent access control without requiring agents to manually tag individual cases. You can configure tag-based access controls by using the API or the Amazon Connect admin website. For more information, see the section called “Add tags to resources” and the section called “Apply tag-based access control”.

How tag propagation works for cases

When you create a case using a case template, the case automatically inherits the tags configured on that template. This ensures consistent access control and reduces the risk of human error in tagging individual cases. It is important to note that tags specified during case creation will override any conflicting tags from the template.

For example, if you tag a "Fraud Investigation" template with `Department:Fraud`, all cases created using that template will automatically receive the `Department:Fraud` tag, restricting access to users with appropriate permissions. However, if a CreateCase public API request is made with the same "Fraud Investigation" template with `Department:Finance` in the request, the case will instead have the `Department:Finance` tag.

How to enable tag-based access control for cases

To apply tags to control access to cases:

- **Tag your case templates**: Apply tags to case templates that will be inherited by all cases created from those templates. You can add tags when creating or editing templates in the Amazon Connect admin website or by using the Amazon Connect Cases CreateTemplate or UpdateTemplates APIs.
- **Configure security profiles**: Assign users to security profiles that grant access to specific case tags. On the Security profiles page, choose **Show advanced options** to configure tag-based permissions for the Cases resource. For more information about configuring access control tags, see the section called “Apply tag-based access control”.

- **Set appropriate permissions**: Users need one of the following permissions to work with cases:
  - **Cases - Create**: Allows creating new cases (requires permission for tags that will be applied)
  - **Cases - View**: Allows viewing existing cases with matching tags
  - **Cases - Edit**: Allows modifying existing cases with matching tags

Connect Customer Cases event streams

Connect Customer Cases event streams provide you with near real-time updates when cases are created or modified within your Connect Customer Cases domain. The events published to the stream include these resource events:

- Case created
- Cases modified
- Related items (Comments, Calls, Chats, Tasks) are added to a case

You can use the case event streams to integrate streams into your data lake solutions, create dashboards that display case performance metrics, implement business rules or automated actions based on case events, and configure alerting tools to trigger custom notifications of specific case activity.

Topics

- Set up Connect Customer Cases event streams
- Allow Connect Customer Cases to send updates to conversational analytics rules
- Case event payload and schema in Connect Customer Cases

Set up Connect Customer Cases event streams

This topic explains how to set up and use case event streams. Some of the onboarding steps require you to call Connect Customer Cases APIs.

Step 1: Create a Connect Customer instance and enable Customer Profiles

1. Make sure you have a working Connect Customer instance in one of the AWS Regions where Cases is available. See Cases availability by Region.

2. Enable Connect Customer Customer Profiles. For instructions, see Enable Customer Profiles for your Connect Customer instance.

   Connect Customer Cases requires Customer Profiles because each case must be associated with a customer profile from the Customer Profiles service.

Step 2: Add a Cases domain to your Connect Customer instance

For instructions, see Enable Cases using the Connect Customer console.

If you want to add a case domain using the API, see the CreateDomain API in the *Connect Customer Cases API Reference*.

Step 3: Create a case template

Create a case template. In *Step 6: Test case event streams*, you'll use the template.

If you want to create a case template using the API, see the CreateTemplate API in the *Connect Customer Cases API Reference*.

Step 4: Enable case event streams and setup to receive events into an SQS queue

Run the following command to enable case event streams for your Cases domain. After this command runs, when cases are created or updated, an event is published to the default-bus of the EventBridge service in your account (it must be in the same AWS Region as your Cases domain).

```
aws connectcases put-case-event-configuration --domain-
id dad5efb6-8485-4a55-8241-98a88EXAMPLE --event-bridge enabled=true
```

By default, the events published by Connect Customer Cases only contain metadata about the case, such as `templateId`, `caseId`, `caseArn`, `approximateChangeTime`, and more. You can run the following command to get more information about the case (at the time the event was generated) to be included in the event.

> **Note**
>
> If you want to include a custom field in the event, use the custom field ID. For instructions about how to locate the custom field ID, see Find the custom field ID.

```
# You can include any other field defined in your cases domain in the fields section.
# To list the fields that are defined in your cases domain, call the Cases ListFields
 API.
# To include case fields that you create (custom fields) in the event, enter the custom
 field ID.
aws connectcases put-case-event-configuration --domain-id YOUR_CASES_DOMAIN_ID --event-
bridge "{
    \"enabled\": true,
    \"includedData\": {
       \"caseData\": {
          \"fields\": [
          {
          \"id\": \"status\"
          },
          {
          \"id\": \"title\"
          },
          {
          \"id\": \"customer_id\"
          },
         {
          \"id\": \"your custom field ID\"
          }
        ]
      },
      \"relatedItemData\": {
      \"includeContent\": true
      }
    }
  }"
```

Next, create an Amazon SQS queue and set that as a target for the Connect Customer Cases events on your EventBridge bus so that all the case events are delivered to the SQS queue for later processing.

```
# Create an SQS queue
aws sqs create-queue --queue-name case-events-queue --attributes "{\"Policy\": \"{ \\
\"Version\\\": \\\"2012-10-17\\\", \\\"Statement\\\": [{ \\\"Sid\\\": \\\"case-event-
subscription\\\", \\\"Effect\\\": \\\"Allow\\\", \\\"Principal\\\": { \\\"Service\\\":
 \\\"events.amazonaws.com\\\"}, \\\"Action\\\": \\\"SQS:SendMessage\\\", \\\"Resource\\
\": \\\"*\\\"}]}\"}"
```

```
# Create an rule on the EventBridge default bus that represents the case events
aws events put-rule --name case-events-to-sqs-queue --event-pattern "{\"source\":
 [\"aws.cases\"], \"detail-type\": [\"Amazon Connect Cases Change\"]}" --state ENABLED

# Ask event bridge to publish case events to the SQS queue.
aws events put-targets --rule case-events-to-sqs-queue --target "[{
\"Id\": \"target-1\",
\"Arn\": \"arn:aws:sqs:The AWS Region of your Amazon Connect instance:your AWS account
 ID:case-events-queue\"
}]"
```

Step 5: Test case event streams

Use the Connect Customer agent workspace to:

1. Accept a chat contact.
2. Create a customer profile and associate that to the chat contact.
3. Create a case.

> **Note**
>
> The **Create case** button on the **Cases** tab is inactive until you accept a contact and associate that contact with a customer profile.

Navigate to the Amazon SQS console and check that a case event (type: `CASE.CREATED`) for the newly created case is available in your SQS Queue. Similarly, you can modify the case created above and get a corresponding case event (type: `CASE.UPDATED`) in your SQS queue. You can associate the contact to the case, and leave a comment on the case to get case events for those actions, too.

Step 6: Use cases for the case event streams

Case event streams publish events every time a case is created, case is updated, contact is associated to the case, and comment is added on a case. You can use these events for:

- Metrics, analytics and dashboards
- Build Apps that notify users (for example, send emails)
- Automated actions that are triggered based on certain type of case updates

For example, you can use the SQS target on EventBridge (as shown on step 4) to temporarily store the case events in the SQS queue, and use Lambda functions to process events in the SQS to build custom applications such as sending emails to the customer when their case is updated, automatically resolving any tasks linked to the case, and more. Similarly, you can use the Firehose target on the EventBridge to store the case events into an S3 bucket and then use the AWS Glue for ETL, Athena for ad-hoc analytics, and Quick for dashboards.

Allow Connect Customer Cases to send updates to conversational analytics rules

> **Note**
>
> To perform the instructions in this procedure, you need to have developer skills, or be experienced with Connect Customer CLI.

Complete this one-time procedure so your users can set up rules that run when a case is created or updated.

1. Verify Connect Customer Cases is enabled for your Connect Customer instance.
2. Complete the steps to enable Connect Customer Cases event streams. For more information see Set up Connect Customer Cases event streams. Note the following changes to the procedure:

    a. You can skip the part that asks you to create a SQS queue, as it is not required.

    b. Run the `put-case-event-configuration` CLI command to include all case fields information in the event. Make sure to include all of the fields that you need for the Rules engine to work.

    > **Note**
    >
    > To make sure that Cases SLA Breach rules work properly, you must set `relatedItemData.includeContent` to `true`, as shown in the following example.

```
aws connectcases put-case-event-configuration --domain-id
 01310a0e-24ba-4a3c-89e9-9e1daeaxxxx --event-bridge "{
   \"enabled\": true,
   \"includedData\": {
      \"caseData\": {
          \"fields\": [
            {
              \"id\": \"status\"
            },
            {
              \"id\": \"title\"
            },
            {
              \"id\": \"assigned_queue\"
            },
            {
              \"id\": \"assigned_user\"
            },
            {
              \"id\": \"case_reason\"
            },
            {
              \"id\": \"last_closed_datetime\"
            },
            {
              \"id\": \"created_datetime\"
            },
            {
              \"id\": \"last_updated_datetime\"
            },
            {
              \"id\": \"reference_number\"
            },
            {
              \"id\": \"summary\"
            }
          ]
     },
     \"relatedItemData\": {
     \"includeContent\": true
     }
   }
```

```
  }"
```

c. If there are custom case fields, make sure to include a custom field ID the fields array in the previous payload as well. You can find field IDs by running the following `list-fields` CLI command:

```
aws connectcases list-fields --domain-id 01310a0e-24ba-4a3c-89e9-9e1daeaxxxx
```

d. Repeat step 2 if you need to add new custom fields.

3. Make a CreateEventIntegration API call, or run the `create-event-integration` CLI command, as shown in the following example command.

   - Payload:

```
aws appintegrations create-event-integration --name amazon-connect-cases --
description amazon-connect-cases --event-filter '{"Source":"aws.cases"}' --event-
bridge-bus default
```

   - The output will look similar to the following sample:

```
{
    "EventIntegrationArn": "arn:aws:app-integrations:us-
west-2:111222333444:event-integration/amazon-connect-cases"
}
```

4. Make a CreateIntegrationAssociation API call, or run the `create-integration-association` CLI command, as shown in the following example command.

   - Payload:

     The `IntegrationArn` is the response you get from step 3.

```
aws connect create-integration-association --instance-id bba5df5c-6a5f-421f-
a81d-9c16402xxxx --integration-type EVENT --integration-arn arn:aws:app-
integrations:us-west-2:111222333444:event-integration/amazon-connect-cases --
source-type CASES
```

   - The output will be similar to the following sample:

```
{
    "IntegrationAssociationId": "d49048cd-497d-4257-ab5c-8de797a123445",
    "IntegrationAssociationArn": "arn:aws:connect:us-
west-2:111222333444:instance/bba5df5c-6a5f-421f-a81d-9c16402bxxxx/integration-
association/d49048cd-497d-4257-ab5c-8de797a123445"
}
```

Your users should now be able to create rules that run when a case is created or updated.

Case event payload and schema in Connect Customer Cases

When you request to include case data in the event payload, the data reflects the version of the case after that particular edit.

Connect Customer Cases default limits guarantee that the payload will be less than 256KB (the maximum size of an EventBus event). Since you can customize the case object model (for example, you can define custom fields on case objects to capture business specific information), case event schema reflect the customizations made to the case object as shown in the following examples (for example, see how customer-specific UUIDs are being use as JSON properties).

Example case event payload for the case resource

```
// Given the limits on the "includedData" configuration
// this payload is guaranteed to less than 256KB at launch.
{
    "version": "0",
    "id": "event ID",
    "detail-type": "Amazon Connect Cases Change",
    "source": "aws.cases",
    "account": "your AWS account ID",
    "time": "2022-03-16T23:43:26Z",
    "region": "The AWS Region of your Connect Customer instance",
    "resources": [
        "arn:aws:cases:your Connect Customer AWS Region:your AWS account ID:domain/case
 domain ID",
        "arn:aws:cases:your Connect Customer AWS Region:your AWS account ID:domain/case
 domain ID/case/case ID"
    ],
    "detail": {
        "version": "0",
```

```
        "eventType": "CASE.UPDATED",
        "approximateChangeTime": "2022-03-16T23:16:57.893Z",  // Can be used for
 ordering
        "changedFieldIds": ["status", "last_updated_datetime"],
        "performedBy": {
            "user": {
                "userArn": "arn:aws:connect:your Connect Customer AWS Region:your AWS
 account ID:instance/connect instance ID/user/connect user ID"
            },
            "iamPrincipalArn": "arn:aws:iam::your Connect Customer AWS Region:role/role
 name"
        },
        "case": {
            "caseId": "case ID",
            "templateId": "template ID",
            "createdDateTime": "2022-03-16T23:16:57.893Z",

            // This section contains only non-null field values for the
            // fields that customers have configured in the "includedData".

            // Field values included in this section reflects the case
            // after this particular change is applied.
            "fields": {
                "status": {
                    "value": {
                        "stringValue": "open"
                   }
                },
                "case_reason": {
                    "value": {
                        "stringValue": "Shipment lost"
                    }
                },
                "custom-field-uuid-1": {
                    "value": {
                        "stringValue": "Customer didn't receive the product"
                    }
                }
            }
        }
    }
}
```

Example case event payload for the related-item resource

```
// Given the limits on the "includedData" configuration
// this payload is guaranteed to less than 256KB
{
    "version": "0",

                    }
                }
            }
        }
    }
}
```

Connect Customer conversational analytics

> **Note**
>
> **Powered by Amazon Bedrock**: AWS implements automated abuse detection. Because Connect Customer conversational analytics is built on Amazon Bedrock, users can take full advantage of the controls implemented in Amazon Bedrock to enforce safety, security, and the responsible use of artificial intelligence (AI).

Connect Customer conversational analytics provides contact center analytics and quality management capabilities that you can use to monitor, measure, and continuously improve contact quality and agent performance for a better overall customer experience.

- Analyze conversations using conversational analytics. You can uncover trends and improve customer service by understanding sentiment, conversation characteristics, emerging contact themes, self-service user experiences, and agent compliance risks.

  Conversational analytics helps you protect your customer's privacy by enabling you to automatically redact sensitive data from conversation transcripts, audio files, and email messages.

- Evaluate performance. You can review conversations alongside contact details, recordings, transcripts, and summaries, without the need to switch applications. You can define and assess agent performance criteria (for example, script adherence, sensitive data collection, and customer greetings) and automatically pre-populate evaluation forms.
- Set up and review agent screen recordings. You can review agent actions handling customer contacts by reviewing screen recordings. This helps you ensure adherence to quality standards, compliance requirements, and best practices. It also helps you identify coaching opportunities and bottlenecks so you can streamline workflows.
- Search for completed and in-progress contacts. You can search for contacts as far back as two years ago.
- Monitor live & recorded conversations. You can monitor live conversations (both voice and chat) and barge live voice conversations. This is especially helpful for agents in training.
- Transfer, reschedule, or end in-progress contacts. While on the **Contact details** page, you can manage in-progress contacts.

Analyze conversations using conversational analytics in Connect Customer conversational analytics

With conversational analytics, you can analyze conversations between customers and agents or customers and conversational AI, across voice, chat, and email, using natural language processing. Conversational analytics performs sentiment analysis and detects issues. You can also automatically categorize contacts.

Speech analytics support

- **Real-time call analytics**: Use to detect and resolve customer issues more proactively while the call is in progress. For example, it can analyze and alert you when a customer is getting frustrated because the agent is unable to resolve a complicated problem. With real-time call analytics, you can provide more immediate assistance.
- **Post-call analytics**: Use to understand trends of customer conversations, self-service interactions, and agent compliance. This helps you identify opportunities to improve conversational AI and coach agents after the call.

Chat analytics support

- **Real-time chat analytics**: As with real-time call analytics, you can detect and resolve customer issues more proactively while the chat is in progress and receive an alert. For example, managers can get a real-time email alert when customer sentiment for a chat contact turns negative, allowing them to join the in-progress contact and help resolve the customer issue.
- **Post-chat analytics**: Use to understand trends of customer conversations with both bots and agents. It provides information specific to a chat interaction, such as the agent greeting time, and agent and customer response times. The response times and sentiments help you investigate the customer's experience with the bot versus the agent, and identify areas for improvement.
- Each processed chat message is charged the same way. While not all messages might have all features applied (for example, summarization is applied to `text/plain` messages only), if conversational analytics is enabled on the contact, the message is counted for billing. For more information about pricing, see Connect Customer Pricing.

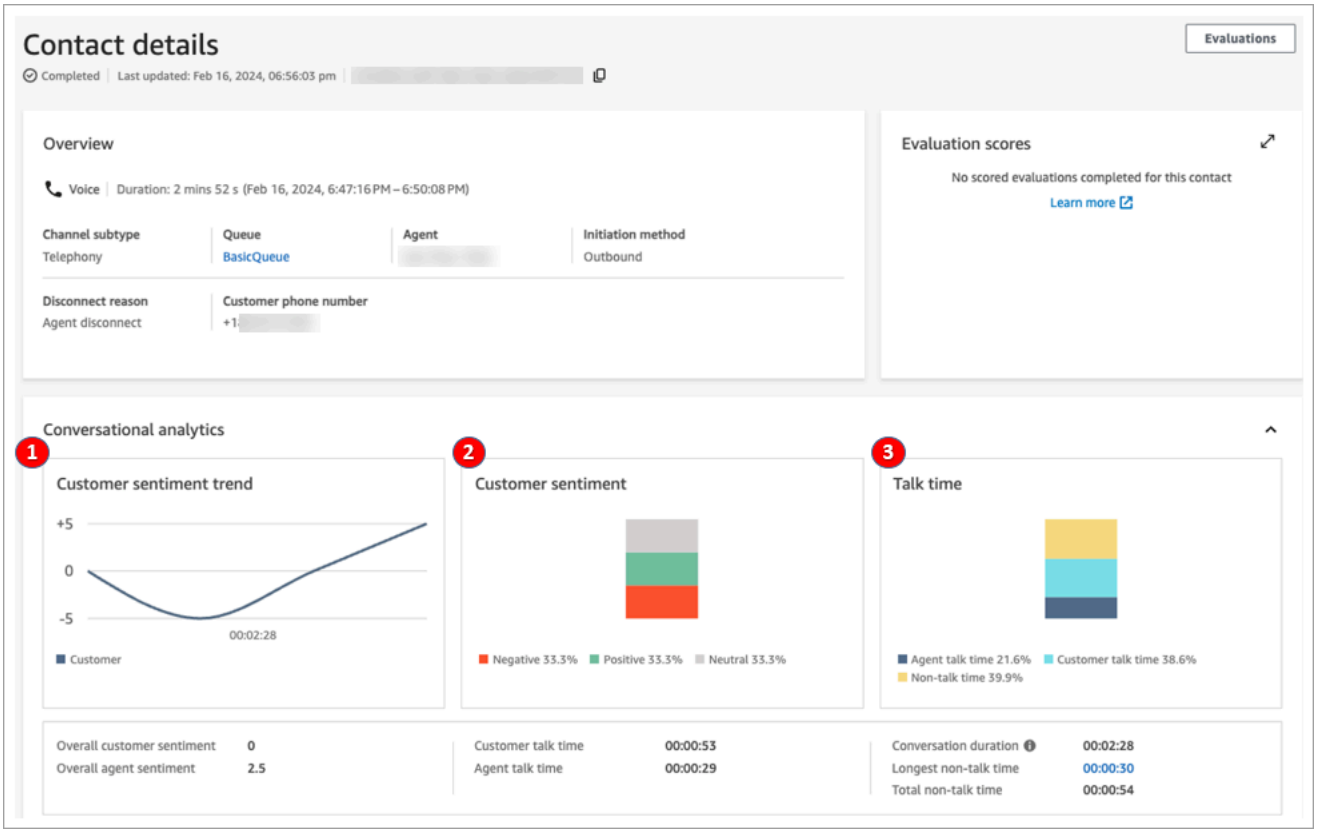
Email analytics support

- **Email analytics**: Use to analyze email conversations between customers and agents. conversational analytics automatically categorizes email contacts, redacts sensitive data from email transcripts, and generates contact summaries. This helps you understand email conversation trends and ensure compliance across your email channel.
- Because email contacts are asynchronous, with one participant acting at a time, the real-time and post-contact distinction that applies to voice and chat does not apply to email. An email analysis is initiated as soon as the Flow block in Connect Customer: Set recording, analytics and processing behavior is used when an email contact is received or sent.

You can protect your customer's privacy by redacting sensitive data, such as name, address, and credit card information from transcripts and audio recordings.

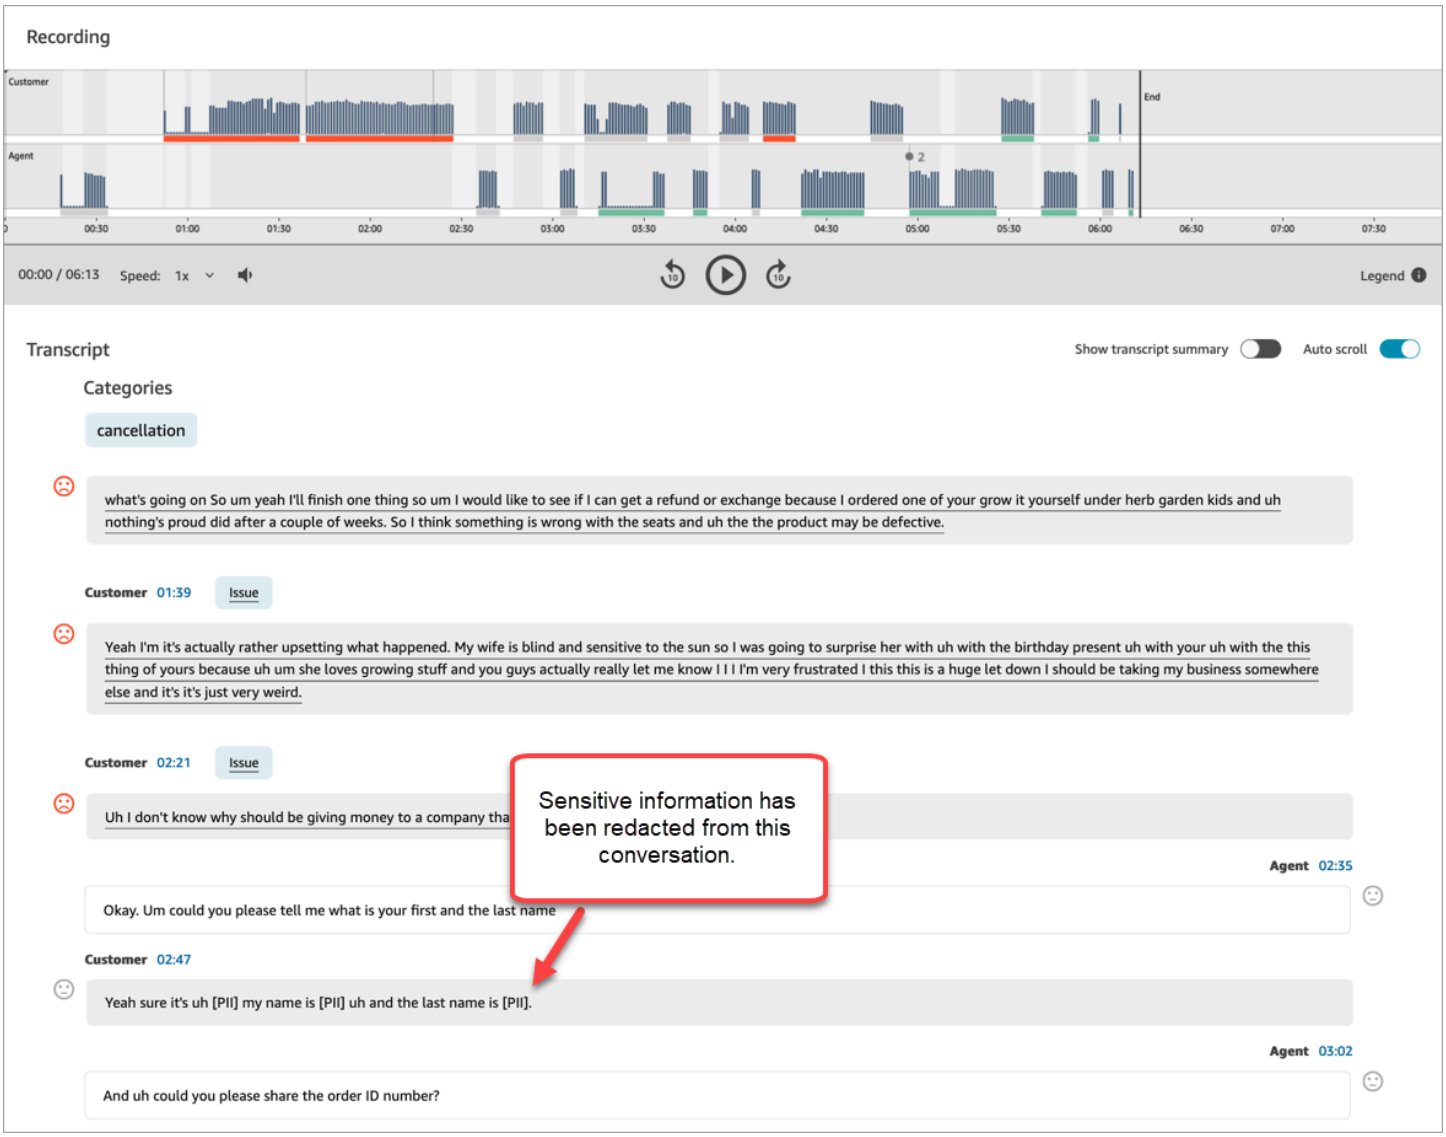
Sample Contact details page for a call

The following image shows the conversational analytics for a voice call. Notice that it includes **Talk time** metrics.



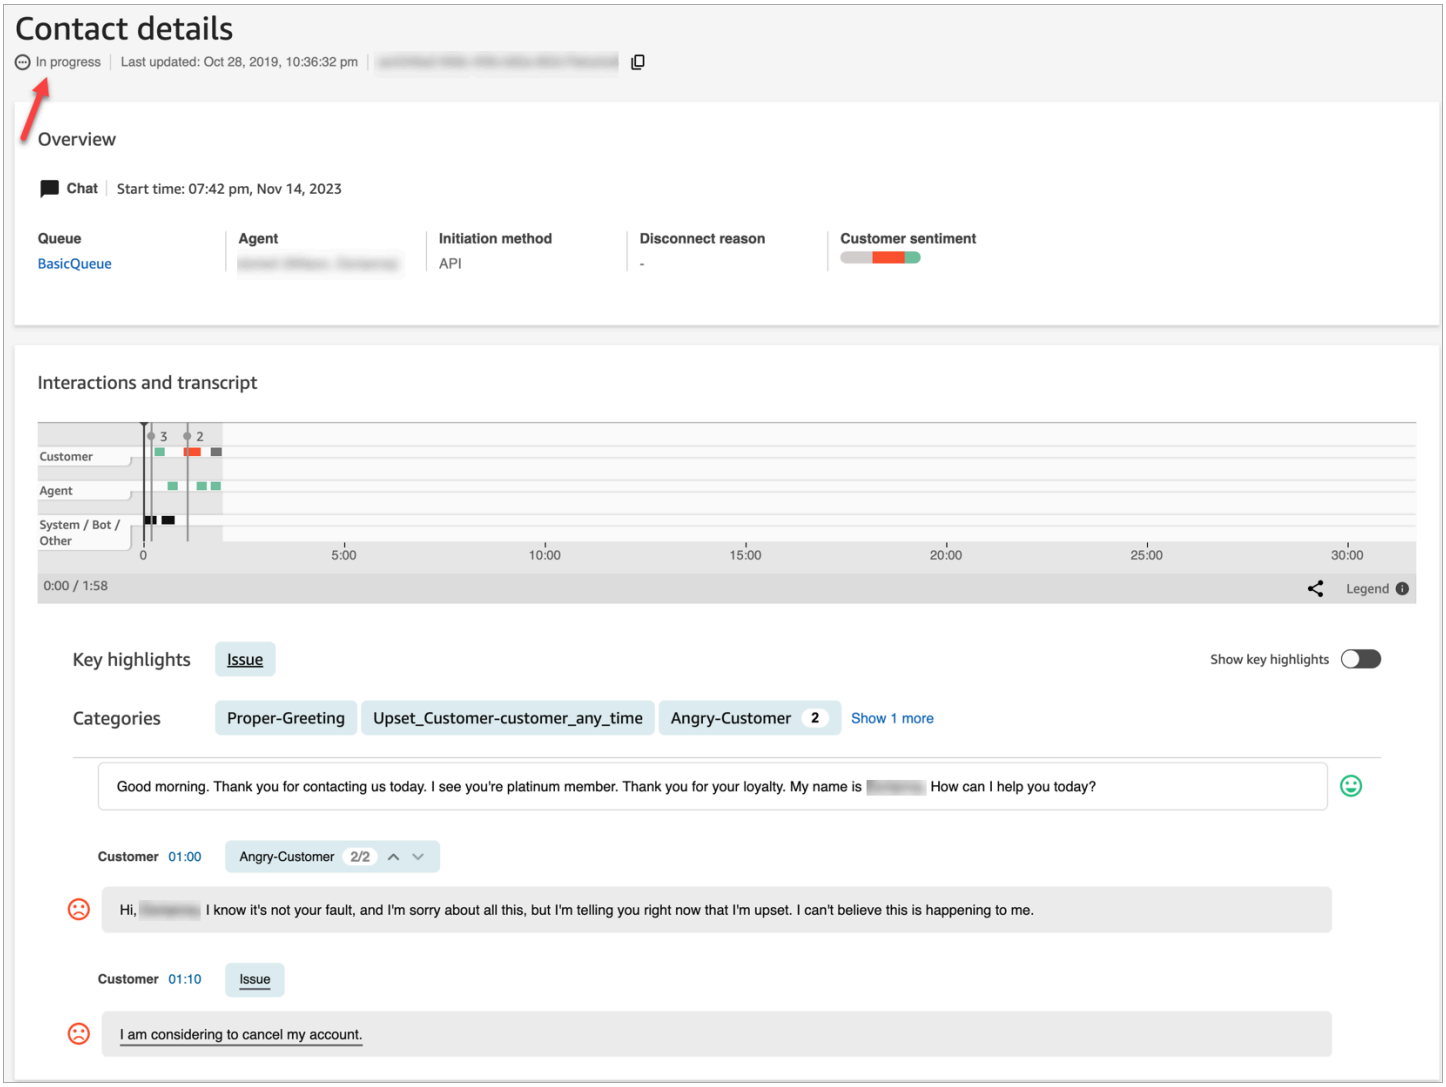
1. **Customer sentiment trend**: This graph shows how customer sentiment changes as the contact progresses. For more information, see Investigate sentiment scores.
2. **Customer sentiment**: This graph shows the distribution of customer sentiment for the entire call. This is calculated by counting the total number of conversation turns or chat messages where a customer had Positive, Neutral, and Negative sentiment.
3. **Talk time**: This graph shows the distribution of talk time and non talk-time during the entire call. The talk time is further split into agent and customer talk time.

The following image shows the next section on the **Contact details** page for a voice call: the audio analysis and transcript. Notice that personally identifiable information (PII) has been redacted from the transcript.



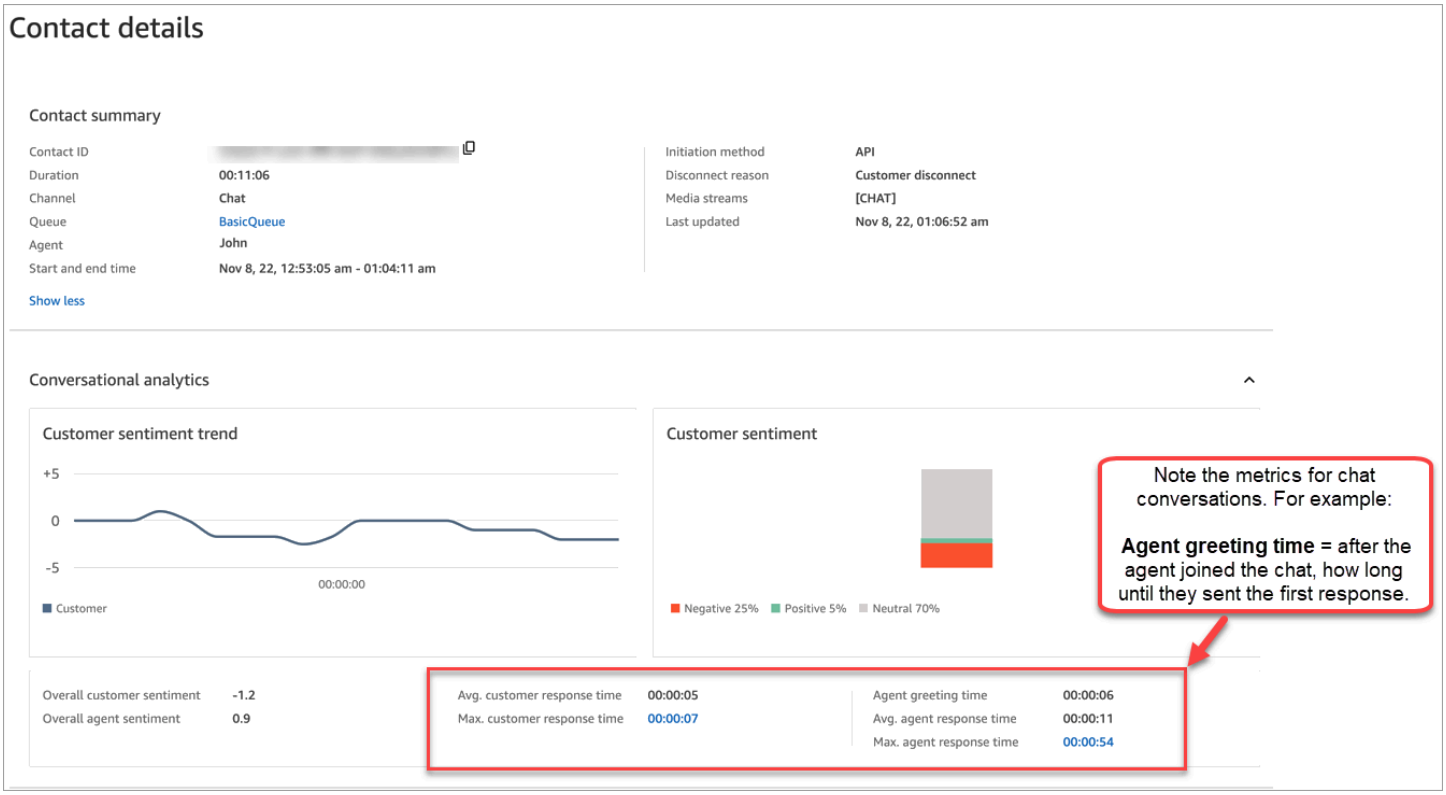
Sample Contact details page for real-time chat analytics

The following image shows the conversational analytics for a real-time chat. Notice that it includes Key highlights and customer sentiment.

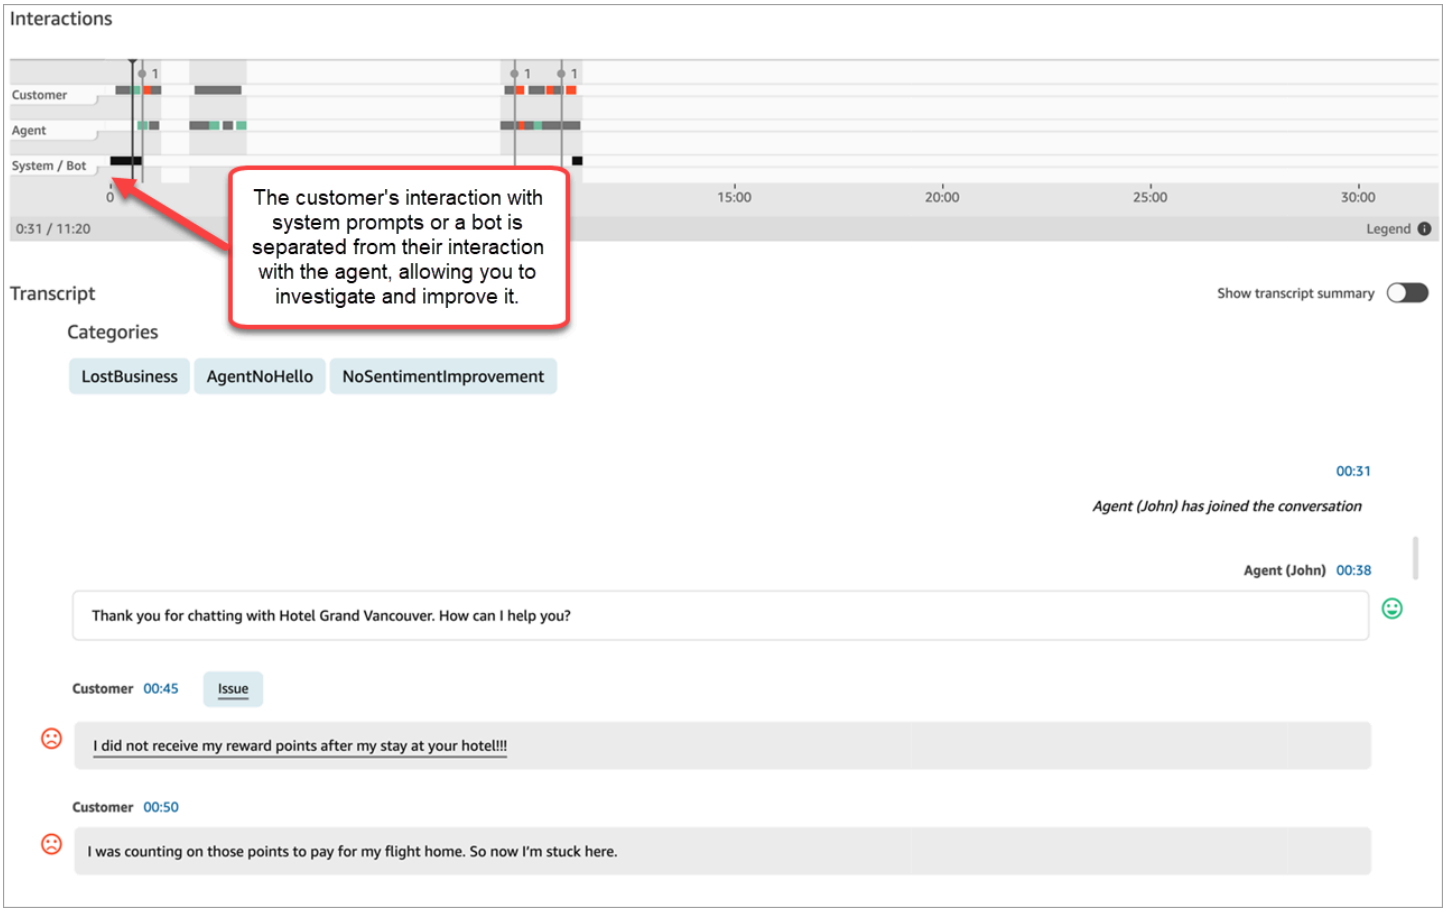


Sample Contact details page for post-chat analytics

The following image shows post-chat analytics. Notice that it includes chat response metrics, such as **Agent greeting time** (the time from the agent joining the chat to when they send the first response), **Customer response time**, and **Agent response time**.

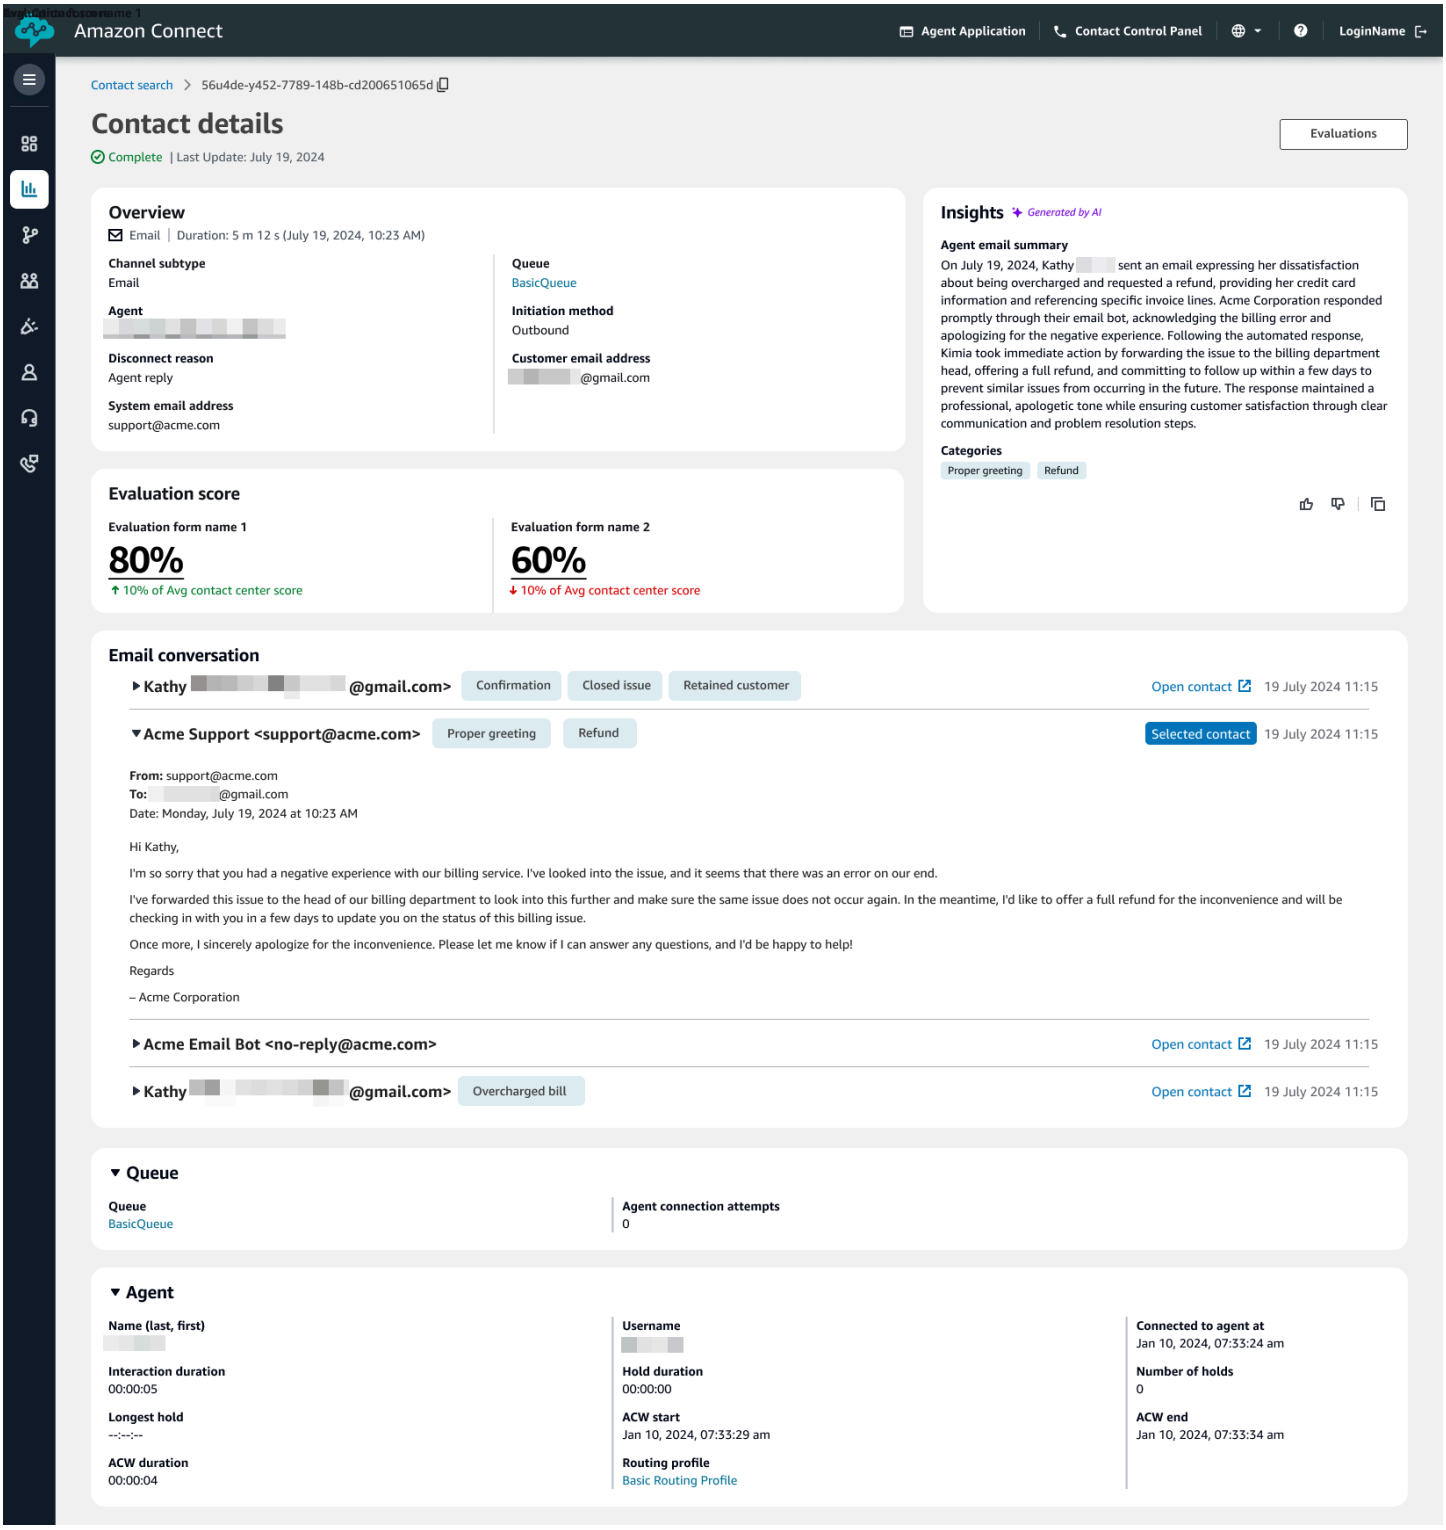


The following image shows the next section on the **Contact details** page for a chat: the interaction analysis and transcript. Notice that you can investigate the customer's interaction with a bot versus the agent.



Sample Contact details page for email analytics

The following image shows the conversational analytics for an email contact. Email analytics includes categorization, sensitive data redaction, and contact summaries. Because email contacts are asynchronous, there are no real-time analytics or sentiment scores.

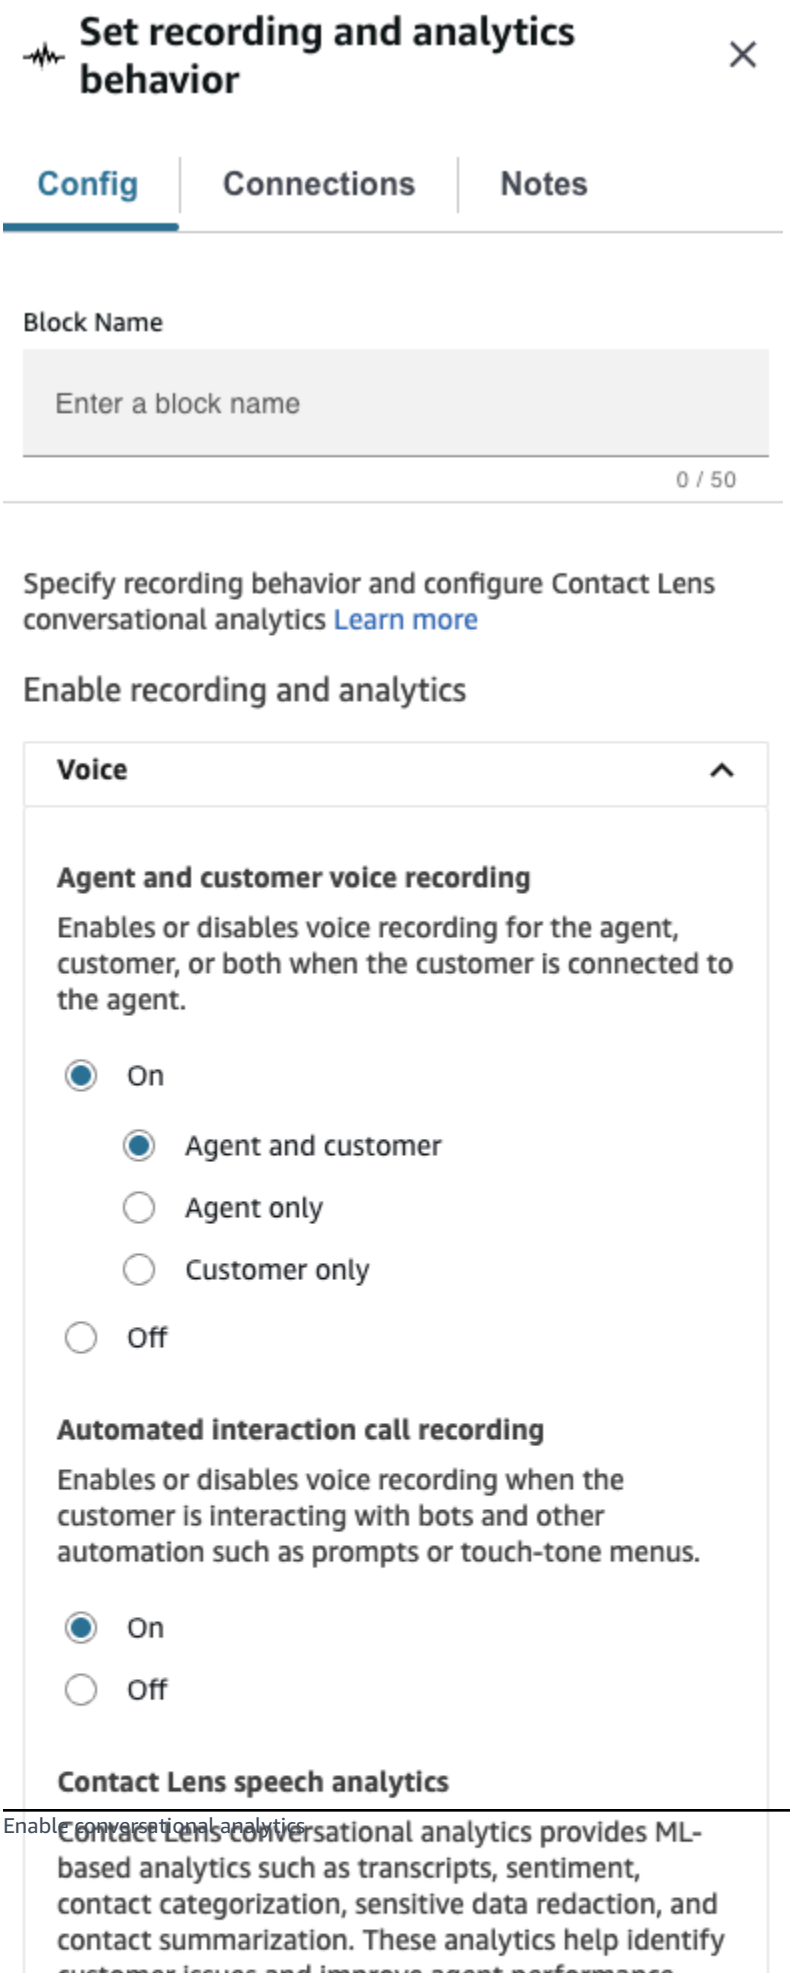


Enable conversational analytics in Connect Customer conversational analytics

You can enable conversational analytics in a few steps:

1. Check whether you need to enable conversational analytics on your Connect Customer instance. Conversational analytics is enabled by default on new instances. You only need to enable it on older instances, or on instances where it was previously disabled.
2. Add a Set recording and analytics behavior block to a flow, and configure it to enable conversational analytics for voice, chat, email, or a combination of channels.

The following image shows a block that's configured for call recording and speech analytics. The **Call recording** option is set to **Agent and customer**. In the **Analytics** section, the options are selected for automated interactions and agent interactions.



Set recording and analytics behavior
Config
Connections
Notes
Block Name

Contact Lens speech analytics
Contact Lens conversational analytics provides ML-based analytics such as transcripts, sentiment, contact categorization, sensitive data redaction, and contact summarization. These analytics help identify

The procedures in this topic describe the steps to enable conversational analytics for calls, chats, or emails.

> **Note**
>
> For new flows, the Set recording, analytics and processing behavior block replaces the Set recording and analytics behavior block. The new block reorganizes the analytics options. The following procedures and images describe the earlier block, which remains supported in existing flows. The steps to enable conversational analytics are equivalent in both blocks.

Topics

- Important things to know
- Enable conversational analytics for your Connect Customer instance
- Enable call recording and speech analytics
- Enable chat analytics
- Enable email analytics
- Enable redaction of sensitive data
- Review sensitive data redaction for accuracy
- Disable sentiment analysis
- Dynamically enable redaction based on the customer's language
- Design a flow for key highlights
- What if the flow block fails to enable conversational analytics?
- Multi-party calls and conversational analytics

Important things to know

- **Multiple analytics flow blocks**: If your flow has multiple analytics configuration flow blocks, real-time analytics for automated interactions and agent interactions use the configuration in the first analytics configuration block executed in the flow. If you configure post-call agent analytics, it will use the configuration in the last analytics configuration block executed in the flow.

> **Important**
>
> Starting October 2026, automated interaction conversational analytics is transitioning from post-contact to real-time in Connect Customer instances. If you have multiple analytics configuration flow blocks, the automated interaction analytics configuration will transition from the last to the first analytics configuration flow block. Customer Basic instances will continue to have post-contact analytics for automated interactions that use the last analytics configuration flow block.

- **Collect data after transferring a contact**: If you want to continue using conversational analytics to collect data after transferring a contact to another agent or queue, you need to add another Set recording and analytics behavior block with **Enable analytics** enabled for the flow. This is because a transfer generates a second contact ID and contact record. Conversational analytics needs to run on that contact record as well.

  > **Note**
  >
  > For queue-to-queue transfers the configuration information for conversational analytics is copied to the transferred contact.

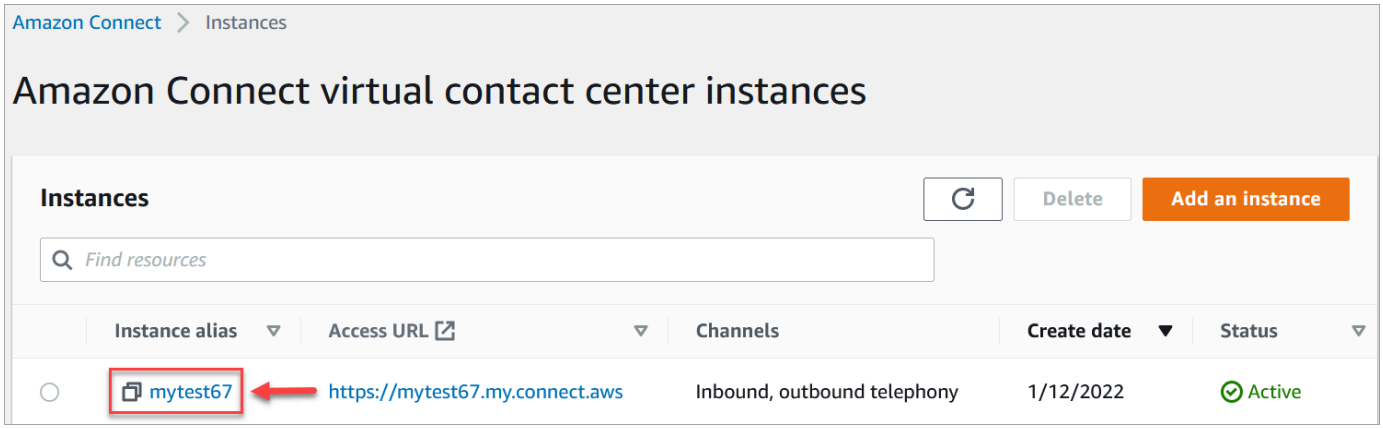
- When you choose a language that is supported by sentiment analysis, AND select **Enable conversational analytics speech analytics**, **Enable chat analytics**, or **Enable email analytics** in the Set recording and analytics behavior block, sentiment analysis is enabled by default. You can choose to disable sentiment analysis.
- Where you place the Set recording and analytics behavior block in a flow affects the agent's experience with key highlights. For more information, see Design a flow for key highlights.

Enable conversational analytics for your Connect Customer instance

Conversational analytics (conversational analytics) is enabled by default on new instances. Check whether conversational analytics is already enabled for your instance. You only need to follow the steps below to enable it if you have an older instance, or if it was previously disabled.

1. Open the Connect Customer console at https://console.aws.amazon.com/connect/.

2. On the instances page, choose the instance alias. The instance alias is also your **instance name**, which appears in your Connect Customer URL. The following image shows the **Connect Customer virtual contact center instances** page, with a box around the instance alias.



3. In the Connect Customer console, in the navigation pane, choose **Analytics tools**, and then choose **Enable conversational analytics**.
4. Choose **Save**.

Enable call recording and speech analytics

After conversational analytics is enabled for your instance, you can add Set recording and analytics behavior blocks to your flows. You then enable conversational analytics when you configure the **Set recording and analytics behavior** block.

1. In the flow designer add a Set recording and analytics behavior block to your flow.

   For information about which flow types you can use with this block and other tips, see Set recording and analytics behavior.
2. Open the **Set recording and analytics behavior** properties page. Under **Call recording**, choose **On**, **Agent and Customer**.

   Both agent and customer call recordings are required to use conversational analytics for voice contacts.
3. Under **Analytics**, choose **Enable conversational analytics**, **Enable speech analytics**.

   If you don't see this option, Connect Customer conversational analytics hasn't been enabled for your instance. For instructions to enable it, see Enable conversational analytics for your Connect Customer instance.
4. Choose one of the following:

a. **Post-call analytics**: conversational analytics analyzes the call recording after the conversation and After Contact Work (ACW) is complete. This option provides the best transcription accuracy.

b. **Real-time analytics**: conversational analytics provides both real-time insights during the call, and post-call analytics after the conversation has ended and After Contact Work (ACW) is complete.

   If you choose this option, we recommend setting up alerts based on keywords and phrases that the customer might utter during the call. conversational analytics analyzes the conversation real-time to detect the specified keywords or phrases, and alerts supervisors. From there, supervisors can listen in on the live call and provide guidance to the agent to help them resolve the issue faster.

   For information about setting up alerts, see Alert supervisors in real-time for calls.

   If your instance was created before October 2018, additional configuration is needed to access real-time call analytics. For more information, see Service-linked role permissions.

5. Choose from the list of available languages.

   For instructions about specifying the language dynamically, see Dynamically enable redaction based on the customer's language.

6. Optionally, enable redaction of sensitive data. For more information, see the next section, Enable redaction.

7. Choose **Save**.

8. If the contact is going to be transferred to another agent or queue, repeat these steps to add another Set recording and analytics behavior block with **Enable conversational analytics for conversational analytics** enabled.

Enable chat analytics

You can enable conversational analytics for chat contacts to get both real-time and post-chat analytics. Post-contact summaries help agents review the key points of a chat without rereading the full transcript. When you also select **Post-contact summary** under **Generative AI capabilities**, agents can view a generative AI-powered post-contact summary on the CCP during After Contact Work (ACW). For more information about post-contact summaries, see View generative AI-powered post-contact summaries.

1. In the Set recording and analytics behavior block, under **Analytics**, choose **Enable conversational analytics**, and **Enable chat analytics**.

   > **Note**
   >
   > By choosing this option you will receive both real-time and post-chat analytics.

   If you don't see this option, Connect Customer conversational analytics hasn't been enabled for your instance. For instructions to enable it, see Enable conversational analytics for your Connect Customer instance.
2. Choose from the list of available languages.

   For instructions on choosing the language and redaction dynamically, see Dynamically enable redaction based on the customer's language.
3. Optionally, enable redaction of sensitive data. For more information, see the next section, Enable redaction.
4. Choose **Save**.
5. If the contact is going to be transferred to another agent or queue, repeat these steps to add another Set recording and analytics behavior block with **Enable conversational analytics for conversational analytics** enabled.

Enable email analytics

You can enable conversational analytics for email contacts to automatically categorize emails, redact sensitive data, and generate contact summaries.

1. In the flow designer, add a Set recording, analytics and processing behavior block to your inbound email flow. Place the block before the email contact is routed to a queue or agent.
2. Open the block properties. For **Action**, choose **Set recording and analytics behavior**.
3. For **Channel**, choose **Email**.
4. Under **Analytics**, choose **Enable conversational analytics**, and **Enable email analytics**.

   If you don't see this option, Connect Customer conversational analytics hasn't been enabled for your instance. For instructions to enable it, see Enable conversational analytics for your Connect Customer instance.

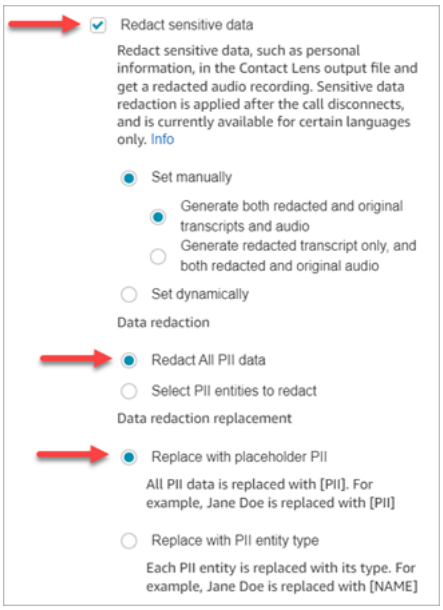
5. Choose from the list of available languages.
6. Optionally, enable redaction of sensitive data. For more information, see Enable redaction.
7. Optionally, under **Generative AI capabilities**, enable **Contact summary** to generate summaries for email contacts.
8. Choose **Save**.
9. If the email contact is going to be transferred to another agent or queue, repeat these steps to add another Set recording, analytics and processing behavior block with **Enable conversational analytics for conversational analytics** enabled.

Enable redaction of sensitive data

When you configure the Set recording and analytics behavior block for conversational analytics, you also have the option to enable redaction of sensitive data in a flow. When redaction is enabled you can choose from the following options:

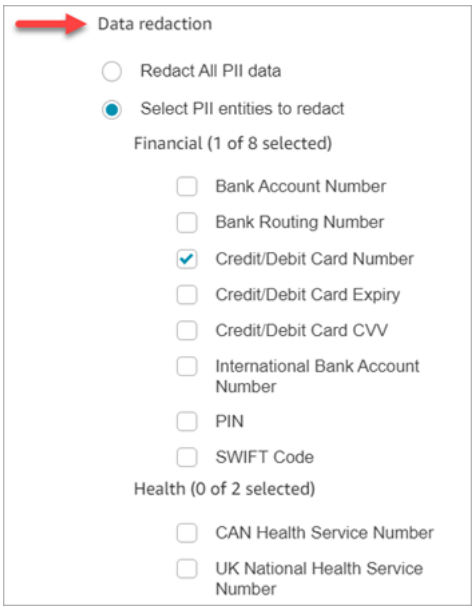
- Redact all personally identifiable information (PII) data (all PII entities supported).
- Choose which PII entities to redact from the list of supported entities.

If you accept the default settings, conversational analytics redacts all personally identifiable information (PII) it identifies, and replaces it with **[PII]** in the transcript. The default settings are shown in the following image because the following options are selected: **Redact sensitive data**, **Redact All PII data**, and **Replace with placeholder PII**.



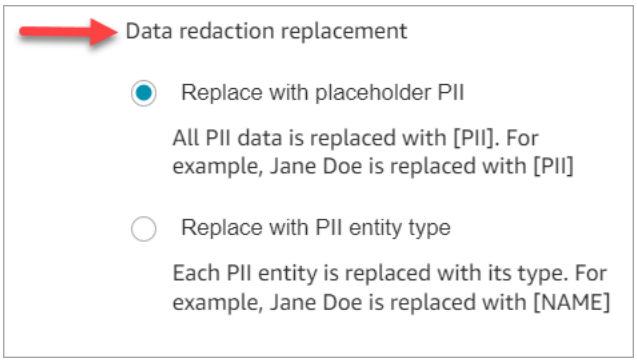
Select PII entities to redact

Under the **Data redaction** section, you can select specific PII entities to redact. The following image shows that **Credit/Debit Card Number** is going to be redacted.



Choose data redaction replacement

Under the **Data redaction replacement** section, you can choose the mask to be used as data redaction replacement. For example, in the following image, the **Replace with placeholder PII** option indicates that **PII** will replace the data.



For more information about using redaction, see Use sensitive data redaction.

Review sensitive data redaction for accuracy

The redaction feature is designed to identify and remove sensitive data. However, due to the predictive nature of machine learning, it may not identify and remove all instances of sensitive

data in a transcript generated by conversational analytics. We recommend you review any redacted output to ensure it meets your needs.

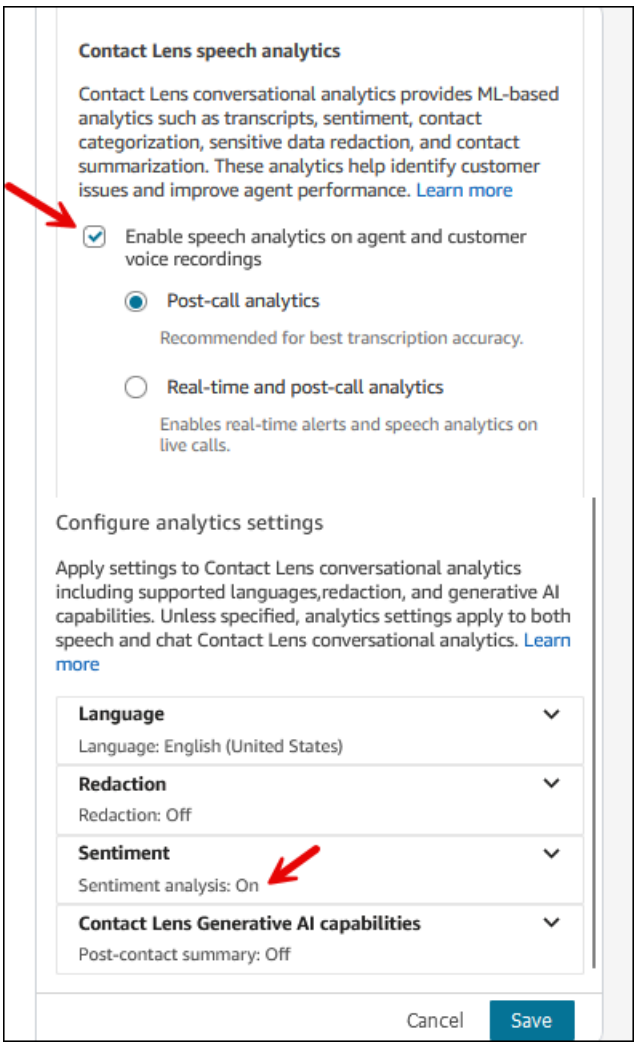
> **Important**
>
> The redaction feature does not meet the requirements for de-identification under medical privacy laws like the U.S. Health Insurance Portability and Accountability Act of 1996 (HIPAA), so we recommend you continue to treat it as protected health information after redaction.

For the location of redacted files and examples, see Output file locations.

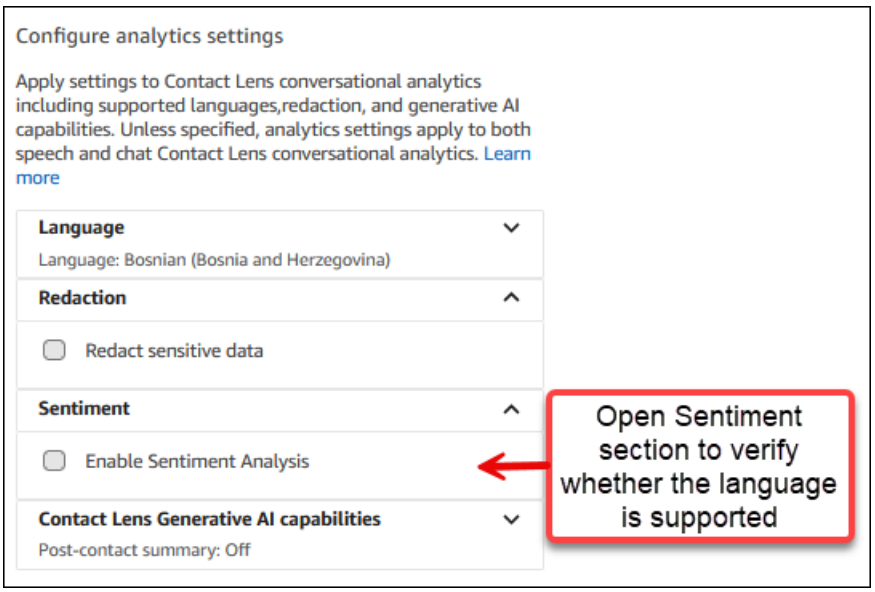
Disable sentiment analysis

When you choose a language that is supported by sentiment analysis, AND choose **Enable speech analytics** or **Enable chat analytics**, sentiment analysis is enabled by default for all agents and customers. For a list of languages supported by sentiment analysis, see AI features.

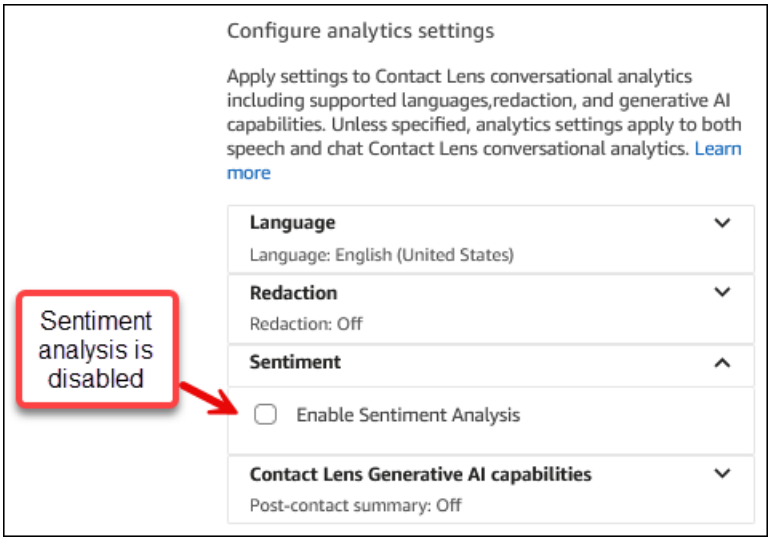
The following image shows the sentiment analysis option is enabled on the **Set recording and analytics behavior** block.



The following image shows a language that is not supported by sentiment analysis. We recommend opening the **Sentiment** section to verify whether it is enabled or disabled.



To disable sentiment analysis for all agents and customers, deselect the **Enable Sentiment Analysis** option, as shown in the following image.



Dynamically enable redaction based on the customer's language

You can dynamically enable the redaction of the output files based on the language of the customer. For example, for customers using en-US, you might want only a redacted file whereas for those using en-GB, you might want both the original and redacted output files.

- Redaction: choose one of the following (they are case sensitive)
  - None
  - RedactedOnly

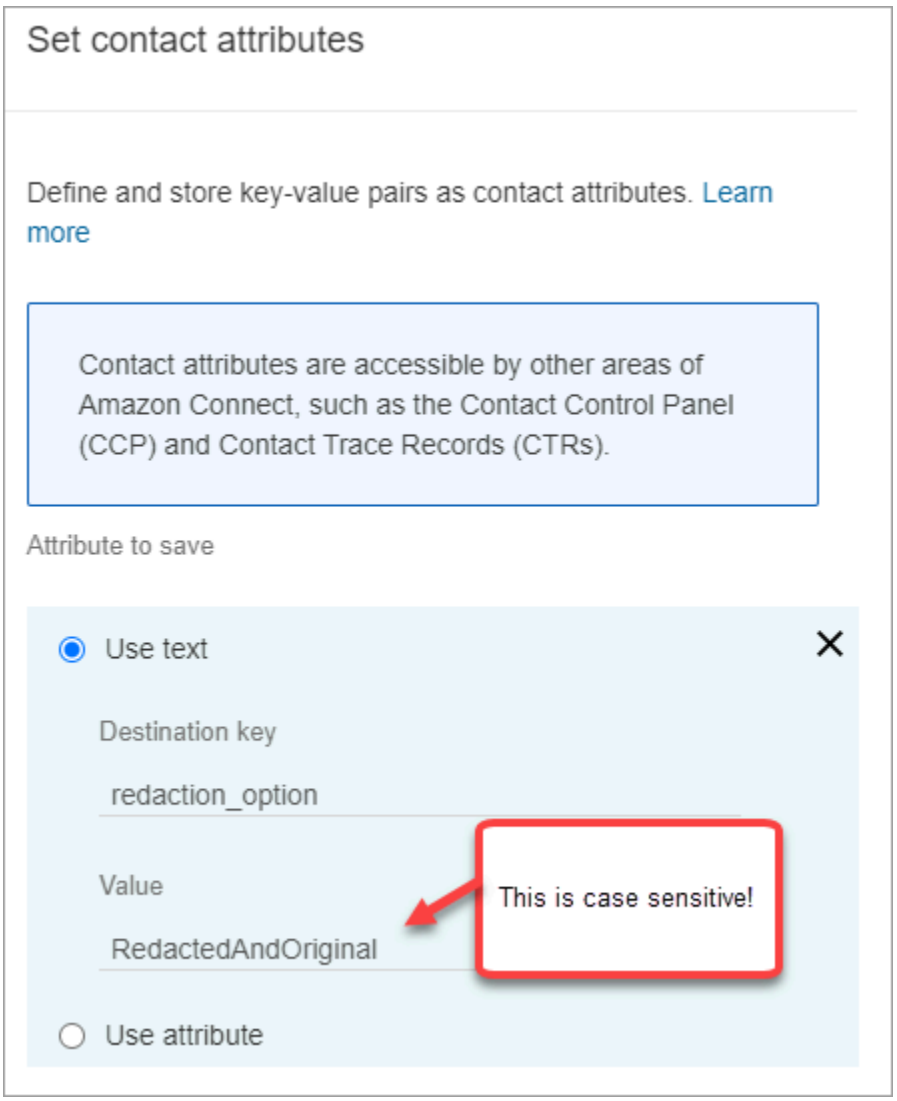
  - RedactedAndOriginal
- Language: Choose from the list of available languages.

You can set these attributes in the following ways:

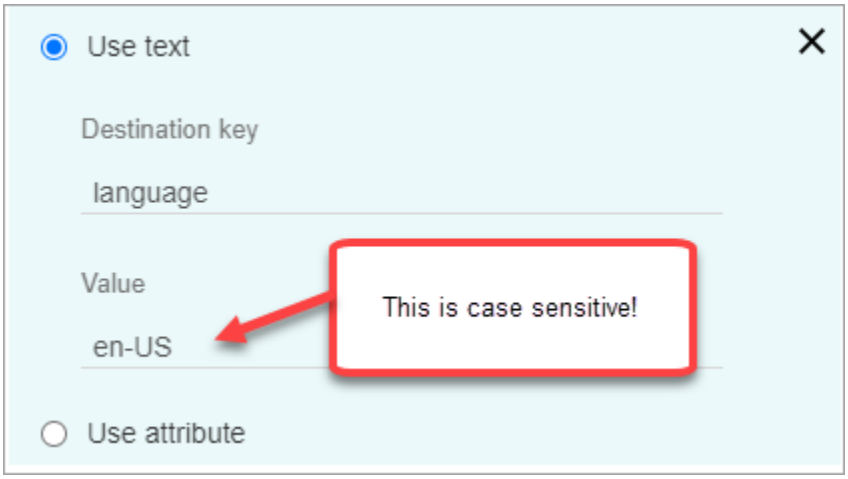
- User defined: use a **Set contact attributes** block. For general instructions about using this block, see How to reference contact attributes. Define the **Destination key** and **Value** for redaction and language as needed.

  The following image shows an example of how you can configure the **Set contact attributes** block to use contact attributes for redaction. Choose the **Use text** option, set **Destination key** to **redaction_option**, and set **Value** to **RedactedAndOriginal**.

  > **Note**
  >
  > **Value** is case sensitive.



The following image show how to use contact attributes for language. Choose the Use text option, set Destination key to language, set **Value** to **en-US**.



- Use a Lambda function. This is similar to how you set up user-defined contact attributes. An AWS Lambda function can return the result as a key-value pair, depending on the language of the Lambda response. The following example shows a Lambda response in JSON:

```
{
   'redaction_option': 'RedactedOnly',
   'language': 'en-US'
}
```

Design a flow for key highlights

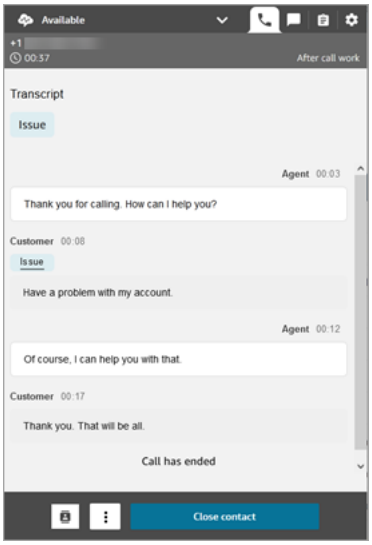
Transcripts are visible to agents using the Contact Control Panel (CCP) depending on whether conversational analytics is enabled in the Set recording and analytics behavior in the inbound flow, or a transfer flow.

This section provides three use cases for enabling conversational analytics in the Set recording and analytics behavior block, and describes how they affect the agent's experience with key highlights.

Use case 1: Conversational analytics is enabled in an inbound flow only

- A contact enters the inbound flow, and there are no call transfers. Following is the agent experience:

  The agent receives the full transcript during After Contact Work (ACW). The transcript includes everything said by the agent and the customer, from the moment the agent accepts the initial call, until the call has ended, as shown in the following image.



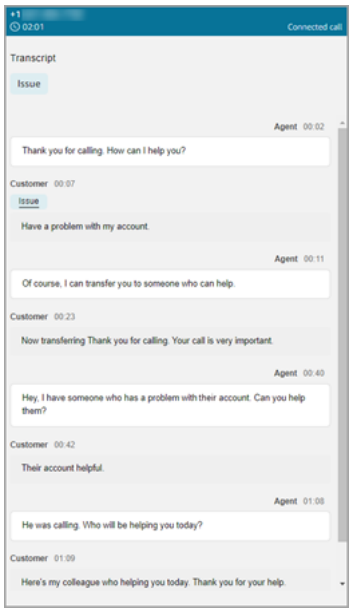
- A contact enters the inbound flow, and there is a call transfer. Following is the agent experience:
  - Agent 1 receives a call transcript after they leave the conference/warm transfer, during ACW.

    The transcript includes everything said by agent 1 and the customer, from the moment the agent accepts the initial call, until the agent 1 leaves the conference/warm transfer portion of the call. The transcript includes the flow (transfer/queue flow) prompt messages, as shown in the following image.

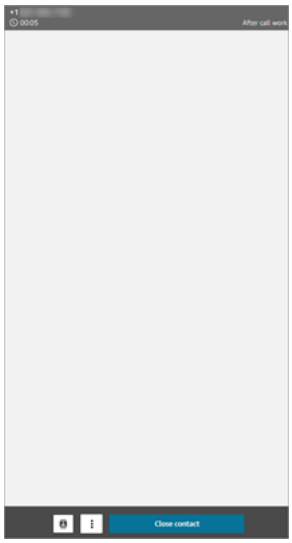
  - Agent 2 receives a call transcript at the time of accepting the conference/warm transfer call from agent 1.

    The transcript includes everything said by agent 1 and the customer, from the moment agent 1 accepts the initial call until the agent 1 leaves the conference/warm transfer portion of the

call. The transcript includes the flow (transfer/queue flow) prompt messages, and the warm transfer conversation, as shown in the following image.



Because conversational analytics is not enabled in the transfer flow, agent 2 doesn't see the remainder of the transcript when the call has ended and they enter ACW. The following image of ACW for agent 2 shows the transcript is empty.

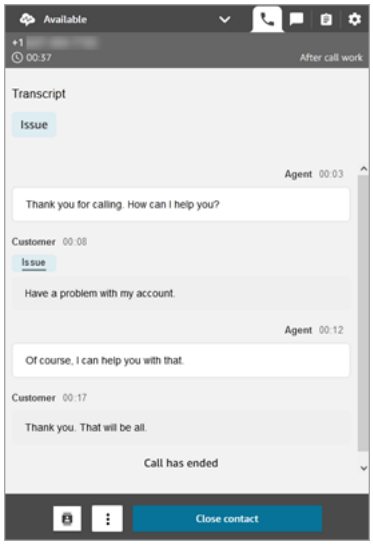


Use case 2: Conversational analytics is enabled in an inbound flow and a transfer flow (quick connect)

- A contact enters the inbound flow, and there are no call transfers. Following is the agent experience:

- Agent 1 receives a full call transcript (unredacted) during ACW.

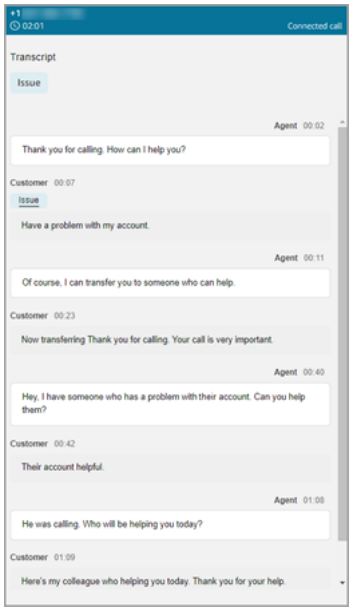
  The transcript includes everything said by agent 1 and the customer from the moment the agent accepts the call, until the call has ended. This is shown in the following image of the CCP for agent 1.



- A contact enters the inbound flow, and there is a call transfer. Following is the agent experience:
  - Agent 1 receives a call transcript after they leave the conference/warm transfer, during ACW.

    The transcript includes everything said by agent 1 and the customer from the moment agent 1 accepts the call, until agent 1 leaves the conference/warm transfer portion of the call. The transcript includes flow (transfer/queue flow) prompt messages.

    The full call transcript until warm transfer is shown in the following image.

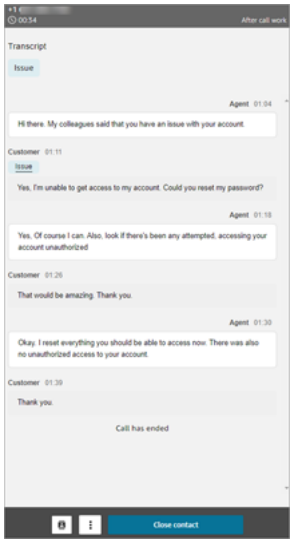


- Agent 2 receives a call transcript at the time of accepting the conference/warm transfer call from agent 1.

  The transcript includes everything said by agent 1 and the customer, from the moment agent 1 accepts the call, until agent 1 leaves the conference/warm transfer portion of the call. The transcript includes the flow (transfer/queue flow) prompt messages.

- Because conversational analytics is enabled in the transfer flow, agent 2 receives a call transcript after the call is completed, during ACW.

  The transcript includes only the remaining portion of the call between agent 2 and customer, after agent 1 has left the call. The transcript includes everything said by agent 2 and the customer, from the moment they are conferenced/warm transferred in, until the call has ended. An example transcript is shown in the following image.



What if the flow block fails to enable conversational analytics?

It's possible that the Set recording and analytics behavior block can fail to enable conversational analytics on a contact. If conversational analytics isn't enabled for a contact, check the flow logs for the error.

Multi-party calls and conversational analytics

Conversational analytics supports calls with up to 2 participants. For example, if there are more than two parties (agent and customer) on a call, or a call is getting transferred to a third party, the quality of the transcription and analytics, such as sentiment, redaction, categories among others, can get degraded. We recommend you disable conversational analytics for multi-party or third-party calls if there are more than two parties (agent and customer). To do this, add another Set recording and analytics behavior block to the flow and disable conversational analytics. For more information about the behavior of the flow block, see Configuration tips.

Assign permissions to use conversational analytics in Connect Customer

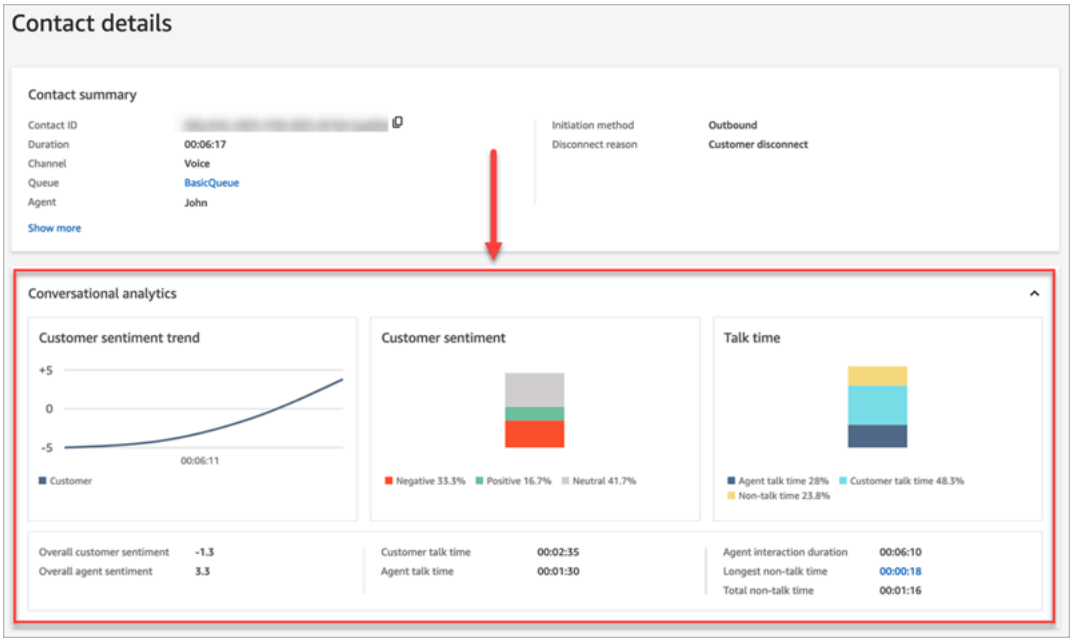
To keep customer data secure, you set security profile permissions to determine who can access information generated by conversational analytics.

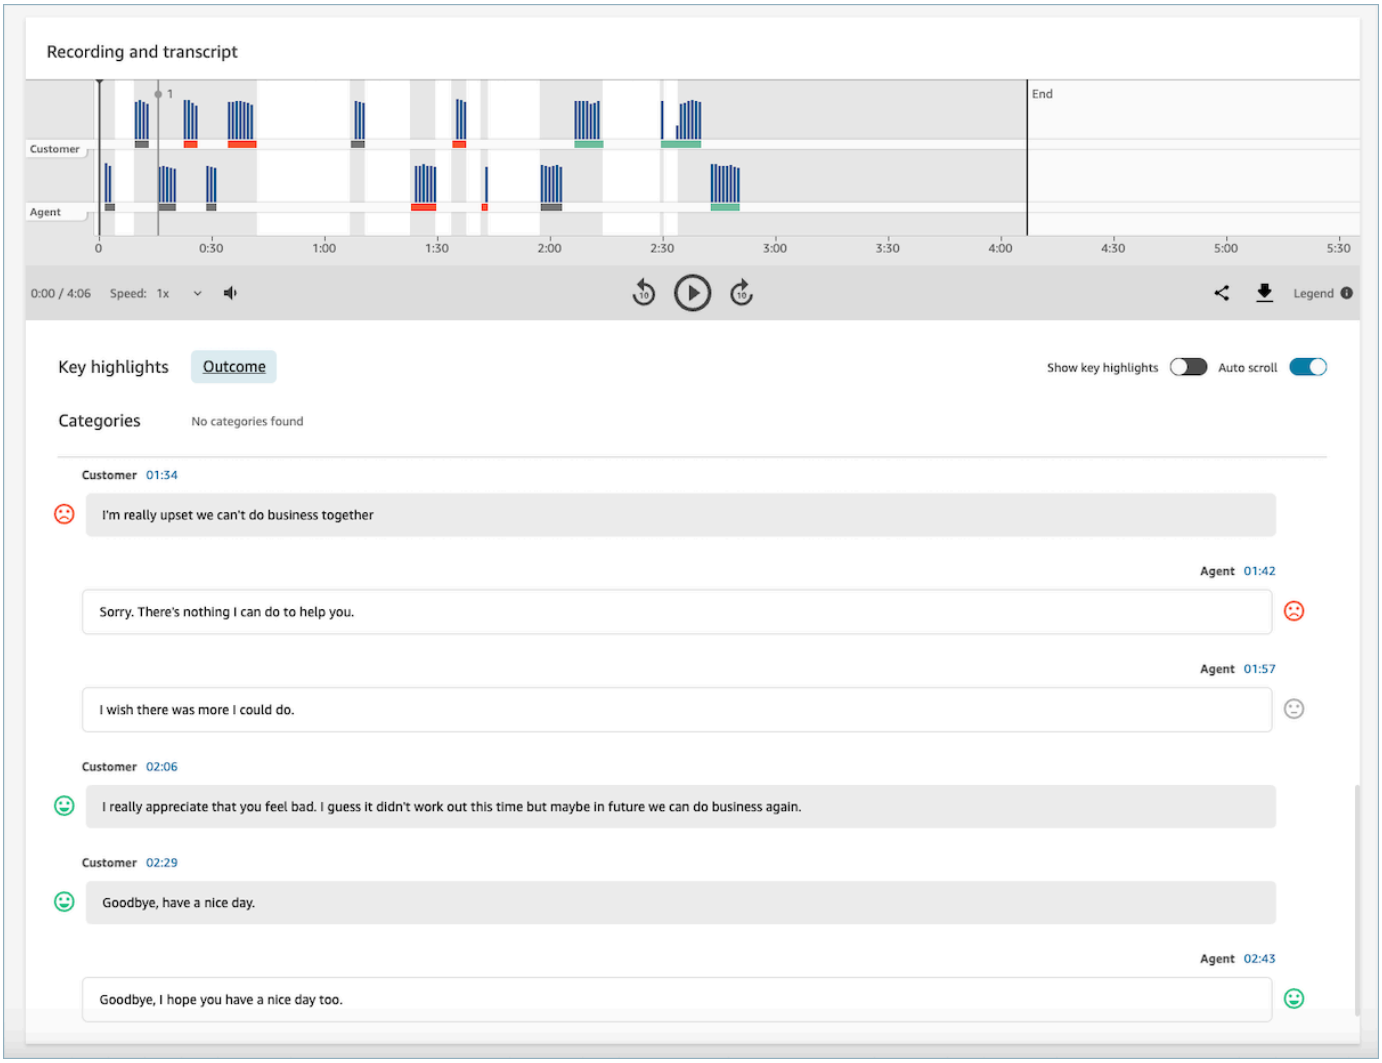
Following is a description of the required security profile permissions, as well as some permissions that are helpful to have but not required. Several of these are Search permissions, which are needed so you can find the contacts you want to analyze. They aren't specific to conversational analytics.

Conversational analytics permissions

- **conversational analytics - conversational analytics**
  - On the **Contact details** page you can view graphs that summarize conversational analytics (customer sentiment, talk time for voice contacts), as well as sentiment colors and indicators for each conversation turn on transcripts and recordings. For example, the following image shows how this information is displayed on the **Contact details** page for a voice contact.

    conversational analytics - View permission is also required to view sentiment indicators on conversation recordings and transcripts.





- **Call recordings (unredacted)**

  On the **Contact details** and **Contact search** pages for a contact, view unredacted audio recordings.

- **Call recordings (redacted)**

  On the **Contact details** and **Contact search** pages for a contact, listen to call recordings in which the sensitive data has been redacted.

- **Contact transcripts (unredacted)**

  On the **Contact details** and **Contact search** pages for a contact, view unredacted chat, email conversations and unredacted voice transcripts produced by conversational analytics.

- **Contact transcripts (redacted)**

On the **Contact details** and **Contact search** pages for a contact, view chat and voice transcripts in which the sensitive data has been redacted.

Important

If you have permissions to:

- Both **Contact transcripts (unredacted) - Access** and **Contact transcripts (redacted) - Access**

– OR –

- Both **Call recordings (unredacted) - Access** and **Call recordings (redacted) - Access**

Note the following behavior:

- When redaction is enabled on the flow, redacted content is displayed on the **Contact details** and **Contact search** pages.
- When redaction is disabled on the flow or the contact is not analyzed by conversational analytics, unredacted content is displayed on the **Contact details** and **Contact search** pages.

You cannot access both the redacted and unredacted version of a conversation at the same time.

Search permissions

- **Contact search**

  This permission is required so you can access the **Contact search** page, which is where you can search contacts so you can review the analyzed recording and transcript. In addition, you can do fast, full-text search on call transcripts, and search by sentiment score and non-talk time.

- **View my contacts**

This permission is required if you need to access the **Contact search** page, review only those contacts that you handled, and review the analyzed recording and transcripts.

> **Important**
>
> If both **Contact search** and **View my contacts** permissions are granted, then the user will have access to all contacts.

- **Search contacts by conversation characteristics**

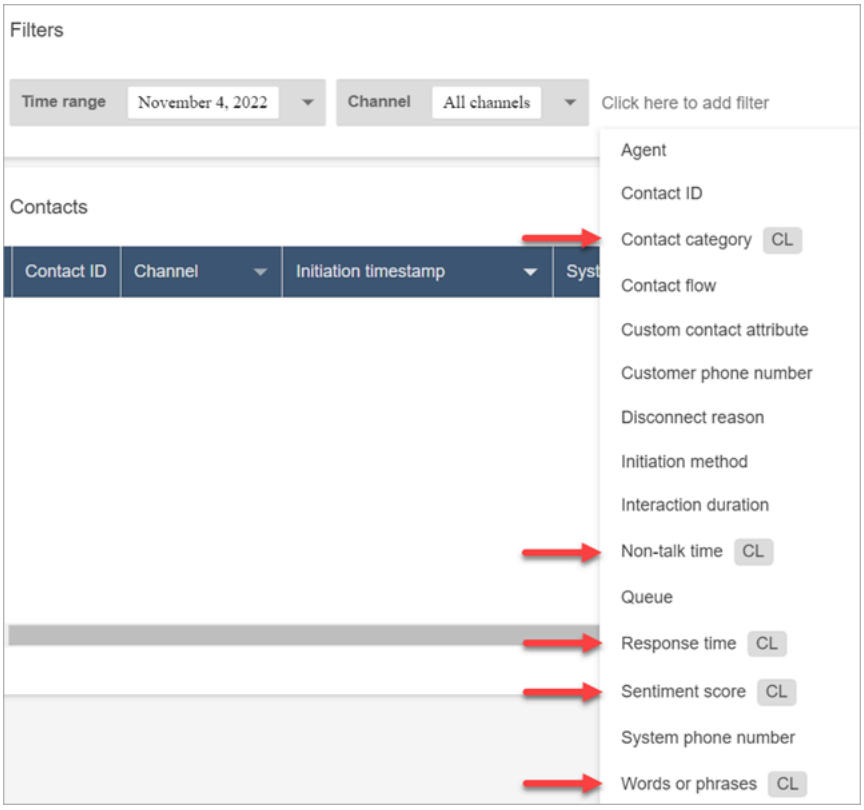
  This permission isn't required by conversational analytics but it's helpful as it provides more search options.

  On the **Contact Search** page:

  - For voice contacts, you can access additional filters that you can use to return results by sentiment score and non-talk time.
  - For chat contacts, you can access an additional filter to search for contacts by response time.
  - For both voice and chat, you can search conversations that fall into specific contact categories.

  For more information, see Search for sentiment score/shift, Search for non-talk time, and Search a contact category.

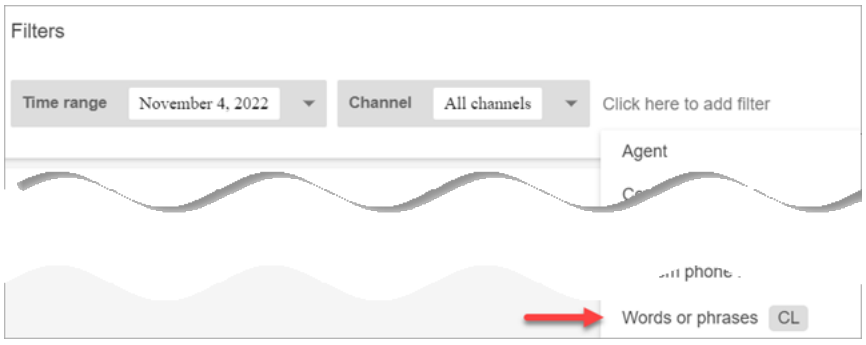
  The following image shows of the **Filters** section of the **Contact Search** page, and the **Filters** dropdown menu. Filters with **CL** next to them are only available to users who have this security profile permission.



- **Search contacts by keywords**

  This permission isn't required by conversational analytics but it's helpful as it provides more search options.

  - On the **Contact Search** page, you can access additional filters that you can use to search contacts by **Words or phrases**, such as "*thank you for your business*." For more information, see Search for words or phrases.



Conversational analytics metrics in Connect Customer

The following metrics are derived from conversational analytics. These metrics are available only when conversational analytics is enabled for your instance and conversational analytics is enabled on the contact.

These metrics are displayed on the Real-time and Historical metrics reports. For instructions about how add these metrics to your report, see How to create a historical metrics report.

Also check out the conversational analytics dashboard for data visualizations about the trends of contact drivers over time.

Agent talk time percent

This metric measures the talk time by an agent in a voice conversation as a percent of the total conversation duration.

Metric type: Percent

Metric category: Conversational analytics driven metric

How to access using the Connect Customer API:

- GetMetricDataV2 API metric identifier: `PERCENT_TALK_TIME_AGENT`

How to access using the Connect Customer admin website:

- Historical metrics reports: Agent talk time percent

Calculation logic:

- Sum all the intervals in which an agent was engaged in conversation (talk time agent).
- Divide the sum by the total conversation duration.

Notes:

- This metric is available only for contacts analyzed by conversational analytics.

Average agent greeting time

This metric provides the average first response time of agents on chat, indicating how quickly they engage with customers after joining the chat.

Metric type: String (*hh:mm:ss*)

Metric category: Conversational analytics driven metric

How to access using the Connect Customer API:

- GetMetricDataV2 API metric identifier: `AVG_GREETING_TIME_AGENT`

How to access using the Connect Customer admin website:

- Historical metrics reports: Average agent greeting time

Calculation logic:

- This metric is calculated by dividing the total time it takes for an agent to initiate their first response by the number of chat contacts.

Notes:

- This metric is available only for contacts analyzed by conversational analytics.

Average agent interruptions

This metric quantifies the average frequency of agent interruptions during customer interactions.

Metric type: String (*hh:mm:ss*)

Metric category: Conversational analytics driven metric

How to access using the Connect Customer API:

- GetMetricDataV2 API metric identifier: `AVG_INTERRUPTIONS_AGENT`

How to access using the Connect Customer admin website:

- Historical metrics reports: Average agent interruptions

Calculation logic:

- This metric is calculated by dividing the total number of agent interruptions by the total number of contacts.

Notes:

- This metric is available only for contacts analyzed by conversational analytics.

Average agent interruption time

This metric measures the average of total agent interruption time while talking to a contact.

Metric type: String (*hh:mm:ss*)

Metric category: Conversational analytics driven metric

How to access using the Connect Customer API:

- GetMetricDataV2 API metric identifier: `AVG_INTERRUPTION_TIME_AGENT`

How to access using the Connect Customer admin website:

- Historical metrics reports: Average agent interruption time

Calculation logic:

- Sum the interruption intervals within each conversation.
- Divide the sum the number of conversations that experienced at least one interruption.

Notes:

- This metric is available only for contacts analyzed by conversational analytics.

Average agent talk time

This metric measures the average time that was spent talking in a conversation by an agent.

Metric type: String (*hh:mm:ss*)

Metric category: Conversational analytics driven metric

How to access using the Connect Customer API:

- GetMetricDataV2 API metric identifier: `AVG_TALK_TIME_AGENT`

How to access using the Connect Customer admin website:

- Historical metrics reports: Average agent talk time

Calculation logic:

- Sum the durations of all intervals during which the agent was speaking.
- Divide the sum by the total number of contacts.

Notes:

- This metric is available only for contacts analyzed by conversational analytics.

Average conversation duration

This metric measures the average conversation duration of voice contacts with agents.

Metric type: String (*hh:mm:ss*)

Metric category: Conversational analytics driven metric

How to access using the Connect Customer API:

- GetMetricDataV2 API metric identifier: `AVG_CONVERSATION_DURATION`

How to access using the Connect Customer admin website:

- Historical metrics reports: Average conversation duration

Calculation logic:

- This metric is calculated by the total time from the start of the conversation until the last word spoken by either the agent or the customer.
- This value is then divided by the total number of contacts to provide an average representation of the conversation time spent on the call.

Notes:

- This metric is available only for contacts analyzed by conversational analytics.

Average customer talk time

This metric measures the average time that was spent talking in a conversation by a customer.

Metric type: String (*hh:mm:ss*)

Metric category: Conversational analytics driven metric

How to access using the Connect Customer API:

- GetMetricDataV2 API metric identifier: `AVG_TALK_TIME_CUSTOMER`

How to access using the Connect Customer admin website:

- Historical metrics reports: Average customer talk time

Calculation logic:

- Sum the durations of all intervals during which the customer was speaking.
- Divide the sum by the total number of contacts.

Notes:

- This metric is available only for contacts analyzed by conversational analytics.

Average non-talk time

This metric provides the average of total non-talk time in a voice conversation. Non-talk time refers to the combined duration of hold time and periods of silence exceeding 3 seconds, during which neither the agent nor the customer is engaged in conversation.

Metric type: String (*hh:mm:ss*)

Metric category: Conversational analytics driven metric

How to access using the Connect Customer API:

- GetMetricDataV2 API metric identifier: `AVG_NON_TALK_TIME`

How to access using the Connect Customer admin website:

- Historical metrics reports: Average non-talk time

Calculation logic:

- Sum all the intervals in which both participants remained silent.
- Divide the sum by the number of contacts.

Notes:

- This metric is available only for contacts analyzed by conversational analytics.

Average talk time

This metric measures the average time that was spent talking during a voice contact across either the customer or the agent.

Metric type: String (*hh:mm:ss*)

Metric category: Conversational analytics driven metric

How to access using the Connect Customer API:

- GetMetricDataV2 API metric identifier: `AVG_TALK_TIME`

How to access using the Connect Customer admin website:

- Historical metrics reports: Average talk time

Calculation logic:

- Sum all the intervals in which either an agent, a customer, or both were engaged in conversation.
- Divide the sum by the total number of contacts.

Notes:

- This metric is available only for contacts analyzed by conversational analytics.

Customer talk time percent

This metric provides the talk time by a customer in a voice conversation as a percent of the total conversation duration.

Metric type: Percent

Metric category: Conversational analytics driven metric

How to access using the Connect Customer API:

- GetMetricDataV2 API metric identifier: `PERCENT_TALK_TIME_CUSTOMER`

How to access using the Connect Customer admin website:

- Historical metrics reports: Customer talk time percent

Calculation logic:

- Sum all the intervals in which a customer was engaged in conversation.
- Divide the sum by the total conversation duration.

Notes:

- This metric is available only for contacts analyzed by conversational analytics.

Non-talk time percent

This metric provides the non-talk time in a voice conversation as a percent of the total conversation duration.

Metric type: Percent

Metric category: Conversational analytics driven metric

How to access using the Connect Customer API:

- GetMetricDataV2 API metric identifier: `PERCENT_NON_TALK_TIME`

How to access using the Connect Customer admin website:

- Historical metrics reports: Non-talk time percent

Calculation logic:

- Sum all the intervals in which participants remained silent (non-talk time).
- Divide the sum by the total conversation duration.

Notes:

- This metric is available only for contacts analyzed by conversational analytics.

Talk time percent

This metric provides the talk time in a voice conversation as a percent of the total conversation duration.

Metric type: Percent

Metric category: Conversational analytics driven metric

How to access using the Connect Customer API:

- GetMetricDataV2 API metric identifier: `PERCENT_TALK_TIME`

How to access using the Connect Customer admin website:

- Historical metrics reports: Talk time percent

Calculation logic:

- Sum all the intervals in which either an agent, a customer, or both were engaged in conversation (talk time).
- Divide the sum by the total conversation duration.

Notes:

- This metric is available only for contacts analyzed by conversational analytics.

Connect Customer conversational analytics notification types

Conversational analytics provides the following notification types:

- Conversational analytics Post Call/Chat Rules Matched: An EventBridge event is delivered whenever a conversational analytics rule is matched and has triggered the EventBridge rule action.

  This event contains useful information about the conversational analytics rule that is triggered including the category assigned, and details of the agent, contact and queue.
- Conversational analytics Real Time Call/Chat Rules Matched: An EventBridge event is delivered whenever a conversational analytics rule is matched and has triggered in real time.

  This event contains useful information about the conversational analytics rule that is triggered including the category assigned, and details of the agent, contact and queue.
- Conversational analytics Analysis State Change: An EventBridge event is delivered when conversational analytics is unable to analyze a contact recording. The event contains the Event Reason Code which provides the details on why it was unable to process the recording.

You can use these notification types in a variety of scenarios. For example, use conversational analytics analysis State Change events to signal unexpected errors in the processing of a contact file where EventBridge event details can be subsequently stored in a CloudWatch log for additional review, trigger additional workflows, or alert relevant support teams for further investigation.

The conversational analytics events for speech and chat analytics enable numerous new use cases such as surfacing and visualization of additional insights, for example:

- Generate alerts on real-time customer sentiment drops across all call and chat conversations
- Aggregating and reporting on reoccurring issues and topics
- Measuring the impact of the latest marketing campaign by detecting how many customers referenced it during a call
- Customizing agent compliance standards for each Region and lines of business, and enrolling agents into additional training where required.

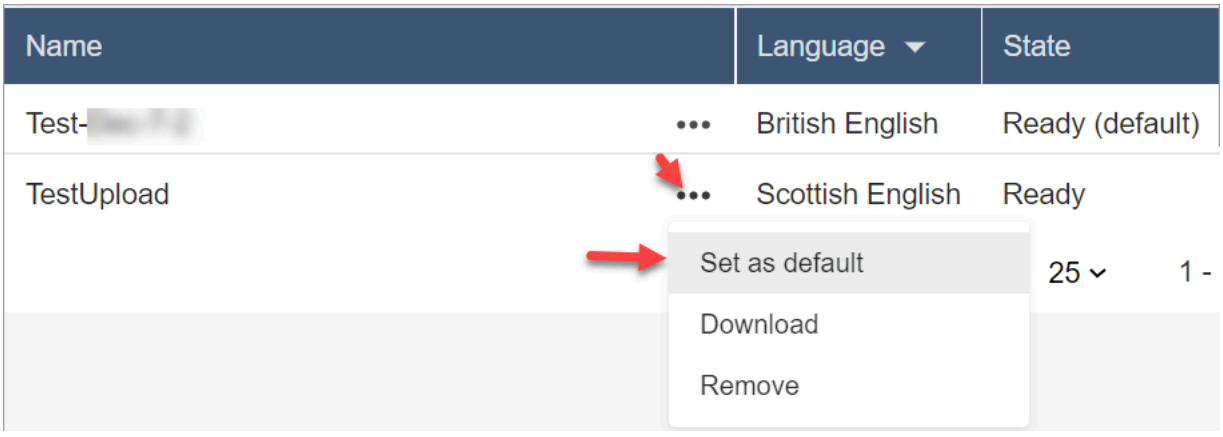
Add custom vocabularies to conversational analytics using the Connect Customer admin website

You can improve the accuracy of speech recognition for product names, brand names, and domain-specific terminology, by expanding and tailoring the vocabulary of the speech-to-text engine in conversational analytics.

This topic explains how to add custom vocabularies using the Connect Customer admin website. You can also add them using the CreateVocabulary and AssociateDefaultVocabulary APIs.

Things to know about custom vocabularies

- You must set a vocabulary as the **default** for it to be applied to the analyses to generate transcripts. The following image shows the **Custom vocabularies** page. Choose the ellipsis, and then choose **Set as default**.



- You can have one vocabulary per language applied to the analyses. This means only one file per language can be in the **Ready (default)** state.

- You can upload and activate up to 20 vocabulary files. You can activate all 20 files at the same time.
- Transcription is a one-time event. A newly uploaded vocabulary isn't applied retroactively to existing transcriptions.
- Your text file must be in LF format. If you use any other format, such CRLF format, your custom vocabulary is not accepted by Amazon Transcribe.
- The sample vocabulary file can be downloaded only when you choose an English language setting.
- For limits to the size of a vocabulary file and other requirements, see Custom vocabularies in the *Amazon Transcribe Developer Guide*.
- Custom vocabularies apply to speech analytics only. They do not apply to chat conversations because the transcripts already exist.

Required permissions

Before you can add custom vocabularies to Connect Customer, you need the **Analytics and Optimization**, **conversational analytics - custom vocabularies** permission assigned to your security profile.

By default, in new instances of Connect Customer the **Admin** and **CallCenterManager** security profiles have this permission.

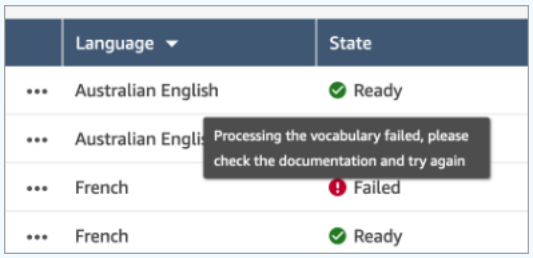
For information about how to add more permissions to an existing security profile, see Update security profiles in Connect Customer.

Add a custom vocabulary

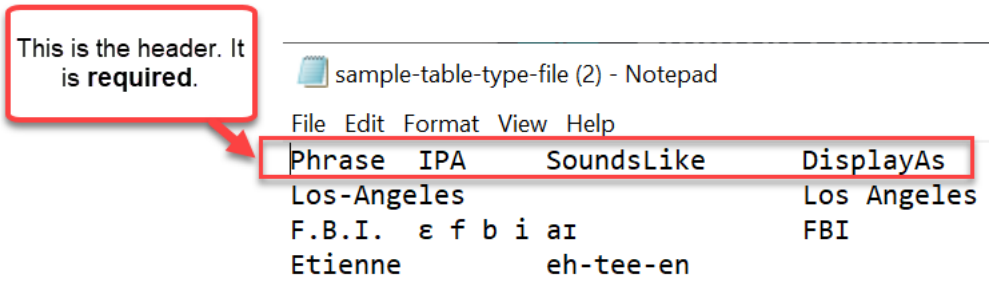
1. Log in to Connect Customer with a user account that has the required permissions to add custom vocabularies.
2. Navigate to **Analytics and optimization**, **Custom vocabularies**.
3. Choose **Add custom vocabulary**.
4. On the **Add custom vocabulary** page, enter a name for the vocabulary, choose an English language, and then choose **Download a sample** file.

Note

The sample vocabulary file can be downloaded only when you choose an English language setting. Otherwise, an error message is displayed, as shown in the following image.

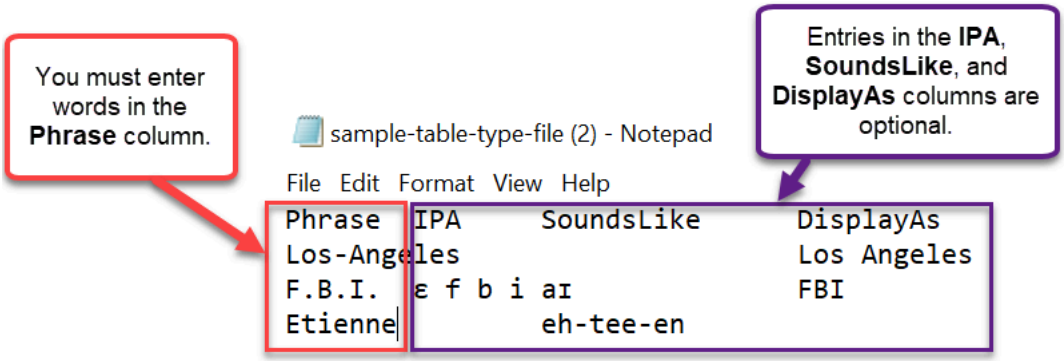


The following image shows what the sample vocabulary file looks like. The header contains `Phrase`, `IPA`, `SoundsLike`, `DisplayAs`. The header is required.



5. The information in the file is separated by one [TAB] per entry. For details about how to add words and acronyms to your vocabulary file, see Creating a custom vocabulary using a table in the *Amazon Transcribe Developer Guide*.

   The following image shows words in a sample vocabulary file. Words in the Phrase column are required. The `DisplayAs` column is optional. Amazon Transcribe no longer processes the `IPA` and `SoundsLike` columns.



To enter multiple words in the **Phrase** column, separate each word with a hyphen (-); do not use spaces.

> **IPA and SoundsLike columns ignored**
>
> Amazon Transcribe ignores values in the `IPA` and `SoundsLike` columns. When you create a custom vocabulary table, you only need the `Phrase` column (required) and optionally the `DisplayAs` column.

Vocabulary states

- **Ready (default)**: The vocabulary is being applied to the analyses to generate transcripts. It is applied to both real-time and post-call analyses.
- **Ready**: The vocabulary is not being applied to analyses, but it is a valid file and available. To apply it to analyses, set it to default.
- **Processing**: Connect Customer is validating your uploaded vocabulary and trying to apply it to the analyses to generate transcripts.
- **Deleting**: You chose to **Remove** the vocabulary, and Connect Customer is deleting it now.

  It takes about 90 minutes for Connect Customer to delete a vocabulary.

If you attempt to upload a vocabulary that does not validate, it results in a **Failed** state. For example, if you add multiple-word phrases to the **Phrase** column, and separate them with spaces instead of hyphens, it will fail.

Download and view a custom vocabulary

To view a custom vocabulary that has been uploaded, you download and open the file. Only files in the **Ready** state can be downloaded and viewed.

1. Navigate to **Analytics and optimization**, **Custom vocabularies**.
2. Choose **More**, **Download**. The location of **Download** is shown in the following image.

3. Open the download to view the contents.
4. You can change the contents, and then choose **Save and upload**.

Create conversational analytics rules using the Connect Customer admin website

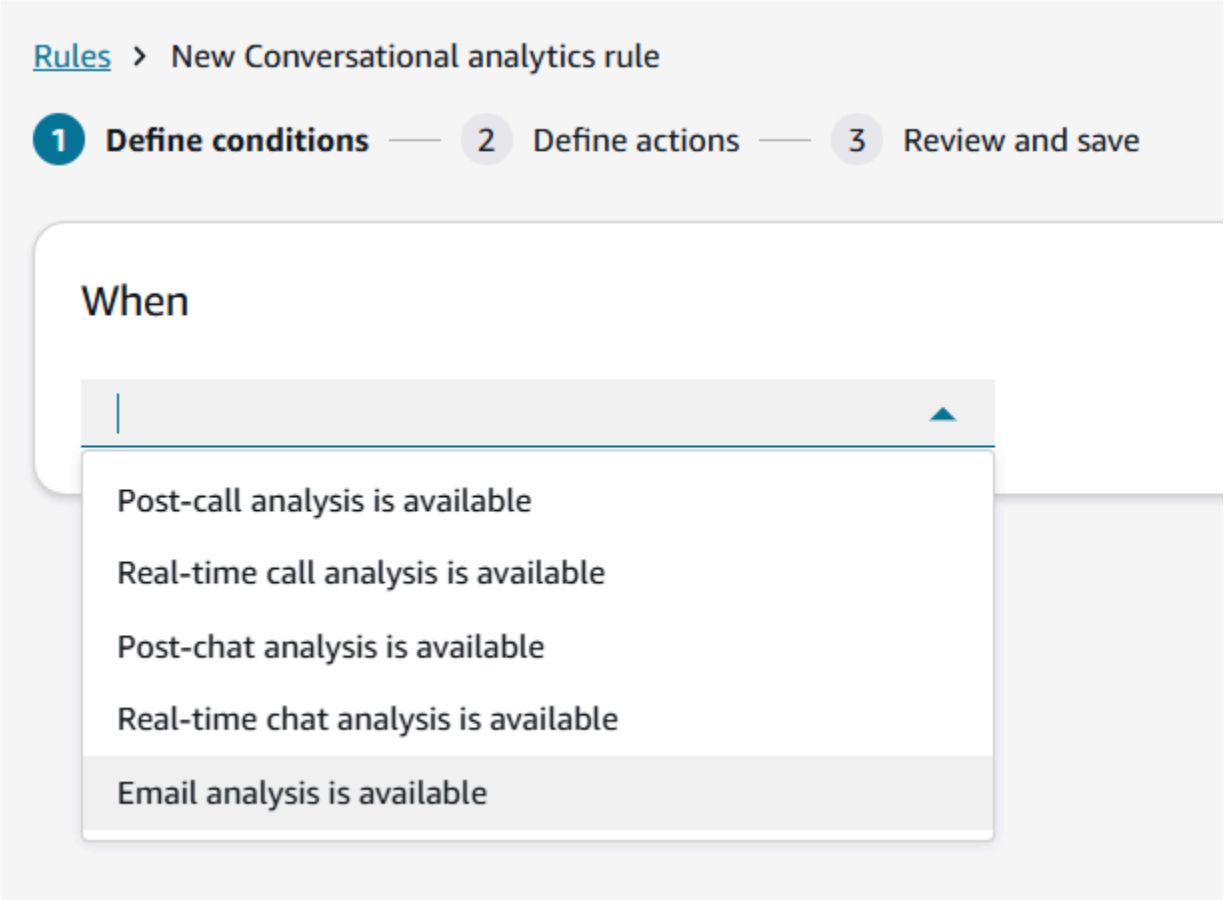
With Conversational analytics rules, you can automatically categorize contacts, receive alerts, or generate tasks based on keywords that are used during a call, chat, or email, sentiment scores, customer attributes, and other criteria.

This topic explains how to create rules using the Connect Customer admin website. To create and manage rules programmatically, see Rules actions and the Connect Customer Rules Function language in the *Connect Customer API Reference Guide*.

> **Tip**
>
> For a list of rules feature specifications (for example, how many rules you can create), see Connect Customer Rules feature specifications.

Step 1: Define rule conditions for conversational analytics

1. On the navigation menu, choose **Analytics and optimization**, **Rules**.
2. Select **Create a rule**, **Conversational analytics**.
3. Under **When**, use the dropdown list to choose **post-call analysis**, **real-time analysis**, **post-chat analysis**, or **email analysis**.



4. Choose **Add condition**.

   You can combine criteria from a large set of conditions to build very specific conversational analytics rules. Following are the available conditions:

   - **Words or phrases**: Choose from Exact match, Pattern match, or Semantic match to trigger an alert or task when keywords are uttered.
   - **Natural Language - Semantic Match**: Provide a natural language statement (for example, customer called to cancel their account) to match with conversation transcripts using generative AI, and take an action (for example, triggering a task, performing an evaluation) For more information, see Generative AI-powered semantic match
   - **After contact work (ACW)**: Build rules to measure agent efficiency in completing after contact work.
   - **Agent hierarchy**: Build rules that run on a specific agent hierarchy. Agent hierarchies might represent geographical locations, departments, products, or teams.

To see list of agent hierarchies so you can add them to rules, you need the **Agent hierarchy - View** permission in your security profile.

- **Agent**: Build rules that run on a subset of agents. For example, create a rule to ensure newly hired agents comply with company standards.

  To see agent names so you can add them to rules, you need **Users - View** permissions in your security profile.

- **AI agent**: Identify contacts where a particular Connect AI agent performed self-service or agent assistance. You can select multiple AI agents, or select a specific version of an agent.

  To see AI agent names so you can add them to rules, you need **AI agents - View** permissions in your security profile.

- **AI agent - Escalation**: Identify contacts when a Connect AI agent used for customer self-service escalated to a human.

  To see AI agent names so you can add them to rules, you need **AI agents - View** permissions in your security profile.

- **Agent interaction duration**: Build rules to identify contacts that had an agent interaction longer or shorter than what was expected. This feature applies to calls only.

- **Contact segment attributes**: You can identify contacts within rules using custom contact segment attributes with values populated from other systems or using custom logic. You can define an attribute and set its value in flows. Custom segment attributes are only present on that specific contact ID, and not the entire contact chain. For example, you can build a rule that identifies that contact was pre-authenticated in IVR, before being connected with the agent.

  To see the list of contact segment attributes to add to a rule, you need **Predefined attributes - View** permissions.

- **Disconnect reason**: Build rules that check for why a contact disconnected. For example, if the agent disconnected before the customer, or if the contact was transferred.

- **Highest loudness score**: Build rules that check for the peak loudness score (in decibels) during the conversation for the agent or the customer. Higher loudness (for example, over 70Db) might be associated with excitement or anger, while speech below a certain loudness score (for example, 30Db or lower) might be hard to understand.

- **Hold time**: Build rules to identify contacts that had unusual hold times to identify opportunities to handle contacts more efficiently. You can set rules using longest hold time,

total hold time, and number of holds. You can also check for hold time as a percentage of the total time the customer was connected with the agent (customer hold time divided by agent interaction duration and customer hold time).

- **Initiation method**: Build rules that check whether a contact was inbound, outbound, transferred.
- **Contact attributes**: Build rules that run on the values of custom contact attributes. For example, you can build rules specifically for a particular line of business or for specific customers, such as based on their membership level, their current country of residence, or if they have an outstanding order.

  You can add up to five contact attributes to a rule.
- **Sentiment - Time period**: Build rules that run on the sentiment analysis results (positive, negative, or neutral) over a trailing window of time.

  For example, you can build a rule for when customer sentiment has remained negative for a set period of time. If the participant joined the contact later, the time period set here applies to when participant was present.

  When rules are applied to contacts that don't have sentiment data, neutral sentiment is used.
- **Sentiment - Entire contact**: Build rules that run on the value of sentiment scores over an entire contact. For example, you can build a rule when customer sentiment has remained low for the entire contact, you can create a task for a customer experience analyst to review the call transcript and follow-up.

  When rules are applied to contacts that don't have sentiment data, neutral sentiment is used.
- **Interruptions**: Build rules that detect when the agent has interrupted the customer for more than X times. This feature applies to calls only.
- **Non-talk time**: Build rules that check for no speech detected. This might include periods of a customer being put on hold. You can check for total non-talk time, longest non-talk time period within a conversation, or percentage of non-talk time during the conversation. High non-talk time, such as a percentage of non-talk time exceeding 50 percent of the conversation, might indicate an opportunity to improve processes or agent coaching opportunities. This feature applies to calls only.

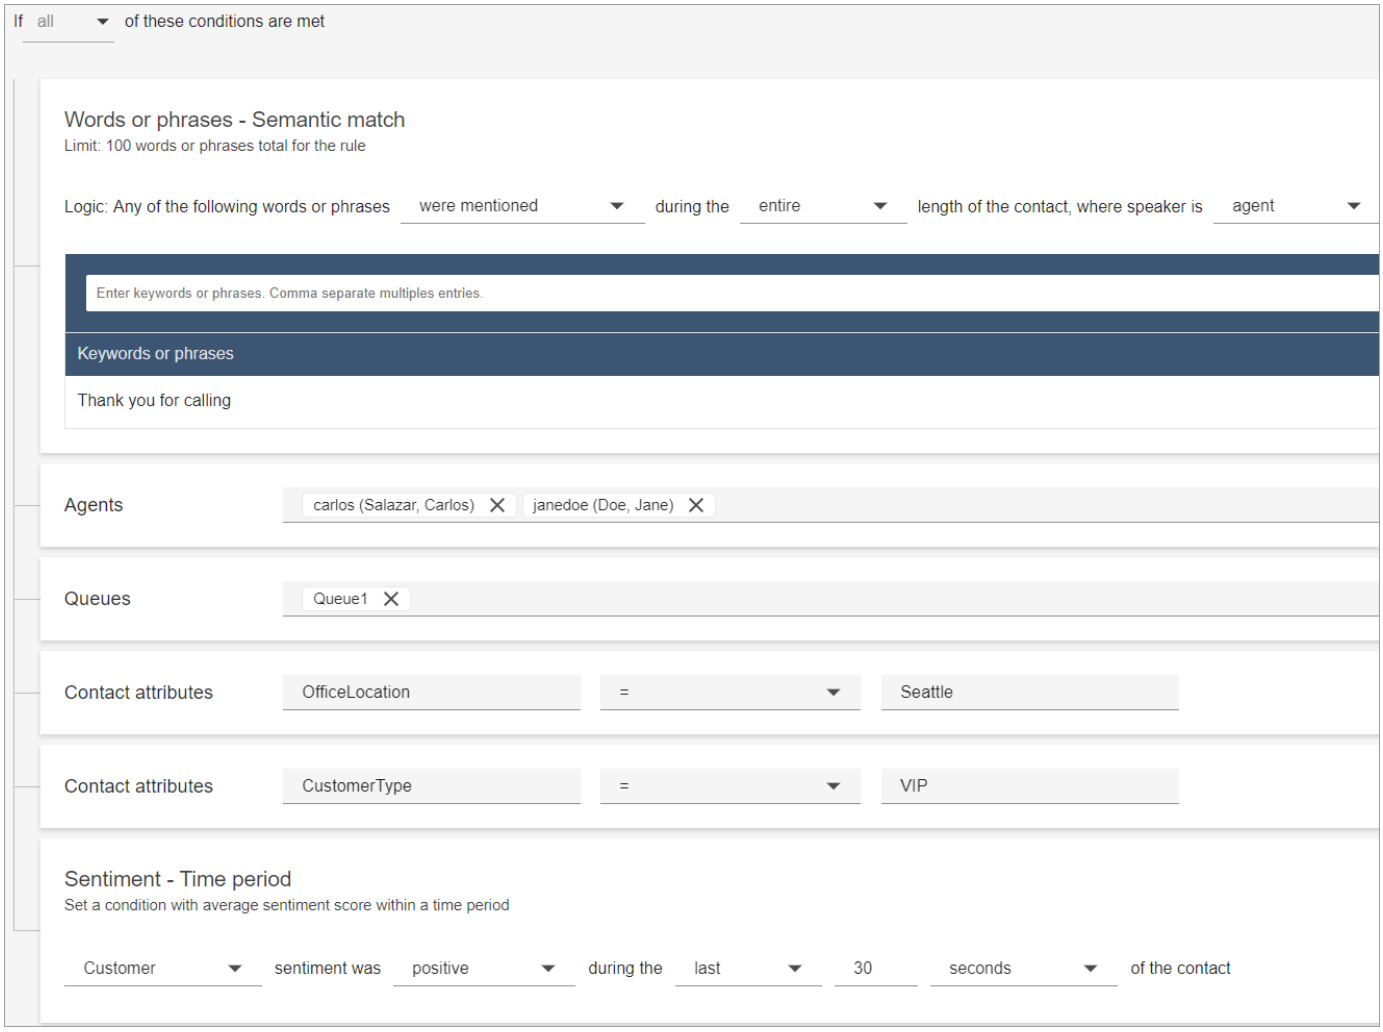
- **Response time**: Build rules to identify contacts where the participant had a response time longer or shorter than what was expected: Average or Maximum.

  For example, you can set a rule on the **Agent greeting time**, also known as **First response time**: after the agent joined the chat, how long until they sent the first greeting message. This will help you to identify when an agent took too long to engage with the customer.
- **Potential disconnect issue**: Build rules that check for any technical issues (such as network connectivity, device problems). You can use this to exclude contacts from automated agent performance evaluations, where there were connectivity issues out of the agent's control.
- **Queues**: Build rules that run on a subset of queues or check if the contact was not queued. Often organizations use queues to indicate a line of business, topic, or domain. For example, you could build rules specifically for your sales queues, tracking the impact of a recent marketing campaign, or, alternatively, rules for your customer support queues, tracking overall sentiment. For self-service interactions, you can check if the contact was never queued, potentially indicating successful self-service with an AI agent.

  To see queue names so you can add them to rules you need **Queues - View** permissions in your security profile.
- **Routing profile**: Identify contacts handled by agents mapped to a specific routing profile. The routing profile might indicate agent department or skill proficiency. For example, you might perform automated evaluations of agents with the routing profile New hires, trained on basic troubleshooting using different evaluation criteria versus tenured multi-skilled agents.

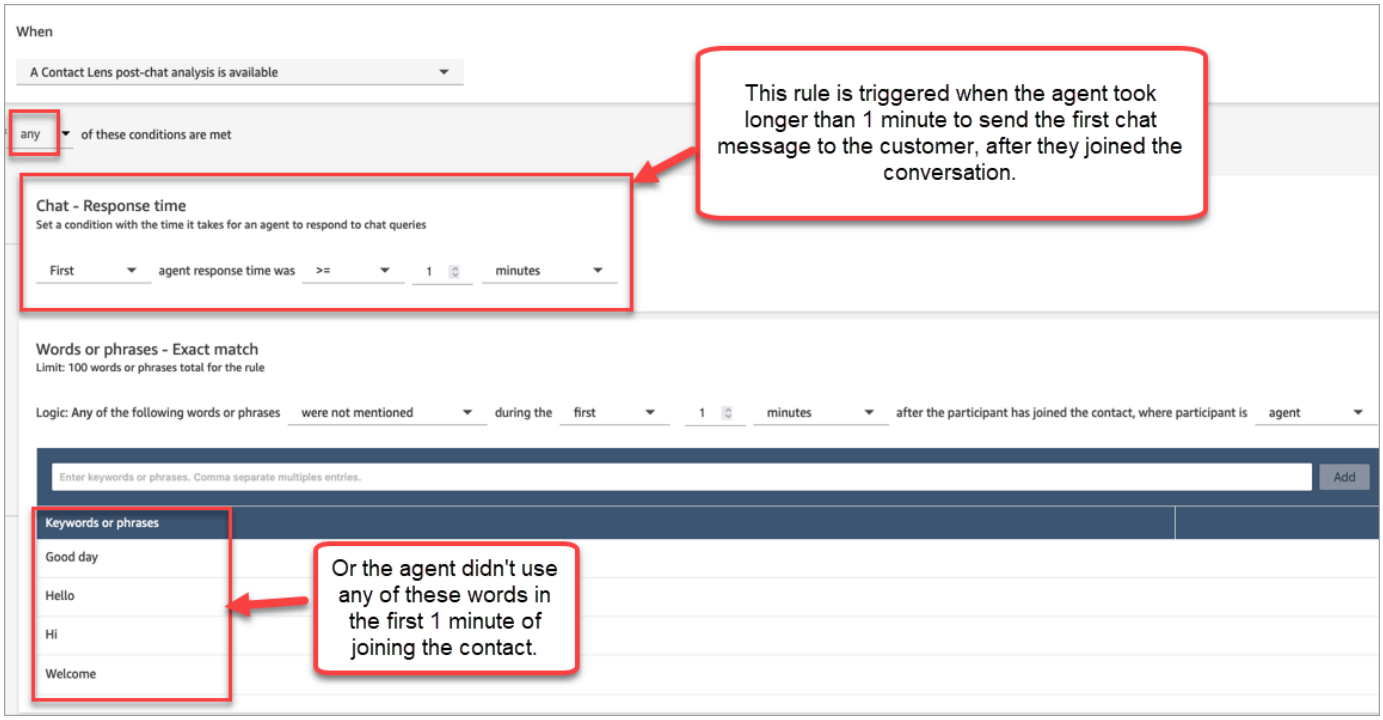
  To see the routing profiles so you can add them to rules, you need **Routing Profiles - View** permissions in your security profile.
- **Talk time**: Build rules using threshold of absolute time spent talking by the agent or the customer. This can be used to identify where the customer did not speak at all, leading the agent to disconnect or where the agent exhibited call avoidance behaviors such as not speaking after picking up the phone.
- **Agent interaction duration**: Build rules to identify contacts that had an agent interaction longer or shorter than what was expected. This feature applies to calls only.

The following image shows a sample rule with multiple conditions for a voice contact.



The following image shows a sample rule with multiple conditions for a chat contact. The rule is triggered when the **First** response time is greater than or equal to 1 minute, and the agent did not mention any of the listed greeting words or phrases in their first response.

First response time = after the agent has joined the chat, how long until they sent the first message to the customer.

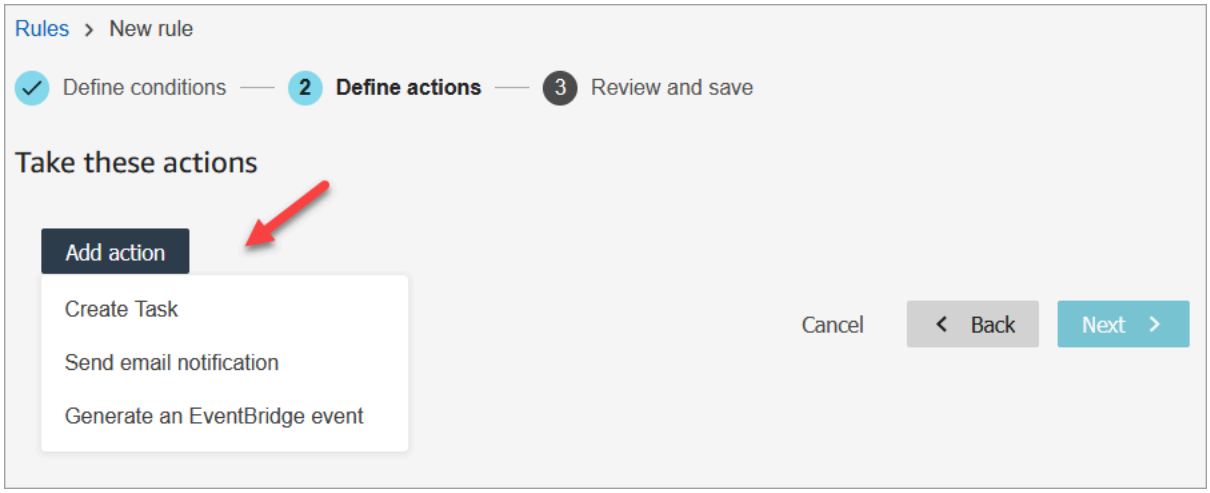


5. Choose **Next**.

Step 2: Define rule actions

1. Choose **Add action**. You can choose the following actions:

   - Create Task: this option is not available for real-time chat
   - Send email notification
   - Send in-app notification
   - Generate an EventBridge event

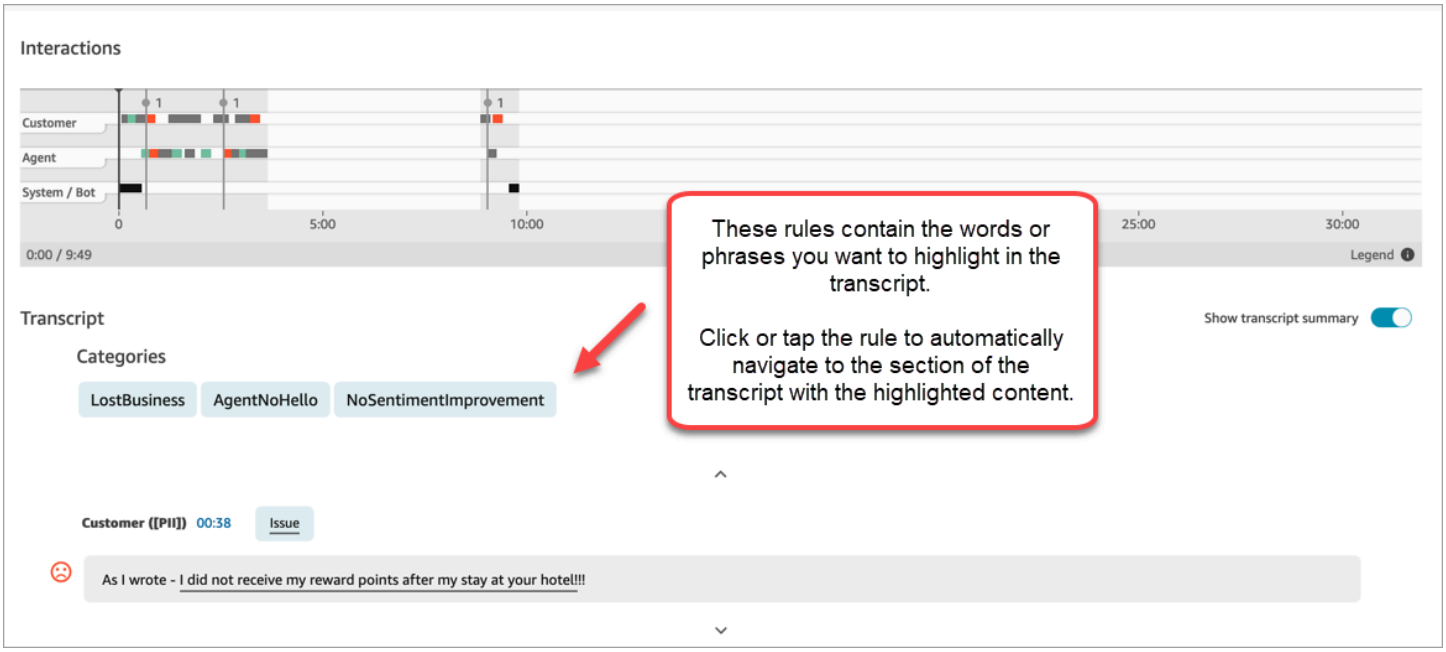


2. Choose **Next**.
3. Review and make any edits, then choose **Save**.
4. After you add rules, they are applied to new contacts that occur after the rule was added. Rules are applied when Connect Customer conversational analytics analyzes conversations.

   You cannot apply rules to past, stored conversations.

Automatically categorize contacts by matching conversations with natural language statements, or specific words and phrases

With Conversational analytics, you can automatically categorize contacts to identify top drivers, customer experience, and agent behavior for your contacts. On the **Contact details** page for a chat, categories appear above the transcript, as shown in the following image.



Following are some of the key things you can do when you categorize contacts:

- With generative AI-powered contact categorization, you can provide criteria to categorize contacts in natural language (for example, did the customer try to make a payment on their balance?).
- You can provide specific words or phrases spoken by agents or customers to match with a conversation. conversational analytics then automatically labels contacts that meet the match criteria, and provides relevant points from the conversation.
- You can define actions to receive alerts and generate tasks on categorized contacts.
- You can specify additional criteria to categorize contacts, such as customer sentiment score, queues, or any custom attributes that you have added to contacts, like customer loyalty information.

When to use words or phrases

Using specific words or phrases is useful when there is a well-defined list of words or phrases that you wish to detect, for example, monitoring agent script adherence or assessing customer interest in a product.

When to use natural language

Using natural language statements to match with contacts is useful when there are too many possible words or phrases or when you want to match with context-specific criteria, for example,

"The customer wanted to make a change to their subscription plan.", "The agent resolved all of the customer's issues."

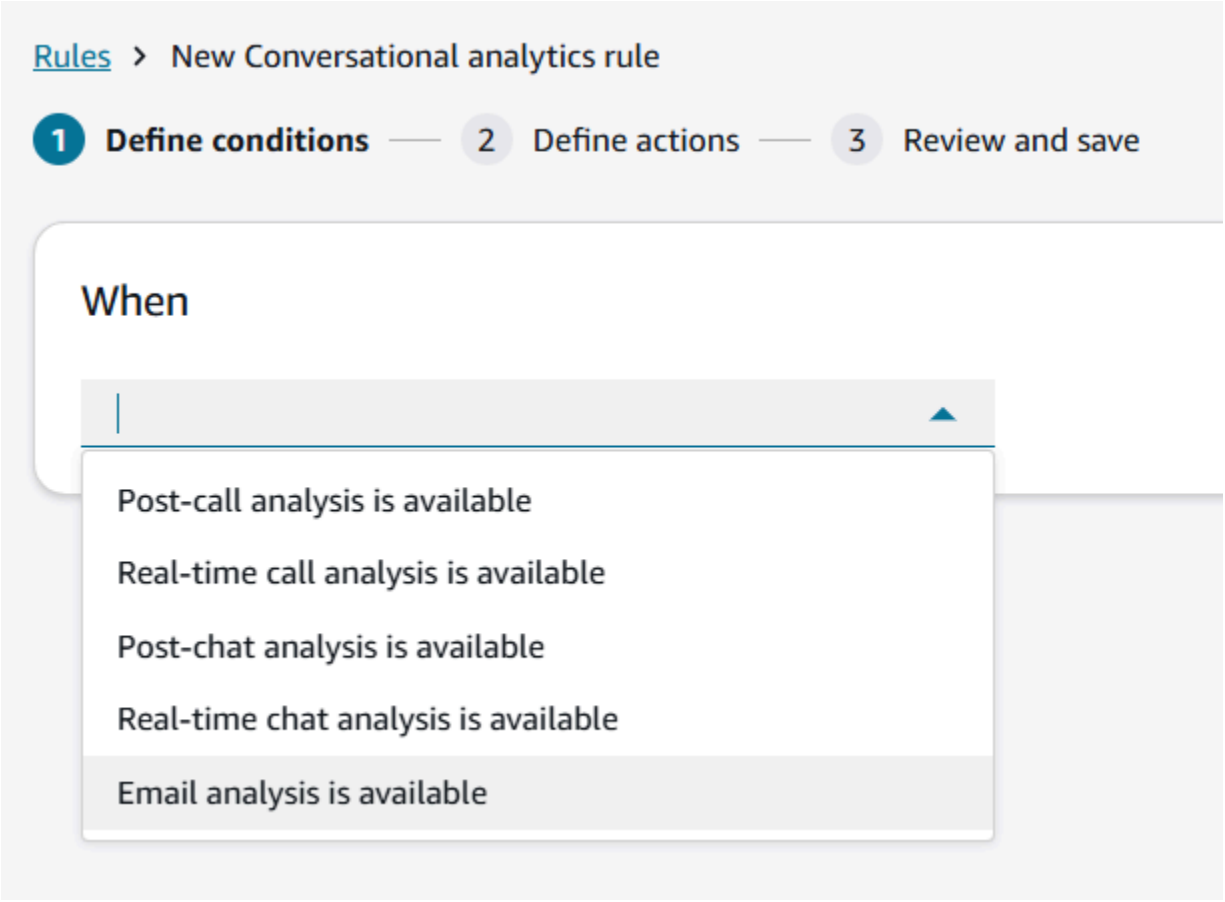
Add rules to categorize contacts

In this section:

- Step 1: Define conditions
- Step 2: Define actions

Step 1: Define conditions

1. Log in to Connect Customer with a user account that is assigned the **CallCenterManager** security profile, or that is enabled for **Rules** permissions.
2. On the navigation menu, choose **Analytics and optimization**, **Rules**.
3. Select **Create a rule**, **Conversational analytics**.
4. Assign a name to the rule.
5. Under **When**, use the dropdown list to choose **post-call analysis**, **real-time analysis**, **post-chat analysis**, **real-time chat analysis**, or **email analysis**.



6. Choose **Add condition**, and then choose the type of match:

   - **Words or Phrases - Exact Match**: Finds contacts that match with the exact words or phrases. Enter the words or phrases, separated by a comma.
   - **Words or Phrases Pattern Match**: Finds contacts by looking for a pattern of words or phrases. You can also specify the distance between words. For example, if you are looking for contacts where the word "credit" was mentioned but you do not want to see any mention of the words "credit card," you can define a pattern matching category to look for the word "credit" that is not within a one-word distance of "card."
   - **Natural Language - Semantic Match**: Use generative AI to find contacts that match the provided natural language statement. The statement should be answerable with a yes or no answer. Natural language - Semantic match is used when you want to match contacts with context-specific criteria or when there are too many possible words or phrases for matching. The following are examples:
     - "The customer wanted to make a change to their subscription plan."
     - "The customer indicated a desire to terminate their current services."

- "The agent offered multiple payment options."
- "The agent assured the customer that their call was important and requested additional waiting time."
- "The agent resolved all of the customer's issues."

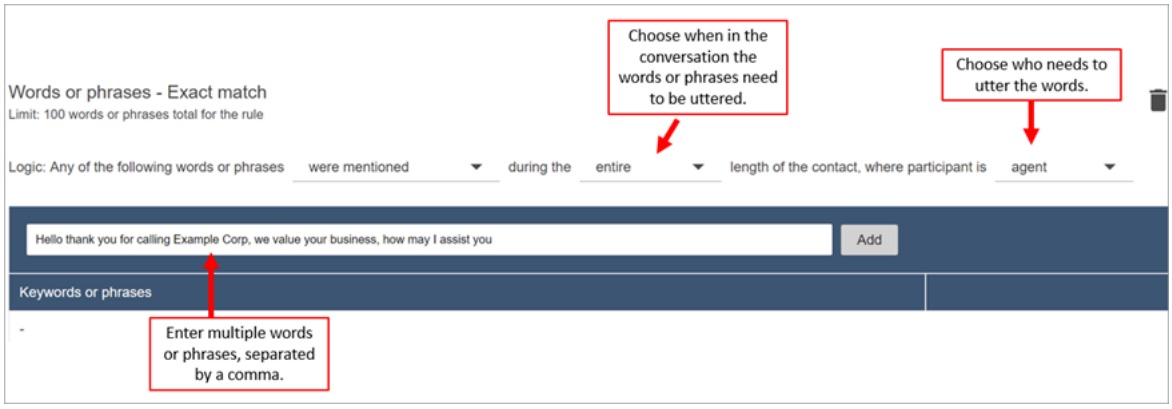
> **Note**
>
> - Natural Language - Semantic Match conditions cannot be used for real-time analysis.
> - To create rules that use generative AI requires an additional permission: **Rules - Generative AI**.

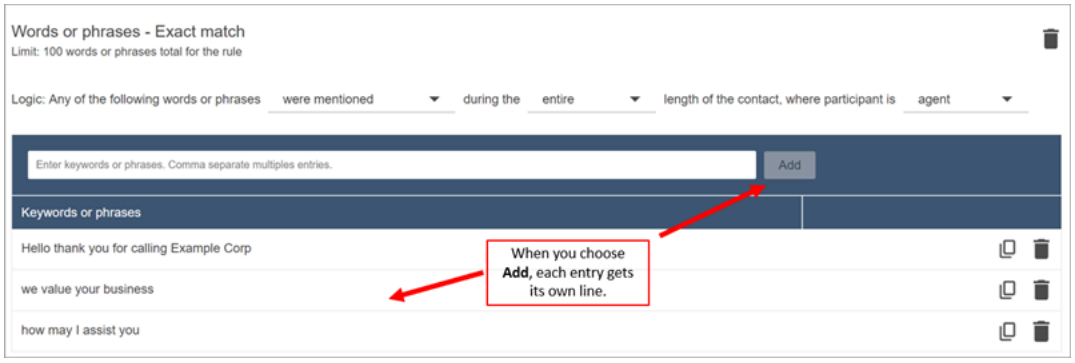
Pro Tip: Use generative AI-powered **Natural language- Semantic match** if you previously used **Words or Phrases - Semantic Match**.

- **Words or Phrases - Semantic Match**: Finds words that might be synonyms. For example, if you enter "upset" it can match "not happy," or "hardly acceptable" can match with "unacceptable," and "unsubscribe" can match with "cancel subscription." Similarly, it can semantically match phrases. For example, "thank you so much for helping me out," "thanks a lot and this is so helpful," and "I am so happy that you are able to help me."

  This removes the need to define an exhaustive list of keywords while creating categories, and provides you the ability to cast a wider net for searching similar phrases that are important to you. For best semantic matching results, provide keywords or phrases with similar meaning within a semantic matching card. Currently, you can provide a maximum of four keywords and phrases per semantic matching card.

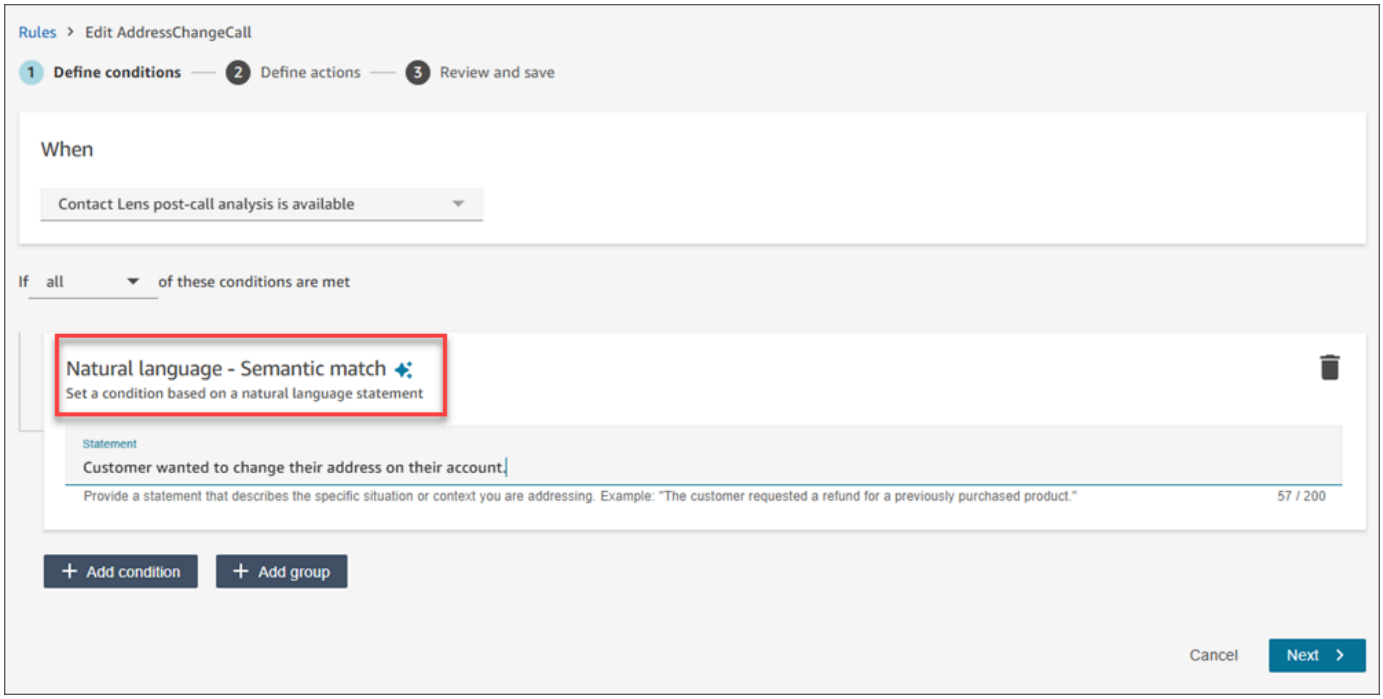
7. Using **Words or Phrases - Exact Match** as an example, enter the words or phrases, separated by a comma, that you want to highlight and choose **Add**. Each word or phrase separated by a comma gets its own line in the card.



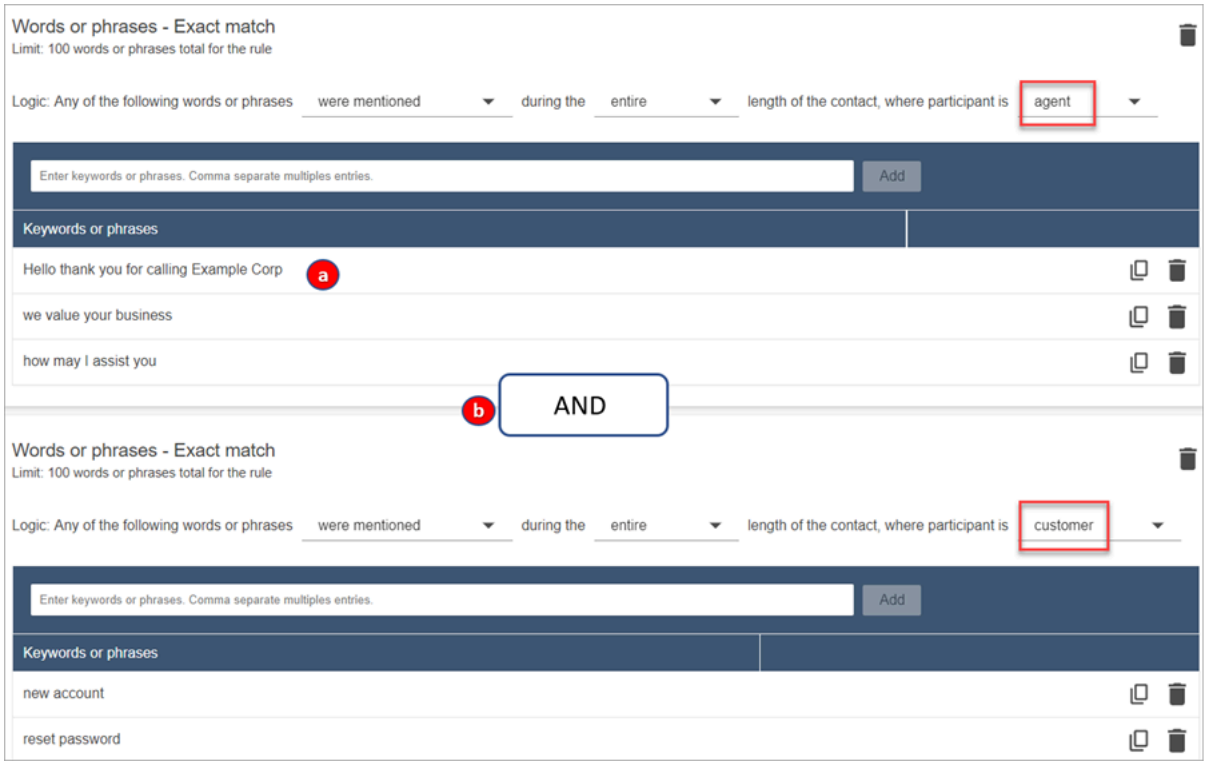


The logic that conversational analytics uses to read these phrases is: (Hello AND thank AND you AND for AND calling AND Example AND Corp) OR (we AND value AND your AND business) OR (how AND might AND I AND assist AND you).

Alternatively, use a **Natural Language - Semantic Match** condition and enter a natural language statement in the textbox, that Generative AI should be able to evaluate as either True or False.



8. To add more words or phrases, choose **Add group of words or phrases**. In the following image, the first group of words or phrases are what the agent might utter. The second group is what the customer might utter.



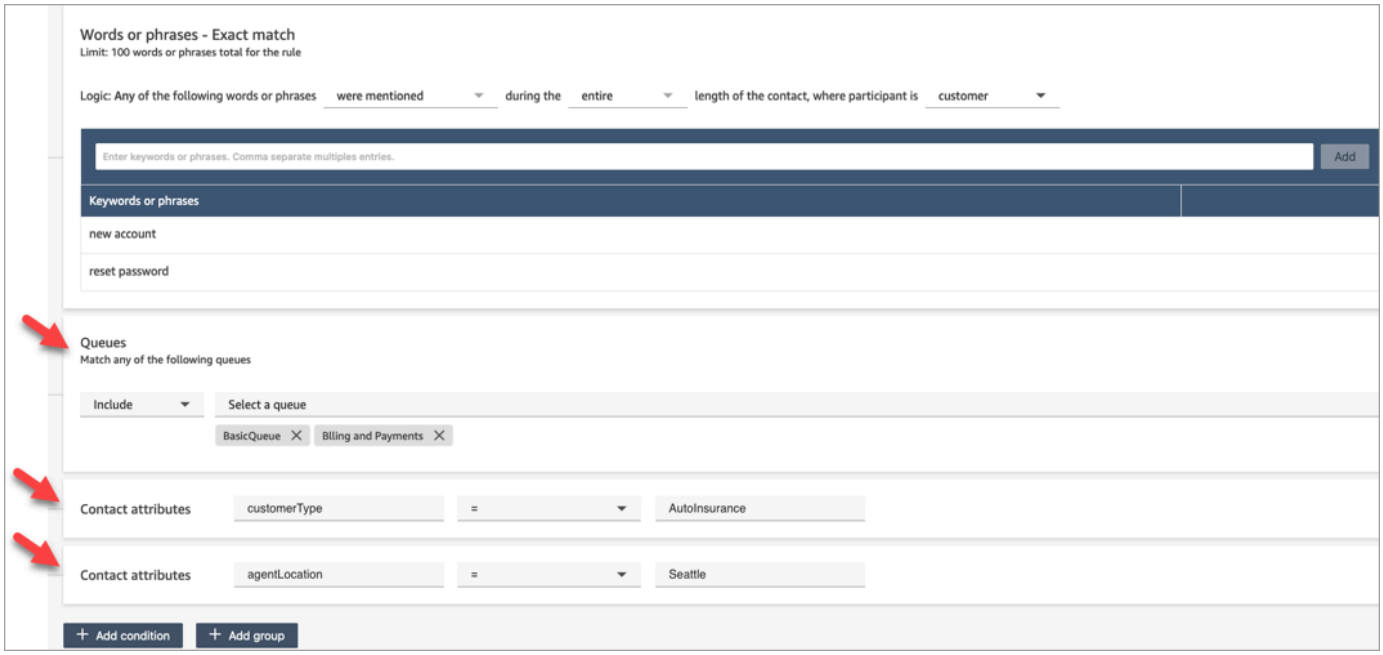
1. The logic that conversational analytics uses to read these phrases is: (Hello AND thank AND you AND for AND calling AND Example AND Corp) OR (we AND value AND your AND business) OR (how AND may AND I AND assist AND you).
2. The two cards are connected with an AND. This means, one of the rows in the first card needs to be uttered AND then one of the phrases in the second card needs to be uttered.

The logic that conversational analytics uses to read the two cards of words or phrases is (card 1) AND (card 2).

9. Choose **Add condition** to apply the rules to:

- Specific queues
- When contact attributes have certain values
- When sentiment scores have certain values

For example, the following image shows a rule that applies when an agent is working the BasicQueue or Billing and Payments queues, the customer is for auto insurance, and the agent is located in Seattle.



Step 2: Define actions

In addition to categorizing a contact, you can define what actions Connect Customer should take:

1. Generate an EventBridge event
2. Create Task
3. Create Case
4. Send email notifications
5. Send in-app notification
6. Create a rule that submits an automated evaluation

Step 3: Review and save

1. When done, choose **Save**.
2. After you add rules, they are applied to new contacts that occur after the rule was added. Rules are applied when Connect Customer conversational analytics analyzes conversations.

   You cannot apply rules to past, stored conversations.

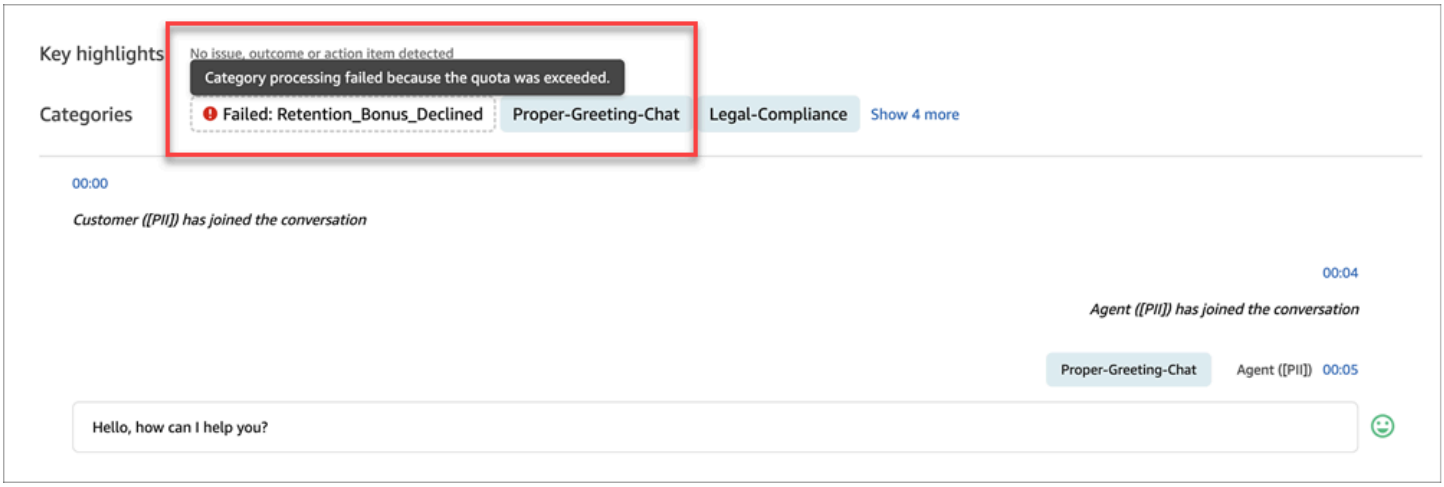
When a rule or category fails to be evaluated by Connect Customer conversational analytics

When Connect Customer conversational analytics evaluates a rule or category during a post-contact analysis for a voice or chat contact, it is possible that the rule or category fails to evaluate.

Following are the possible category outcomes when a rule or category is evaluated during contact analysis:

1. **Successfully matched and applied to the contact**. When categories are displayed on the **Contact details** page, it indicates they were successfully matched and applied to the contact.
2. **Successfully evaluated but they don't apply to the contact**. When categories are absent from the **Contact details** page, it indicates they don't apply to the contact but were successfully evaluated by conversational analytics rules.
3. **The contact analysis was completed but a specific category was not evaluated**. When a category fails to be evaluated, it doesn't mean the category doesn't apply to the contact (based on its criteria), but rather that conversational analytics completed the contact analysis without evaluating this specific category.

The following image shows that failed categories are denoted with their dashed borders, transparent backgrounds, error icons, and failed prefixes. When you pause on a failed category, details about why the category failed to evaluate are displayed.



These failed categories only exist from rules with the semantic match condition. The two possible reasons are:

1. **Quota exceeded**: Your generative AI actions limit was exceeded for that time span. You can request a quota increase through AWS Support.
2. **Failed safety guidelines**: Category processing failed because it did not satisfy security and quality guardrails.

We recommend adding more conditions to your semantic match rules to narrow down the number of contacts it might apply to. This will help avoid quota exceeded failures.

Conversational analytics post-contact analysis output customer S3 file

Failed categories appear in the analysis file under JobDetails > Skipped Analysis.

The `SkippedAnalysis` section shows contact analysis that was marked as 'Skipped', even though the analysis was completed for that contact. It contains the properties "Feature" and "ReasonCode". `POST_CONTACT_SUMMARY` is one of the existing features.

`CATEGORIZATION` is added as a new feature to skipped analysis. There is one unique categorization element in the `SkippedAnalysis` array for each unique `ReasonCode` that resulted in failed categorization. A new `SkippedEntities` property is introduced for each unique element, containing a list of all category names (and their associated rule IDs) that failed due to the associated reason code.

Following is an example of failed categories within `JobDetails`:

```
"JobDetails": {
    "SkippedAnalysis": [
        {
            "Feature": "CATEGORIZATION",
            "ReasonCode": "QUOTA_EXCEEDED",
            "SkippedEntities": [
                {
                    "CategoryName": "PotentialFraud",
                    "RuleId": "a1130485-9529-4249-a1d4-5738b4883748"
                },
                {
                    "CategoryName": "Refund",
                    "RuleId": "bbbbbbb-9529-4249-a1d4-5738b4883748"
                }
            ]
        },
        {
            "Feature": "CATEGORIZATION",
            "ReasonCode": "FAILED_SAFETY_GUIDELINES",
            "SkippedEntities": [
                {
                    "CategoryName": "ManagerEscalation",
                    "RuleId": "cccccccc-9529-4249-a1d4-5738b4883748"
                }
            ]
        },
        {
            "Feature": "POST_CONTACT_SUMMARY",
            "ReasonCode": "INSUFFICIENT_CONVERSATION_CONTENT"
        }
    ]
},
```

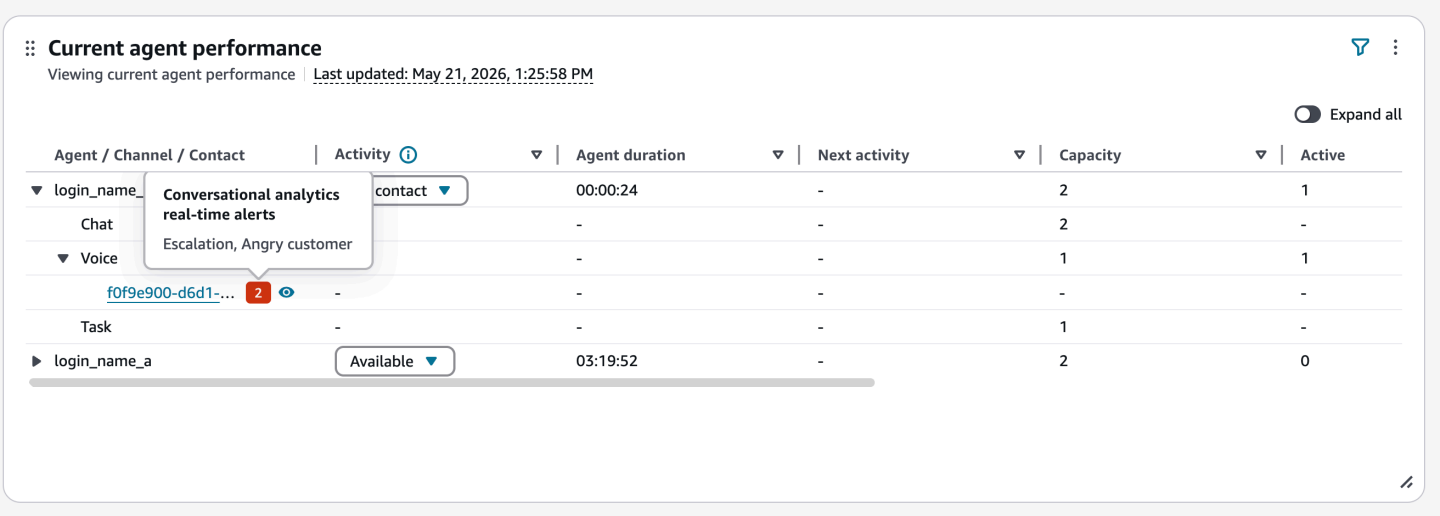
For more information, see Example conversational analytics output files for a call.

Add real-time alerts to conversational analytics for supervisors based on keywords and phrases in a call

After you enable real-time analytics in your flow, you can add rules that automatically alert supervisors when a customer experience issue occurs.

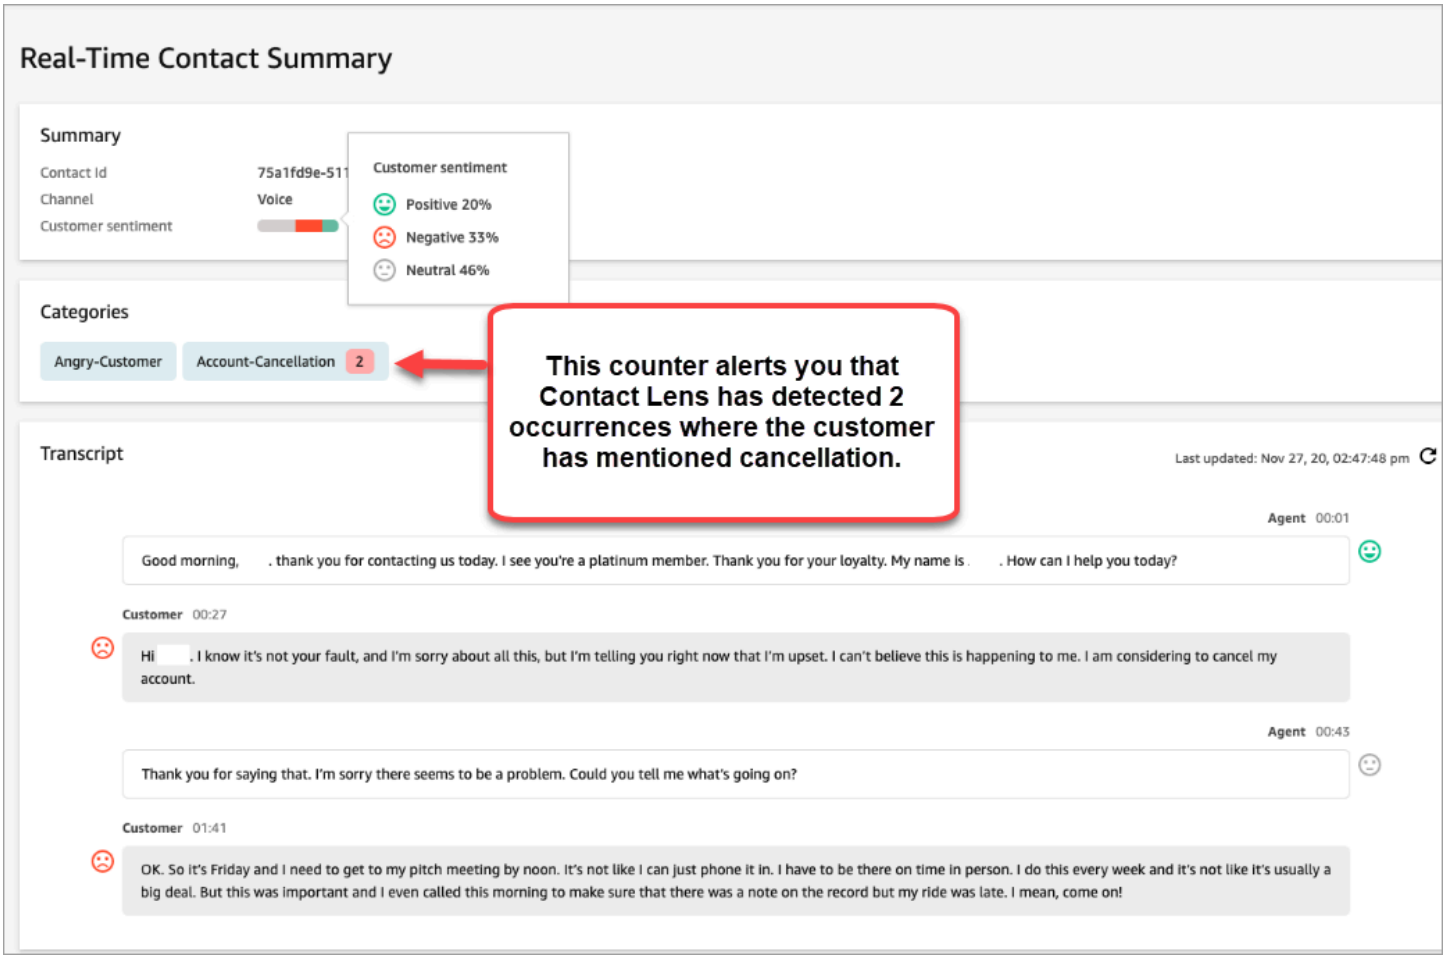
For example, Conversational analytics can automatically send an alert when certain keywords or phrases are mentioned during the conversation, or when it detects other criteria. The supervisor sees the alert on the **Current agent performance** widget on the Queue and agent performance dashboard analytics dashboard. From there, supervisors can listen in to the live call, and provide guidance to the agent over chat to help them resolve the issue faster.

The following image shows an example of what a supervisor would see on the real-time analytics dashboard when they get an alert. In this case, Conversational analytics has detected an angry customer situation.



When the supervisor listens in to a live call, conversational analytics provides them with a real-time transcript and customer sentiment trend that helps them understand the situation and assess the appropriate action. The transcript also eliminates the need for customers to repeat themselves if they are transferred to another agent.

The following image shows a sample real-time transcript.



Add rules for real-time alerts for calls

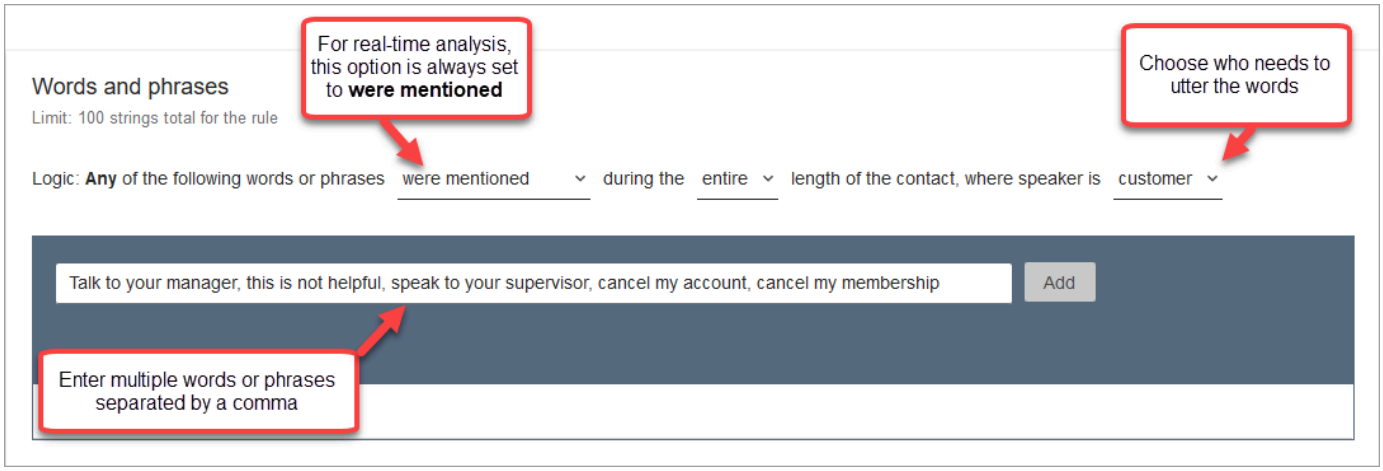
1. Log in to Connect Customer with a user account that is assigned the **CallCenterManager** security profile, or that is enabled for **Rules** permissions.
2. On the navigation menu, choose **Analytics and optimization**, **Rules**.
3. Select **Create a rule**, **Conversational analytics**.
4. Assign a name to the rule.
5. Under **When**, use the dropdown list to choose **real-time analysis**.
6. Choose **Add condition**, and then choose the type of match:

   - **Exact Match**: Finds only the exact words or phrases.
   - **Pattern Match**: Finds matches that might be less than 100 percent exact. You can also specify the distance between words. For example, you might look for contacts where the word "credit" was mentioned, but you do not want to see any mention of the words "credit

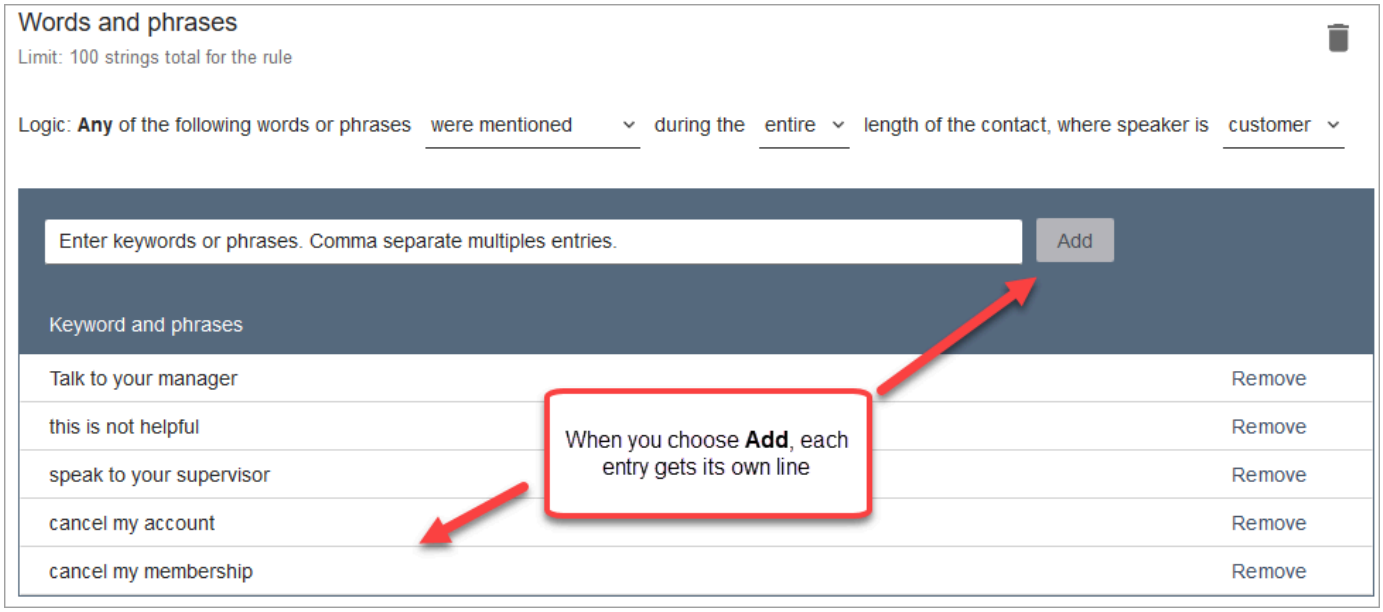
card." You can define a pattern matching category to look for the word "credit" that is not within a one-word distance of the word "card."

> **Tip**
>
> Semantic Match isn't available for real-time analysis.

7. Enter the words or phrases, separated by a comma, that you want to highlight. Real-time rules only support any keywords or phrases that **were mentioned**.

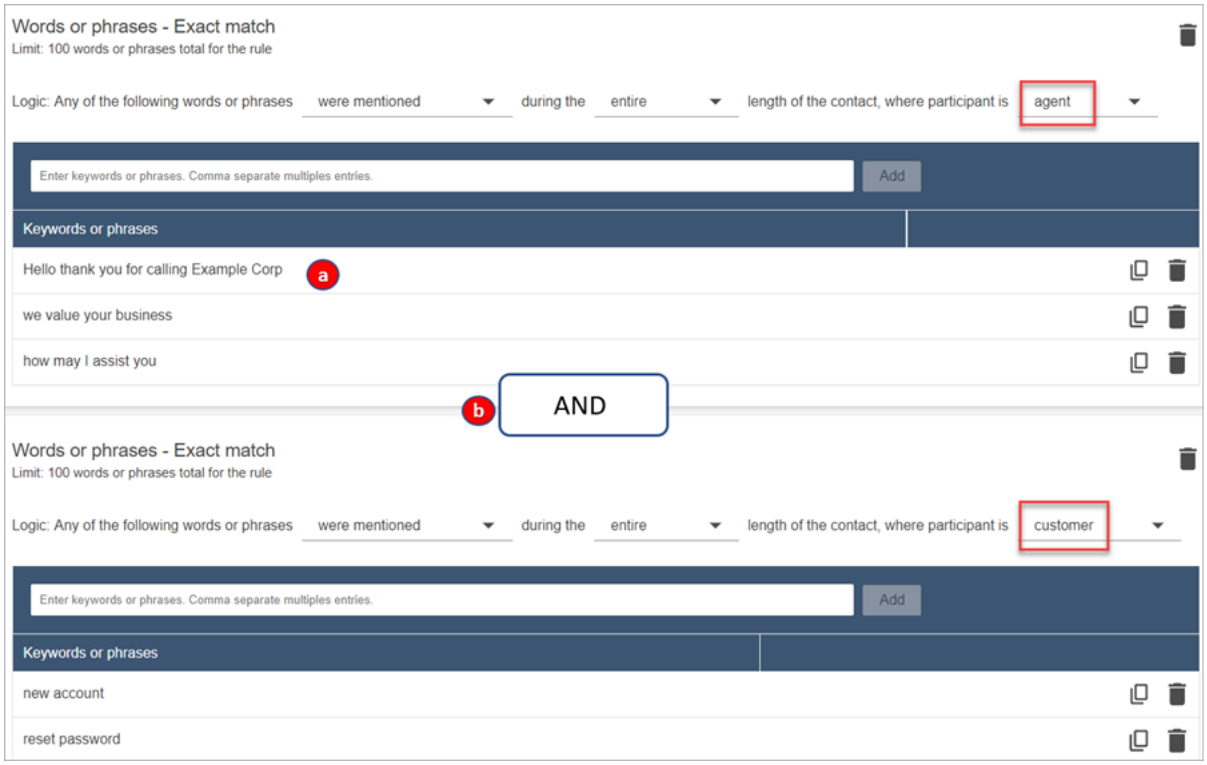


8. Choose **Add**. Each word or phrase separated by a comma gets its own line.



The logic that conversational analytics uses to read these words or phrases is: (Talk OR to OR your OR manager) OR (this OR is OR not OR helpful) OR (speak OR to OR your OR supervisor).

9. To add more words or phrases, choose **Add group of words or phrases**. In the following image, the first group of words or phrases are what the agent might utter. The second group is what the customer might utter.



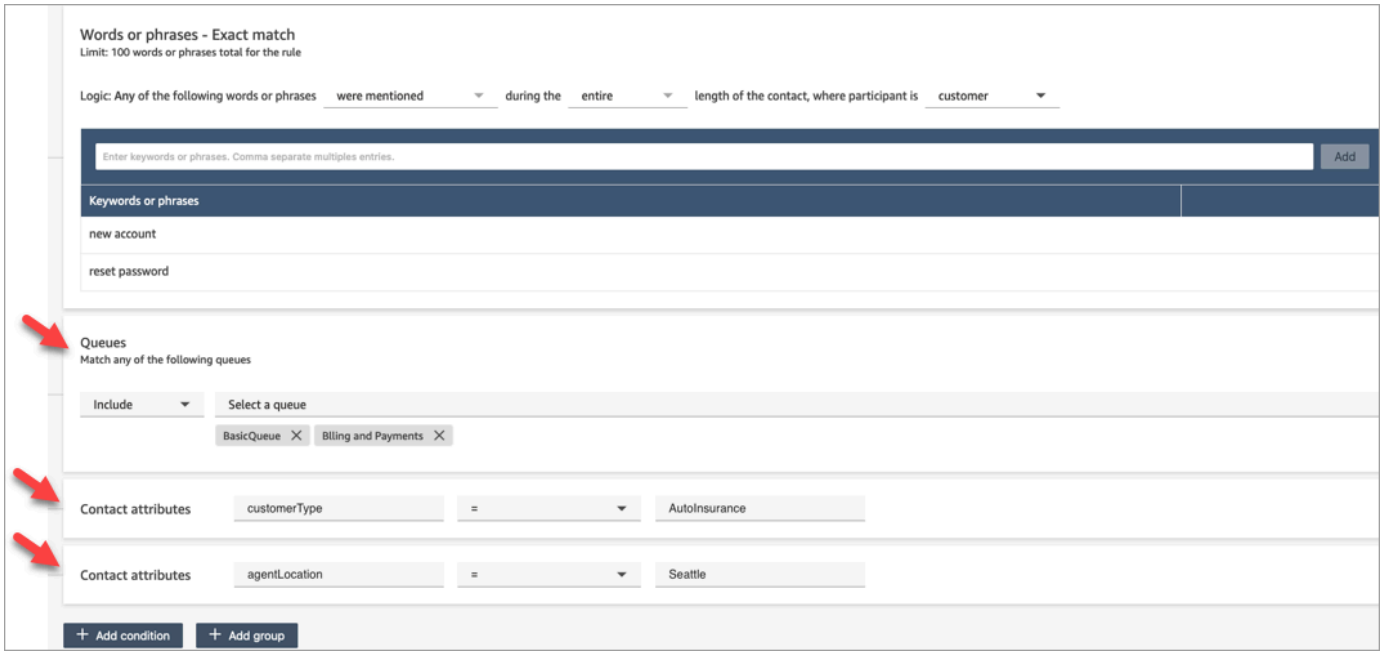
1. In this first card, conversational analytics reads each line as an OR. For example: (Hello) OR (thank OR you OR for OR calling OR Example OR Corp) OR (we OR value OR your OR business).
2. The two cards are connected with an AND. This means, one of the rows in the first card needs to be uttered AND then one of the phrases in the second card needs to be uttered.

The logic that conversational analytics uses to read the two cards of words or phrases is (card 1) AND (card 2).

10. Choose **Add condition** to apply the rules to:

- Specific queues
- When contact attributes have certain values
- When sentiment scores have certain values

For example, the following image shows a rule that applies when an agent is working the BasicQueue or Billing and Payments queues, the customer is for auto insurance, and the agent is located in Seattle.



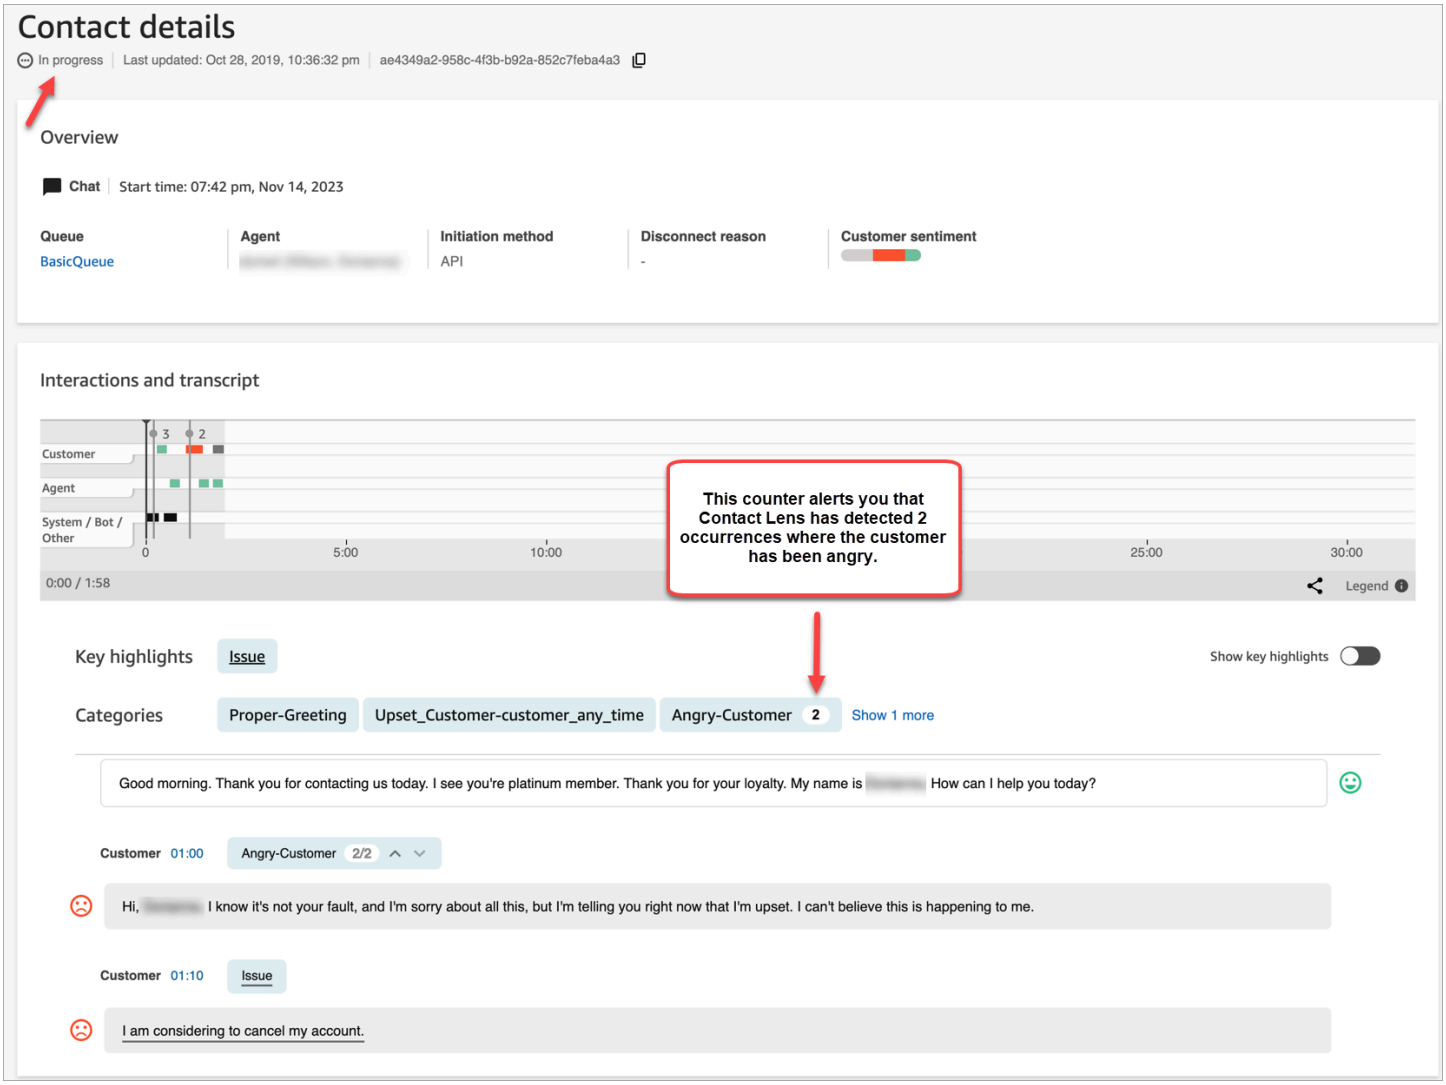
11. When done, choose **Next**.
12. In the **Assign contact category** box, add a name for the category. For example, **Compliant** or **Not_Compliant**.
13. Choose **Next**, then choose **Save and publish**.

Add real-time alerts to conversational analytics for supervisors based on keywords and phrases in a chat

After you enable real-time analytics in your flow, you can add rules that automatically alert supervisors when a customer experience issue occurs.

For example, conversational analytics can automatically send an alert when certain keywords or phrases are mentioned during the chat, or when it detects other criteria. The supervisor can then view the **Contact details** page for a real-time chat to view the issue. From there, supervisors can join the chat, and provide guidance to the agent over chat to help them resolve the issue faster.

The following image shows an example of what a supervisor would see on the **Contact details** page when they get an alert for a real-time chat. In this case, conversational analytics has detected an angry customer situation.

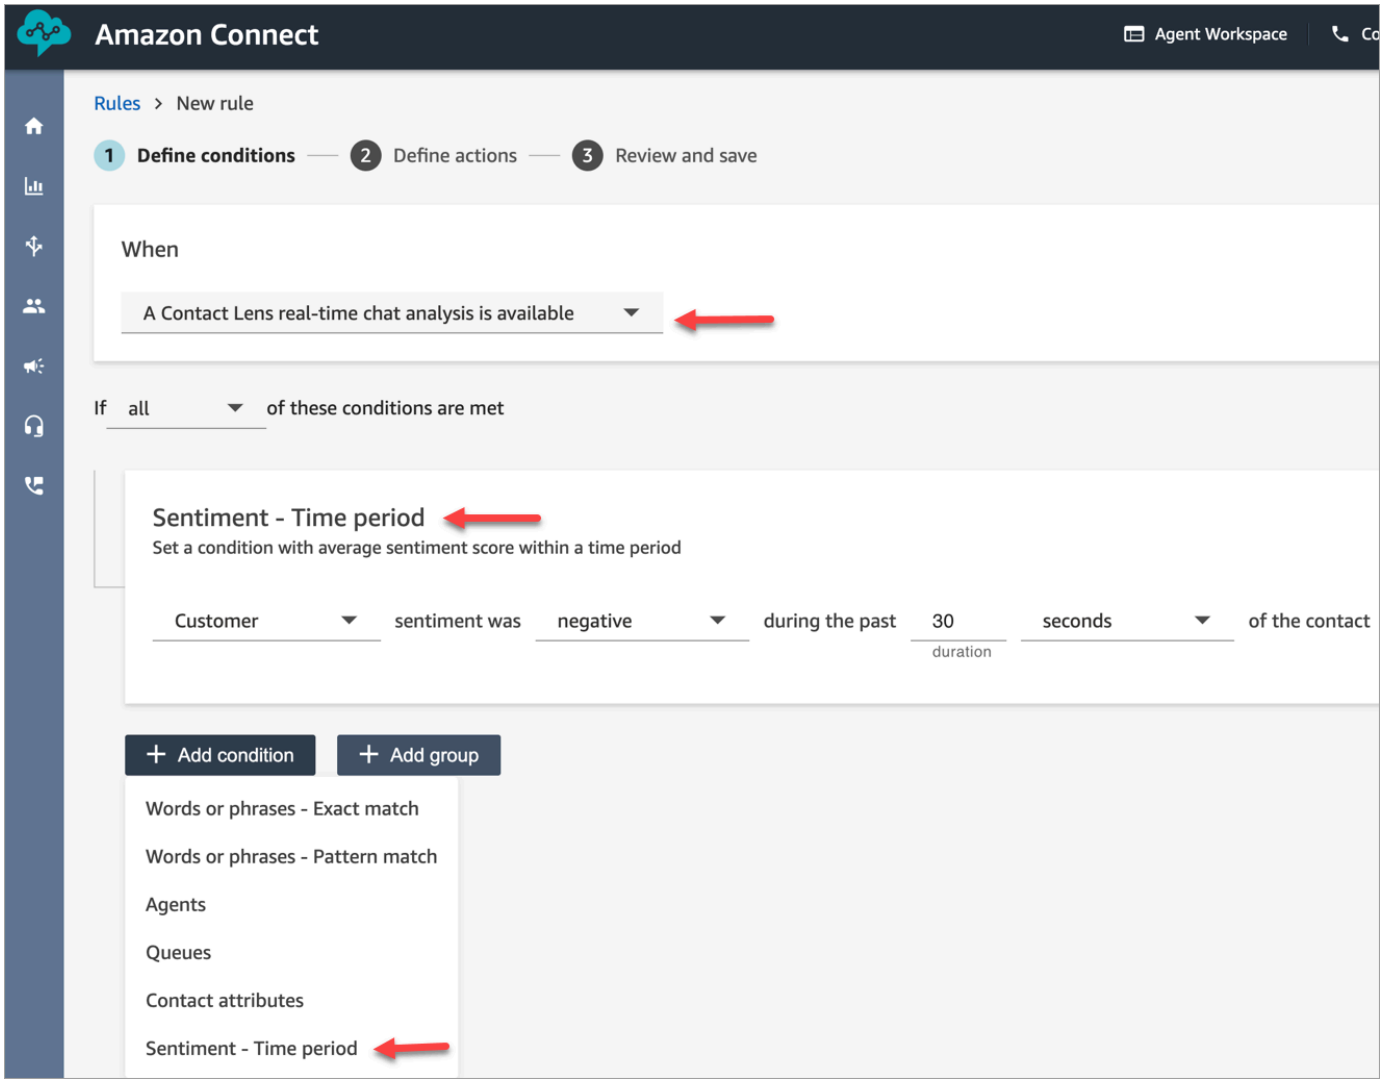


When the supervisor monitors a chat, conversational analytics provides them with a real-time transcript and customer sentiment trend that helps them understand the situation and assess the appropriate action. The transcript also eliminates the need for customers to repeat themselves if they are transferred to another agent.

Add rules for real-time alerts for chats

1. Log in to Connect Customer with a user account that is assigned the **CallCenterManager** security profile, or that is enabled for **Rules** permissions.
2. On the navigation menu, choose **Analytics and optimization**, **Rules**.

3. Select **Create a rule**, **Conversational analytics**.
4. Assign a name to the rule.
5. Under **When**, use the dropdown list to choose **real-time analysis**.
6. Choose **Add condition**, and then choose the type of match. The following image shows a rule configured for a **Sentiment - Time period** condition.



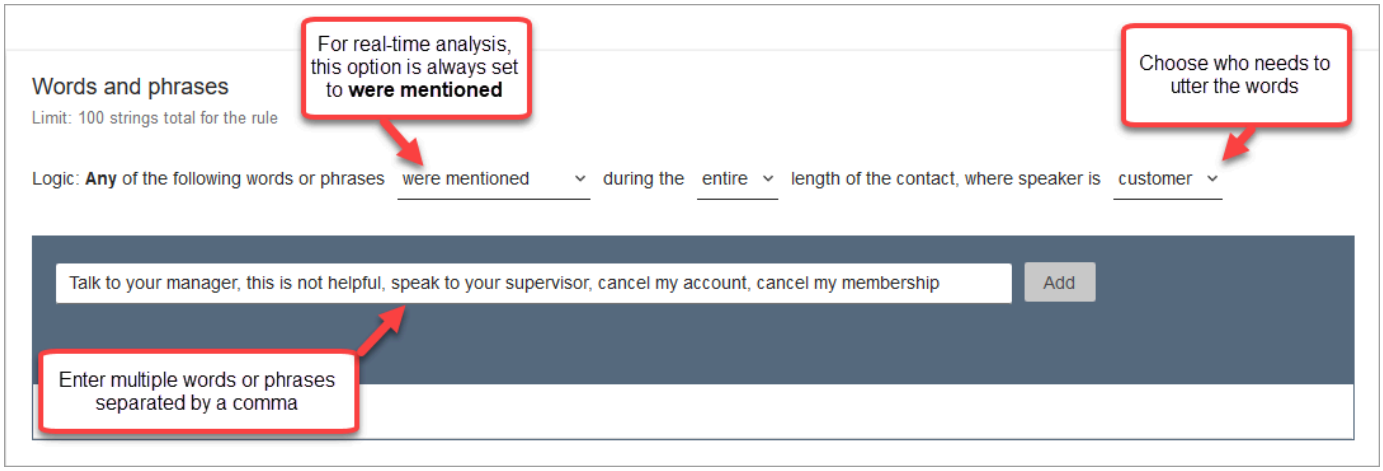
Choose from the following options:

- **Exact Match**: Finds only the exact words or phrases.
- **Pattern Match**: Finds matches that might be less than 100 percent exact. You can also specify the distance between words. For example, you might look for contacts where the word "credit" was mentioned, but you do not want to see any mention of the words "credit

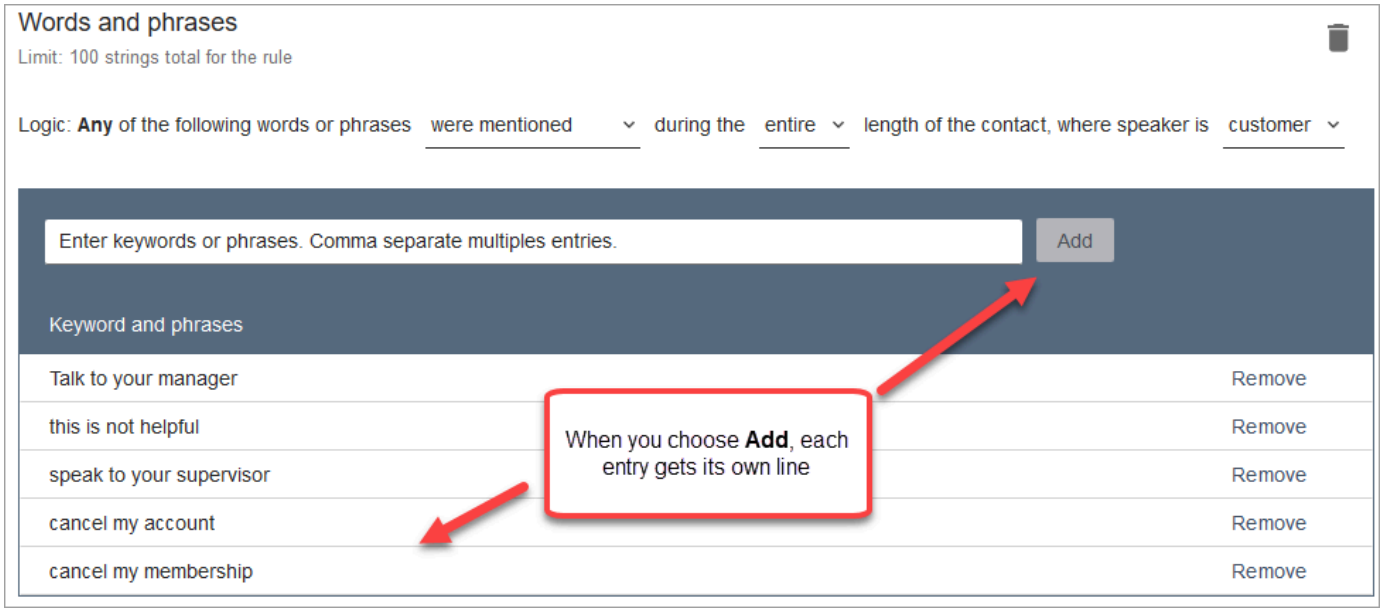
card." You can define a pattern matching category to look for the word "credit" that is not within a one-word distance of the word "card."

> **Tip**
>
> Semantic Match isn't available for real-time analysis.

7. Enter the words or phrases, separated by a comma, that you want to highlight. Real-time rules only support any keywords or phrases that **were mentioned**.

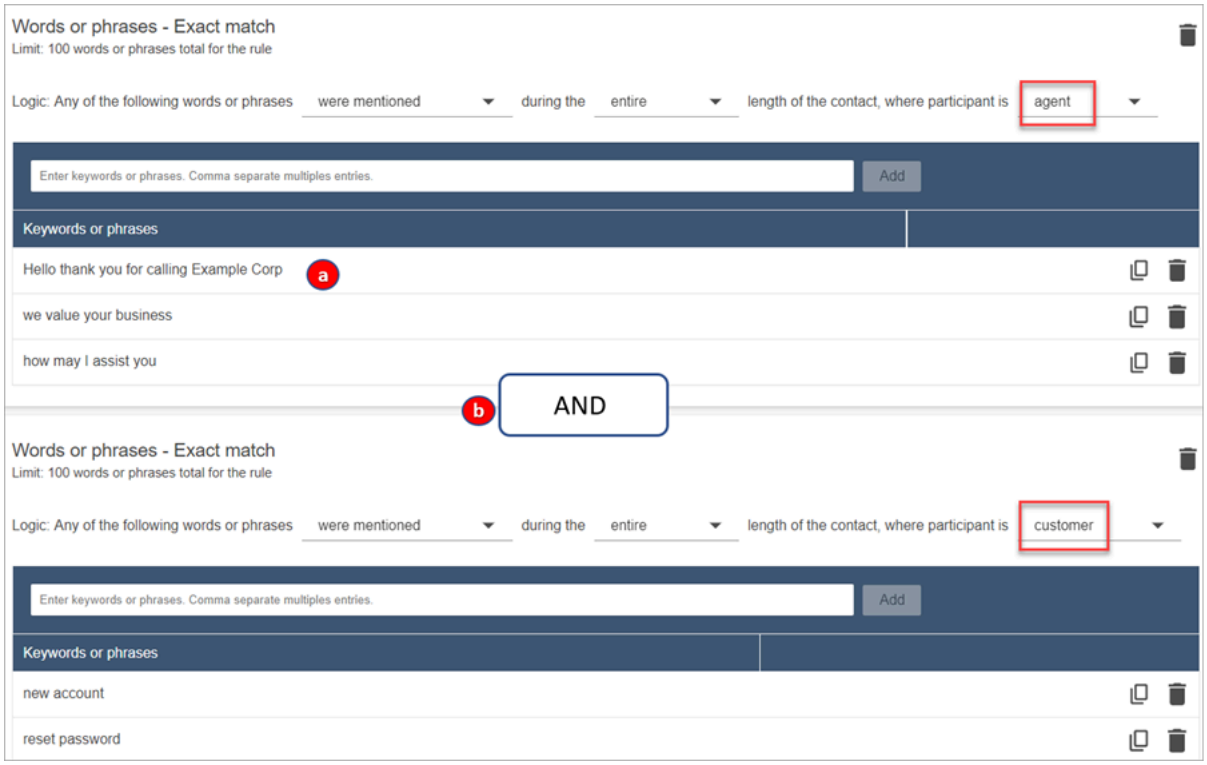


8. Choose **Add**. Each word or phrase separated by a comma gets its own line.



The logic that conversational analytics uses to read these words or phrases is: (Talk OR to OR your OR manager) OR (this OR is OR not OR helpful) OR (speak OR to OR your OR supervisor).

9. To add more words or phrases, choose **Add group of words or phrases**. In the following image, the first group of words or phrases are what the agent might mention. The second group is what the customer might mention.



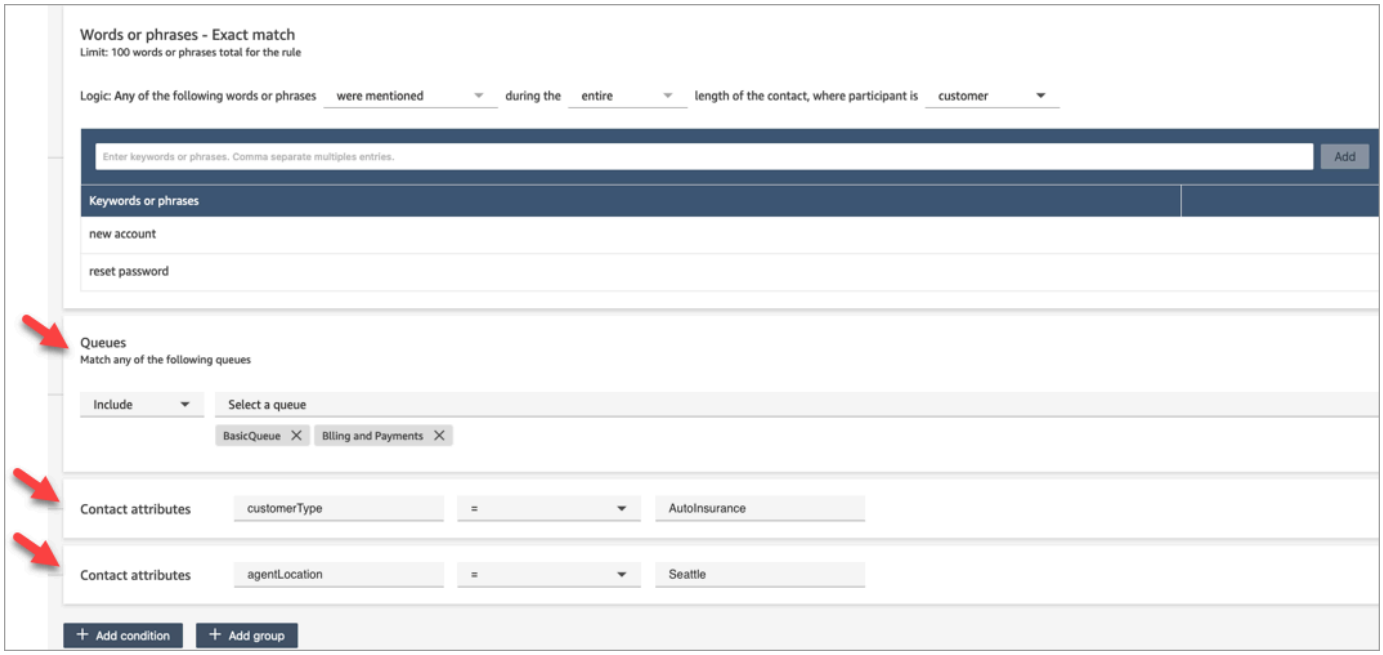
1. In this first card, conversational analytics reads each line as an OR. For example: (Hello) OR (thank OR you OR for OR calling OR Example OR Corp) OR (we OR value OR your OR business).
2. The two cards are connected with an AND. This means, one of the rows in the first card needs to be mentioned AND then one of the phrases in the second card needs to be mentioned.

   The logic that conversational analytics uses to read the two cards of words or phrases is (card 1) AND (card 2).

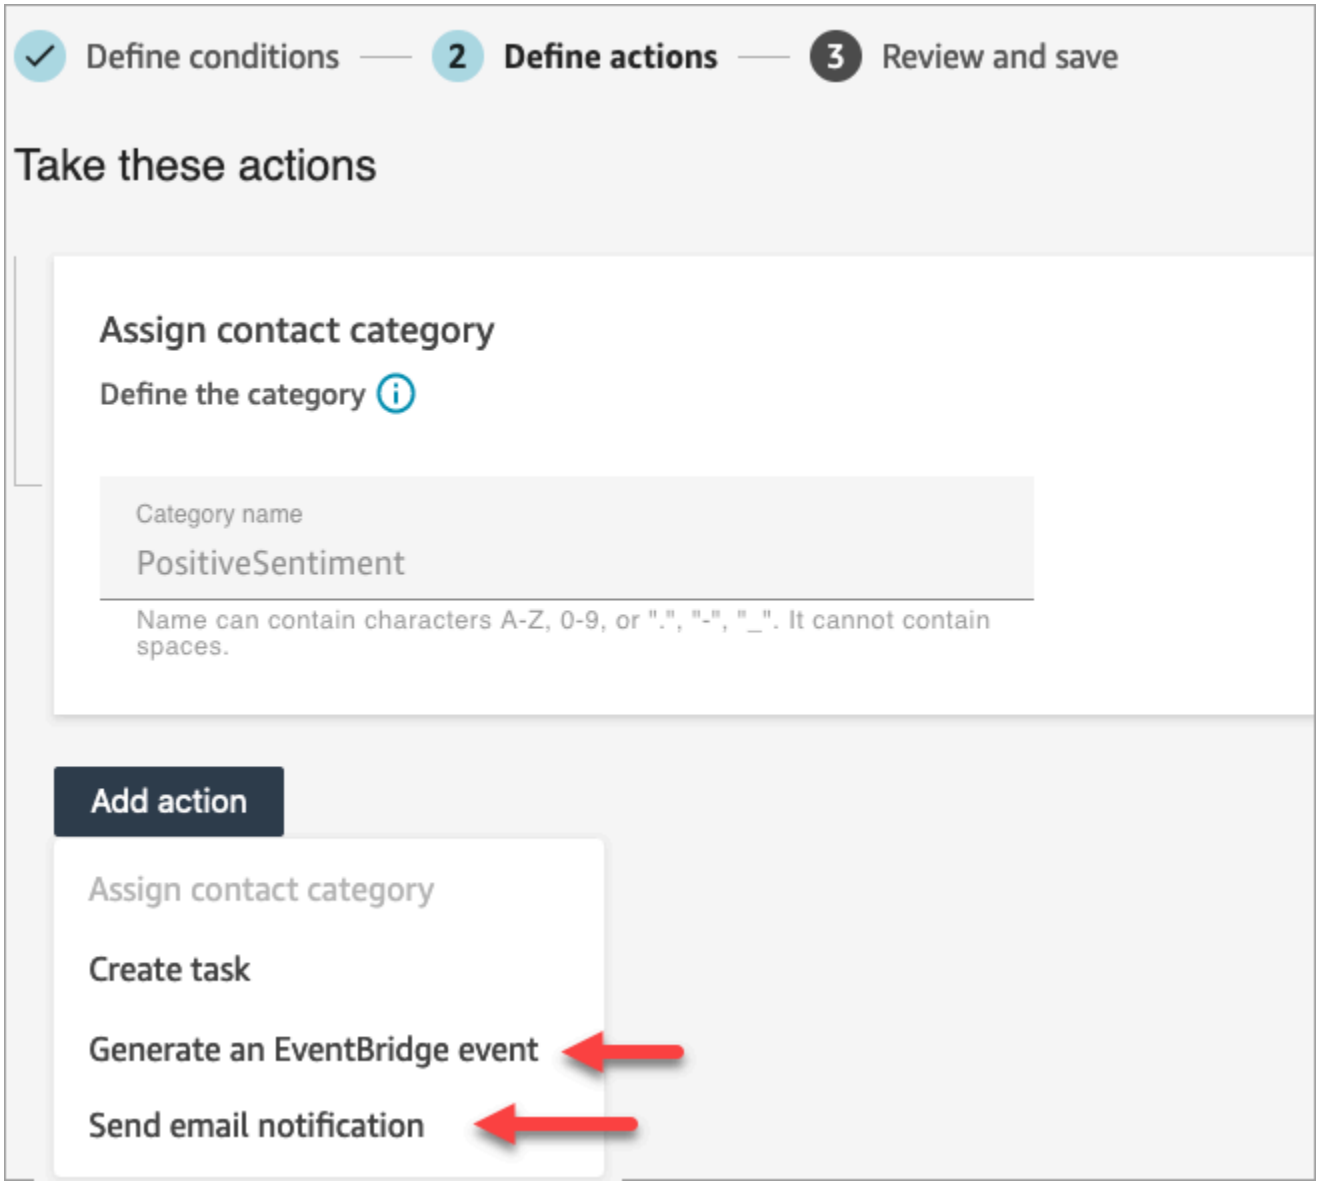
10. Choose **Add condition** to apply the rules to:

    - Specific queues
    - When contact attributes have certain values
    - When sentiment scores have certain values

For example, the following image shows a rule that applies when an agent is working the BasicQueue or Billing and Payments queues, the customer is for auto insurance, and the agent is located in Seattle.



11. When done, choose **Next**.
12. In the **Assign contact category** box, add a name for the category. For example, **Compliant** or **Not_Compliant**.
13. Choose **Add action** to specify what action Connect Customer should take when the conditions are met. You can configure supervisor alerts by using email notifications or by developing a custom integration with EventBridge.



14. If you chose **Send email notification**, see Create rules that send email notifications for more details about completing the page and for information about email limits.

    If you chose **Generate an EventBridge event**, see Create a rule that generates an EventBridge event for more details about completing the page and for information about subscribing to EventBridge event types.

Create rules that send email notifications

You can create rules that send email notifications to people in your organization. This helps you to respond more expediently to potential issues in your contact center. For example, you can create a rule to notify:

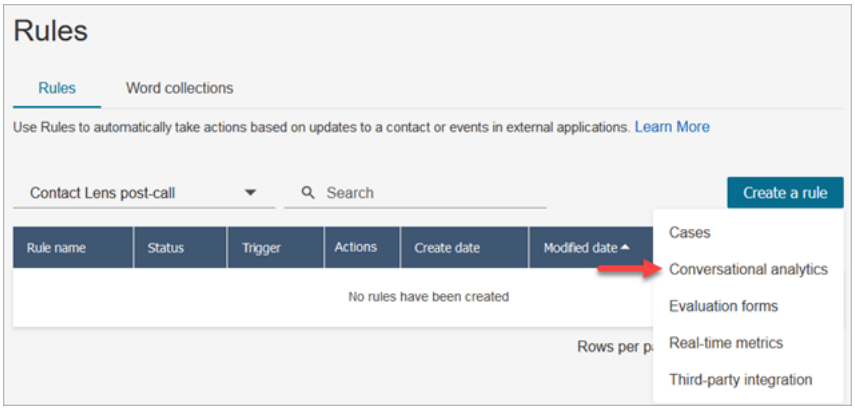
- A team supervisor when there is an account escalation or cancellation.
- A group of people in your contact center as a result of certain words being mentioned during a conversation.
- A designated person in your contact center when a disagreement occurs during the call.
- An agent who had handled the contact that was analyzed or evaluated with Amazon Connect conversational analytics.

Important

- All emails are sent from `no-reply@amazonconnect.com`.
- SAML users do not have primary email addresses or passwords. They use a username to log in. A username is typically an email address but it does not have to be. For these users the field label **Email address** is empty inside Connect Customer. When email notifications are sent for SAML users, they must have a secondary email configured in order to get it. If a secondary email is not configured, the user will not receive the email.

To create a rule that sends an email notification

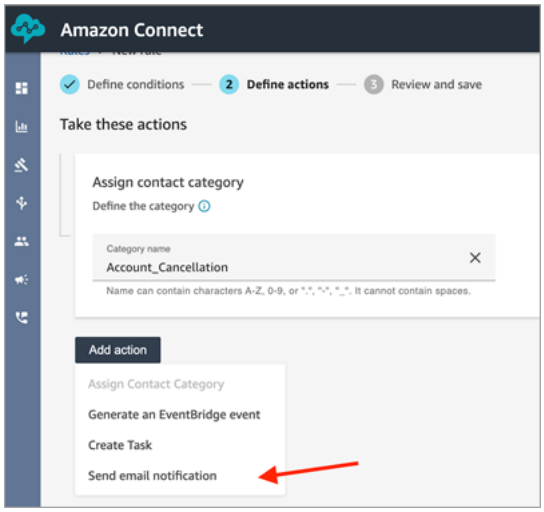
1. Log in to Connect Customer with a user account that has the required permissions to create rules.
2. Navigate to **Analytics and optimization**, **Rules**.
3. On the **Rules** page, choose **Create a rule**, and then from the dropdown list, choose **Conversational analytics** or **Evaluation forms**.



4. On the **New rule** page, define the conditions for the rule. For more information, see:

- Define rule conditions for conversational analytics
- Define rule conditions for evaluation forms.

5. When you define actions for the rule, choose **Send email notification** for the action.



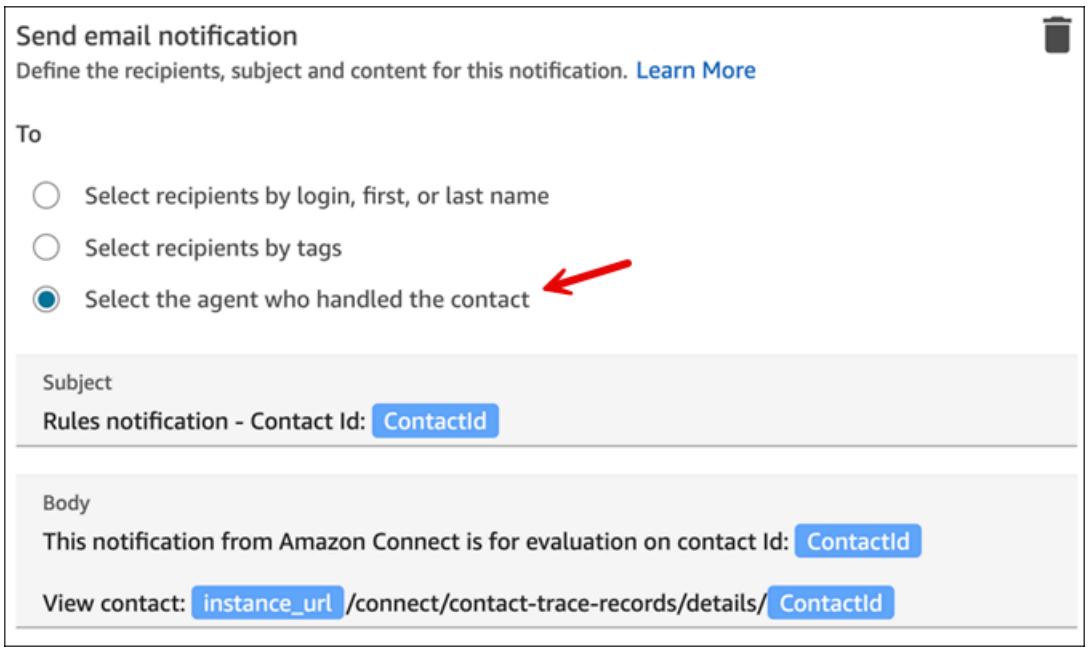
6. In the **Send email notification** section, choose who is going to receive the email by using one of these options:

- **Select recipients by login**: Routes the email to the specified user.

> **Important**
>
> SAML users must have a secondary email configured in order to get it. If a secondary email is not configured, the user will not receive the email.

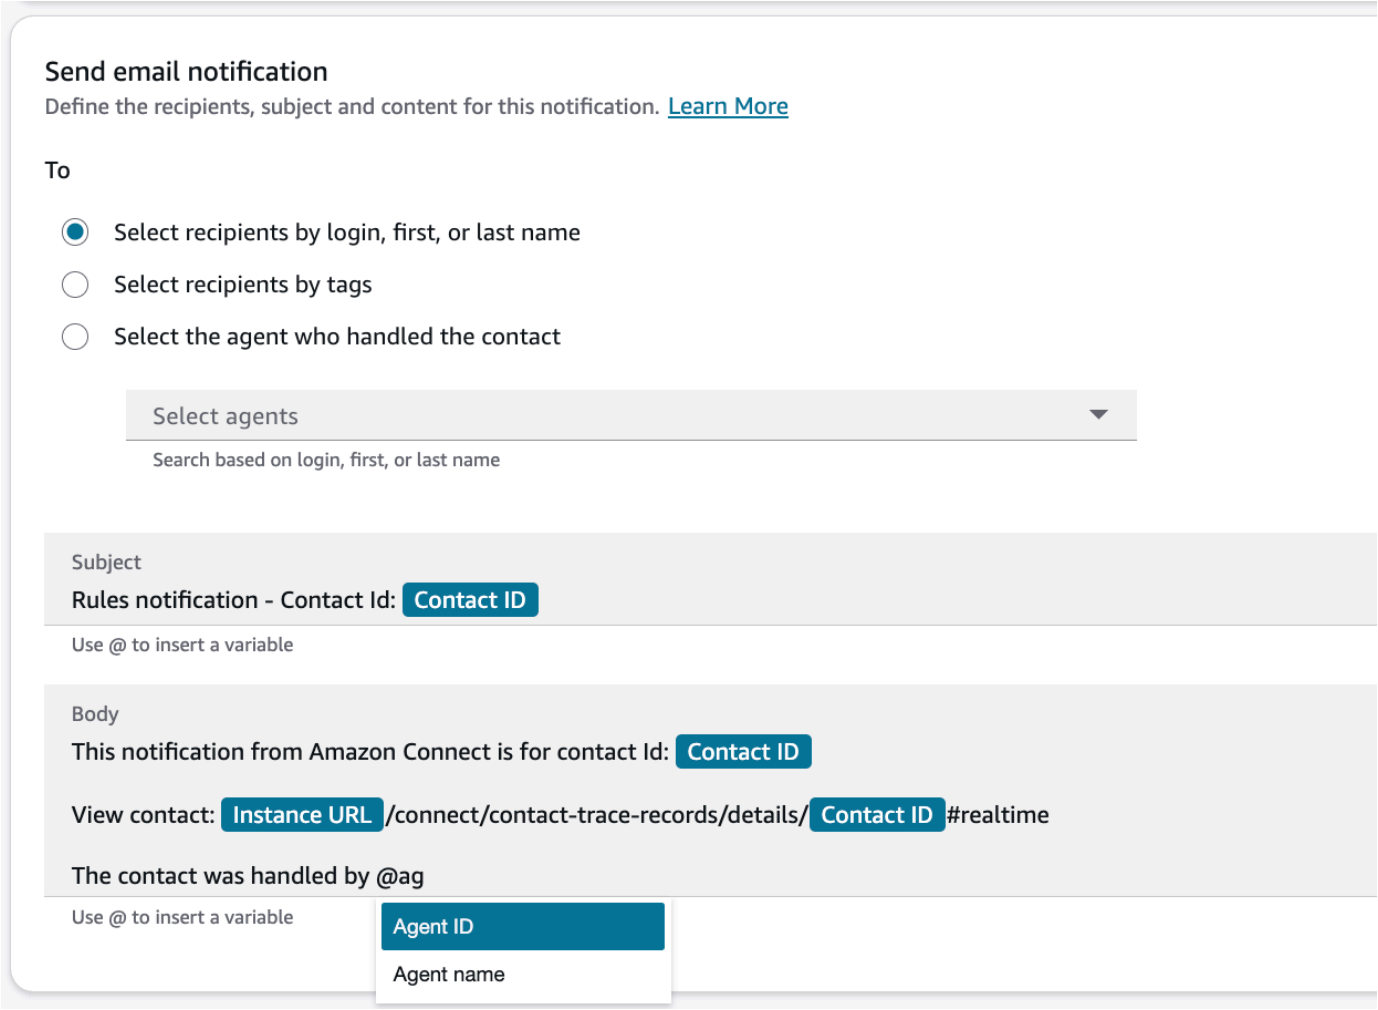
- **Select recipients by tags**. Routes the email dynamically based on the agent's tag values.
- **Select the agent who handled the contact**. Routes the email to the agent who handled the contact.

In the following image, the rule sends a notification email to the agent who handled the contact.



7. In **Subject**, add the email subject. In **Body**, add the contents of the email notification.

   Use **@ to add dynamic variables** that are populated during execution of the rule. For conversational analytics rules and evaluation forms rules, you can add **rule name, instance URL, contact, agent** and **queue** information for the contact that matched the rule. With evaluation forms rules, you can additionally insert the **evaluation ID**.



> **Note**
>
> Other rule types support different variables:
>
> - With real-time metrics rules, you can enter **rule name, instance URL** and list of **agents, queues, flows or routing profile** that breached the threshold to trigger the alert.
> - With rules for cases, you can insert **rule name, instance URL** and **case ID**.

8. Choose **Next**. Review your selections, and then choose **Save**.
9. After you add rules, they are applied to new contacts that occur after the rule was added. Rules are applied when Connect Customer conversational analytics analyzes conversations.

   You cannot apply rules to past, stored conversations.

Email limits

- Connect Customer has a default limit of 500 emails a day. When that limit is exceeded, the Connect Customer instance is blocked for 24 hours from sending more email. This is because the emails are subject to bounce and complaint limits. For more information, see the **Bounce** and **Complaint** sections in Understanding email deliverability in Amazon SES.
- All emails are sent from `no-reply@amazonconnect.com`, which you cannot customize.
- SAML users do not have primary email addresses or passwords. They use a username to log in. A username is typically an email address but it does not have to be. For these users the field label **Email address** is empty inside Connect Customer. When email notifications are sent for SAML users, they must have a secondary email configured in order to get it. If a secondary email is not configured, the user will not receive the email.

If the default option for sending emails does not meet your requirements, contact your Technical Account Manager or Support to discuss with the Connect Customer service team.

Create rules that send in-app notifications

You can create rules to automatically notify people in your organization through in-app notifications within Connect Customer's admin and agent workspaces. Example use cases include:

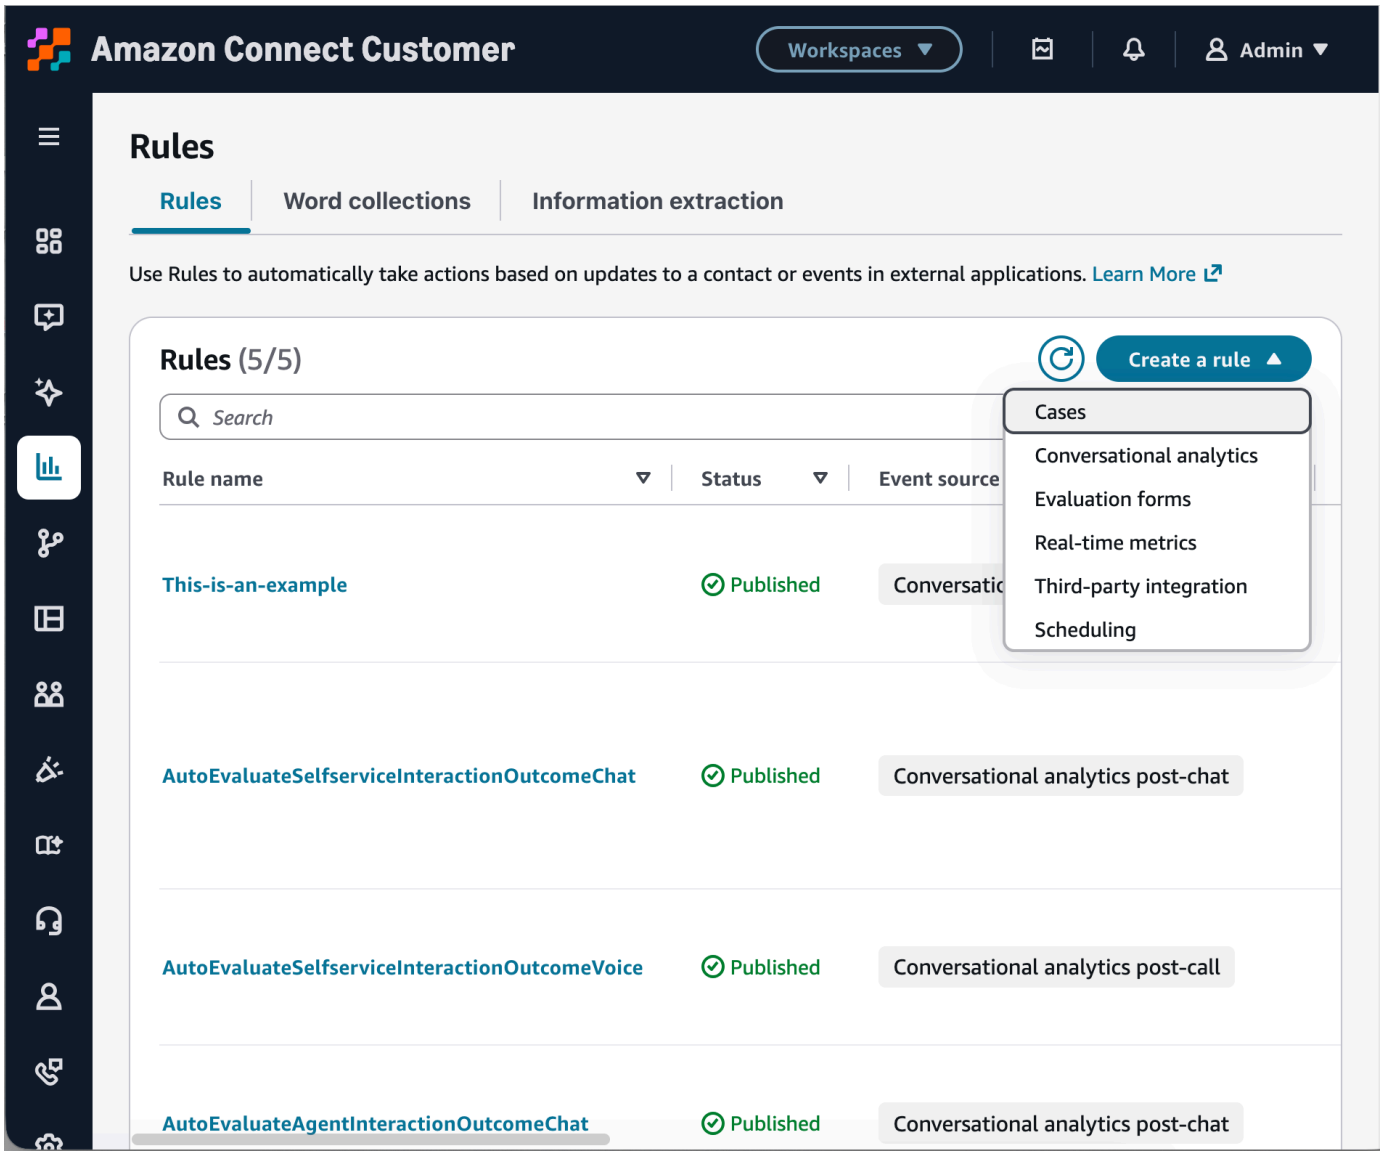
- Notifying an agent when they receive a performance evaluation.
- Notifying a supervisor when an SLA is breached on a case.
- Notifying the agent handling a case when the case is updated.
- Notifying a centralized compliance team when an agent exhibits non-compliant behaviors on a contact.
- Notifying agents or supervisors on updates to agent schedules or time-off requests.

In-app notifications are also available as a standalone Connect Customer API, for use cases unrelated to rules, such as system notifications or custom messages sent directly from your own applications. For more information about how recipients see and interact with in-app notifications, and how to create them outside of rules, see Notifications in the workspace header.

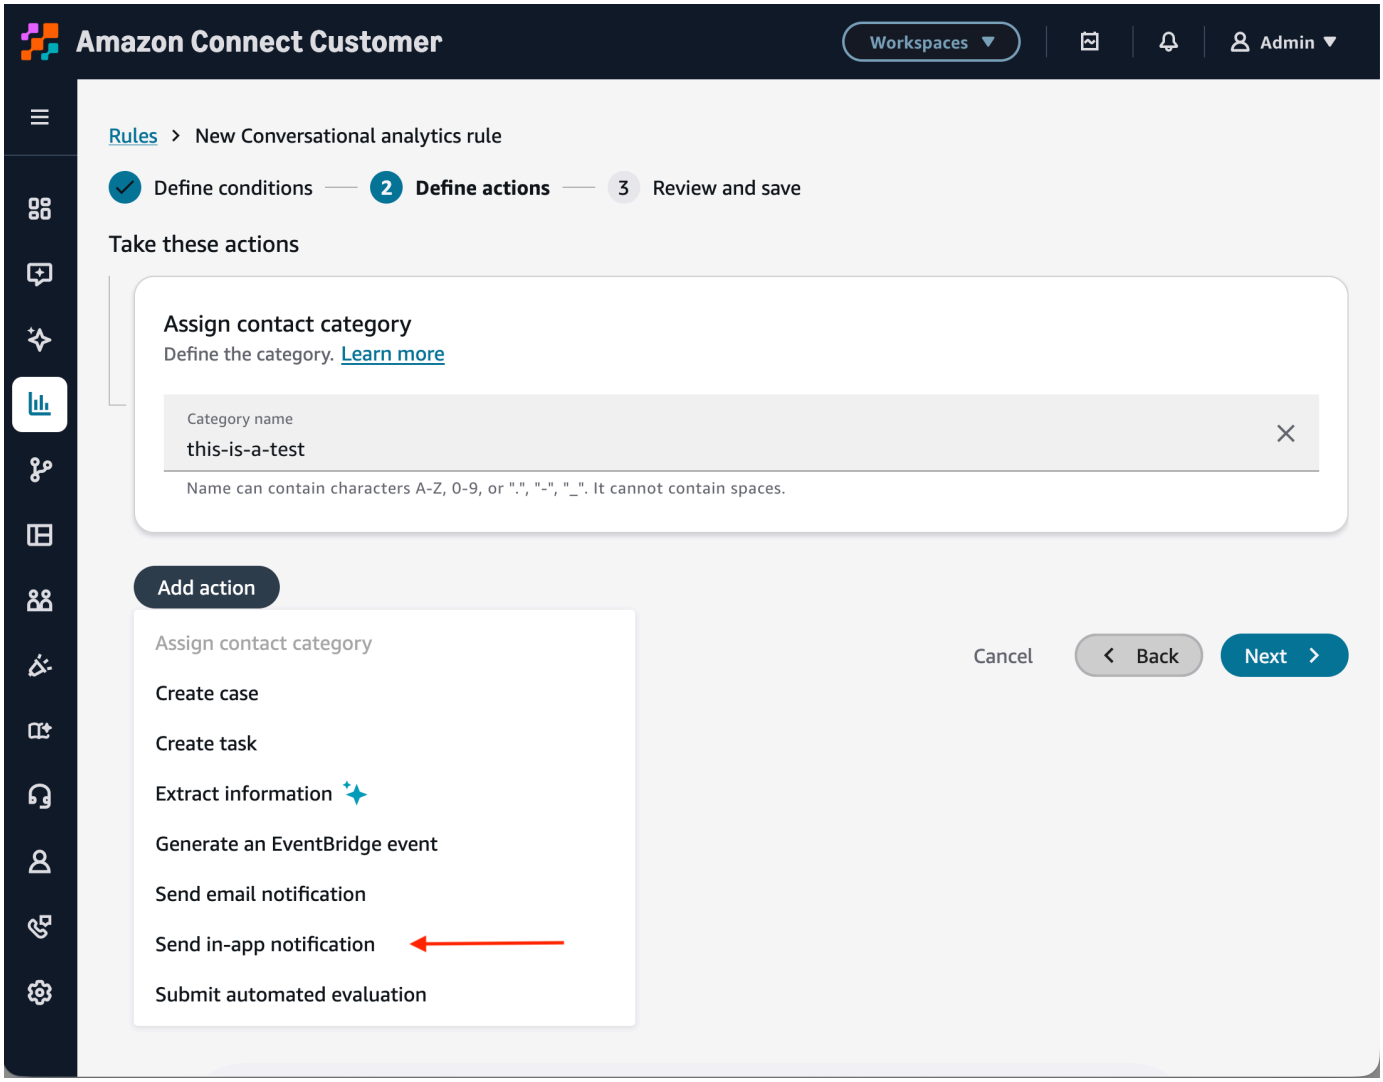
To create a rule that sends an in-app notification

1. Log in to Connect Customer with a user account that has the required permissions to create rules.

2. Navigate to **Analytics and optimization**, **Rules**.
3. On the **Rules** page, choose **Create a rule**, and then from the dropdown list, choose the rule type for the trigger you want. **Send in-app notification** is available for conversational analytics, evaluation forms, cases, cases SLA breach, and scheduling rule types.



4. On the **New rule** page, define the conditions for the rule.
5. When you define actions for the rule, choose **Send in-app notification** for the action.



6. In the **Send in-app notification** section, under **To**, choose who is going to receive the notification by using one of these options:

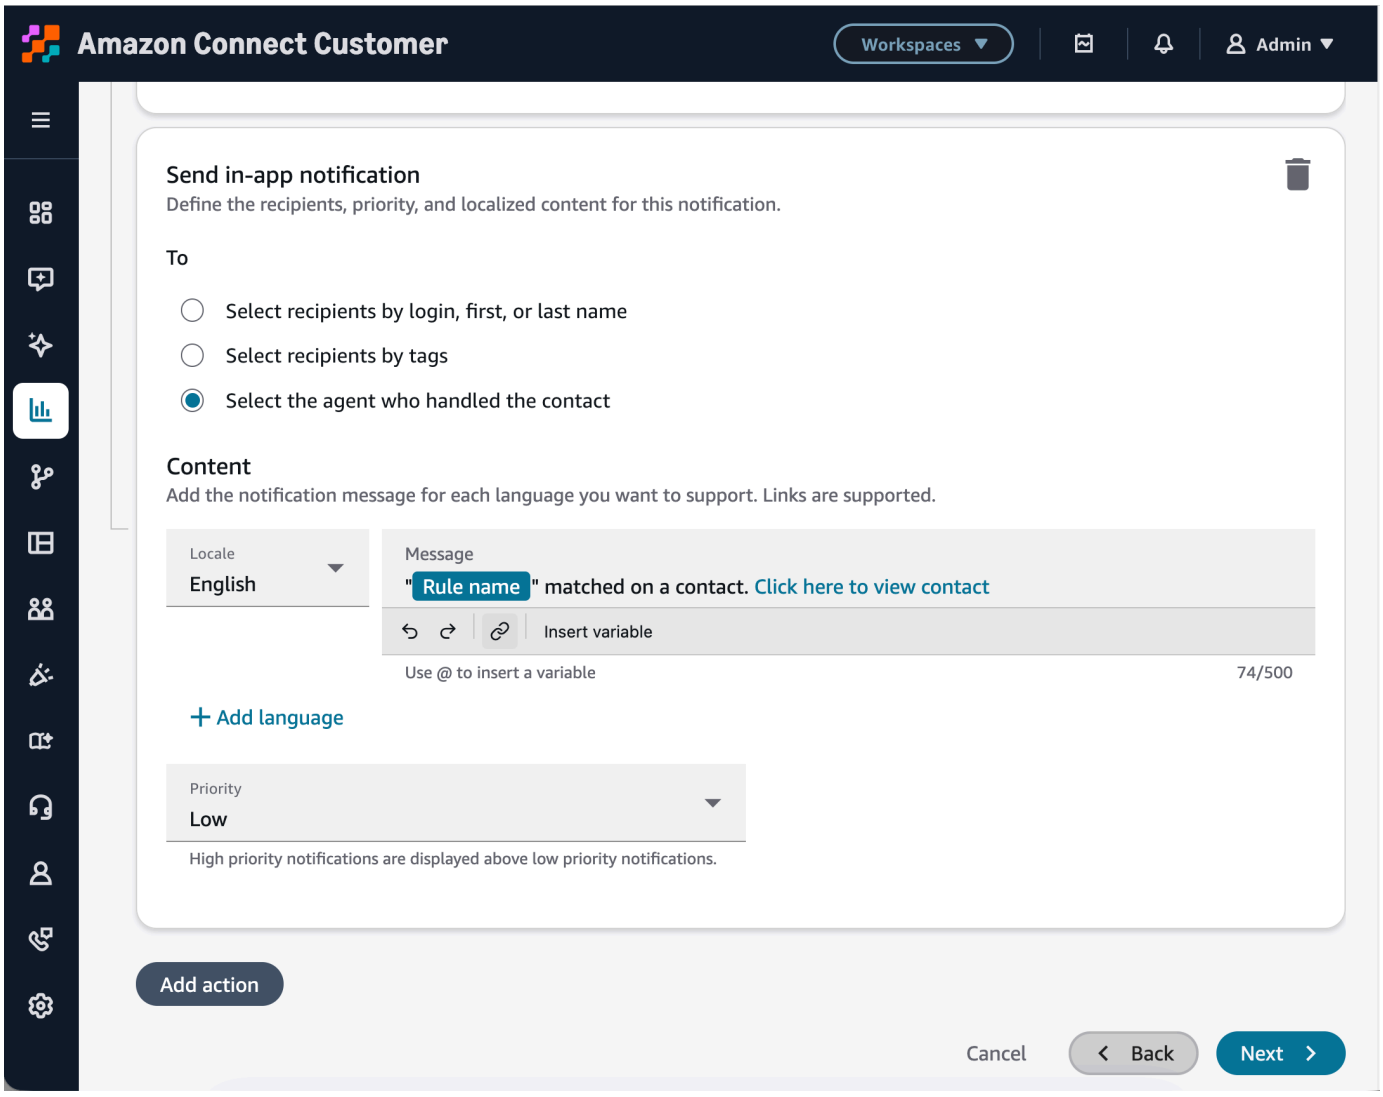
   - **Select recipients by login, first, or last name**: Routes the notification to the agents you select.
   - **Select recipients by tags**: Routes the notification dynamically based on the agent's tag values.
   - **Select the agent who handled the contact** (or the case-assignment equivalent): Routes the notification to the agent associated with the contact or case. This option is available only for supported trigger types.
   - **Select supervisors of the agents impacted by the scheduling change**: Routes the notification to the supervisors of every agent affected by the change. This option is available only for scheduling rules.

7. Under **Content**, add the notification message:

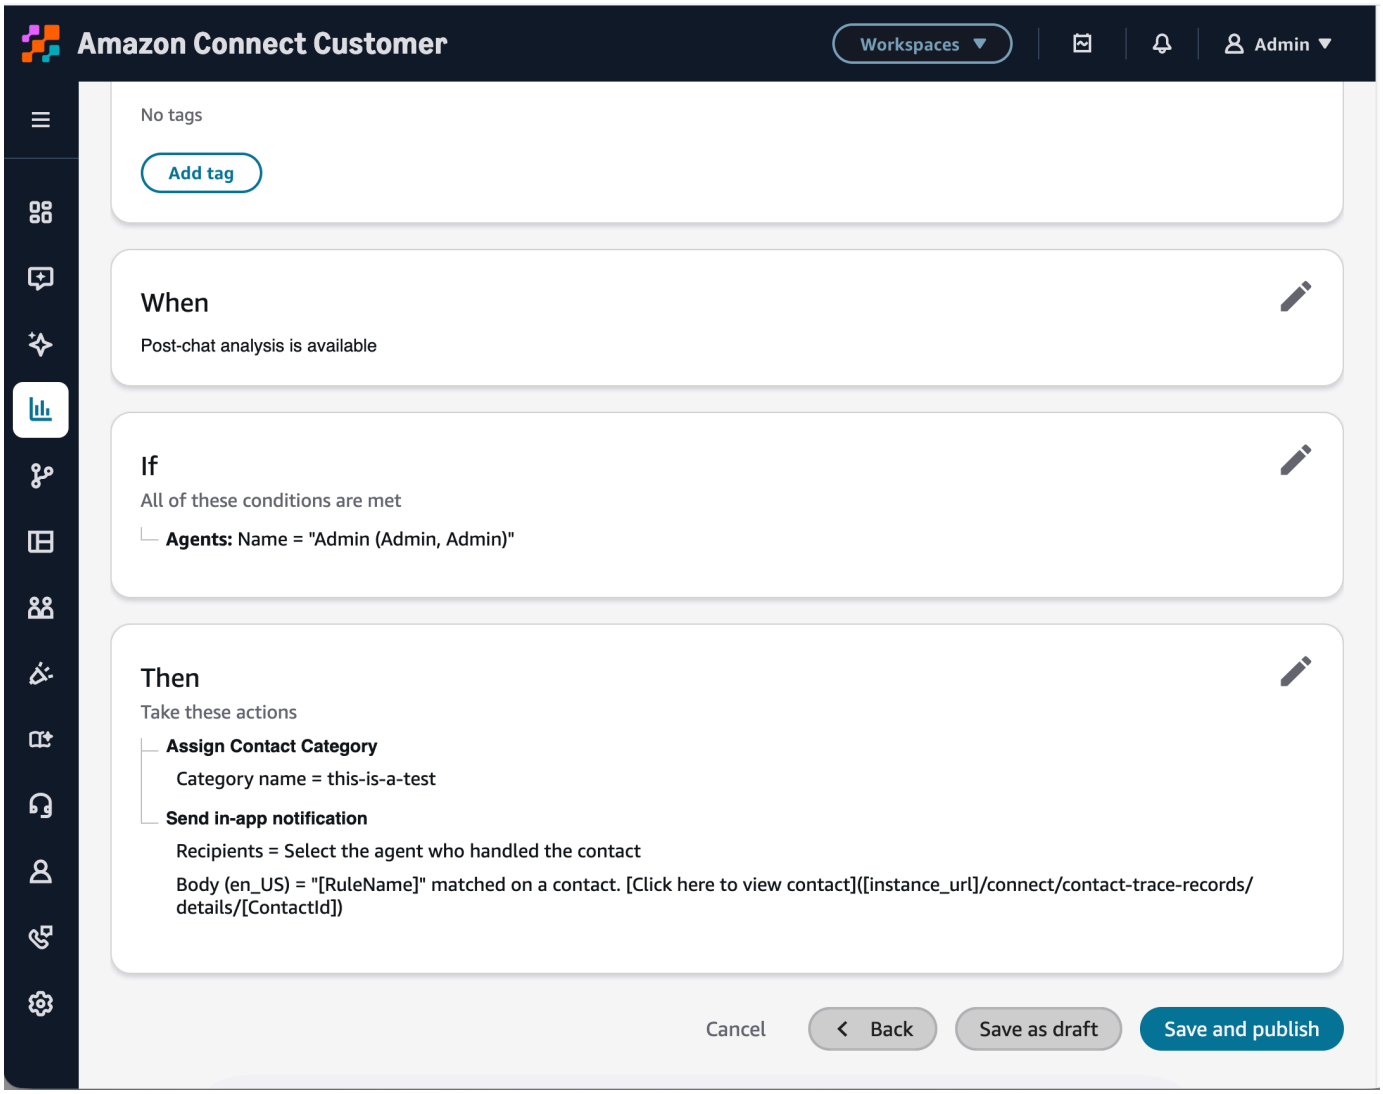
   - Choose a **Locale** for each message. Choose **Add language** to add a message in another locale; each locale can be used only once per notification. Add a message for every locale your recipients use, so that each person sees the notification in their own console locale.
   - In **Message**, enter the notification text. Use **@ to add dynamic variables** that are populated when the rule runs, the same way you would for an email notification's variables.

8. Under **Priority**, choose **High** or **Low**. High priority notifications are displayed above low priority notifications in the recipient's notification panel, and are shown with increased visual emphasis. Reserve **High** for messages that need immediate attention, such as an SLA breach or a critical system event—using it for routine updates reduces its effectiveness over time.

   The following image shows the **Send in-app notification** section with recipients, content, and priority defined.



9. Choose **Next**. Review your selections, and then choose **Save**.



10. After you add rules, they are applied to new contacts that occur after the rule was added. Rules are applied when Connect Customer conversational analytics analyzes conversations.

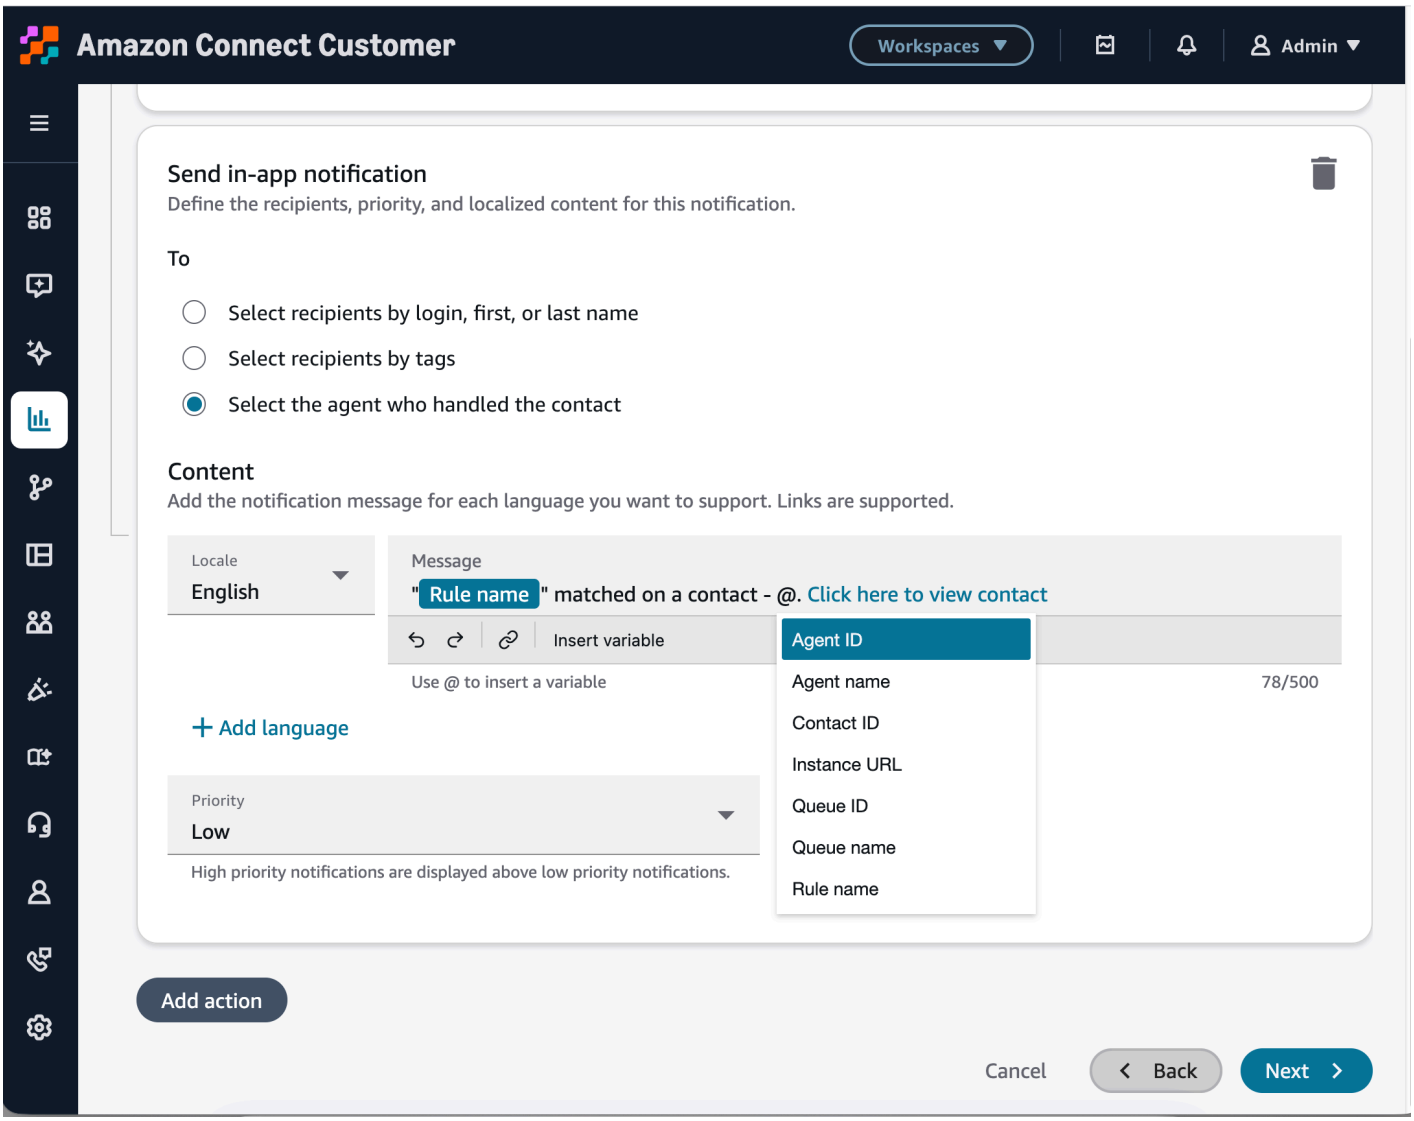
    You cannot apply rules to past, stored conversations.

Inserting variables and links in notification content

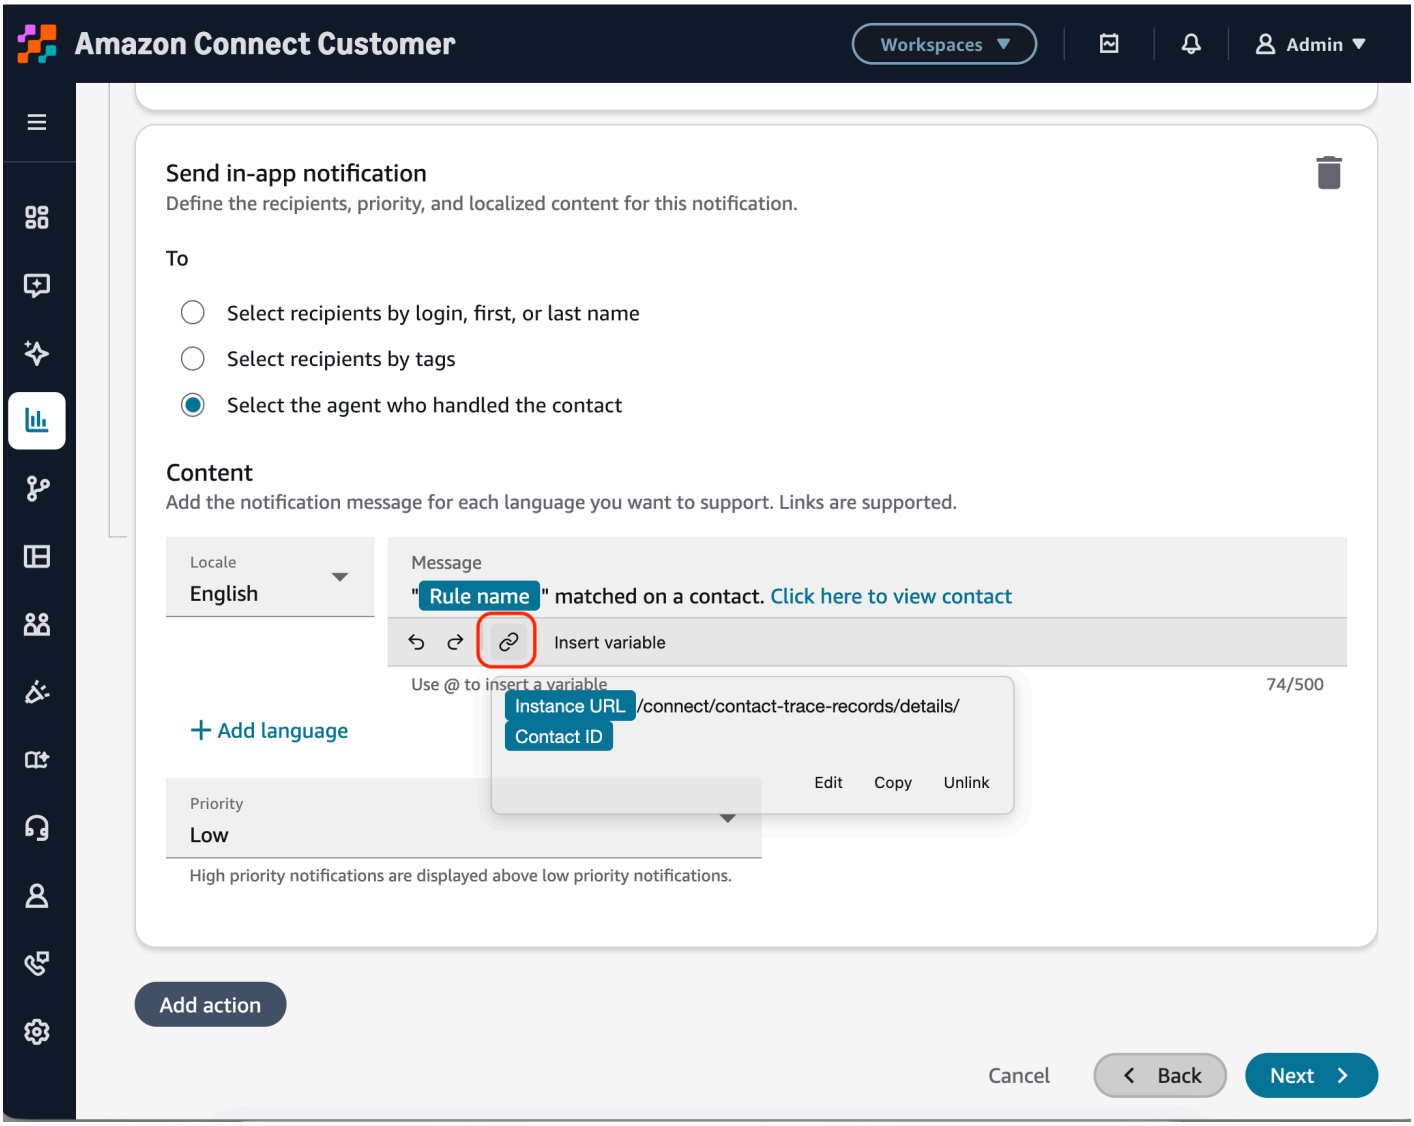
The **Message** field in the **Content** section supports dynamic variables and clickable links, so recipients can jump straight to the relevant contact, case, or evaluation.

- Type @ in the message, or choose **Insert variable** on the toolbar, to open the list of variables available for the rule's trigger type (for example, **Agent ID**, **Agent name**, **Contact ID**, **Instance**

URL, **Queue ID**, **Queue name**, and **Rule name**). Choose a variable to insert it at the cursor position.



- To edit or add a clickable hyperlink, select the text you want to turn into a link, and then choose the link icon on the toolbar. Enter or insert variables for the link text and the URL (for example, combine the **Instance URL** and **Contact ID** variables to link directly to a contact's details page), and then choose **Edit**, **Copy**, or **Unlink** to manage the link.



In-app notification limits

- The notification message is limited to 500 visible characters per locale, after variable values are resolved. Markdown link URLs don't count against this limit.
- You can add one message per supported locale per notification.
- Notifications have a default visibility period of one week. After that, they're automatically removed for the recipient.
- **Select the agent who handled the contact** (or the case-assignment equivalent) is available only for the trigger types that support it.
- **Select supervisors of the agents impacted by the scheduling change** is available only for scheduling rules.

Create a rule that generates an EventBridge event

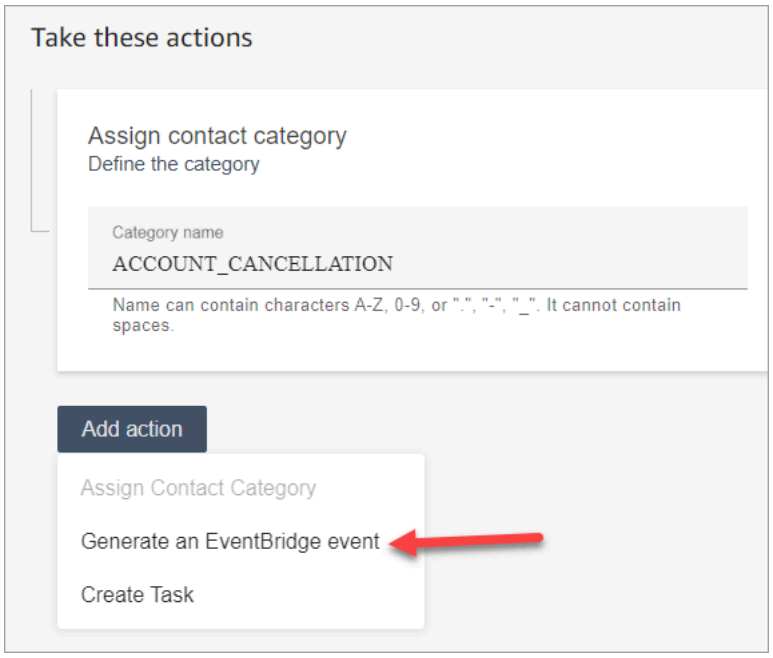
In real-time or post-call/chat, you can get events and use them to trigger subsequent notifications or alerts, or aggregate reports outside of Connect Customer. There's a lot you can do with this data. For example:

- Get real-time alerts in a QuickSight dashboard.
- Create aggregated reported outside of Connect Customer.
- Join data with your CRM.
- Connect your notification solution to EventBridge and make sure that by end of day, all of a certain type of events go to a certain inbox. The payload tells you the contact, agent, and queue.

> **Note**
>
> For real-time metrics rules, the resources triggering the rule will be listed under **resources**. For example, if you create a rule that alerts you on queue metrics such as avg. queue answer time, the list of queues that breached the threshold will be listed under resources.

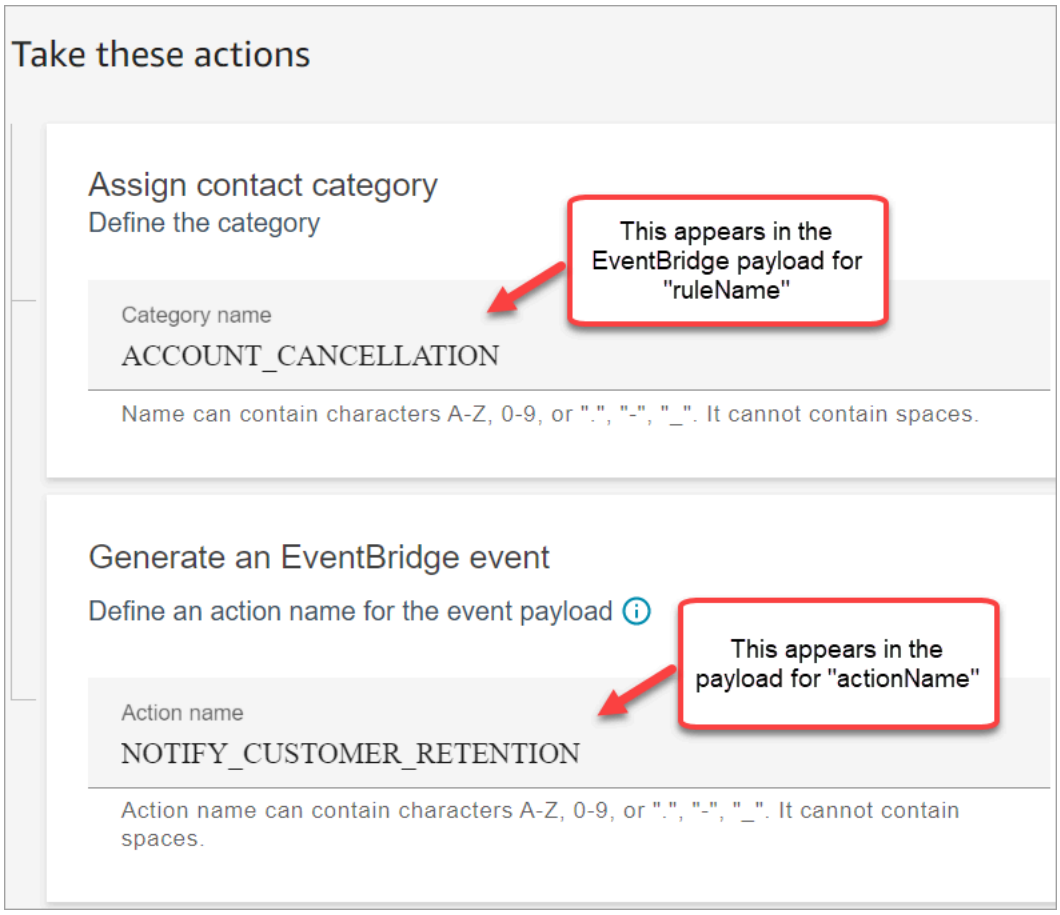
To create a rule that generates an EventBridge event

1. When you create your rule, choose **Generate EventBridge event** for the action.



2. For **Action name**, enter the name for the event payload.

> **Note**
>
> The value you assign for **Action name** is visible in the EventBridge payload. When you aggregate events, the action name provides an additional dimension that you can use to process them. For example, you have 200 category names, but only 50 have a specific action name, such as NOTIFY_CUSTOMER_RETENTION.



3. Choose **Next**. Review and then **Save**.
4. After you add rules, they are applied to new contacts that occur after the rule was added. Rules are applied when Connect Customer conversational analytics analyzes conversations.

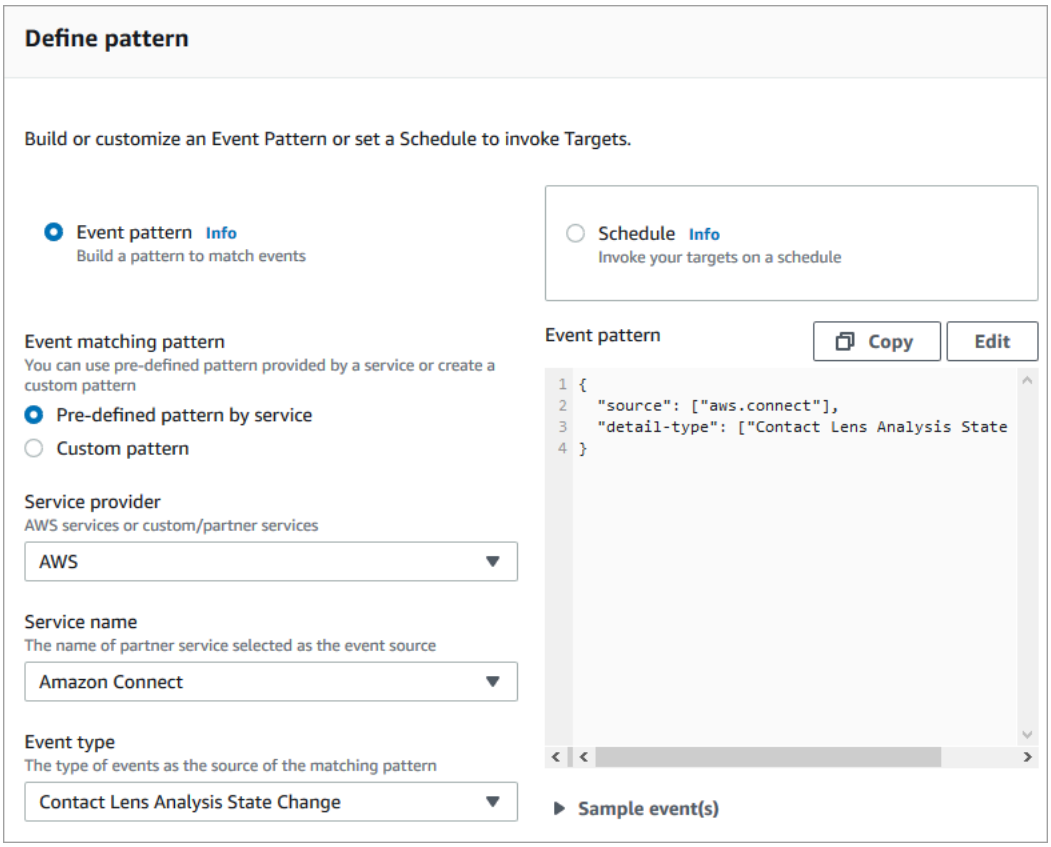
   You cannot apply rules to past, stored conversations.
5. To use the EventBridge data, subscribe to the EventBridge event type. See the next procedure.

Subscribe to EventBridge event types

To subscribe to EventBridge event types, create a custom EventBridge rule that matches the following:

- "source" = "aws.connect"
- "detail-type" = "Contact Lens Post Call Rules Matched" or one of the following:
  - **Contact Lens Realtime Rules Matched**
  - **Contact Lens Realtime Chat Rules Matched**
  - **Contact Lens Post Chat Rules Matched**
  - **Contact Lens Evaluation Rules Matched**
  - **Metrics Rules Matched**

The following image shows these settings in the Event pattern section of the new rule page.



Example EventBridge payloads

Following is an example of what the EventBridge payload looks like when **Contact Lens Post Call Rules Matched**.

```
{
 "version": "0", // set by EventBridge
 "id": "aaaaaaaa-bbbb-cccc-dddd-bf3703467718", // set by EventBridge
 "source": "aws.connect",
 "detail-type": "Contact Lens Post Call Rules Matched",
 "account": "your AWS account ID",
 "time": "2020-04-27T18:43:48Z",
 "region": "us-east-1", // set by EventBridge
 "resources": ["arn:aws:connect:us-east-1:your AWS account ID:instance/instance-ARN"],
 "detail": {
    "version": "1.0",
    "ruleName": "ACCOUNT_CANCELLATION", // Rule name
    "actionName": "NOTIFY_CUSTOMER_RETENTION",
    "instanceArn": "arn:aws:connect:us-east-1:your AWS account ID:instance/instance-
ARN",
    "contactArn": "arn:aws:connect:us-east-1:your AWS account ID:instance/instance-ARN/
contact/contact-ARN",
    "agentArn": "arn:aws:connect:us-east-1:your AWS account ID:instance/instance-ARN/
agent/agent-ARN",
    "queueArn": "arn:aws:connect:us-east-1:your AWS account ID:instance/instance-ARN/
queue/queue-ARN",
    }
}
```

Following is an example of what the payload looks like when **Contact Lens Realtime Rules Matched**.

```
{
 "version": "0", // set by EventBridge
 "id": "aaaaaaaa-bbbb-cccc-dddd-bf3703467718", // set by EventBridge
 "source": "aws.connect",
 "detail-type": "Contact Lens Realtime Rules Matched",
 "account": "your AWS account ID",
 "time": "2020-04-27T18:43:48Z",
 "region": "us-east-1", // set by EventBridge
 "resources": ["arn:aws:connect:us-east-1:your AWS account ID:instance/instance-ARN"],
 "detail": {
     "version": "1.0",
     "ruleName": "ACCOUNT_CANCELLATION", // Rule name
     "actionName": "NOTIFY_CUSTOMER_RETENTION",
      "instanceArn": "arn:aws:connect:us-east-1:your AWS account ID:instance/instance-
ARN",
```

```
     "contactArn": "arn:aws:connect:us-east-1:your AWS account ID:instance/instance-
ARN/contact/contact-ARN",
     "agentArn": "arn:aws:connect:us-east-1:your AWS account ID:instance/instance-ARN/
agent/agent-ARN",
     "queueArn": "arn:aws:connect:us-east-1:your AWS account ID:instance/instance-ARN/
queue/queue-ARN",
      }
}
```

Create a rule that generates a task

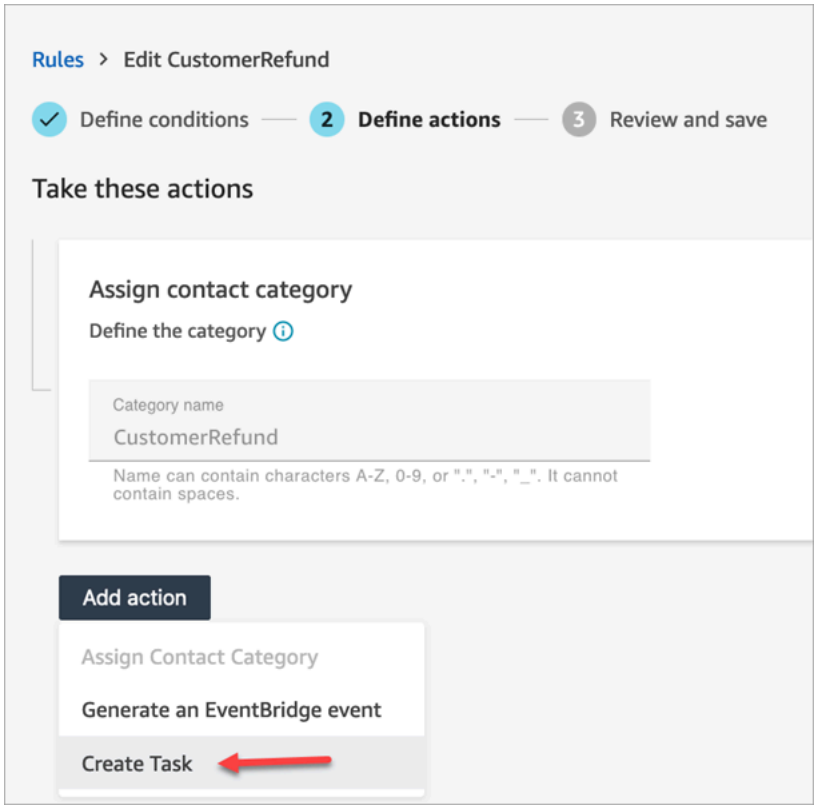
With Connect Customer rules, you can generate tasks. This helps you create traceable actions with owners and provides you visibility on task completion and productivity out the box.

Following are some examples:

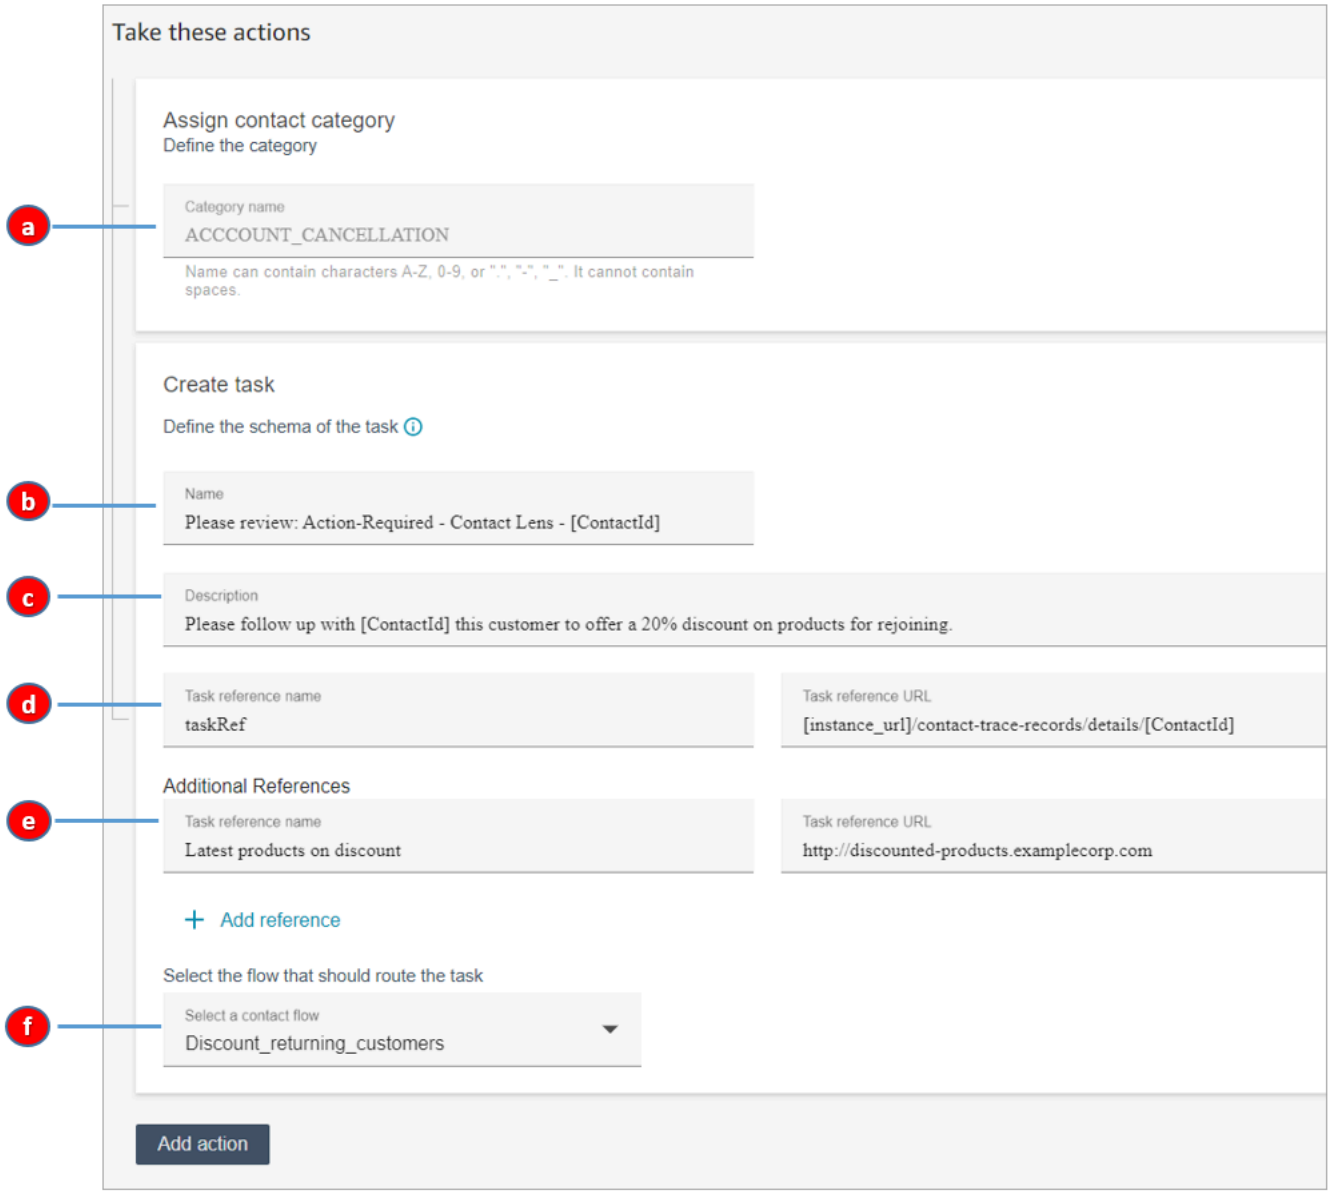
- Review a contact when the customer is fraudulent. For example, you can create a follow-up task when a customer utters words or phrases that makes them appear potentially fraudulent.
- Follow up when the customer mentions specific topics that you want to later on upsell or provide additional support by reaching out.
- Evaluate agent performance in specific scenarios, for example, customer sentiment was very low during the conversation and the customer expressed frustration.
- Take operational actions, such as assigning additional agents to queues on which avg. queue answer time in the last hour has exceeded acceptable thresholds.

To create a rule that creates a task

1. When you create your rule, choose **Create Task** for the action.



2. Complete the task fields as follows:



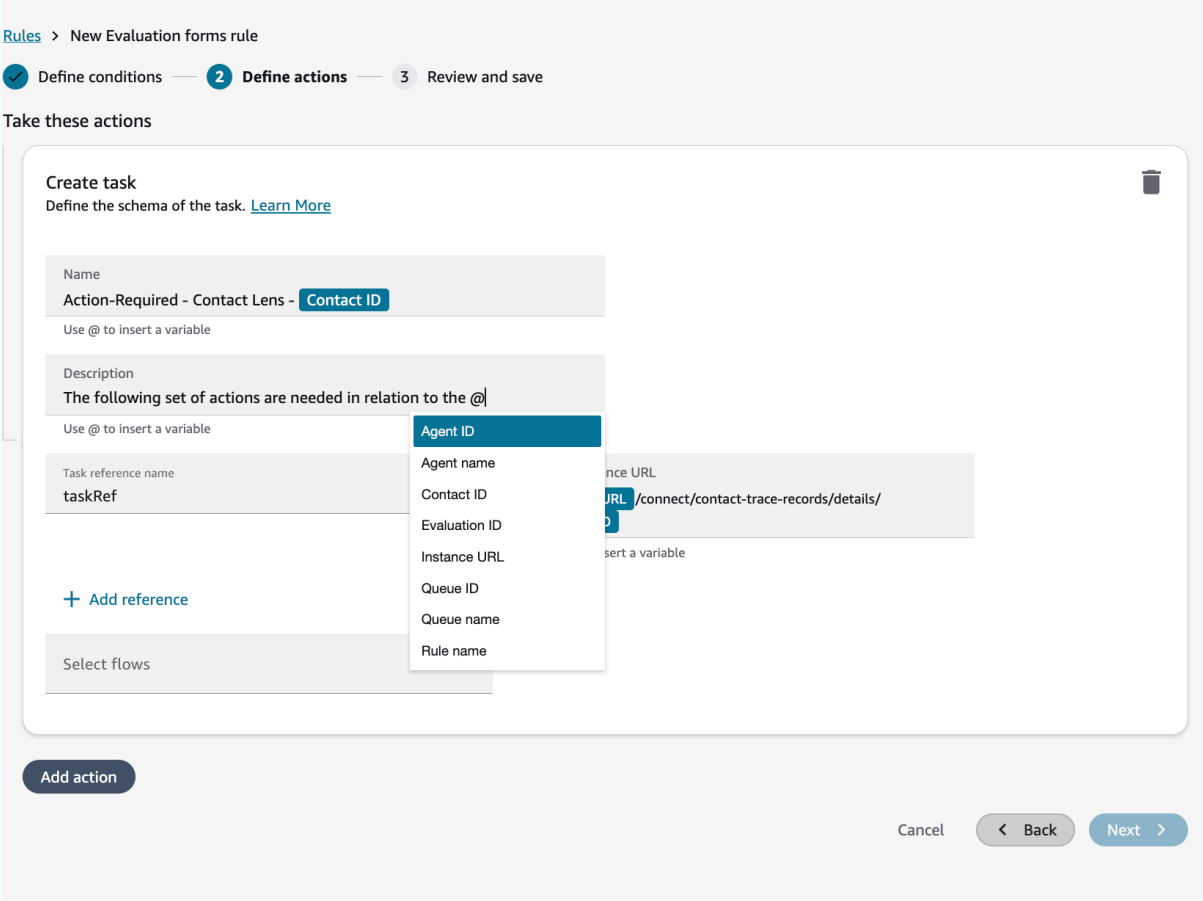
a. **Category name**: The category name appears in the contact record. Max length: 200 characters.

b. **Name**: The name appears in the agent's Contact Control Panel (CCP). Max length: 512 characters.

c. **Description**: The description appears in the agent's Contact Control Panel (CCP). Max length: 4096 characters.

Note

In Name and Description, use **@ to add dynamic variables** that are populated during execution of the rule. For conversational analytics rules and evaluation forms rules, you can add **rule name, instance URL, contact, agent** and **queue** information for the contact that matched the rule. With evaluation forms rules, you can additionally insert the **evaluation ID**.



Other rule types support different variables:

- With real-time metrics rules, you can enter **rule name, instance URL and list of agents, queues, flows or routing profile** that breached the threshold to trigger the alert.
- With rules for cases, you can insert **rule name, instance URL** and **case ID**.

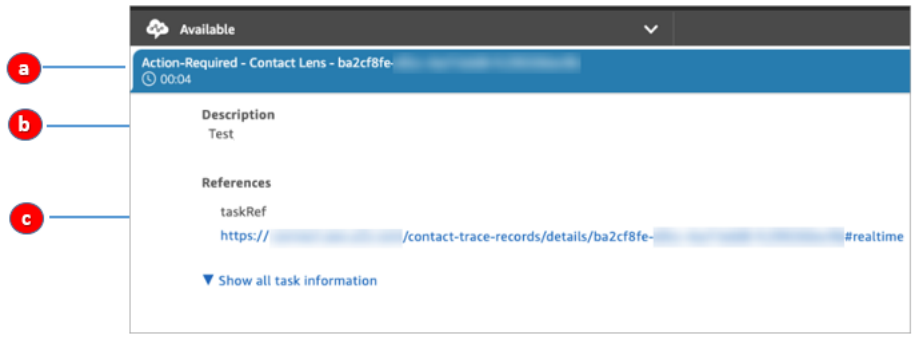
d. **Task reference name**: This is a default reference that automatically appears in the agent's CCP.

- For real-time rules, the task reference links to the Real-time details page.
- For post-call/chat rules, the task reference links to the **Contact details** page.

e. **Additional Reference name**: Max length: 4096 characters. You can add up to 25 references.

f. **Select a flow**: Choose the flow that is designed to route the task to the appropriate owner of the task. The flow must be saved and published for it to appear in your list of options in the dropdown.

3. The following image shows an example of how this information appears in the agent's CCP.



In this example, the agent sees the following values for **Name**, **Description**, and **Task reference name**:

a. **Name** = **Action-Required-Contact Lens- ba2cf8fe....**

b. **Description** = **Test**

c. **Task reference name** = taskRef and the URL to the Real-time details page

4. Choose **Next**. Review and then choose **Save** the task.

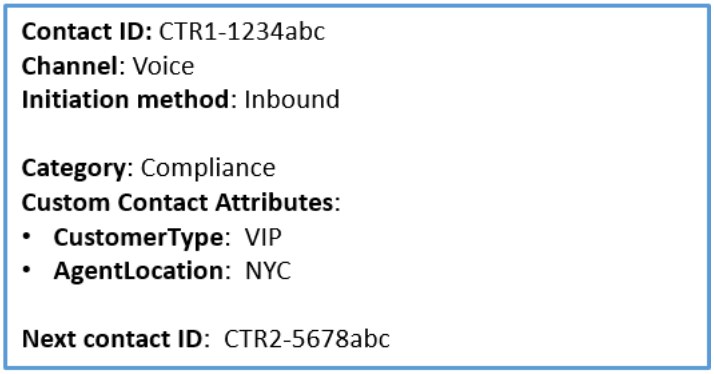
5. After you add rules, they are applied to new contacts that occur after the rule was added. Rules are applied when Connect Customer conversational analytics analyzes conversations.

   You cannot apply rules to past, stored conversations.

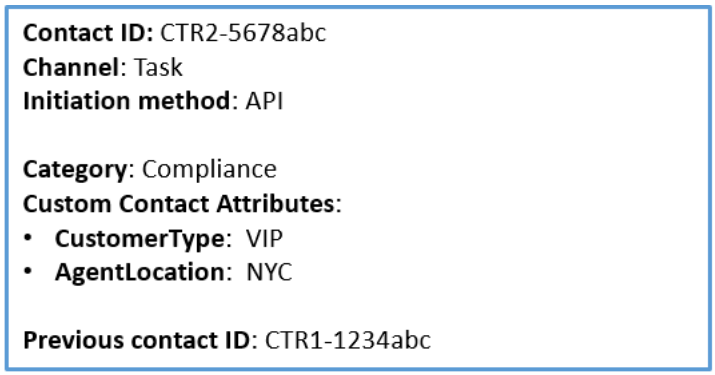
Voice and task contact records are linked

When a rule creates a task, a contact record is automatically generated for the task. It's linked to the contact record of the voice call or chat that met the criteria for the rule to create the task.

For example, a call comes into your contact center and generates CTR1:



The Rules engine generates a task. In the contact record for the task, the voice contact record appears as the **Previous contact ID**. In addition, the task contact record inherits contact attributes from the voice contact record, as illustrated in the following image:



About dynamic values for ContactId, AgentId, QueueId, RuleName

The dynamic values in brackets [ ] are called contact attributes. Contact attributes help you store temporary information about the contact so you can use it in a flow.

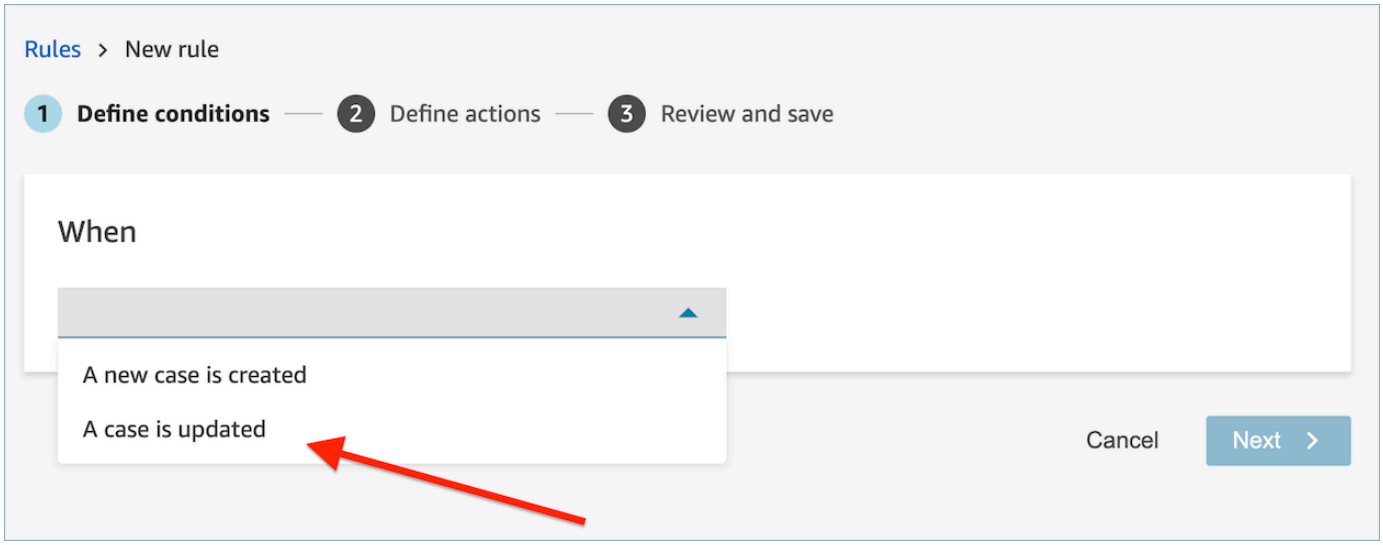
When you add contact attributes in brackets [ ] — such as ContactId, AgentId, QueueId, or RuleName — the value is passed from one contact record to another. You can use contact attributes in your flow to branch and route the contact accordingly.

For more information, see Use contact attributes.

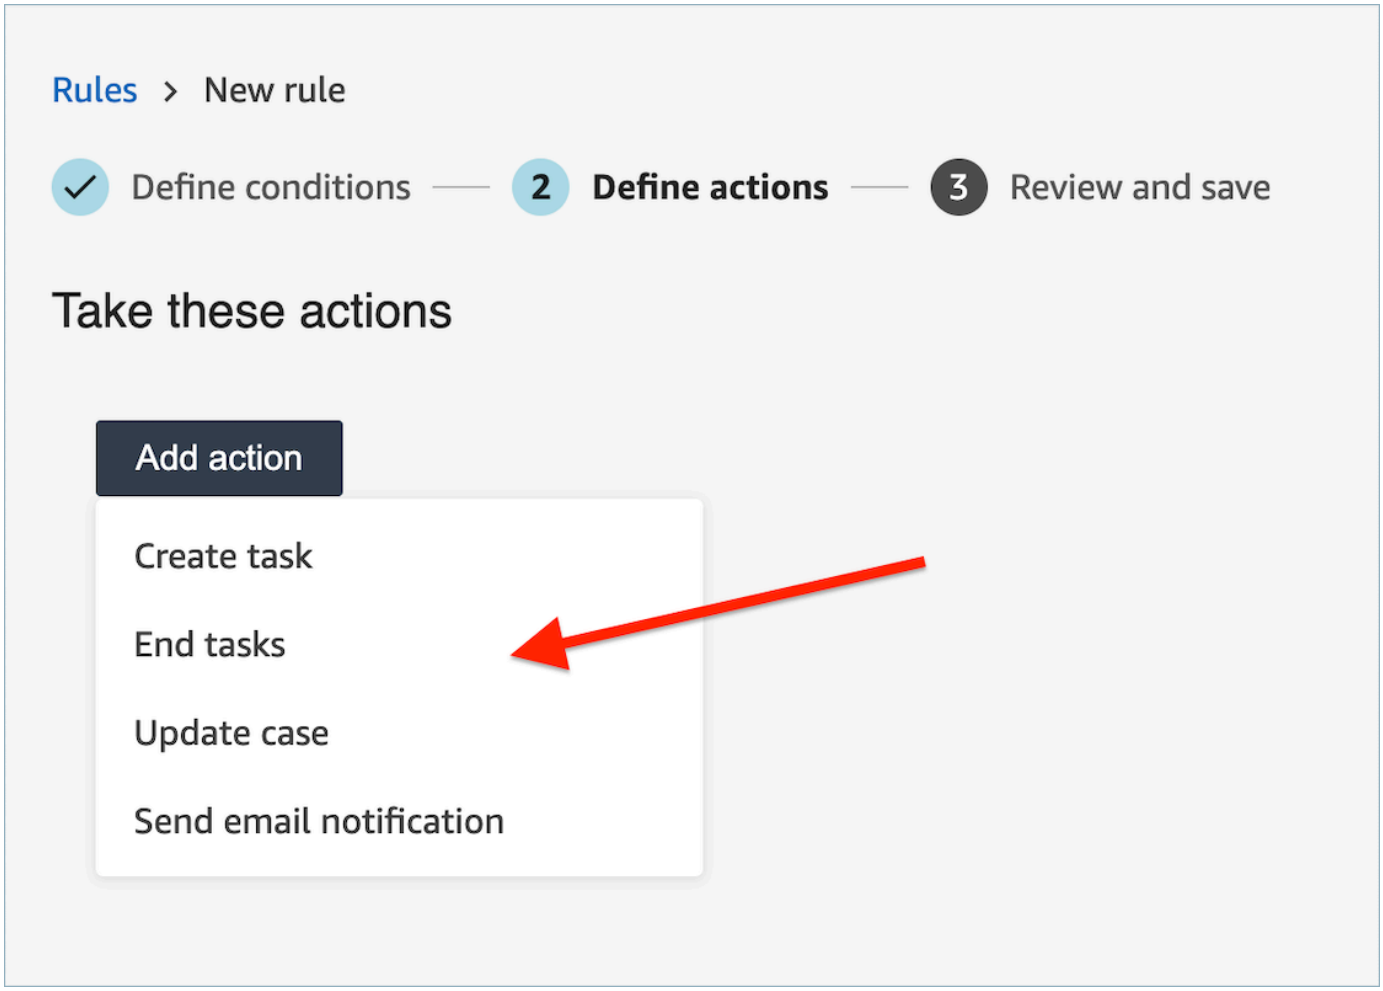
Create a rule in conversational analytics that ends associated tasks from a case

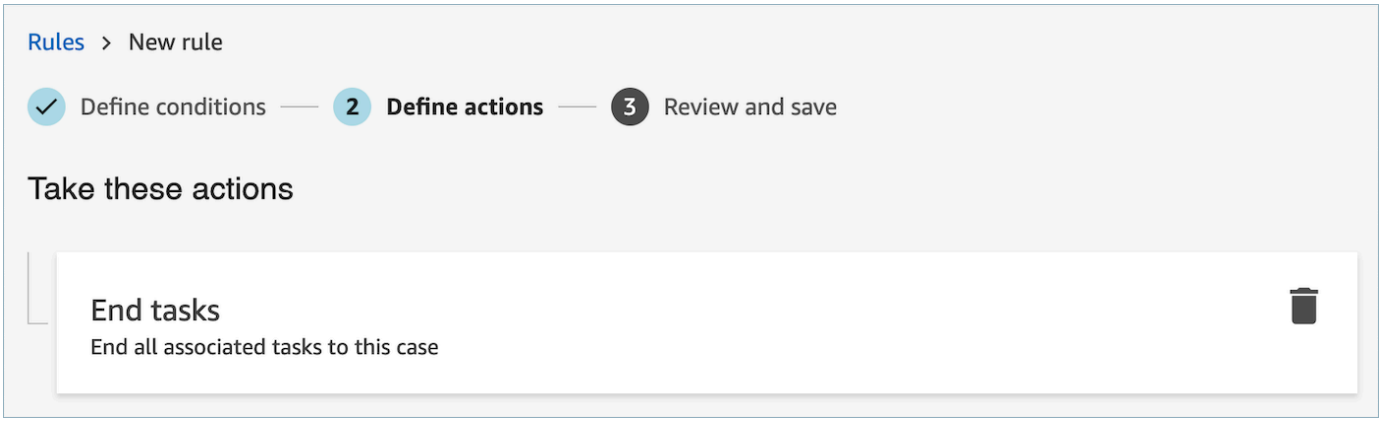
To create a rule that ends associated tasks

1. When you create your rule, choose **A new case is updated** as the event source.



2. When you create your rule, choose **End tasks** for the action.





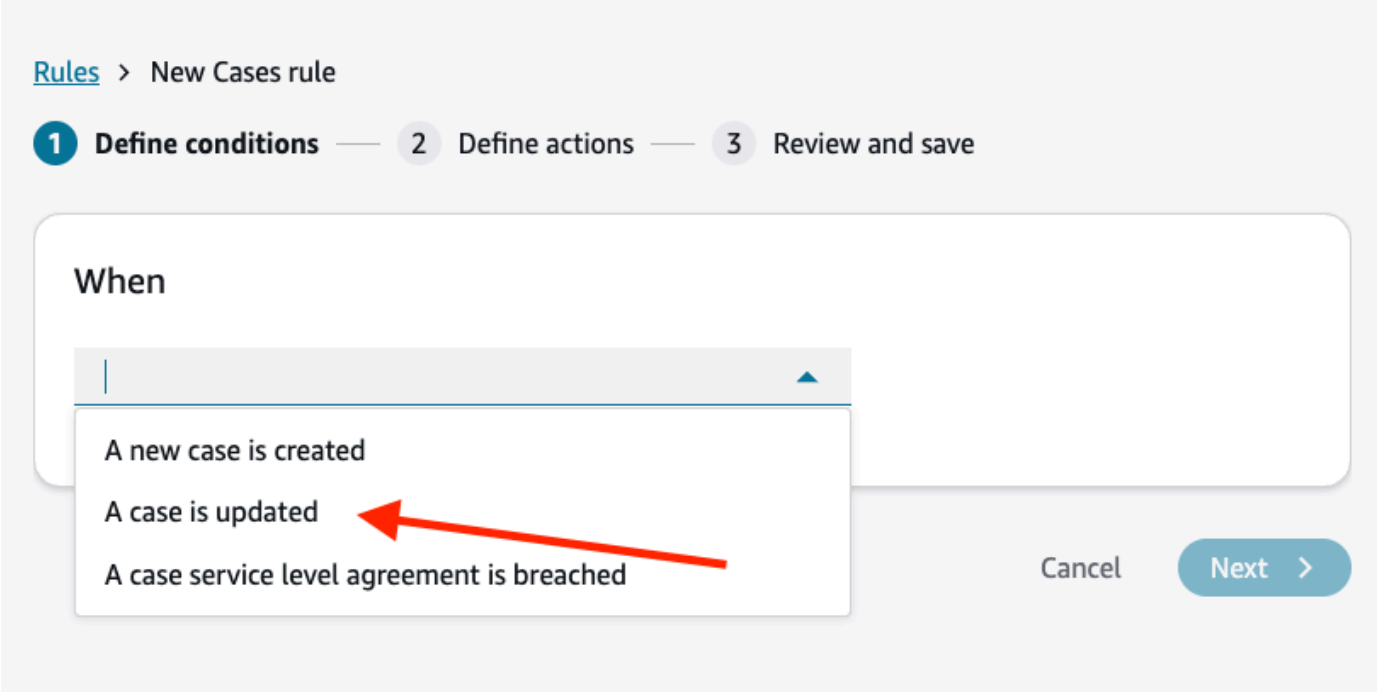
3. Choose **Next**. Review and then choose **Save**.
4. After you add rules, they are applied to new contacts that occur after the rule was added. Rules are applied when Connect Customer conversational analytics analyzes conversations.

   You cannot apply rules to past, stored conversations.

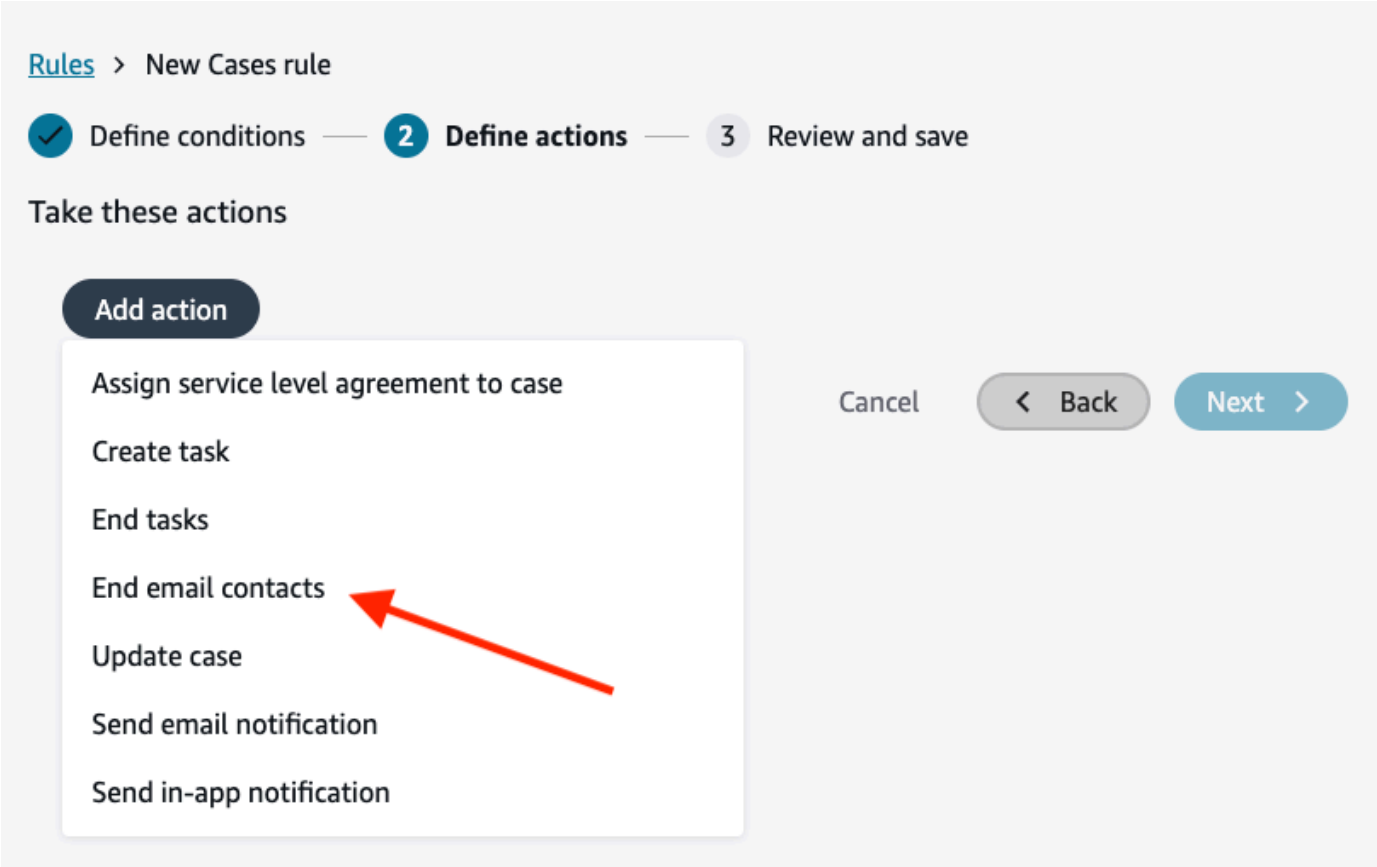
Create a rule in conversational analytics that ends associated email contacts from a case

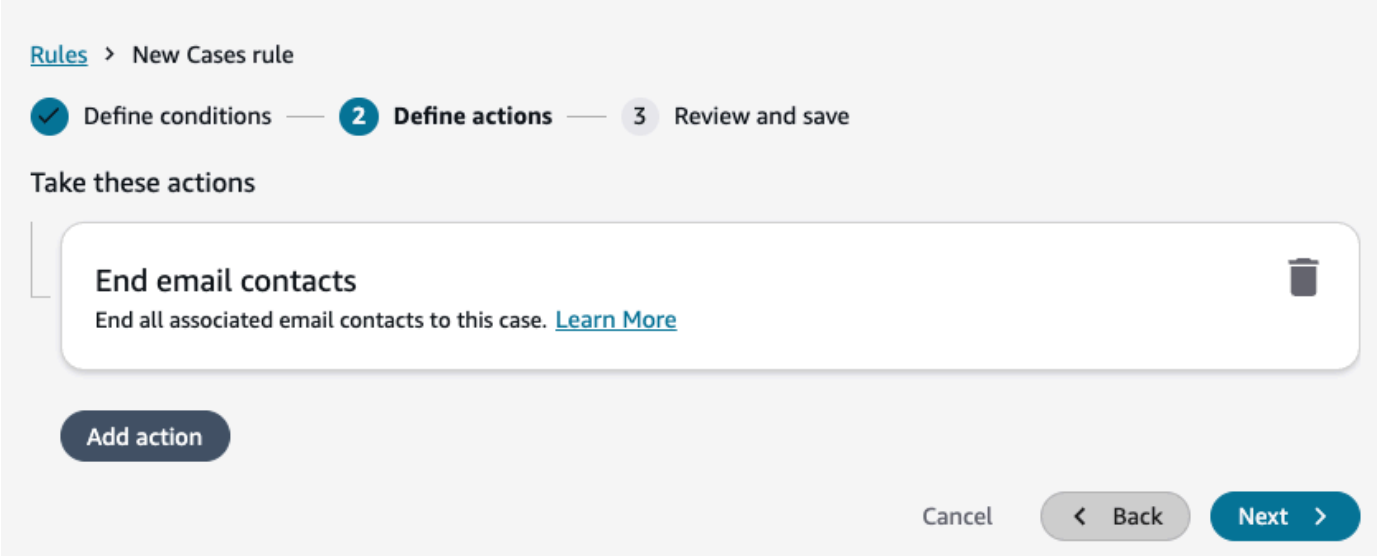
To create a rule that ends associated email contacts

1. When you create your rule, choose **A case is updated** as the event source.



2. When you create your rule, choose **End email contacts** for the action.





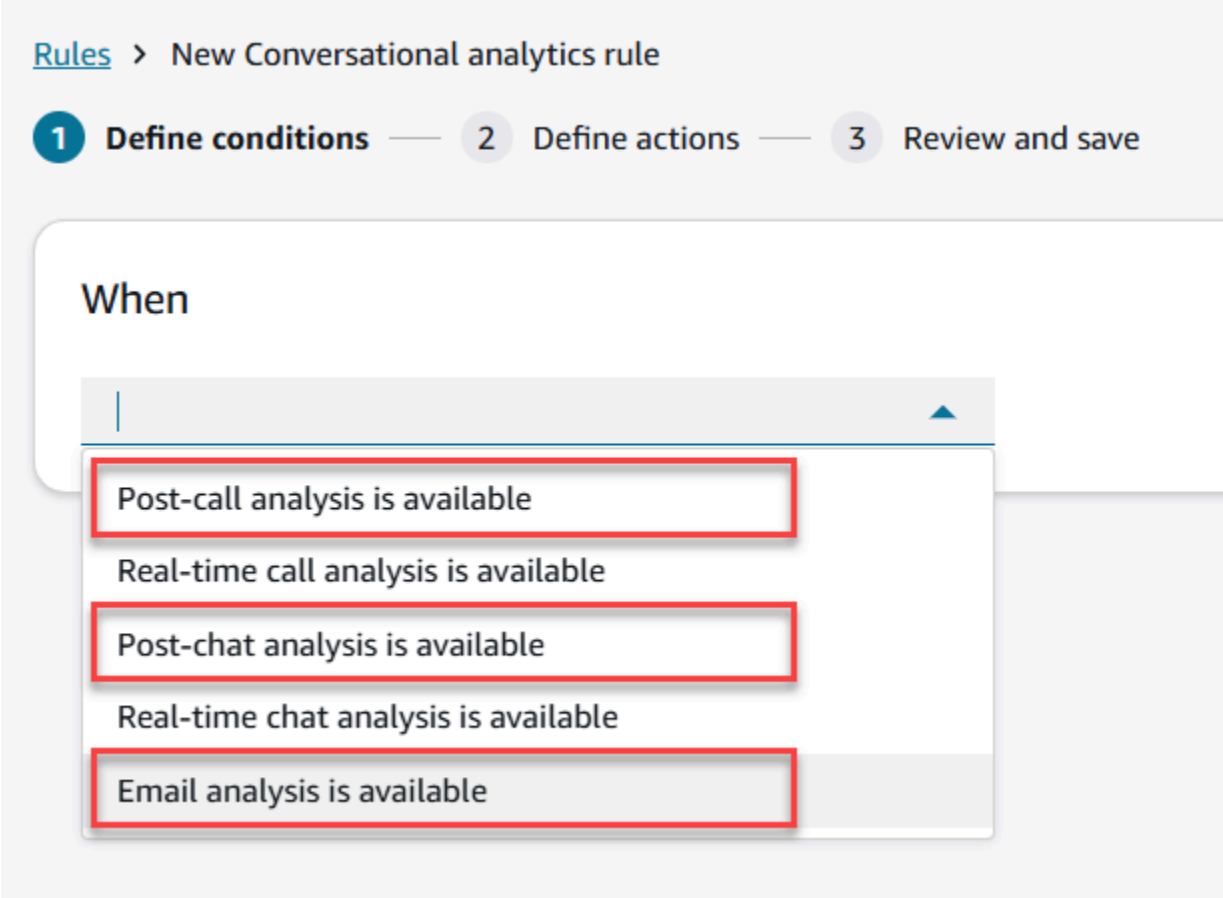
3. Choose **Next**. Name your rule, review it, and then choose **Save**.
4. After you add rules, they are applied to new contacts that occur after the rule was added. Rules are applied when Connect Customer conversational analytics analyzes conversations.

   You cannot apply rules to past, stored conversations.

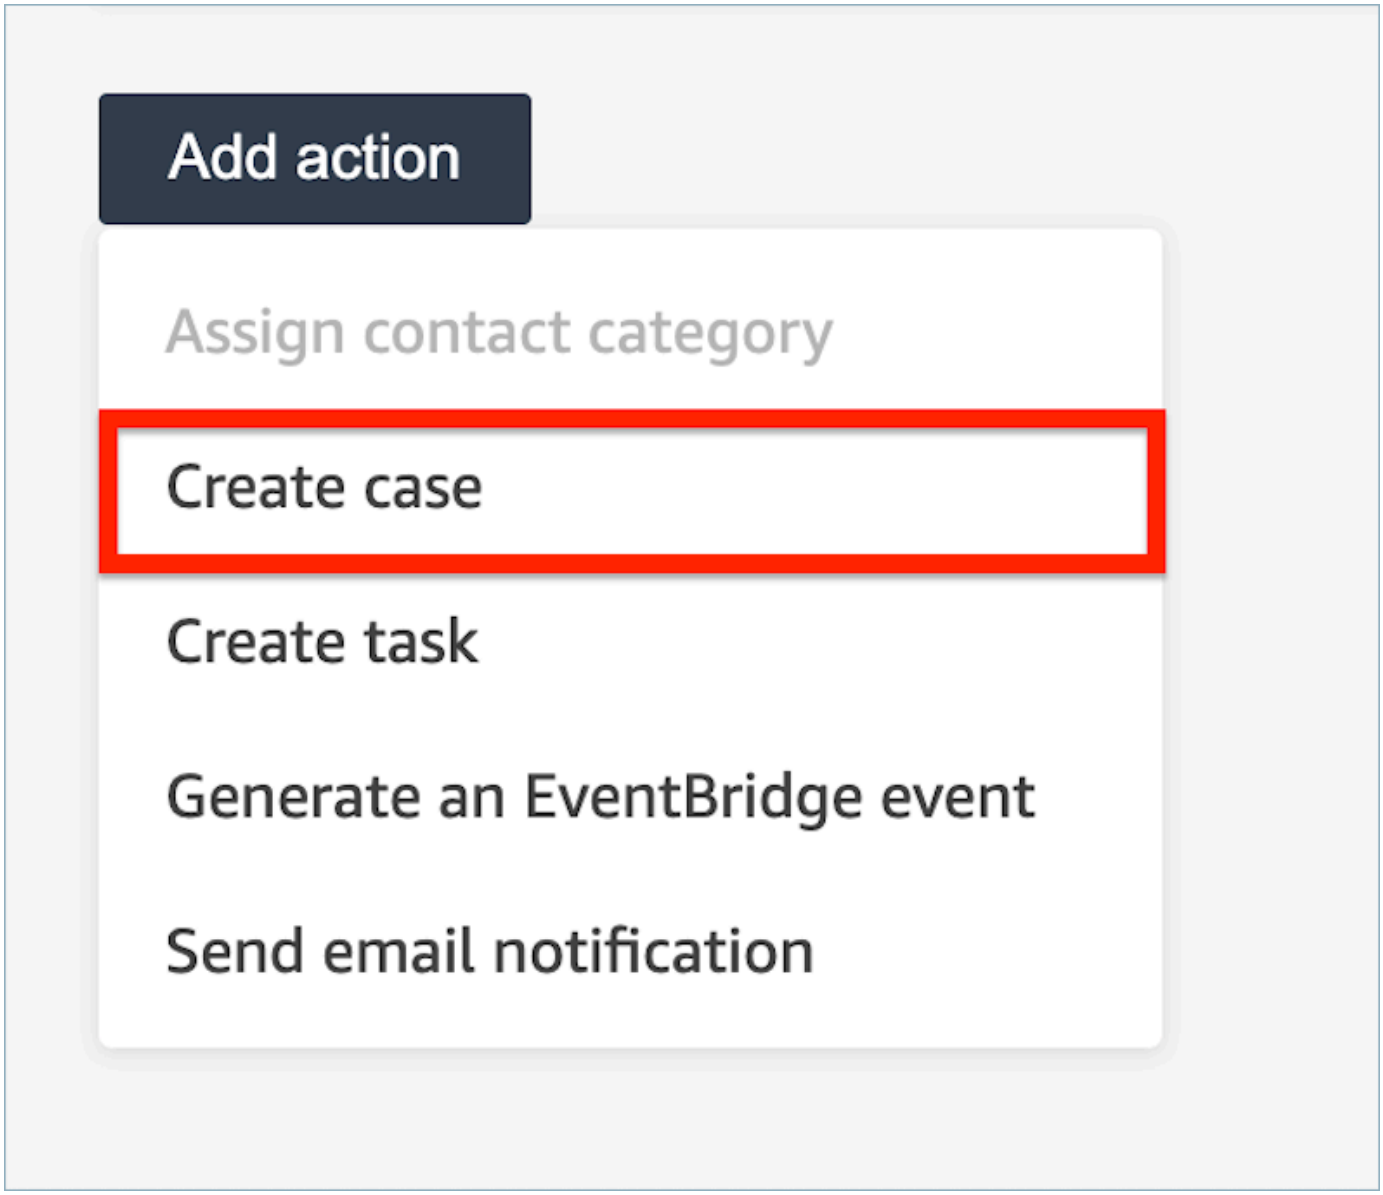
Create a rule in conversational analytics that creates a case

To create a rule that creates a case

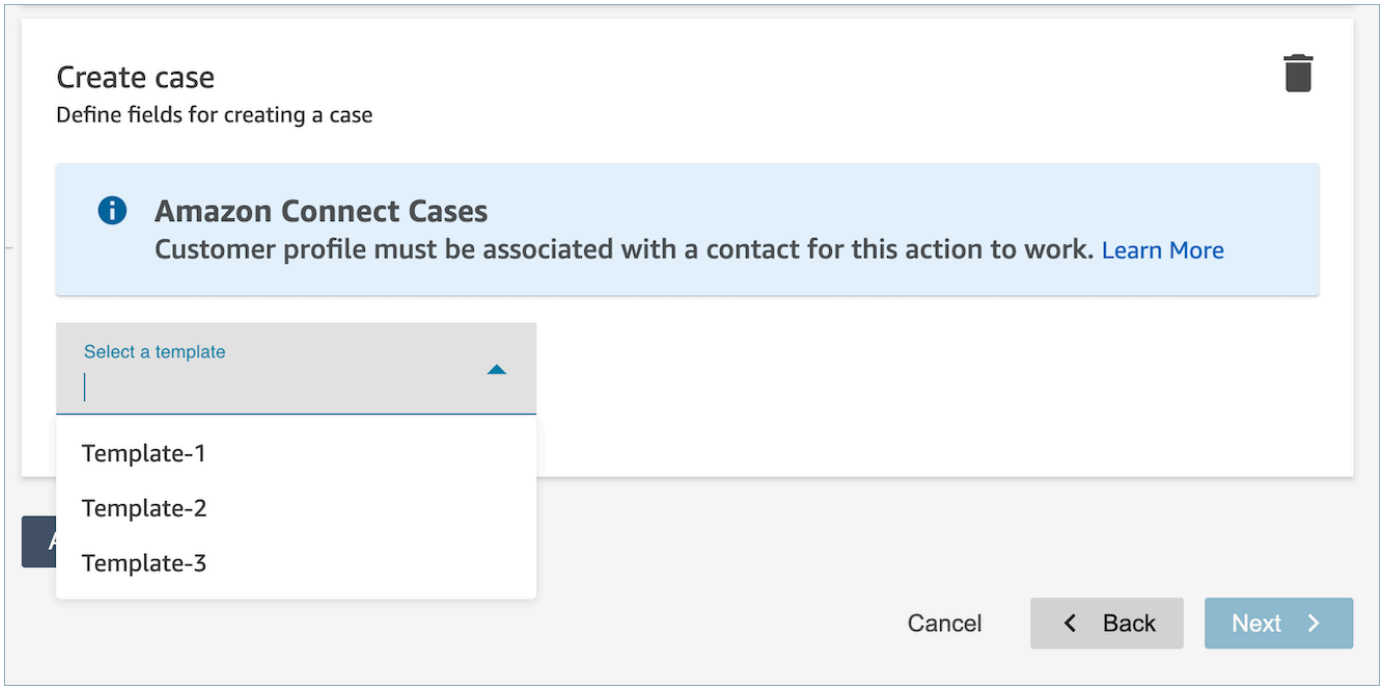
1. When you create your rule, choose **Post-call analysis is available**, **Post-chat analysis is available**, or **Email analysis is available** as the event source.



2. Choose **Next**
3. On the actions page, choose **Create case** for the action.

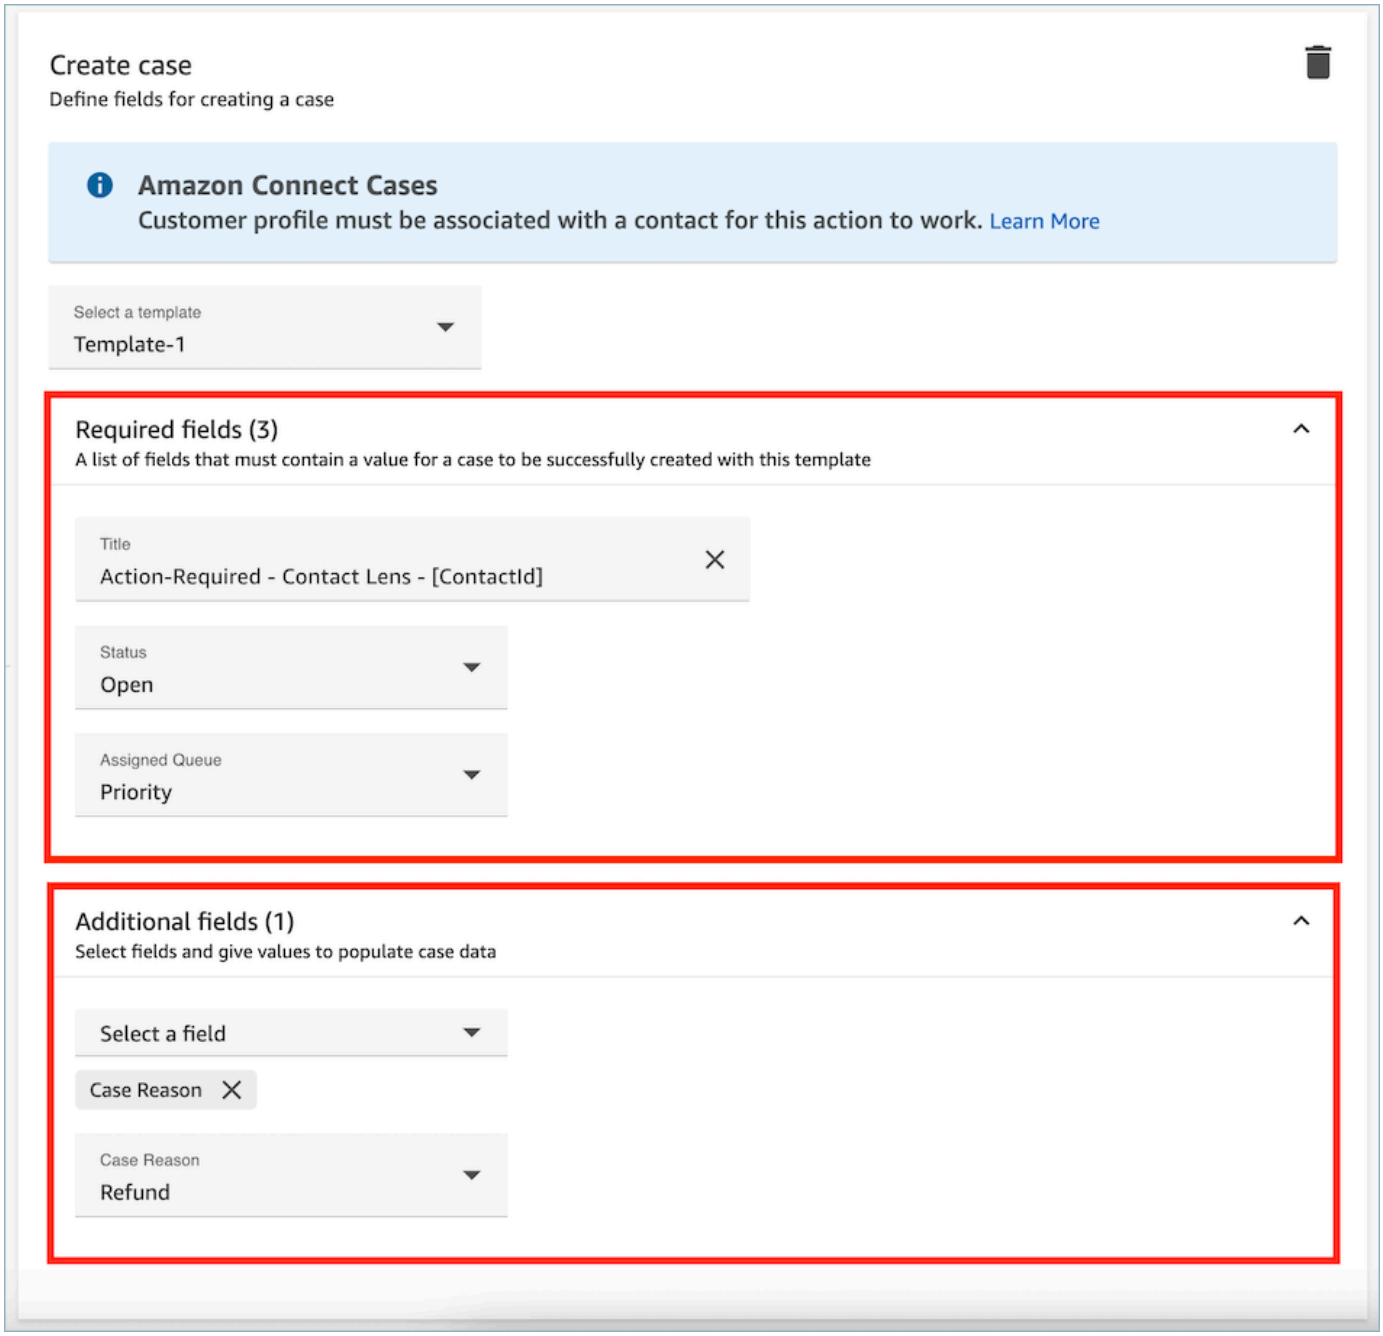


4. In the **Create case** card, select a **Case template**.



5. Fill out the **required fields** and add **optional case fields** to populate case data.

> **Note**
>
> A customer profile must be associated with a contact for this action to work. For more information, see Enable Cases.



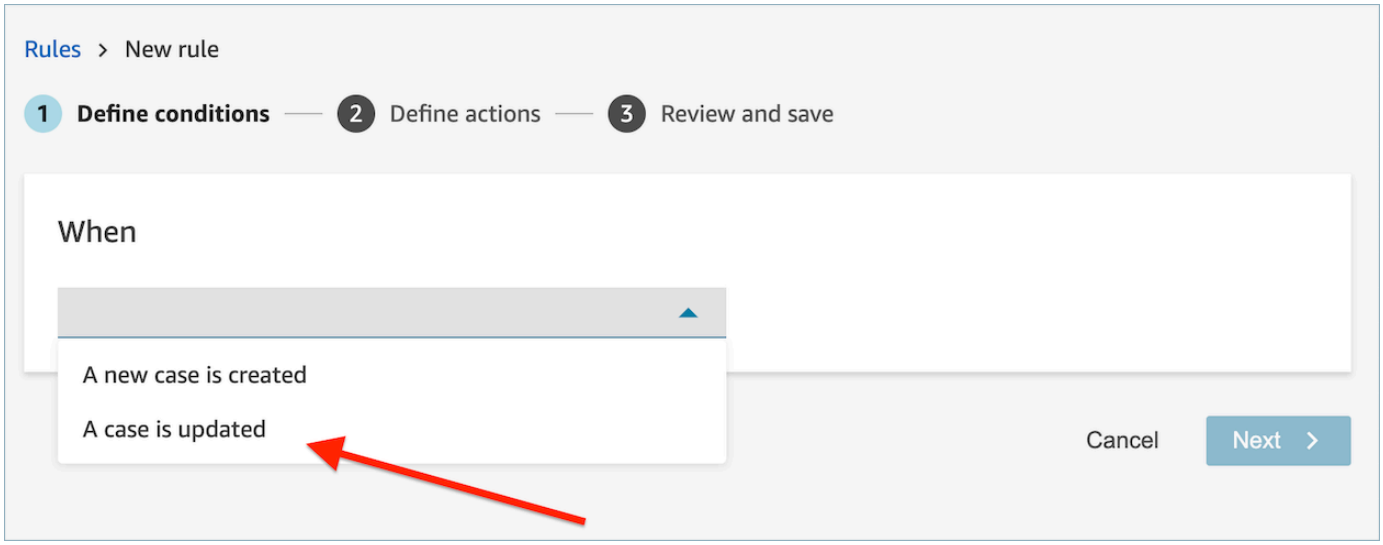
6. Choose **Next**. Review and then choose **Save**.
7. After you add rules, they are applied to new contacts that occur after the rule was added. Rules are applied when Connect Customer conversational analytics analyzes conversations.

   You cannot apply rules to past, stored conversations.

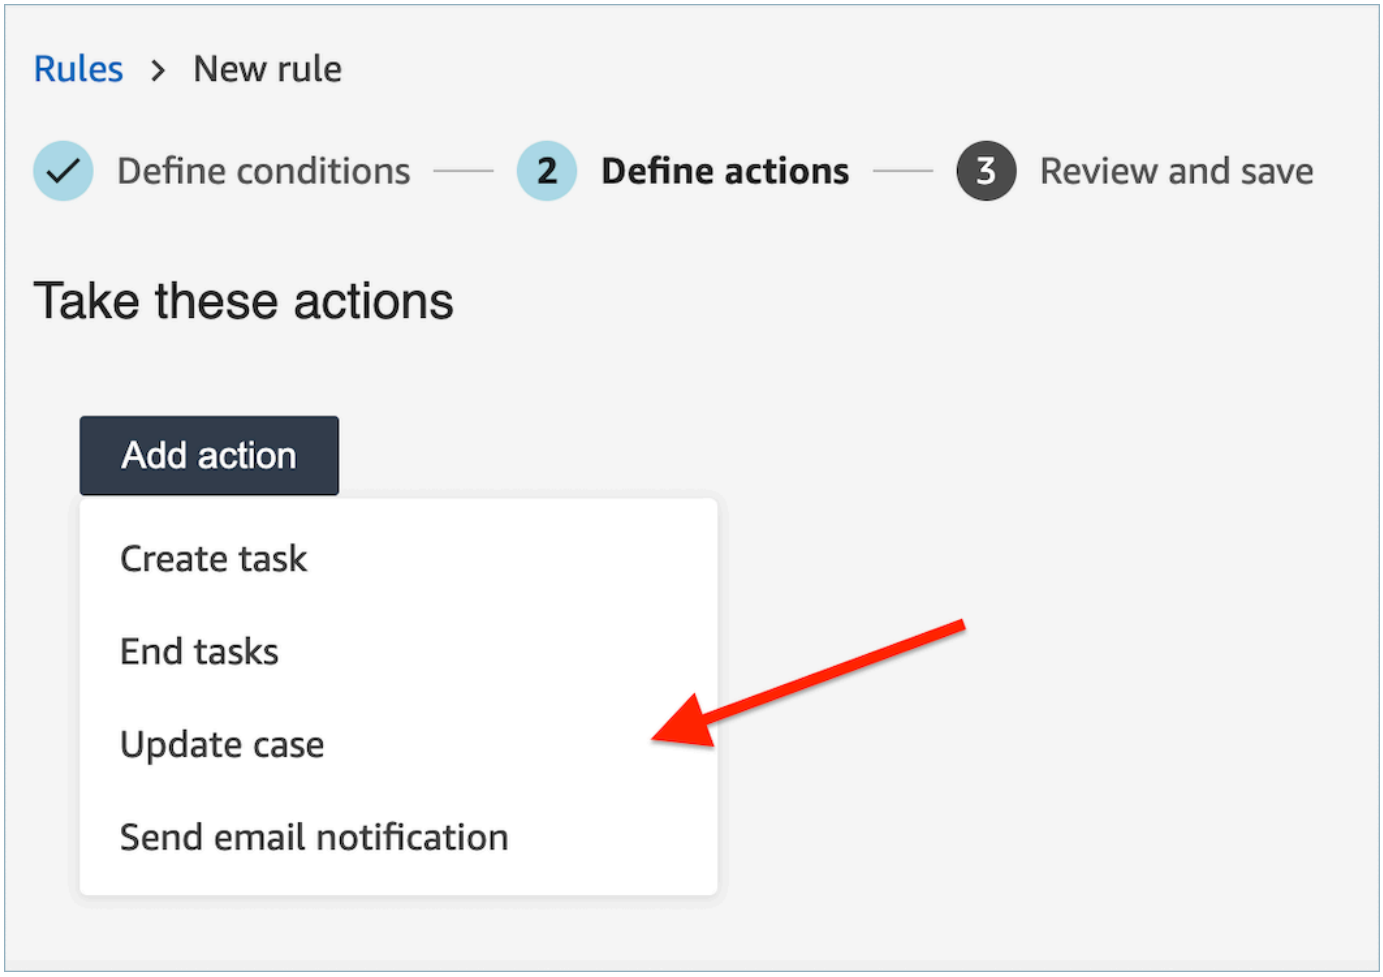
Create a rule in conversational analytics that updates a case

To create a rule that updates a case

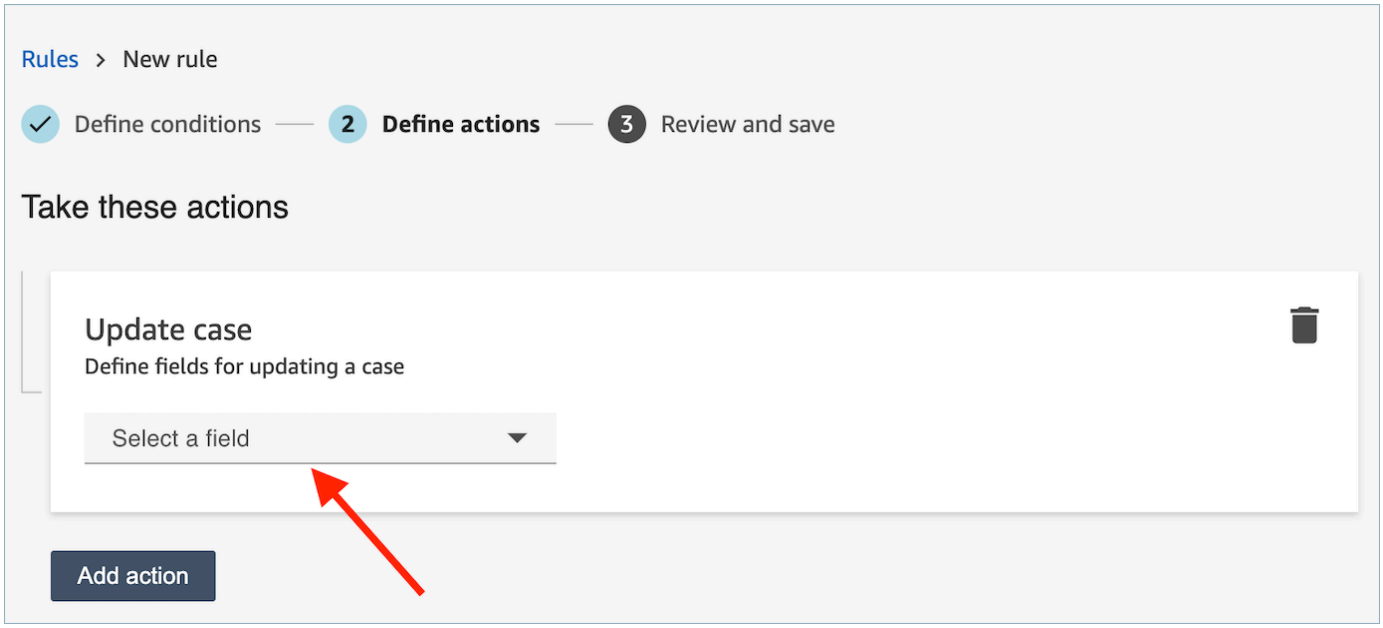
1. When you create your rule, choose **A case is updated** as the event source and choose **Next**.

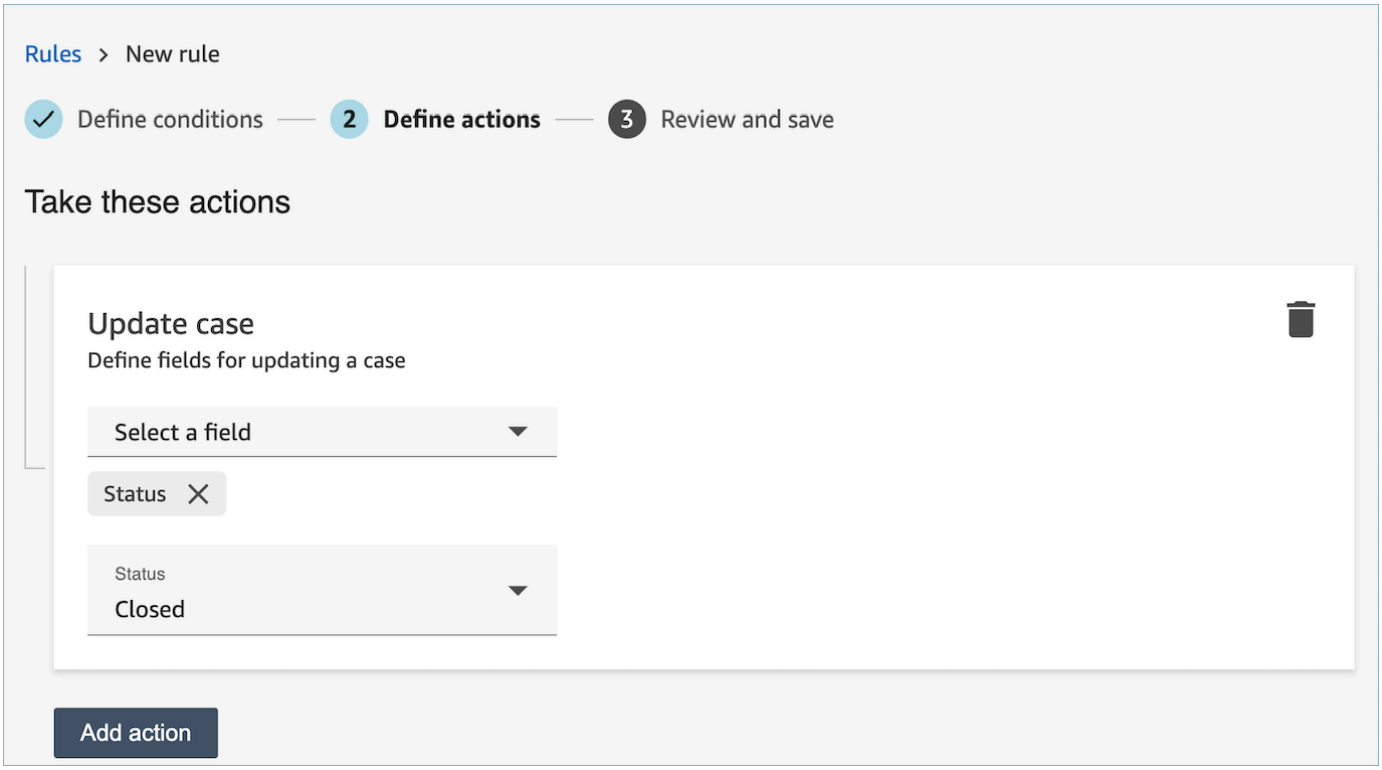


2. When you create your rule, choose **Update case** for the action.



3. Select any case field that you want to update from the dropdown and define its new value.





4. Choose **Next**. Review and then choose **Save**.
5. After you add rules, they are applied to new contacts that occur after the rule was added. Rules are applied when Connect Customer conversational analytics analyzes conversations.

   You cannot apply rules to past, stored conversations.

Create a rule in conversational analytics that submits an automated evaluation

With Conversational analytics, you can automatically fill and submit evaluations by using insights and metrics from conversational analytics.

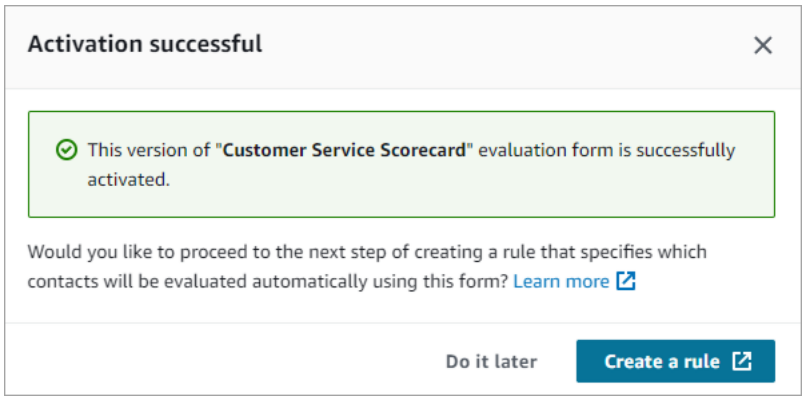
Step 1: Configure automation on the evaluation form

Before you can create a rule that submits an automated evaluation, you need to configure automation on the evaluation form. For detailed instructions, see Step 6: Enable automated evaluations in Create an evaluation form.

Following is an overview of the steps:

1. Setup automation on every question in an evaluation form.
2. Turn on **Enable automated submission of evaluations** before activating the evaluation form.

3. When you activate the evaluation form with automation configured, a prompt is displayed for you to create a rule, as shown in the following image.



4. Choose **Create a rule**.
5. On the **Rules** page, define a rule that specifies which contacts are automatically evaluated using the selected evaluation form. The following procedure provides instructions.

Step 2: Define a rule that specifies which contacts are automatically evaluated

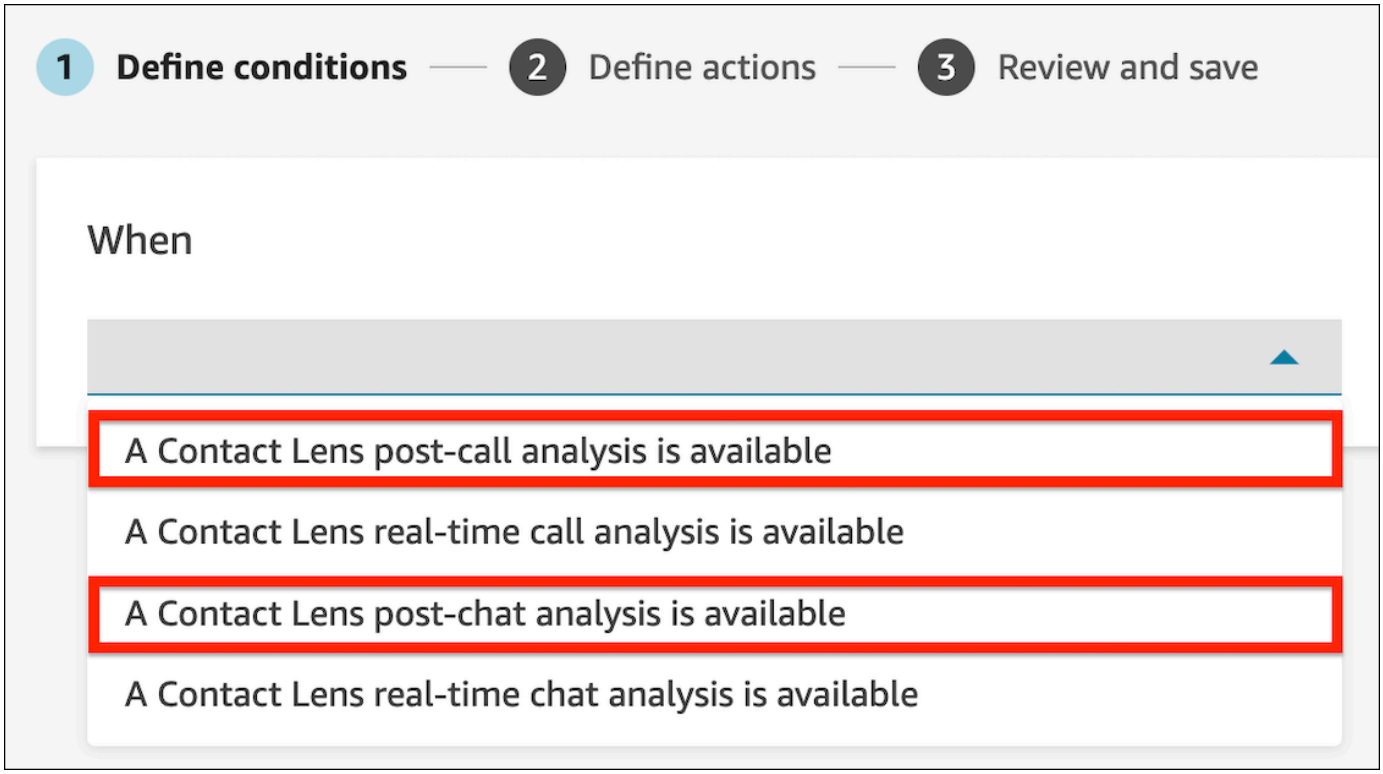
You can trigger automated evaluations with two types of rules:

- A **Conversational analytics** rule that automatically evaluates the contact after conversational analytics completes its analysis.
- An **Evaluation forms** rule that can be used to trigger a situation-specific evaluation form as an outcome of a generic evaluation form. For example, if the answer to the evaluation question *Was the customer interested in purchasing a product* is *Yes*, then you can trigger another evaluation form measuring *Agent sales performance*.

Trigger automated evaluations with a conversational analytics rule

This is the default rule type that is selected when you create a rule to submit an automated evaluation during form activation. You can also create such a rule by selecting **Create a rule**, **Conversational analytics** on the **Rules** page.

1. Choose **A conversational analytics post-call analysis is available** or **A conversational analytics post-chat analysis is available** as the event source. These two options are highlighted in the following image.



2. Define conditions to identify contacts to be automatically evaluated, and then choose **Next**.

   Example conditions that you can use to identify the specific set of agents or contacts on which the evaluation form is applicable are:

   - Agents
   - Agent hierarchy
   - AI agent
   - Queues
   - Initiation method

   In addition, you can exclude contacts that might have ended prematurely due to connectivity or other issues using conditions such as:

   - Interaction duration (for example, over 30 seconds)
   - Talk time (for example, the customer speaks for over 10 seconds)
   - Potential disconnect issue when the issue does not exist or there is no known connectivity or device issue during the conversation

3. On the **Define actions** page provide a category name to identify the rule.

4. Choose **Add action**, select **Submit automated evaluation**, and select the form that you want to use for automatically submitting an evaluation. (This action is already selected on the page if you created the rule when you activate the form.)
5. Choose **Next**. Review and then choose **Save and Publish**.

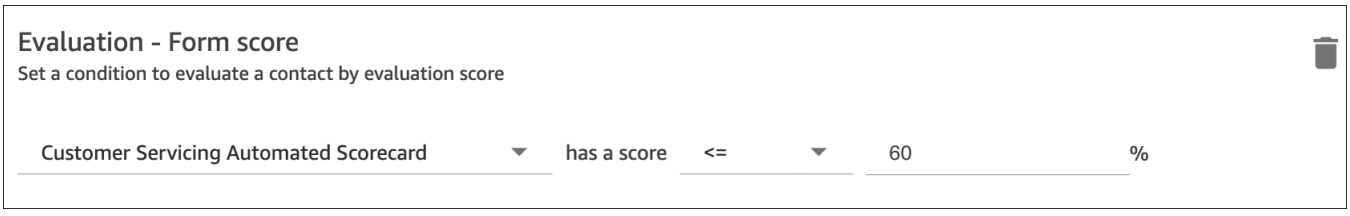
After you add rules, they are applied to new contacts that occur after the rule was added. Rules are applied when Amazon Connect conversational analytics analyzes conversations.

> **Important**
>
> You cannot apply rules to past, stored conversations.

Trigger automated evaluations with an evaluation forms rule

1. Navigate to the **Rules** page. Select **Create a rule**, **Evaluation forms**.
2. Under **When**, select the event source as **A conversational analytics evaluation result is available**.
3. Choose **Add condition** to trigger a situation-specific evaluation. For example:
   - A specific answer on another evaluation, shown in the following image.

   - The score of another evaluation form, shown in the following image.



4. Choose **Add action**, select **Submit automated evaluation**, and select the form that you want to use for automatically submitting an evaluation.
5. Choose **Next**. Review and then choose **Save and Publish**.

Frequently Asked Questions (FAQ)

1. **Can an automated evaluation override an evaluation that has been manually submitted?**

   No, an automated evaluation cannot override a manually submitted evaluation. If an evaluation already exists, then the automated evaluation will fail for that contact and account administrators can see such failure notifications within CloudWatch.

2. **How do I identify automated evaluations?**

   If an evaluation is automatically submitted, it is marked as "submitted by conversational analytics automation" on the **Contact details** page. If an automated evaluation is edited and re-submitted by an evaluator, the "submitted by" contains the name of the evaluator.

3. **Can I automatically evaluate a contact using multiple evaluation forms?**

   Yes, you can automatically submit evaluations on a contact using multiple evaluation forms. You need to create multiple rules to submit automated evaluations using the different evaluation forms.

Use a Word or phrase condition in a conversational analytics rule

Within conversational analytics **conversational analytics** rule, you have the option to specify a Words or phrases condition. You can choose Exact Match, Semantic Match, or Pattern Match for the words or phrases. This topic explains each type of match.

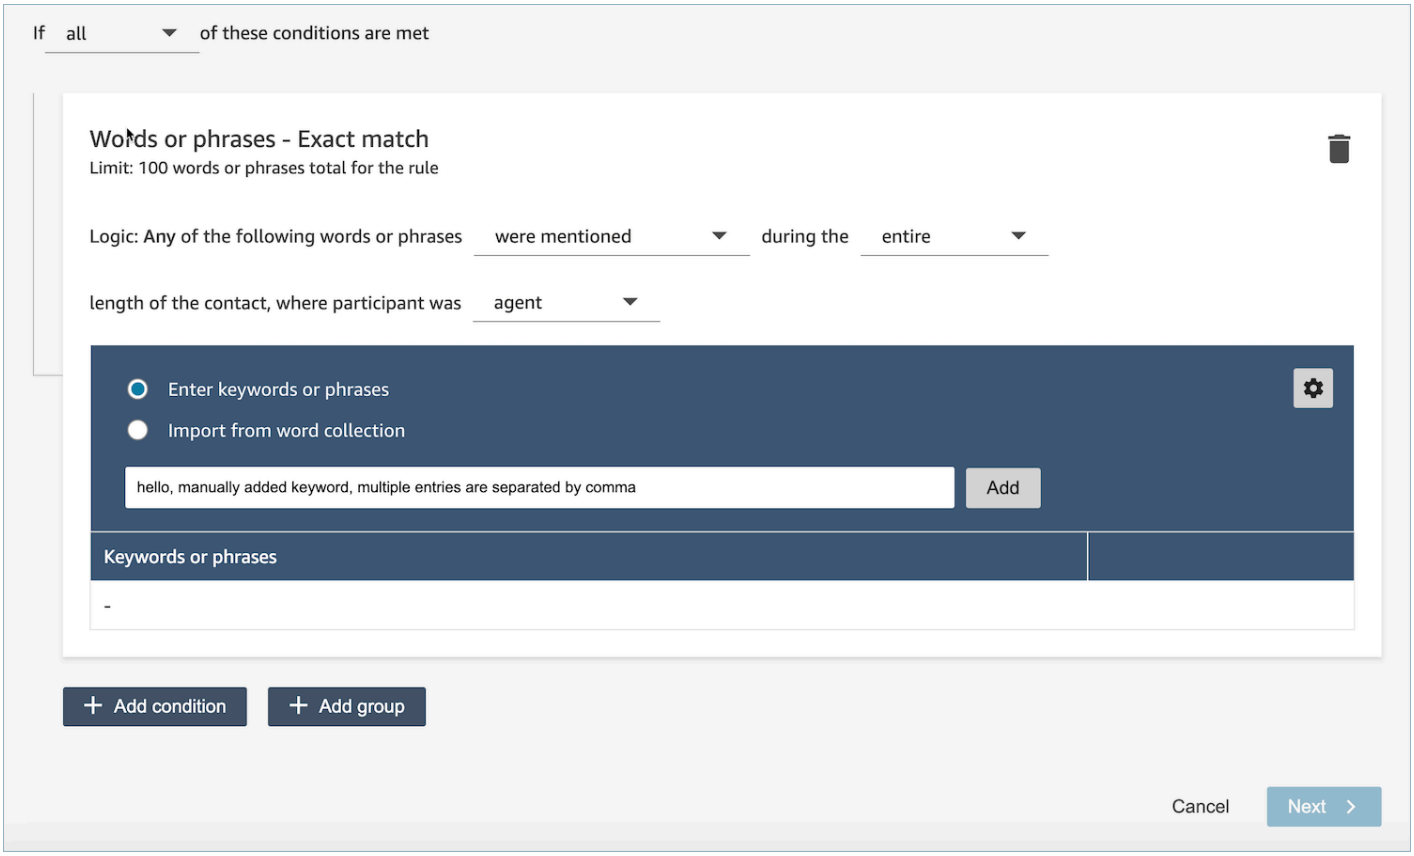
> **Note**
>
> All three match types are not case sensitive, for example, if you have specified the word as "billing", it will also match with the transcript containing the word "Billing".

How to use exact match

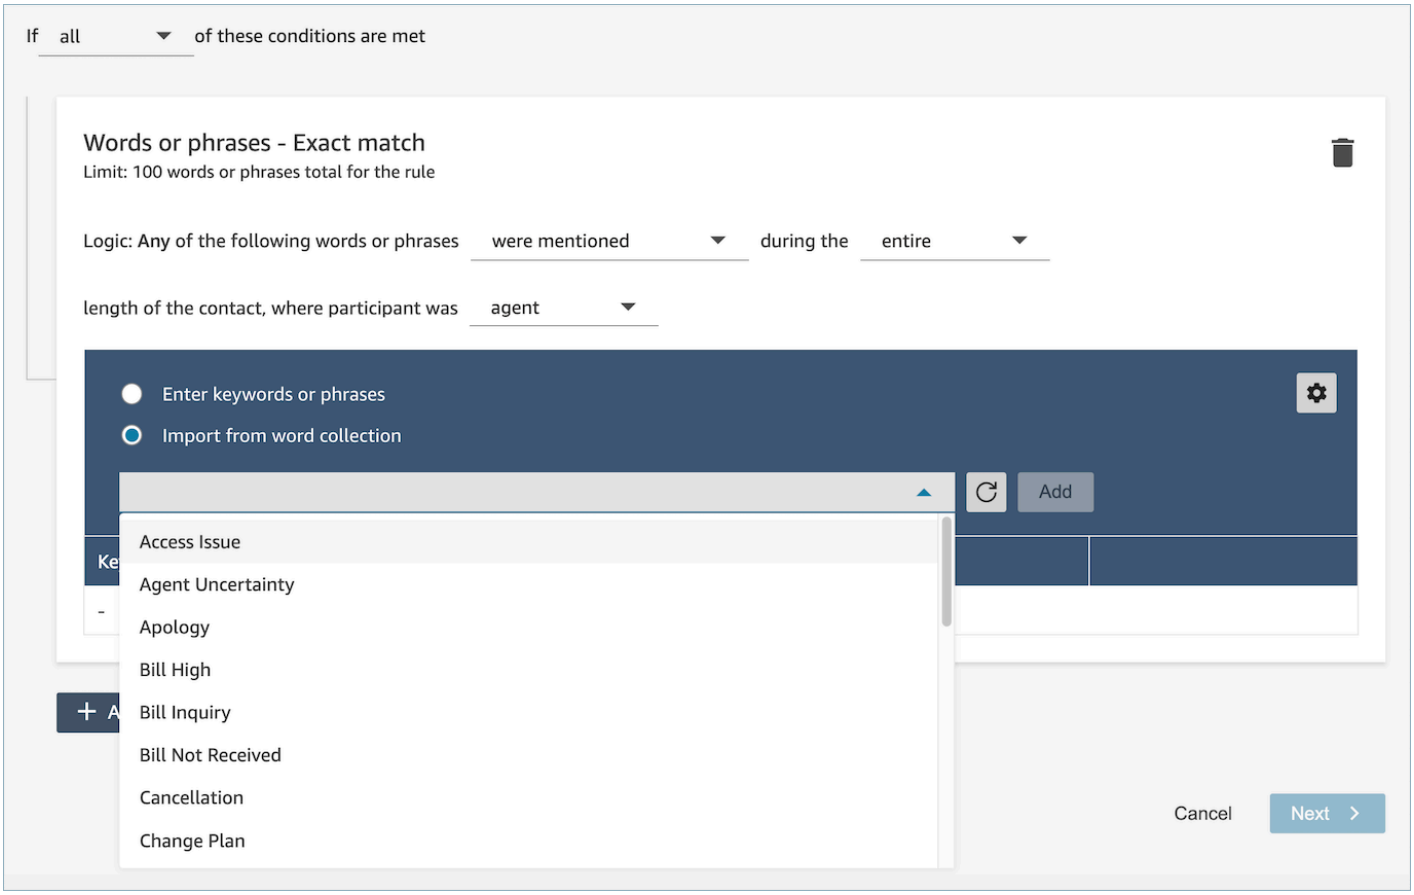
Exact Match is an exact word match, which can be either singular or plural.

You can add the keywords or phrases by using either of the following methods:

- Selecting **Enter keywords or phrases** and entering values manually in the text box. Multiple values can be separated by a comma.



- Selecting **Import from word collection** to import pre-defined words and phrases from word collections.



Word collections can be categorized into two types: user word collections and system word collections. System word collections are pre-defined by Connect Customer, which are non-editable to users. A user word collection can be created, read, updated, and deleted (CRUD) by users. For more information, see Manage word collections when you create conversational analytics rules in conversational analytics.

How to use pattern match

If you want to match related words, append an asterisk (*) to the criteria. For example, if you want to match on all variations of "neighbor" (neighbors, neighborhood) you would type **neighbo***.

With **Pattern Match** you can specify the following:

- **List of values**: This is useful when you want to build expressions with interchangeable values. For example, the expression might be:

  I'm calling about a power outage in ["Beijing" or "London" or "New York" or "Paris" or "Tokyo"]

  Then in your list of values you would add the cities: Beijing, London, New York, Paris, Tokyo.

The advantage of using values is that you can create one expression, instead of multiple. This reduces the number of cards that you need to create.

- **Number**: This option is used most frequently in compliance scripts, or if you're looking for a context when you know somewhere in between there's a number (in digits [0-9]). This way you can put all of your criteria into one expression instead of two. For example, an agent compliance script might say:

  I have been in this industry for [num] years and would like to discuss this topic with you.

  Or a customer might say:

  I have been a member for [num] years.

  > **Note**
  >
  > - When extracting numbers from chat or audio transcripts, only numerical digits (0-9) are recognized.
  > - For voice contacts, certain languages might not convert spoken numbers into digital format during number transcription. This means number pattern matching might not work in these cases. For a list of which languages support number transcription, see Supported languages and language-specific features in the *Amazon Transcribe Developer Guide*.

- **Proximity definition**: Finds matches that might be less than 100 percent exact. You can also specify the distance between words. For example, if you are looking for contacts where the word "credit" was mentioned but you do not want to see any mention of the words "credit card," you can define a pattern matching category to look for the word "credit" that is not within a one-word distance of "card."

  For example, a proximity definition might be:

  credit [is not within 1 word from] card

> **Tip**
>
> For a list of languages supported by pattern match, see AI features.

How to use semantic match

With **Semantic Match**, you can find phrases that have the same meaning as the words you specify, even when the exact wording differs. Unlike **Exact Match** (which requires the same words) or **Pattern Match** (which uses wildcards and proximity), you use semantic match to detect when a customer or agent expresses the same intent with different words.

For example, if you specify "I want to cancel my subscription," semantic match also finds phrases like "Please end my membership" or "How do I stop my plan" because they express the same intent.

> **Post-call and post-chat only**
>
> Semantic matching is supported only for post-call and post-chat analysis.

When you configure a semantic match condition, you provide *intents* and organize them into *cards*.

- An *intent* is an example phrase or sentence that represents the meaning you want to match.
- A *card* is a group of up to four intents. Each card represents one category of meaning that you want to detect.

Group semantically similar intents within one card to improve matching accuracy. For example, if you have a *politeness* category with both greetings and goodbyes, separate them into two cards:

- Card 1 (*greetings*): "How are you today" and "How's everything going."
- Card 2 (*goodbyes*): "Thanks for contacting us" and "Thank you for being our customer."

Separating intents into two cards improves accuracy because you give each card a focused set of meanings to match against.

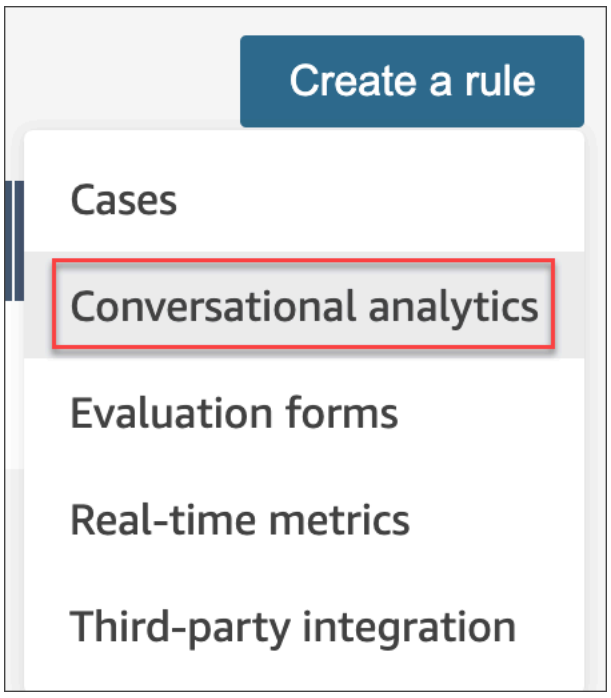
Use Generative AI to semantically match contacts with natural language statements

Within a conversational analytics **conversational analytics** rule, you have the option to specify a **Natural language - semantic match** condition that uses generative AI to find contacts that match a natural language statement. Natural language - Semantic match is used when you want to match contacts with context-specific criteria (for example, the customer's issue was resolved during the call) or when there are too many possible words or phrases to use the **Words or phrases** conditions.

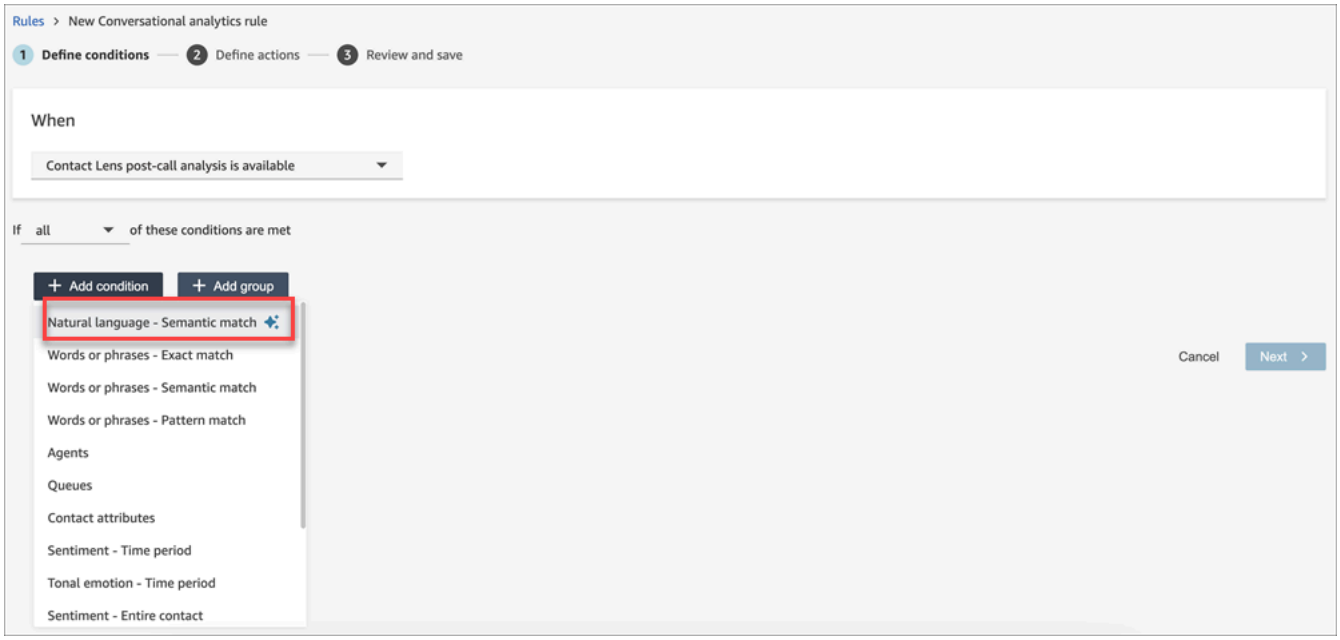
Pro Tip: Use generative AI-powered Natural language- Semantic match if you previously used Words or Phrases - Semantic Match.

How to use Natural language - semantic match

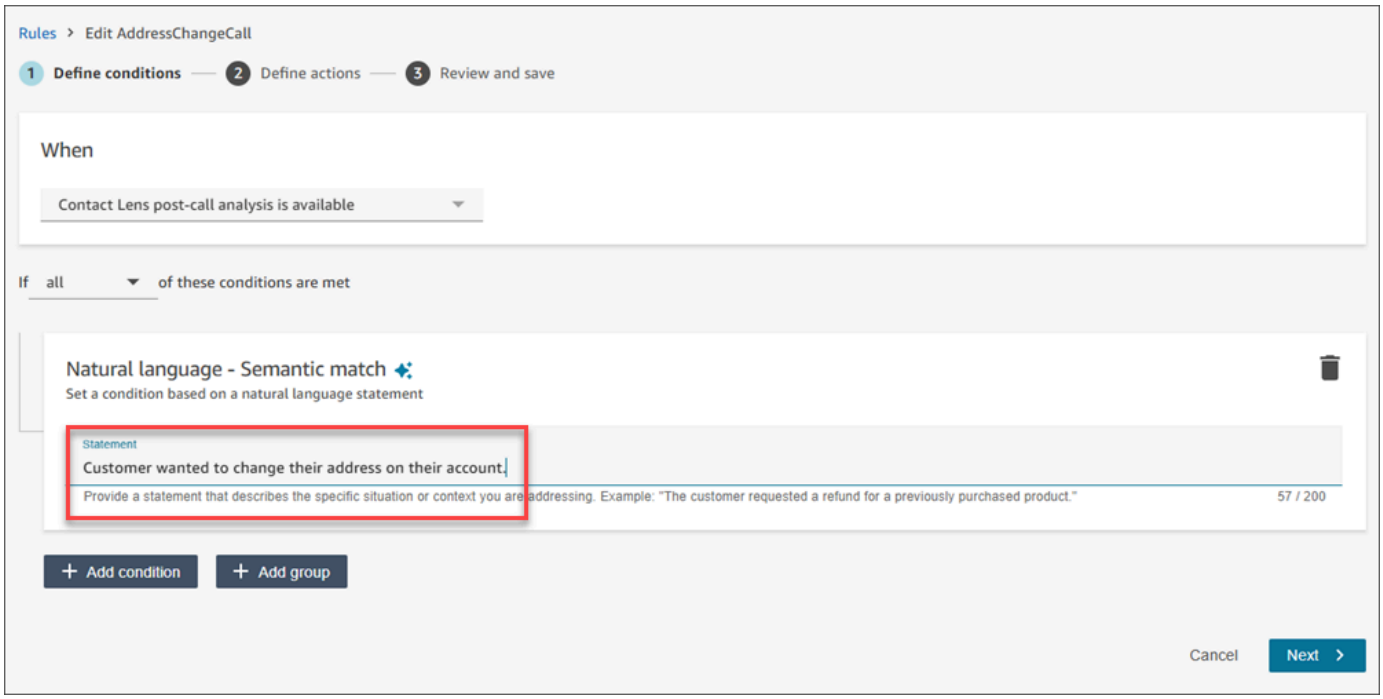
1. Log in to Connect Customer with a user that has permissions **Rules** and **Rules - Generative AI** permissions.
2. On the navigation menu, choose **Analytics and optimization**, and then **Rules**.
3. Then select **Create a Rule** and choose **Conversational analytics**.



4. Select either "A conversational analytics post-call analysis is available" or "A conversational analytics post-chat analysis is available".
5. Select **Add condition** and then choose **Natural language - semantic match**.



6. Enter a natural language statement that can be evaluated by Generative AI as true or false by matching with the conversation transcript.



7. Add any additional conditions, for example, queues, custom contact attributes.
8. Choose **Next** and provide a category name (with no spaces) that would be used to label contacts with the natural language statement, for example, **CustomerAddressChange**.
9. You can specify additional actions, such as generating tasks, sending email notifications, automatically submit evaluations, among others.

10. Choose **Next** to review the rule before you **Save and Publish** the rule. If you are not ready to publish the rule, you can also **Save as draft**.

Guidelines to use semantic-match

The following list details how to best use semantic-match:

- The statement should be something that can be evaluated as true or false.
- Natural language - semantic match only uses the transcript of the conversation. If you want to use other contact attributes (for example, queues) in your match criteria, then those need to be specified as separate conditions within the rule.
- If possible, use the term 'agent' instead of terms like 'colleague', 'employee', 'representative', 'advocate', or 'associate'. Similarly use the term 'customer', instead of terms like 'member', 'caller', 'guest', or 'subscriber'.
- Only use double quotes if you want to check for exact words being spoken by the agent or the customer. For example, If the instruction is to check for the agent saying "Have a nice day", then the generative AI will not detect "Have a nice afternoon". Instead the natural language statement should say "The agent wished the customer a nice day".

Example statements to use with semantic-match

- The customer wanted to make a change to their subscription plan.
- The customer conveyed gratitude towards the agent's support.
- The customer indicated a desire to terminate their current services.
- The customer requested a subsequent interaction.
- The customer asked the agent to repeat information, indicating a lack of understanding.
- The customer asked to talk to the agent's manager.
- The agent asked the customer for additional information or validation before providing a definitive answer.
- The agent offered multiple payment options
- The agent assured the customer that their call was important and requested additional waiting time.
- The agent resolved all of the customer's issues.

Manage word collections when you create conversational analytics rules in conversational analytics

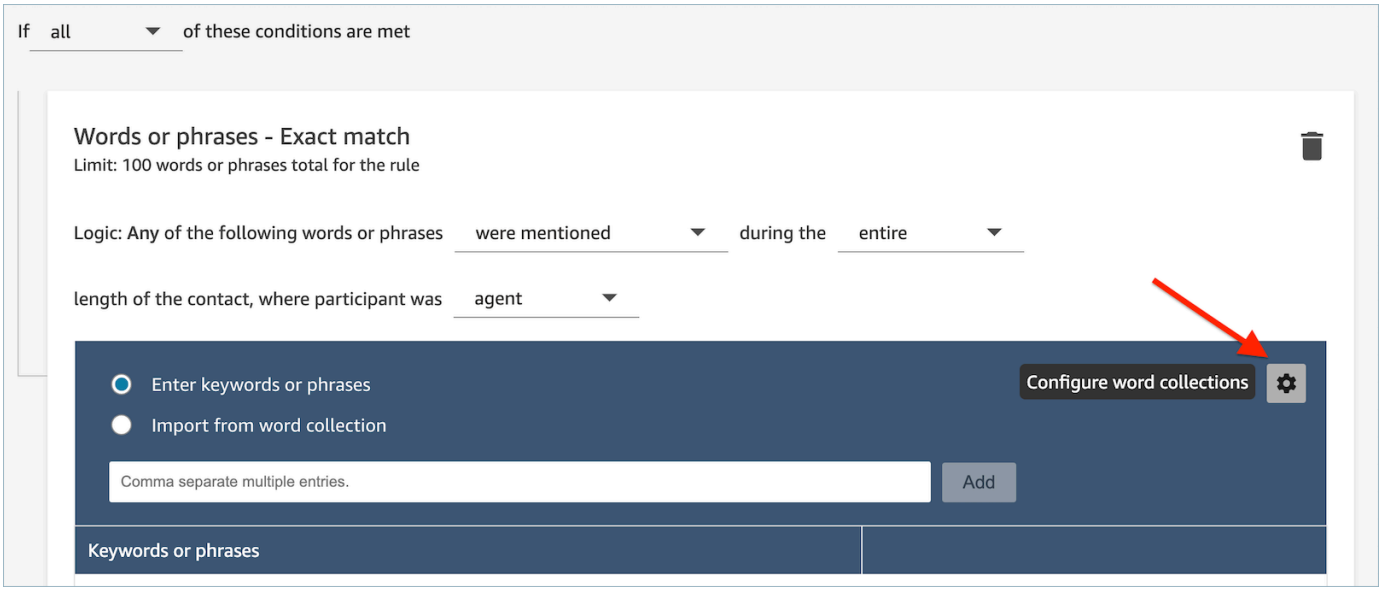
A *word collection* is a set of pre-built words and phrases that you can use to define the exact match condition when you create conversational analytics rules. When you add exact match conditions to a rule, you can choose a list of words and phrases from a dropdown menu.

Required permissions

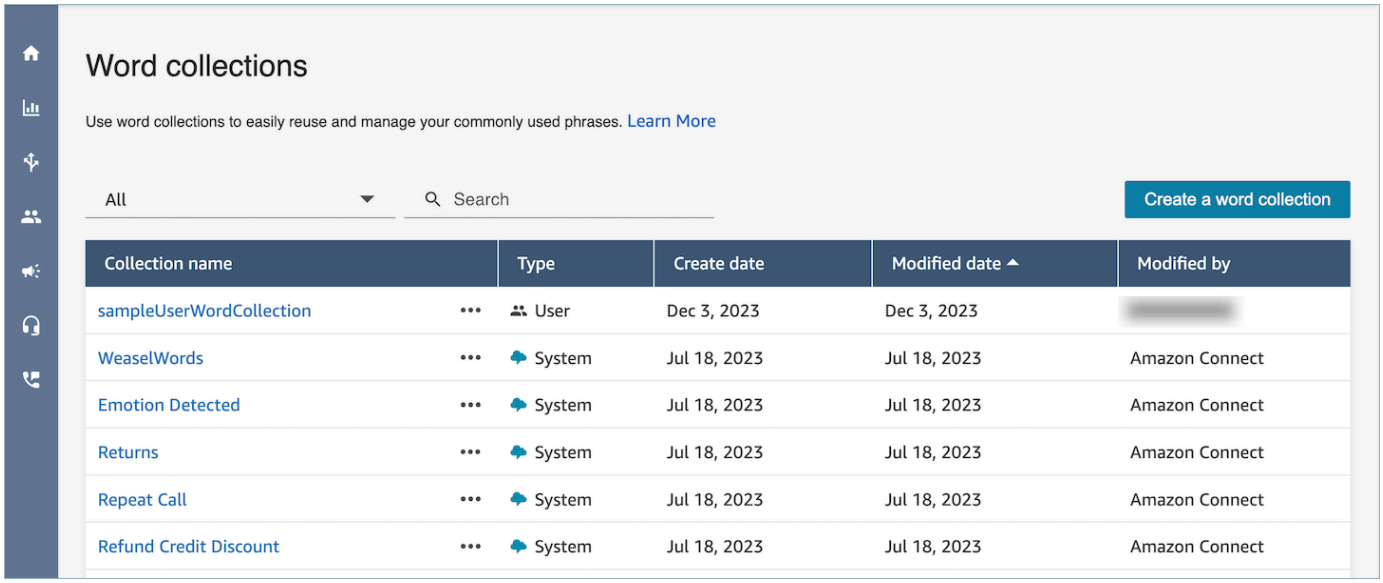
Conversational analytics Rules - Word Collections uses the same set of security profile permissions as conversational analytics Rules. For more information, see Security profile permissions for conversational analytics rules.

How to access the word collection management page

1. When you create or update a conversational analytics rule, choose the gear icon on top right of the **Exact match** condition card, as shown in the following image.

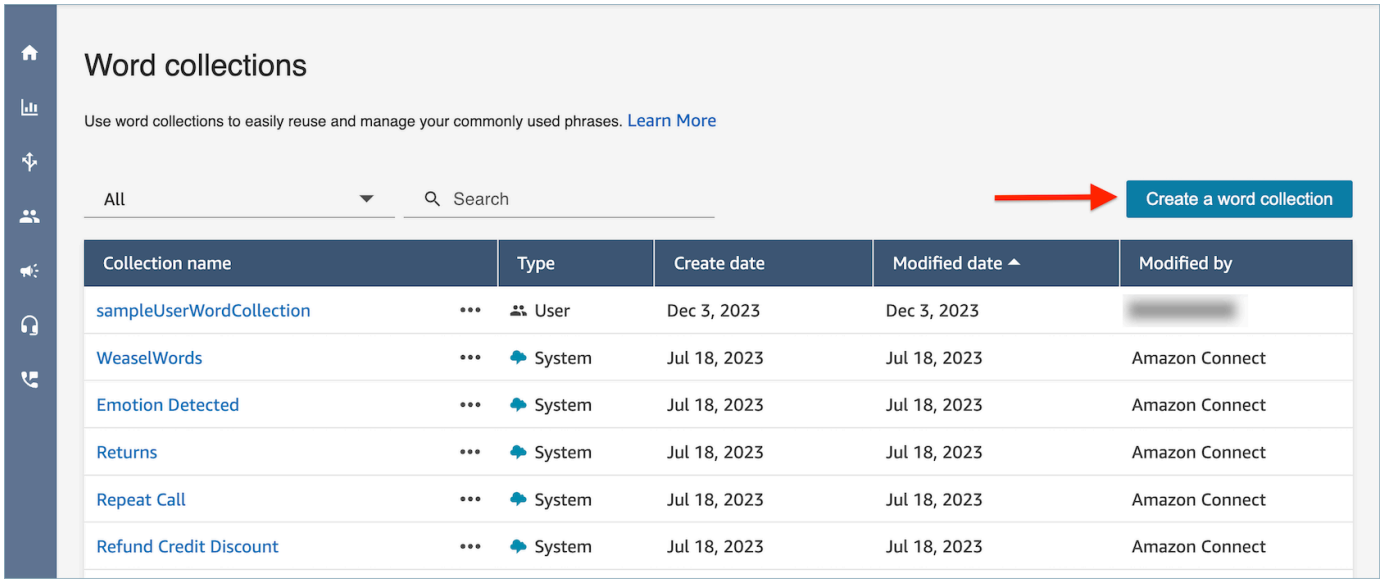


2. On the **Word collections** management page, you can view existing word collections and create new word collections.

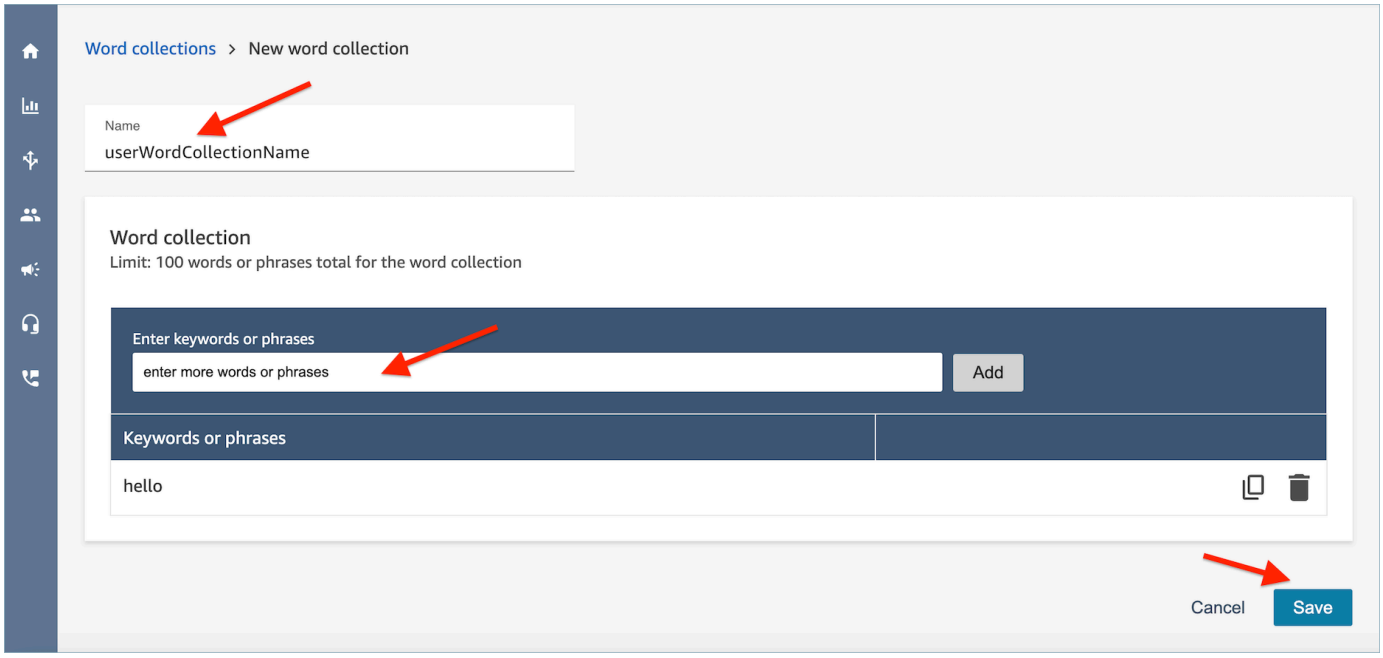


How to create a user word collection

1. On the **Word collections** management page, choose **Create a word collection**.



2. Enter the name of the word collection, add words and phrases, then choose **Save**.



Word collection limits

- Connect Customer has a default limit of 100 user word collections per instance.
- Each word collection can have a maximum of 100 words or phrases.
- Each word or phrase is limited to no more than 512 characters.
- You can manage only user word collections. You can not manage or edit system word collections.

Enter a script in a conversational analytics rule for agents to follow

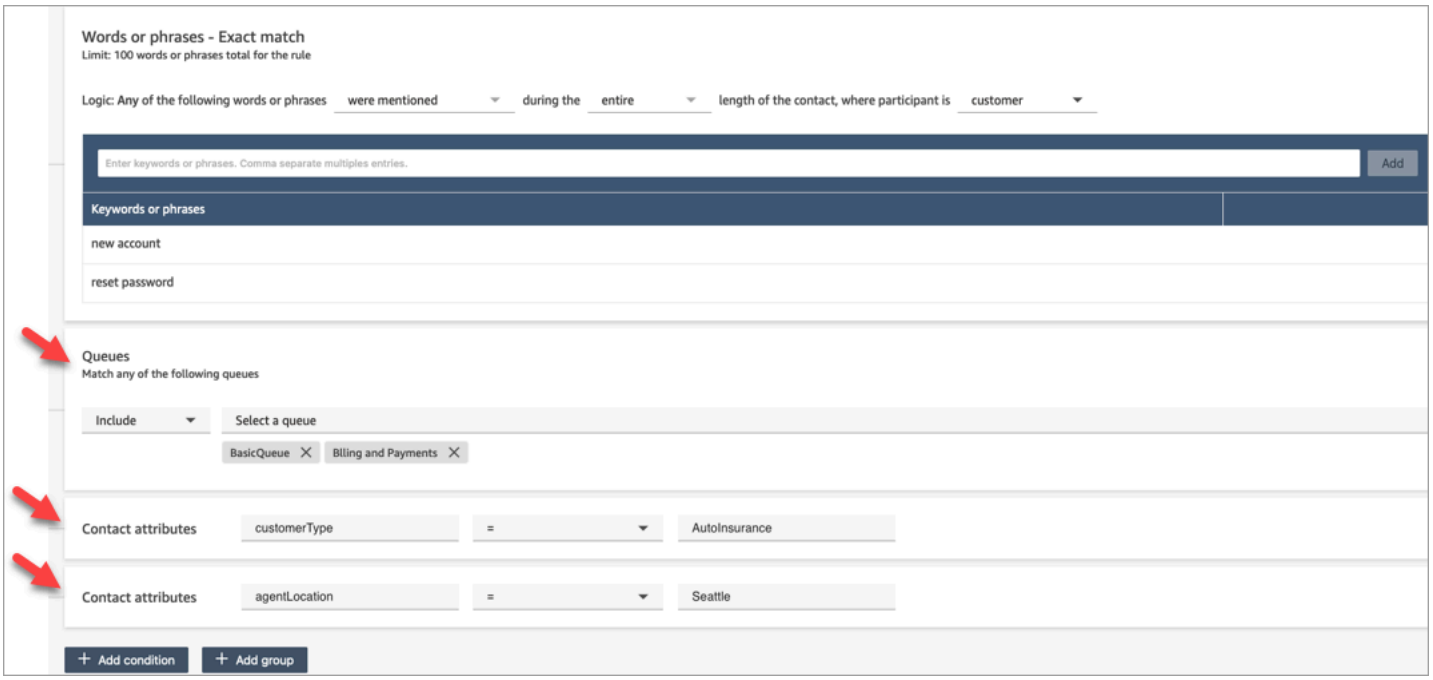
Enter a script in a conversational analytics rule when you need agents to use exact wording in customer calls.

To enter a script in a rule, enter phrases. For example, if you want to highlight when agents say *Thank you for being a member. We appreciate your business*, enter two phrases:

- Thank you for being a member.
- We appreciate your business.

To apply the rule to certain lines of businesses, add a condition for which queues it applies to, or contact attributes. For example, the following image shows a rule that applies when an agent is

working the BasicQueue or Billing and Payments queues, the customer is for auto insurance, and the agent is located in Seattle.



Security profile permissions for conversational analytics rules

To view, edit, or add rules for automatic categorization, you must be assigned to a security profile that has **Analytics and Optimization: Rules** permissions.

To create, edit, or delete rules that use generative AI (using the **Natural language - semantic match** condition), your security profile must also have the **Analytics and Optimization: Rules - Generative AI** permission. To view these rules, the **Rules - View** permission is enough.

For more information, see Assign permissions to use conversational analytics in Connect Customer.

Permissions for resources in rules

To add a resource to a rule condition or action, you need permission to view that resource. The following table lists the resources that you can use in rules, and the permission that you need for each.

Resource	Permission	Where you use it in rules
Queues	**Routing: Queues - View**	Queue conditions, and queue filters in metric conditions

Resource	Permission	Where you use it in rules
Agents	**Users and permissions: Users - View**	Agent conditions, agent filters in metric conditions, and notification recipients and exclusions
Agent hierarchies	**Users and permissions: Agent hierarchy - View**	Agent hierarchy conditions, and agent hierarchy filters in metric conditions
Routing profiles	**Routing: Routing profiles - View**	Routing profile conditions, and routing profile filters in metric conditions
Flows	**Channels and flows: Flows - View**	Flow filters in conditions, and the flow in a **Create Task** action
Flow modules	**Channels and flows: Flow modules - View**	Flow module filters in metric conditions
AI agents	**AI agents - View**	AI agent conditions, and AI agent filters in metric conditions
Evaluation forms	**Analytics and Optimization: Evaluation forms - manage form definitions - View**	Evaluation form conditions, and the form in a **Submit automated evaluation** action
Information extraction definitions	**Analytics and Optimization: Information extraction - definitions - View**	The definitions in an information extraction action

Your security profile might use tag-based or hierarchy-based access control on a resource. If so, you can add only the resources that you have access to. For more information, see Granular access controls on rules.

Granular access controls on rules

With granular access controls on rules, you can:

- Restrict users from accessing the rules of another business line or function.
- Control the scope of a rule, so that the rule doesn't apply to resources that the user doesn't have access to.
- Show users only the rule-based contact categories that are relevant to them, on contacts and in analytics dashboards.

You can add tags to rules, for example `Department:Sales`. Then give users access to only the relevant rule tags in their security profiles. For example, a sales manager can view and edit sales rules, but not the rules that the customer service team uses.

When you configure a rule, you can select only the resources that you have tag-based access to. For example, a sales manager can select only the sales queues that they have access to. Pre-evaluation filters also enforce the scope of a rule, even if you don't select a condition for it. For more information, see Pre-evaluation filters.

Tag-based access control on rules also applies to the contact categories that rules create. For example, if you restrict a user to rules tagged `Function:Fraud`, then on the **Contact details** page and in dashboards, the user sees only the contact categories from rules tagged `Function:Fraud`.

Tagging rules

You can tag a rule when you create it, or when you update an existing rule. You can add tags by using the Connect Customer admin website or the Connect Customer API. For more information about tagging, see Add tags to resources in Connect Customer.

The tags that you can add to a rule depend on the tag-based access controls in your security profiles:

- If your security profiles have no tag-based access controls on rules, you can create or update a rule with any tags.
- If your security profiles have tag-based access controls on rules, you must add all of the tags from at least one of your security profiles to the rule. For example, if one security profile grants you access to `Department:Sales` and another grants you access to `Department:Retention`, you must add either the `Department:Sales` or the `Department:Retention` tag to the rule.

> **Important**
>
> When you enable tag-based access control on rules, users lose access to any rule that doesn't have matching tags. Tag your existing rules before you enable tag-based access control on rules.

Enabling tag-based access control on rules

Use the following procedure to restrict which rules the users of a security profile can view and manage, based on tags.

> **Important**
>
> Before you start, tag your existing rules. After you enable tag-based access control on rules, users lose access to any rule that doesn't have matching tags.

To enable tag-based access control on rules

1. Log in to the Connect Customer admin website. In the following URL, replace *instance name* with the name of your instance: https://*instance name*.my.connect.aws/. Use an account with the **Security profiles - View** and **Security profiles - Edit** permissions.
2. In the navigation menu, choose **Users**, **Security profiles**, and then choose the security profile that you want to change.
3. Choose **Access control**.
4. Under **Tag-based access control**, choose **Edit**.
5. Under **Resources**, choose **Rules**.
6. Enter the tag key and value that users with this security profile can access.
7. Verify that the security profile has the **Rules - View** permission. Without it, users can't see any rules on the **Rules** page.

   Users without **Rules - View** can still see rule-based contact categories if they have the **Conversational analytics - View** permission. They see the categories on pages they have permissions for, such as **Contact details**, **Contact search**, **Real-time metrics**, and analytics dashboards. Tag-based access control on rules still applies to those categories.

8. Choose **Save**.

Users with this security profile can now view and manage only the rules that have the tags you entered.

For more information about tag-based access control, see Apply tag-based access control in Connect Customer.

Tag-based access control on rules: What to expect

Tag-based access control applies when you configure or filter rules. It also applies when you view rule-based contact categories, including in analytics dashboards and contact details.

Rule configuration

- On the **Rules** page, you see only the rules that have all of the tags from at least one of your security profiles.
- You can view, edit, and delete only those rules, based on your **Rules** permissions.

The same controls apply when you call the Rules APIs, such as `CreateRule`, `UpdateRule`, `DescribeRule`, and `SearchRules`.

Rule-based contact categories

You see a contact category only if you have access to the rule that creates it. This applies wherever contact categories appear, for example:

- The **Contact details** page, including during an active contact.
- The **Real-time metrics** page.
- The **Contact search** page, when you search by contact category.
- The conversational analytics dashboard. For more information about dashboards, see Apply tag-based access controls to dashboards and reports in Connect Customer.
- Evaluation forms, when you add a question that refers to a contact category.

In evaluation forms, you can refer only to the contact categories that you have access to.

To view contact categories, you also need the **Conversational analytics - View** permission.

Controlling the scope of rules

When you configure a rule, you can select only the resources that you have access to in conditions and actions. For example, when you select queues in a rule condition, you can add only the queues that you have tag-based access to. This prevents you from running rules on departments or functions that you can't access.

Other commonly used resources that respect tag-based access control in rules include agents and evaluation forms. The agents that you can select in rules are also limited by Apply hierarchy-based access control in Connect Customer. For more information about evaluation forms, see Set up tag-based-access controls on performance evaluations.

Pre-evaluation filters

A pre-evaluation filter limits which resources a rule runs on, based on the tags on those resources. Connect Customer checks the pre-evaluation filters before it checks the rule conditions.

For rules that run when a contact evaluation is submitted, you can filter on the tags of the contact evaluation. If your security profile restricts you to evaluations that have a certain tag, for example `Department:Sales`, that tag is added as a pre-evaluation filter by default. An **Evaluation forms** rule requires `Department:Sales` in its pre-evaluation filters. This ensures that your rules notify on and act on only the data that you can access.

Note the following about pre-evaluation filters:

- Each filter matches one tag key and value exactly.
- If a rule has more than one filter, the resource must match all of them.
- You can add pre-evaluation filters when you create or edit a rule on the Connect Customer admin website. You can also use the `PreEvaluationFilters` parameter of the CreateRule and UpdateRule APIs.

> **Note**
>
> With conversational analytics rules, you can add contact tags as pre-evaluation filters. Currently, Connect Customer doesn't check your access to the contact tags that you add, because tag-based access control isn't yet supported on contacts. When it becomes available, you will need access to the contact tags that you add as filters.

Design a flow to use contact attributes in a rule in conversational analytics

You can have up to 5 contact attributes in a rule.

Contact attributes are retrieved at the beginning of the real-time contact analysis session and whatever is retrieved at that time is used for rule evaluation during the whole session. Any contact attribute update after the session started isn't picked up.

You can design flows to use the contact attributes you specify in a rule, and then route the task accordingly. For example, a call or chat arrives in your contact center. When conversational analytics analyzes the call or chat, it gets a hit on the **Compliance** rule. The contact record that's created for the call, for example, includes information similar to the following image. It shows the **Category** = **Compliance**, and it has two custom contact attributes: **CustomerType** = **VIP**, **AgentLocation** = **NYC**.

Contact ID: CTR1-1234abc
Channel: Voice
Initiation method: Inbound

Category: Compliance
Custom Contact Attributes:
- **CustomerType**: VIP
- **AgentLocation**: NYC

Next contact ID: CTR2-5678abc

The Rules engine generates a task. The contact record for the task inherits the contact attributes from the voice contact record, as illustrated in the following image.

Contact ID: CTR2-5678abc
Channel: Task
Initiation method: API

Category: Compliance
Custom Contact Attributes:
- **CustomerType**: VIP
- **AgentLocation**: NYC

Previous contact ID: CTR1-1234abc

The voice contact record appears as the **Previous contact ID**.

The flow that you specify in the rule should be designed to use the contact attributes and route the task to the appropriate owner. For example, you might want to route tasks where **CustomerType = VIP** to a specific agent.

For more information, see Use contact attributes.

Rules are applied to new contacts when conversational analytics analyzes conversations

After you add rules, they are applied to new contacts that occur after the rule was added. Rules are applied when Connect Customer conversational analytics analyzes conversations.

You cannot apply rules to past, stored conversations.

Error notifications: When conversational analytics can't analyze a contact

It's possible that conversational analytics can't analyze a contact file, even though analysis is enabled on the flow. When this happens, conversational analytics sends error notifications using Amazon EventBridge events.

Events are emitted on a best effort basis.

Subscribe to EventBridge notifications

To subscribe to these notifications, create a custom EventBridge rule that matches the following:

- "source" = "aws.connect"
- "detail-type" = "conversational analytics Analysis State Change"

You can also add to the pattern to be notified when a specific event code occurs. For more information, see Event Patterns in the *Amazon EventBridge User Guide*.

The format of a notification looks like the following sample:

```
{
    "version": "0", // set by CloudWatch Events
    "id": "55555555-1111-1111-1111-111111111111", // set by CloudWatch Events
    "source": "aws.connect",
    "detail-type": "conversational analytics Analysis State Change",
    "account": "111122223333",
    "time": "2020-04-27T18:43:48Z",
    "region": "us-east-1", // set by CloudWatch Events
    "resources": [
        "arn:aws:connect:us-east-1:111122223333:instance/abcd1234-defg-5678-
h9j0-7c822889931e",
```

```
        "arn:aws:connect:us-east-1:111122223333:instance/abcd1234-defg-5678-
h9j0-7c822889931e/contact/efgh4567-pqrs-5678-t9c0-111111111111"
    ],
    "detail": {
        "instance": "arn:aws:connect:us-east-1:111122223333:instance/abcd1234-
defg-5678-h9j0-7c822889931e",
        "contact": "arn:aws:connect:us-east-1:111122223333:instance/abcd1234-defg-5678-
h9j0-7c822889931e/contact/efgh4567-pqrs-5678-t9c0-111111111111",
        "channel": "VOICE",
        "state": "FAILED",
        "reasonCode": "RECORDING_FILE_CANNOT_BE_READ"
    }
}
```

Event codes

The following table lists the event codes that might result when conversational analytics can't analyze a contact.

Event reason code	Description
INVALID_ANALYSIS_CONFIGURATION	Conversational analytics received invalid values when the flow was initiated, such as an unsupported or invalid language code, or an unsupported value for redaction behavior.
RECORDING_FILE_CANNOT_BE_READ	Conversational analytics can't read the recording file. This might be because the file isn't present in the S3 bucket, there are problems with permissions, or an error occurred when conversational analytics tried to read the file.
RECORDING_FILE_TOO_SMALL	The recording file is too small for analysis (less than 500 ms). If file doesn't have expected format, an INVALID error occurs. Empty JSON is also an unexpected object.

Event reason code	Description
RECORDING_FILE_TOO_LARGE	The source file exceeds the duration or size limit for analysis. • Voice: More than 14,400 seconds, or 4 hours • Chat: More than 20K messages in a transcrip t • Email: The HTML body of the email message is larger than 75 KB, or the plain text body is larger than 50 KB
RECORDING_FILE_INVALID	The recording file is invalid.
RECORDING_FILE_EMPTY	The recording file is empty.
RECORDING_SAMPLE_RATE_NOT_S UPPORTED	The sample rate of the audio file is not supported. conversational analytics supports audio files with an 8kHz sample rate. That is the sample rate for Connect Customer recordings.
UNSUPPORTED_RECORDING_FORMAT	The format of the recording file is not supported for analysis.
ANALYSIS_FILES_CANNOT_BE_WRITTEN	Conversational analytics could not write the analysis output files. This might be because of problems with permissions on the output S3 bucket.
MAX_PACKAGE_FEATURE_ONLY	The requested analysis feature is available only for Connect Customer Customer enabled instances.

Event reason code	Description
INSUFFICIENT_CONVERSATION_CONTENT	Conversational analytics did not find enough plain text content in the conversation to generate an analysis. This can occur when the conversation is too short, or the content didn't convert to any plain text.

Error notifications when a Connect Customer rule fails to run

It's important to know when a specific rule action has failed in a production environment, and what caused the failure. Then you can proactively mitigate such failures in future.

To get real-time insights on the actions that failed to run, you integrate Connect Customer Rules with Amazon EventBridge events. With this integration, you can be notified when, for example, the "Create task" action failed to run because the maximum number of **Concurrent active tasks per instance** reached the service quota. When this happens, Connect Customer sends error notifications using Amazon EventBridge events.

Events are emitted on a best effort basis.

Subscribe to EventBridge notifications

To subscribe to these notifications, create a custom EventBridge rule that matches the following:

- "source" = "aws.connect"
- "detail-type" = "conversational analytics Rules Action Execution Failed"

You can also add to the pattern to be notified when a specific event code occurs. For more information, see Event Patterns in the *Amazon EventBridge User Guide*.

The format of a notification looks like the following sample:

```
{
  "version": "0",
  "id": "8d122163-6c07-f8cb-06e7-373a1bcf8fc6",
  "source": "aws.connect",
  "detail-type": "Amazon Connect Rules Action Execution Failed",
```

```
  "account": "123456789012",
  "time": "2022-01-05T01:30:42Z",
  "region": "us-east-1",
  "resources": ["arn:aws:connect:us-east-1:123456789012:instance/cb54730f-5aac-4376-
b2f4-7c822889931e"],
  "detail": {
    "ruleId": "7410c94b-21c2-4db0-a707-c6d751edbe8f",
    "actionType": "CREATE_TASK",
    "triggerEvent": "THIRD_PARTY",
    "instanceArn": "arn:aws:connect:us-east-1:123456789012:instance/cb54730f-5aac-4376-
b2f4-7c822889931e",
    "reasonCode": "ResourceNotFoundException",
    "error": "ContactFlowId provided does not belong to connect instance",
    "additionalInfo": "{\n  \"message\": \"Not Found\",\n  \"code
\": \"ResourceNotFoundException\",\n  \"statusCode\": 404,\n
  \"time\": \"2022-01-03T20:23:07.073Z\",\n  \"requestId\":
 \"048e4403-71c1-47d6-96fc-825744f518e7\",\n  \"retryable\": false,\n  \"retryDelay\":
 28.217537834500316\n}"
  }
}
```

Supported action types

- CREATE_TASK
- GENERATE_EVENTBRIDGE_EVENT
- SEND_NOTIFICATION

For information about ASSIGN_CONTACT_CATEGORY, see Error notifications: When conversational analytics can't analyze a contact.

Supported trigger events

- REAL_TIME_CALL
- REAL_TIME_CHAT
- POST_CALL
- POST_CHAT
- THIRD_PARTY

Reason codes for failed actions

When an action fails, the error notification service collects the reason codes from the supported actions. For more information about the reason codes for Task and EventBridge action failures, see the following topics:

- For reason codes for Task action failures, see Errors in the **StartTaskContact** API topic in the *Connect Customer API Reference Guide*.
- For reason codes for EventBridge action failures, see Errors in the **PutEvents** API topic in the *Amazon EventBridge API Reference Guide*.

Specify variables for certain parameters when creating or managing rules using Connect Customer APIs

When you create or manage rules programmatically using Connect Customer APIs (such as CreateRule or UpdateRule), you can specify variables for certain parameters. The variables are resolved at runtime when the action is triggered, based on the value of the EventSourceName parameter.

For example, let's say you're setting up a task action and you want to add more context. Following is an example of how you could use variable injections to include the ID of the contact and the ID of the agent in the `Description` field of the task:

- Customer is unhappy about the phone call. A swear word was detected during the conversation with agent `$.ContactLens.PostCall.Agent.AgentId` in the contact `$.ContactLens.PostCall.ContactId`

When the action is triggered, this string would resolve to "Customer is unhappy about the phone call. A swear word was detected during a conversation with agent 12345678-1234-1234-1234-EXAMPLEID012 in the contact 87654321-1234-1234-1234-EXAMPLEID345"

The following table lists each event source, and the JSONPath to use for fields that support variable injection.

EventSourceName	JSONPath Reference
OnPostCallAnalysisAvailable	$.ContactLens.PostCall.ContactId

EventSourceName	JSONPath Reference
	$.ContactLens.PostCall.Agent.AgentId $.ContactLens.PostCall.Queue.QueueId
OnRealTimeCallAnalysisAvailable	$.ContactLens.RealTimeCall.ContactId $.ContactLens.RealTimeCall.Agent.AgentId $.ContactLens.RealTimeCall.Queue.QueueId
OnPostChatAnalysisAvailable	$.ContactLens.PostChat.ContactId $.ContactLens.PostChat.Agent.AgentId $.ContactLens.PostChat.Queue.QueueId
OnSalesforceCaseCreate	$.ThirdParty.Salesforce.CaseCreate.CaseNumber $.ThirdParty.Salesforce.CaseCreate.Name $.ThirdParty.Salesforce.CaseCreate.Email $.ThirdParty.Salesforce.CaseCreate.Phone $.ThirdParty.Salesforce.CaseCreate.Company $.ThirdParty.Salesforce.CaseCreate.Type $.ThirdParty.Salesforce.CaseCreate.Reason $.ThirdParty.Salesforce.CaseCreate.Origin $.ThirdParty.Salesforce.CaseCreate.Subject $.ThirdParty.Salesforce.CaseCreate.Priority $.ThirdParty.Salesforce.CaseCreate.CreatedDate $.ThirdParty.Salesforce.CaseCreate.Description

EventSourceName	JSONPath Reference
OnZendeskTicketCreate	$.ThirdParty.Zendesk.TicketCreate.Id $.ThirdParty.Zendesk.TicketCreate.Priority $.ThirdParty.Zendesk.TicketCreate.CreatedAt
OnZendeskTicketStatusUpdate	$.ThirdParty.Zendesk.TicketStatusUpdate.Id $.ThirdParty.Zendesk.TicketStatusUpdate.Priority $.ThirdParty.Zendesk.TicketStatusUpdate.CreatedAt

Search conversations analyzed by conversational analytics

You can search the analyzed and transcribed recordings based on:

- Speaker (agent or customer)
- Keywords
- Sentiment score
- Non-talk time (for calls only)
- Response time (for chats only)

In addition, you can search conversations that are in specific contact categories (that is, the conversation has been categorized based on uttered keywords and phrases).

These criteria are described in the following sections.

Important

When a conversational analytics is enabled on a contact, after a call or chat ends **and** the agent completes After Contact Work (ACW), conversational analytics analyzes (and for calls, transcribes) the recording of the customer-agent conversation. The agent must choose **Close contact** first.

Chat transcripts are indexed for search when conversational analytics is enabled; they are not indexed for search if conversational analytics is not enabled.

Required permissions for searching conversations

Before you can search conversations, you need the following permissions in your security profile. With these permissions, you can do the type of search you want.

- Enable one of the following permissions to access the **Contact Search** page:
  - **Contact search**. You can use it to search for all contacts.
  - **View my contacts**: You can use it to search for only those contacts that you handled as an agent.
- **Search contacts by conversation characteristics**. This includes non-talk time, sentiment score, and contact category.
- **Search contacts by keywords**

For more information, see Assign permissions.

Search for words or phrases

For keyword search, conversational analytics uses the `standard` analyzer in Amazon OpenSearch Service. This analyzer is not case sensitive. For example, if you enter *thank you for your business 2 CANCELLED Flights*, the search looks for:

[thank, you, for, your, business, 2, cancelled, flights]

If you enter *"thank you for your business", two, "CANCELLED Flights"*, the search looks for:

[thank you for your business, two, cancelled flights]

To search conversations for words or phrases

1. In Connect Customer, log in with a user account that is assigned the **CallCenterManager** security profile, or that is enabled for the **Search contacts by keywords** permission.
2. Choose **Analytics and optimization**, **Contact search**.
3. In the **Filter** section, specify the time period that you want to search, and specify the channel.

> **Tip**
>
> When searching by date, you can search up to 8 weeks at a time.

4. Choose **Click here to add filter**, and in the dropdown menu, choose **Words or phrases**.

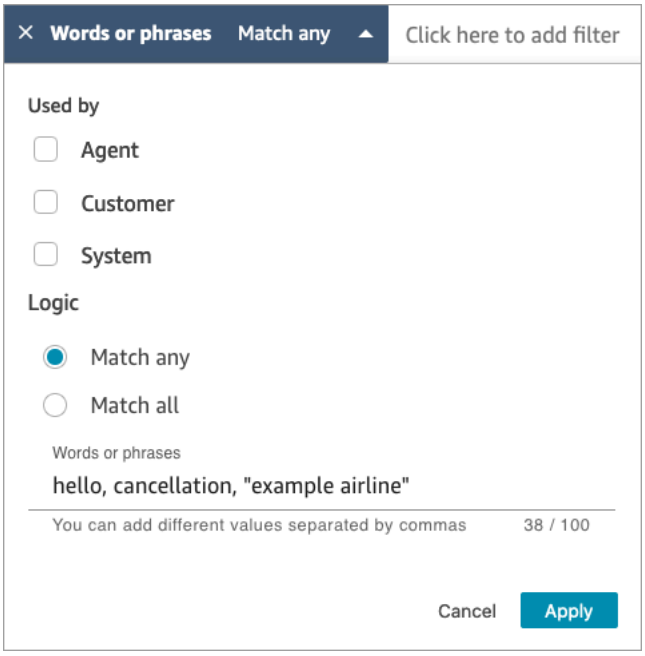
5. In the **Used by** section, choose whose part of the conversation you want to search. Note the following:

   - **System** applies to chat, where the participant might be a Lex bot or prompt.
   - To search for words or phrases that are used by all participants, select **Agent**, **Customer**, **System**.
   - If no boxes are selected, it means search for words or phrases used by any of the participants.

6. In the **Logic** section, choose from the following options:

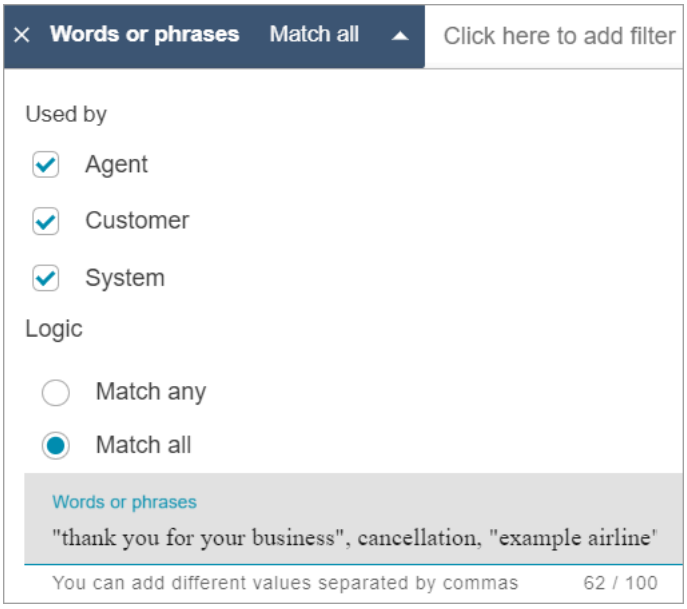
   - Choose **Match any** to return contacts that have any of the words present in the transcripts.

     For example, the following query means match (hello OR cancellation OR "example airline"). And, because no **Used by** boxes are selected, it means "find contacts where any of these words were used by any of the participants."



- Choose **Match all** to return contacts that have all of the words present in the transcripts.

  For example, the following query means match ("thank you for your business" AND cancellation AND "example airline"). And, because all the participant boxes are selected, it means "find contacts where all of these words and phrases were used by all of the participants."



7. In the **Words or phrases** section, enter the words to search, separated by commas. If you enter a phrase, surround it with quotation marks.

   You can enter up to 128 characters.

Search for sentiment score or evaluate sentiment shift

With conversational analytics, you can search conversations for sentiment scores or sentiment shifts on a scale of -5 (most negative) to +5 (most positive). This helps you identify patterns and factors for why calls go well or poorly.

For example, suppose you want to identify and investigate all the contacts where the customer sentiment ended negatively. You might search for all contacts where the sentiment score is **<=** (less than or equal to) -1.

For more information, see Investigate sentiment scores.

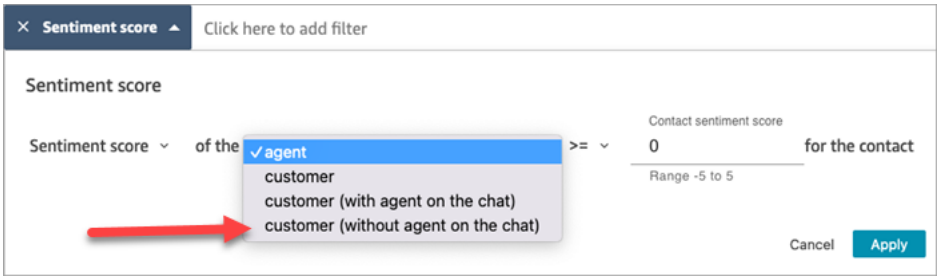
To search for sentiment scores or evaluate sentiment shift

1. In Connect Customer, log in with a user account that is assigned the **CallCenterManager** security profile, or that is enabled for the **Search contacts by conversation characteristics** permission.
2. On the **Contact search** page, specify whether you want the sentiment score for words or phrases spoken by the customer or agent.
3. In **Type of score analysis**, specify what type of scores to return:

   - **Sentiment score**: This returns the average score for the customer or agent's portion of the conversation.

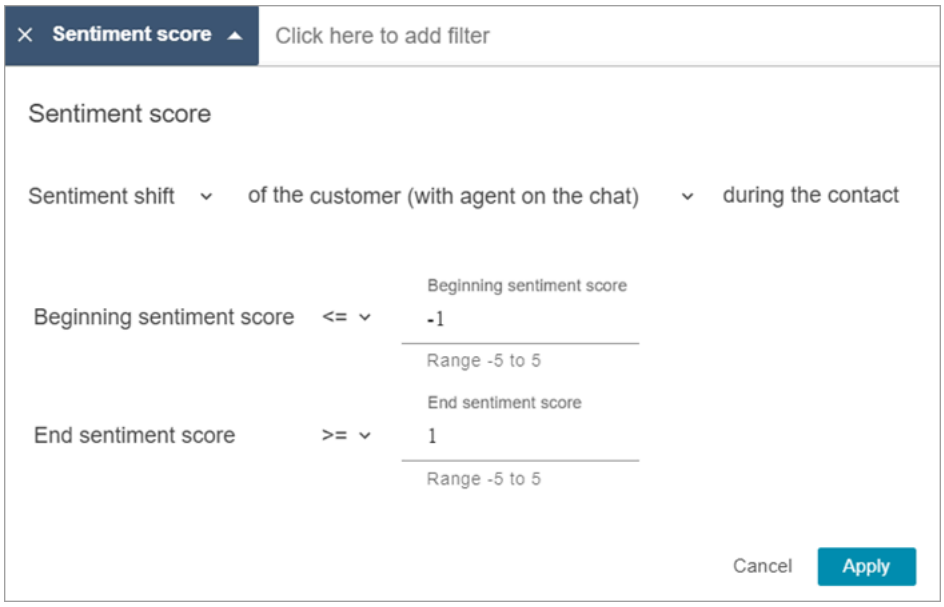
     In addition to searching for sentiment scores when the agent or customer are on the contact, you can filter the search by when the customer is:

     - **With agent on the chat**
     - **Without agent on the chat**: This is the time the customer is chatting with a bot, prompts, and time in queue.



- **Sentiment shift**: Identify where the customer or agent's sentiment changed during the contact.

  For example, the following image shows an example of searching for contacts where the customer's sentiment score begins at less than or equal to -1 and ends at greater than or equal to +1. In addition, the customer is on a chat with the agent present.



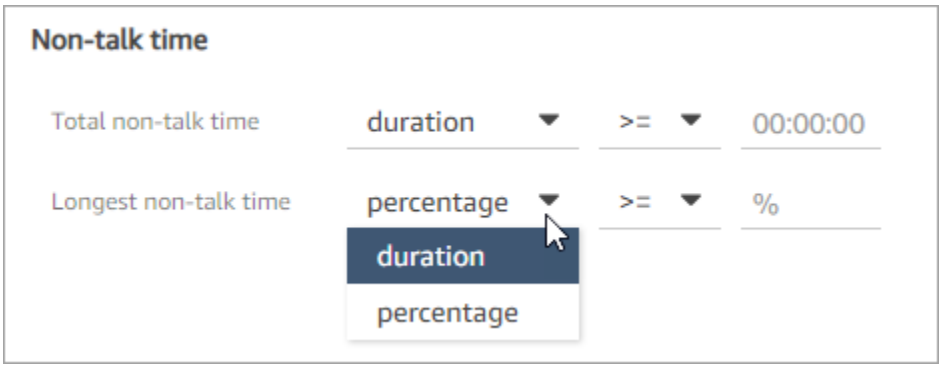
Search for non-talk time

To help you identify which calls to investigate, you can search for non-talk time. For example, you might want to find all calls where the non-talk time is greater than 20%, and then investigate them.

Non-talk time includes hold time and any silence where both participants aren't talking for longer than three seconds. This duration can't be customized.

Use the drop-down arrow to specify whether to search conversations for the duration or percentage of non-talk time. These options are shown in the following image.

For information about how to use this metric, see Investigate non-talk time.



Search by response time for chat conversations

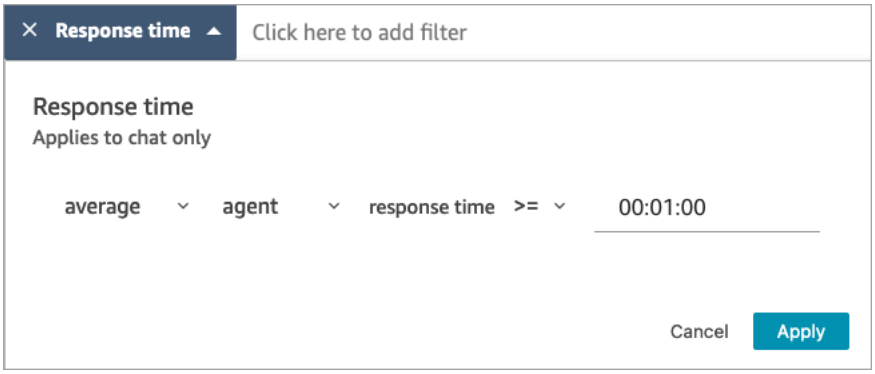
You can search by the:

- Average response time of the agent or customer during the chat
- Maximum response time of the agent or customer during the chat

You specify whether the duration is less or greater than or equal to a specific time. For information about how to use this metric, see Investigate response time during chats in conversational analytics.

For the supported minimum and maximum response times, see Connect Customer Rules feature specifications.

The following image shows a search for contacts where the agent's average response time was greater than or equal to 1 minute.



Search a contact category

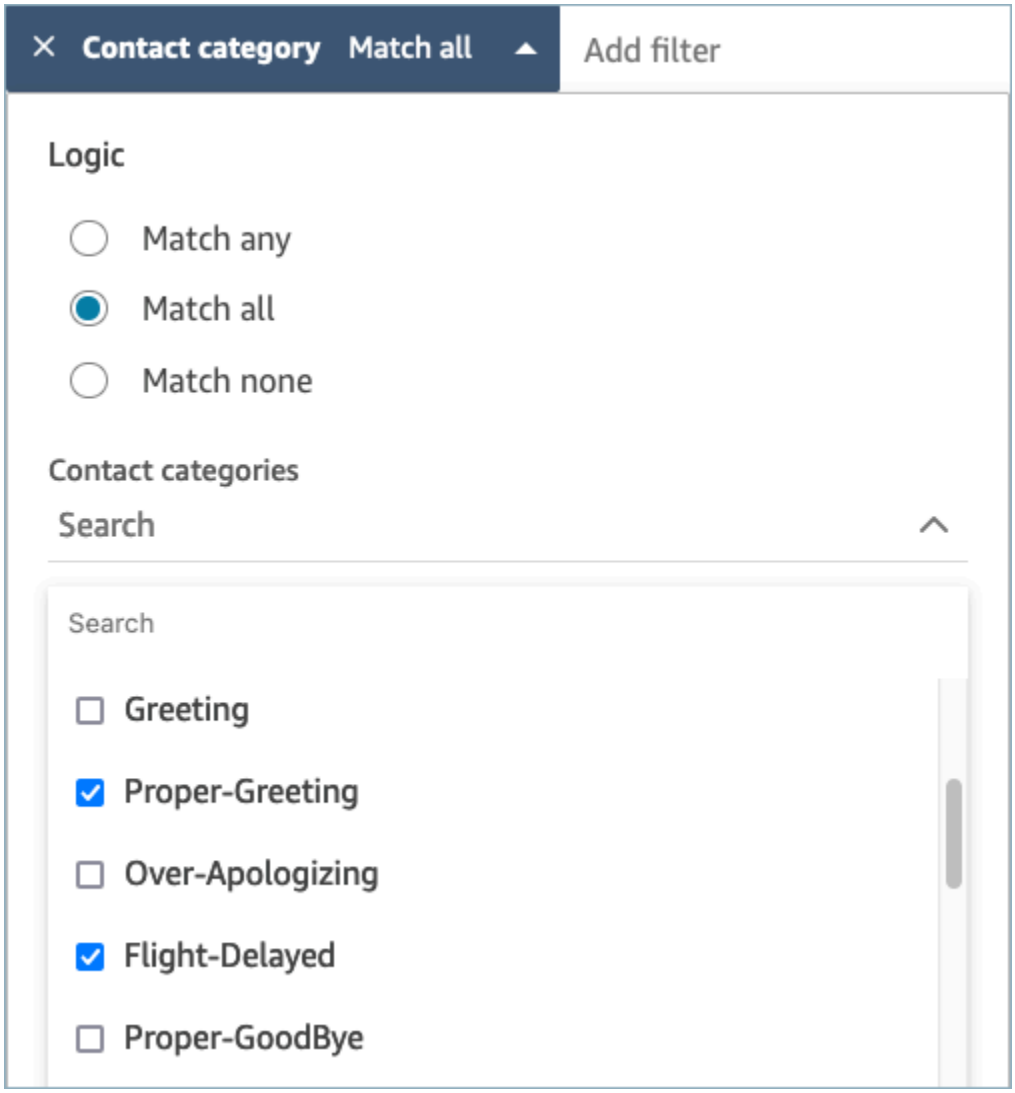
A contact category has the same name as the rule that creates it.

> **Note**
>
> You see a contact category in the **Contact categories** dropdown and on the **Contact details** page only if you have access to the rule that creates it. If your security profile uses tag-based access control on rules, you see only the categories from rules that have tags you can access. For more information, see Granular access controls on rules.

1. On the **Contact search** page, choose **Add filter**, **Contact category**.
2. In the **Contact categories** box, use the dropdown box to list all the current categories that are available for you to search. Or, if you start typing, the input is used to match existing categories and to filter those that don't match.

   - **Match any**: Searches for contacts that match any of the selected categories.
   - **Match all**: Searches for contacts that match all of the selected categories.
   - **Match none**: Searches for contacts that did not match any of the selected categories. This option only returns contacts that were analyzed by conversational analytics.

   The following image shows a dropdown menu with all the current categories listed.

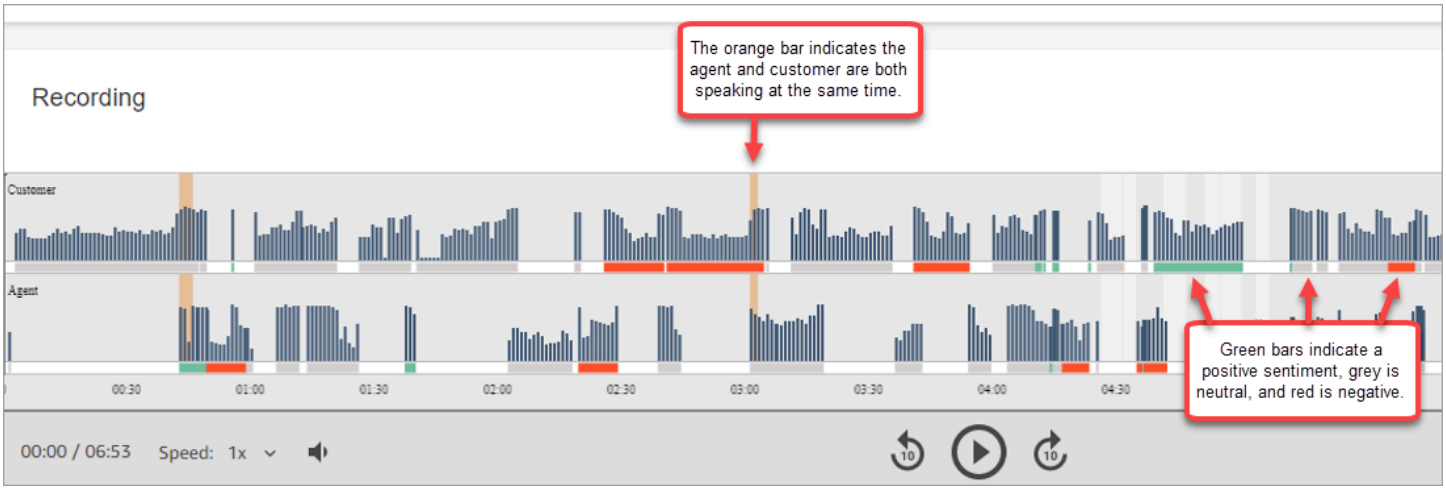


Review analyzed conversations using conversational analytics

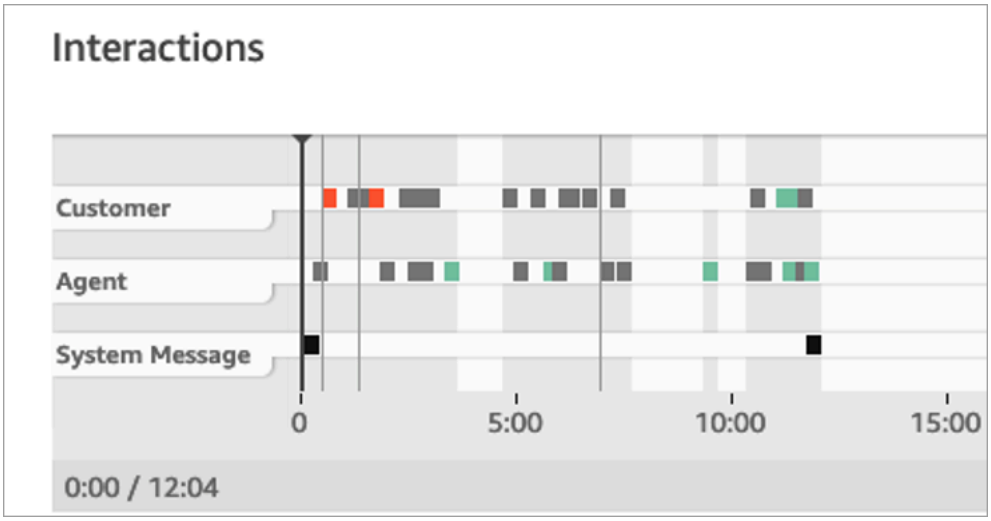
By using Connect Customer conversational analytics, you can review the transcript and identify what part of the contact is of interest. You won't need to listen to an entire call or read an entire chat transcript to find out what's interesting about it. You can focus on specific parts of the audio or transcript. Both are highlighted for you wherever there are points of interest.

For example, you might scan the transcript of the contact and see a red sentiment emoji for a customer turn, which indicates the customer is expressing a negative sentiment. You can choose the timestamp and jump to that portion of audio recording or chat interaction.

The following image shows an example of a voice contact.



The following image shows an example of a chat contact. **System Message** applies to chat, where the participant might be a Lex bot or prompt.



To review analyzed conversations

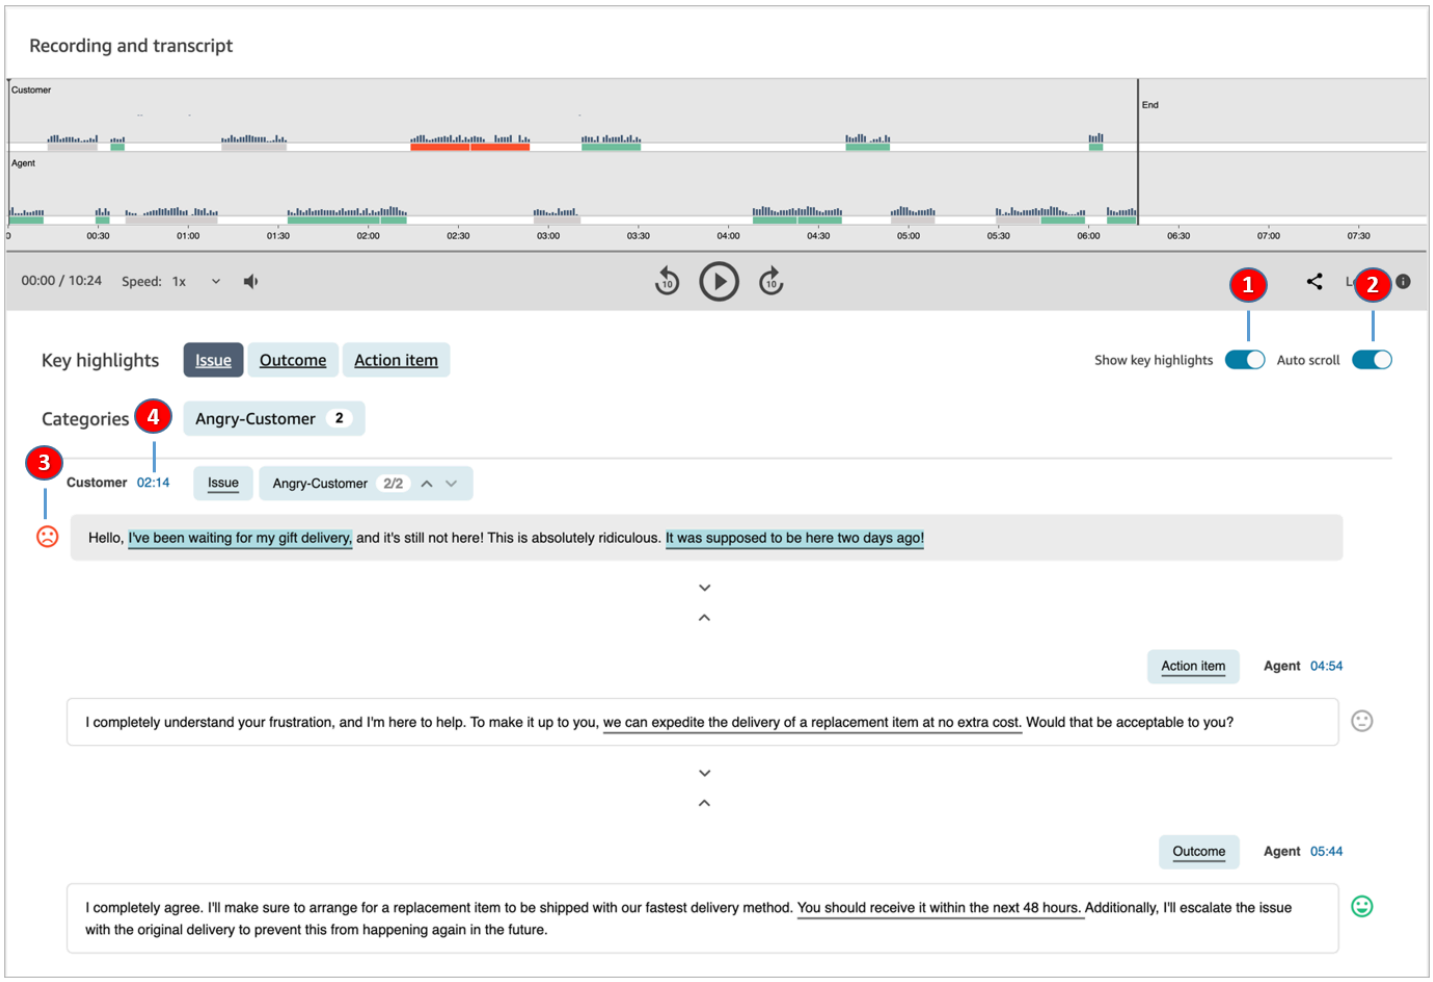
1. Log in to Connect Customer with a user account that has **Contact search** and **conversational analytics - conversational analytics** permissions in the security profile.
2. In Connect Customer, choose **Analytics and optimization**, **Contact search**.
3. Use the filters on the page to narrow your search for a contact. For date, you can search up to 14 days at a time. For more information about searching for contacts, see Search for completed and in-progress contacts.
4. Choose the contact ID to view the contact details for the contact.
5. In the **Recording** and **Transcript** sections of the **Contact details** page, review what was spoken or written, when, and their sentiment.

6. For calls, if desired, choose the play prompt to listen to the recording. Or, choose the relevant part of the recording to listen to the portion you're interested in.
7. For chats, if desired, use the graph to navigate to the portion of the transcript you're interested in.

Navigate transcripts and audio in Connect Customer conversational analytics

Supervisors are often required to review the contacts for many agents, for quality assurance purposes. The turn-by-turn transcript and sentiment data helps you quickly identify and navigate to the portion of the recording that is of interest to you.

The following image of a contact record shows features that you can use to quickly navigate transcripts and audio to find areas that need your attention. While the image shows a voice contact, the same features apply to chat contacts.



1. Use Show key highlights to review only the issue, outcome, or action item.
2. Use Autoscroll for voice contacts, to jump around the audio or transcript. The two always stay in sync.
3. Scan for sentiment emojis to quickly identify a part for the transcript you want to read or listen to.
4. Choose the timestamp to jump to that part of the audio recording or transcript. The timestamp is calculated from the start of the customer interaction within the contact.

Show key highlights

It can be time-consuming to review contact transcripts that are hundreds of lines long. To make this process faster and more efficient, conversational analytics provides the option for you to view key highlights. The highlights show only those lines where conversational analytics has identified an issue, outcome, or action item in the transcript.

- **Issue** represents the call driver. For example, "I'm thinking of upgrading to your online subscription plan."
- **Outcome** represents the likely conclusion or outcome of the contact. For example, "Based on your current plan I would recommend the online essentials plans that we have."
- **Action item** represents the action item the agent takes. For example, "Please keep an eye out for an email with a price quote. I will send it to you shortly."

Each contact has no more than one issue, one outcome, and one action item. Not all contacts will have all three.

> **Note**
>
> If conversational analytics displays the message **There are no key highlights for this transcript**, it means no issue, outcome, or action item was identified.

You don't need to configure key highlights. It works out-of-the-box without any training of the machine learning model.

Turn on autoscroll to synchronize the transcript and audio

For voice contacts, use **Autoscroll** to jump around the audio or transcript, and the two always stay in sync. For example:

- When you listen to a conversation, the transcript moves along with it, showing you sentiment emojis and any detected issue.
- You can scroll through the transcript, and choose the timestamp for the turn to listen to that specific point in the recording.

Because the audio and transcript are aligned, the transcript can help you understand what the agent and customer are saying. This is especially useful when:

- The audio is bad, maybe due to a connection issue. The transcript can help you understand what's being said.
- There's a dialect or language variant. Our models are trained on different accents so the transcript can help you understand what's being said.

Scan for sentiment emojis

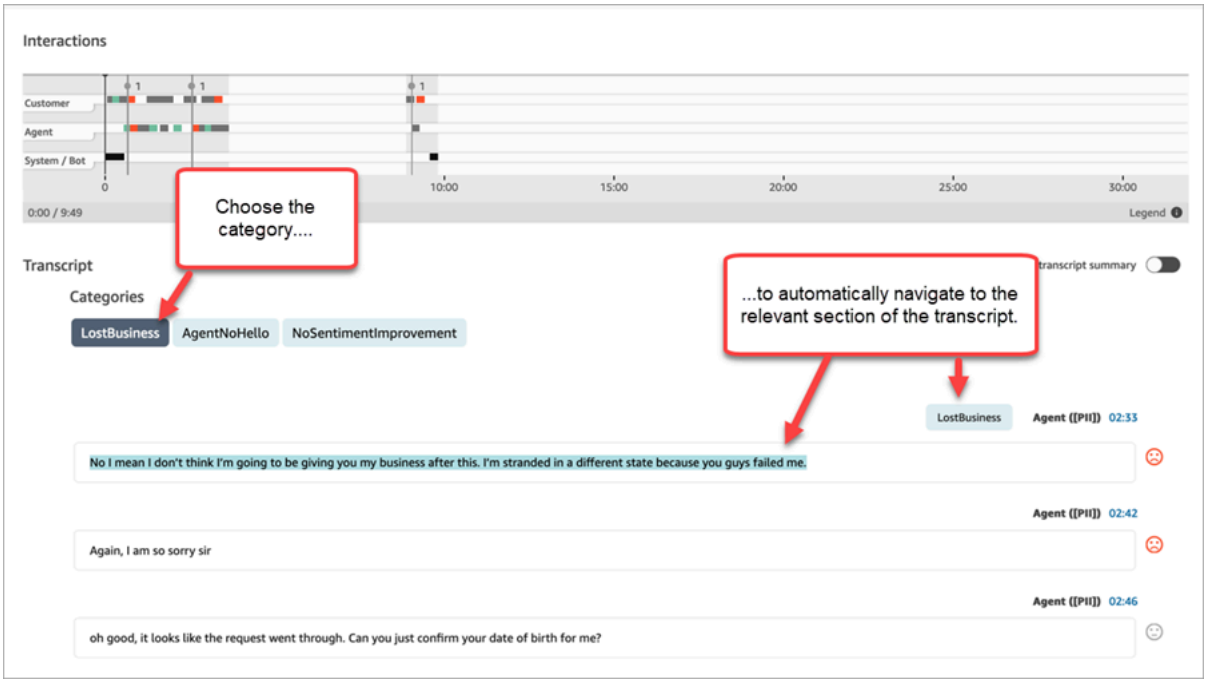
Sentiment emojis help you quickly scan a transcript so you can listen to that part of the conversation.

For example, where you see red emojis for customer turns and then a green emoji, you might choose the timestamp to jump to that specific point of the conversation to check how that agent helped the customer.

Choose category tags to navigate through transcript

When you choose the category tags, conversational analytics auto-navigates to the corresponding point-of-interests in the transcript. There are also category markers in the visualization of the interaction to indicate which part of the recording file has utterances related to the category.

The following image shows part of a **Contact details** page for a chat.



View generative AI-powered post-contact summaries in Connect Customer

> **Note**
>
> **Powered by Amazon Bedrock**: AWS implements automated abuse detection. Because generative AI-powered post-contact summaries is built on Amazon Bedrock, users can take full advantage of the controls implemented in Amazon Bedrock to enforce safety, security, and the responsible use of artificial intelligence (AI).

You can save valuable time with generative AI-powered post-contact summaries that provide essential information from customer conversations in a structured, concise, and easy to read format. You can quickly review the summaries and understand the context instead of reading through transcripts and monitoring calls.

You can access generative AI-powered post-contact summaries multiple ways:

- **Agents** can access post-contact summaries for voice, chat, and email contacts on the Contact Control Panel (CCP). They can use the summaries to quickly complete their After Contact Work (ACW). To learn about the agent's experience, see View post-contact summaries on the CCP.

- **Managers and supervisors** can access summaries for voice, chat, and email contacts on the Connect Customer admin website, on the **Contact details** and the **Contact search** pages. They can use the summaries to quickly understand the issues and outcomes for the contacts they are reviewing. To learn about the managers experience, see View post-contact summaries on the Connect Customer admin website.
- **Developers** can directly ingest the summaries from the APIs into third-party systems. They can also integrate with Amazon Kinesis Data Streams for streaming. This latter option is useful when you have higher loads and you want to avoid having the TPS throttled.

Topics

- Enable post-contact summaries
- Enable contact summaries for email
- View post-contact summaries on the CCP
- View post-contact summaries on the Connect Customer admin website
- Why a summary is not generated

Enable post-contact summaries

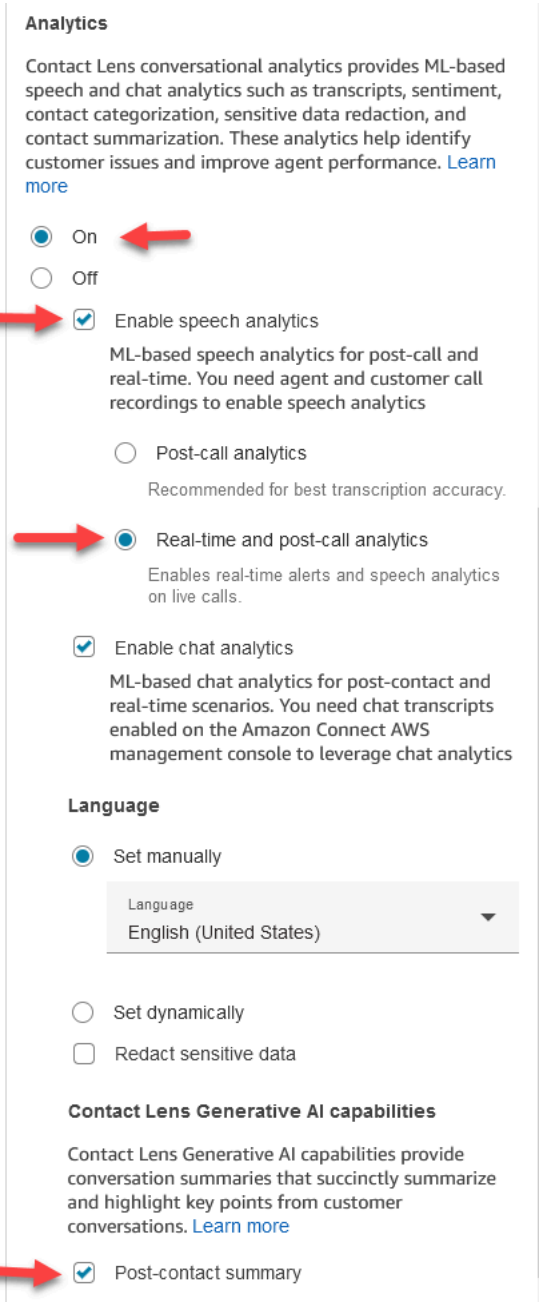
To enable post-contact summaries on the agent's CCP for voice contacts

1. Add a Set recording and analytics behavior block to your flow.
2. Configure the **Properties** page of the block:
    1. Set **Call recording** to **On**. Choose **Agent and customer**, as shown in the following image.

    2. Set **Analytics** to **On**.
    3. Choose **Enable speech analytics**.

4. Choose **Real-time and post-call analytics**.
5. Under **Generative AI capabilities**, choose **Post-contact summary**.

The following image shows the **Analytics** section of a **Properties** page that is configured to enable post-contact summaries on the agent's CCP:



3. Assign the following permissions to the agent's security profile:

- **Contact Control Panel (CCP) - conversational analytics data**

- **Analytics and Optimization - conversational analytics - post-contact summary**
- **Analytics and Optimization - Call recordings (redacted) - Access** or **Call recordings (unredacted) - Access** (least privilege is **redacted**, which we recommend)
- **Analytics and Optimization - Contact transcripts (redacted) - Access** or **Contact transcripts (unredacted) - Access** (least privilege is **redacted**, which we recommend)
- **Analytics and Optimization - View my contacts** or **Contact Search**
- **Analytics and Optimization - conversational analytics - View**

Post-contact summaries help agents complete ACW for chat contacts faster, because they can review the key points of the conversation without rereading the full transcript. Use the following procedure to make post-contact summaries available on the agent's CCP for chat contacts.

To enable post-contact summaries on the agent's CCP for chat contacts

1. Open the Connect Customer console and enable conversational analytics for your instance. For instructions on enabling conversational analytics, see Enable conversational analytics for your Connect Customer instance.
2. Add a Set recording and analytics behavior block to your chat flow.
3. Under **Analytics**, select **Enable conversational analytics** and **Enable chat analytics**. For instructions on enabling chat analytics, see Enable chat analytics.
4. Under **Generative AI capabilities**, select **Post-contact summary**.
5. In the agent's security profile, assign the following permissions:

   - **Analytics and Optimization - View my contacts**
   - **Analytics and Optimization - conversational analytics - conversational analytics - View**
   - **Analytics and Optimization - conversational analytics - post-contact summary - View**
   - **Recordings and Transcripts - Contact transcripts (redacted) - Access** or **Contact transcripts (unredacted) - Access** (least privilege is **redacted**, which we recommend)

After you complete these steps, agents who have these permissions see a post-contact summary on the CCP when a chat contact enters ACW.

To enable post-contact summaries on Connect Customer admin website

1. Configure the **Properties** page of the Set recording and analytics behavior as follows:

1. Set **Analytics** to **On**.
2. Choose either **Enable speech analytics**, **Enable chat analytics**, or both.

   If you choose speech analytics, then choose either:

   - **Post-call analytics**
   - **Real-time and post-call analytics**: Choose this option if the user wants to view post-contact summaries for in progress contacts (that is, the agent is still in ACW but the call has ended).
3. Granular redaction is not supported for post-contact summary. When granular redaction is selected, post-contact summary redacts all PII identified in text and replaces it with a [PII] tag.
4. Under **Generative AI capabilities**, choose **Post-contact summary**.

2. Assign the following permissions to the user's security profile:

   - **Analytics and Optimization - Contact Search** OR **View my contacts**
   - **Analytics and Optimization - conversational analytics - post-contact summary**
   - **Analytics and Optimization - Call recordings (redacted) - Access** or **Call recordings (unredacted) - Access** (least privilege is **redacted**, which we recommend)
   - **Analytics and Optimization - Contact transcripts (redacted) - Access** or **Contact transcripts (unredacted) - Access** (least privilege is **redacted**, which we recommend)
   - **Analytics and Optimization - conversational analytics - View**

Enable contact summaries for email

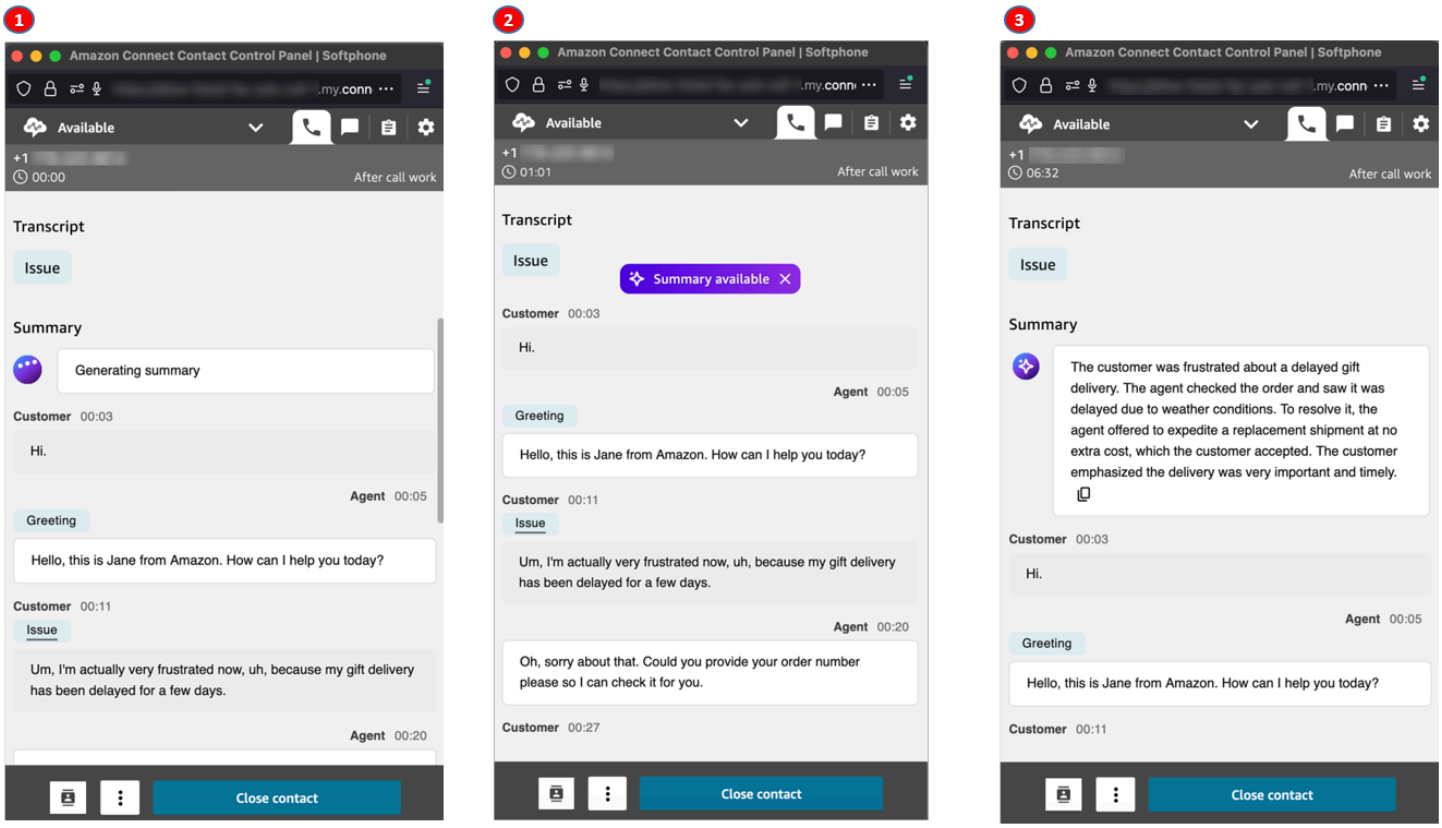
To enable contact summaries for email contacts

1. Add a Set recording, analytics and processing behavior block to your inbound email flow.
2. Configure the **Properties** page of the block:

   1. For **Channel**, choose **Email**.
   2. Set **Analytics** to **On**.
   3. Choose **Enable email analytics**.
   4. Under **Generative AI capabilities**, choose **Contact summary**.
3. Choose **Save**.

View post-contact summaries on the CCP

To help you perform After Contact Work (ACW), a generative AI-powered post-contact summary appears on your CCP. The summary is available for voice, chat, and email contacts. The following image shows an example summary.



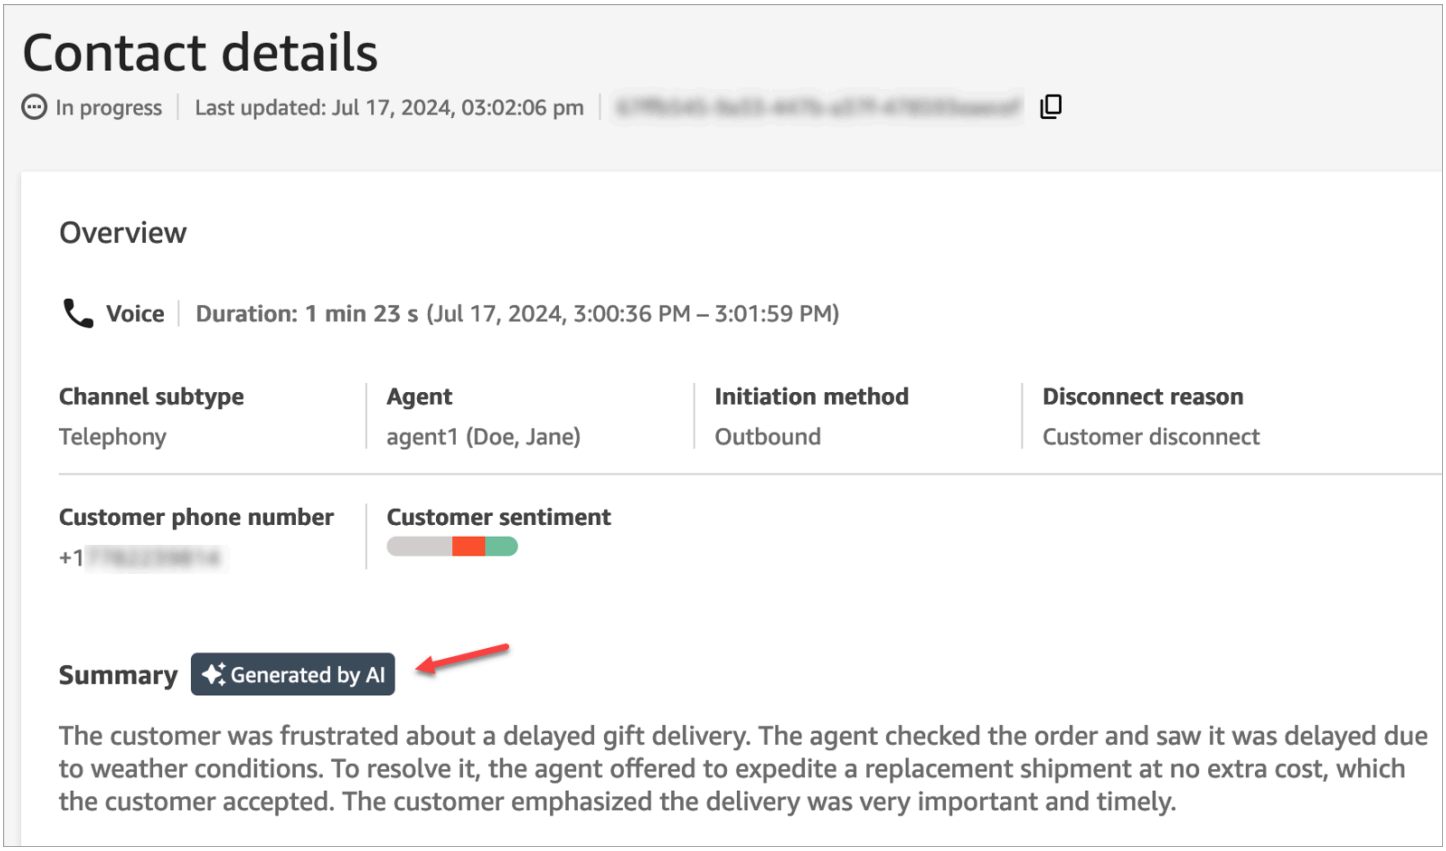
1. The agent is in ACW. They can browse the transcript while a "Generating summary" banner is displayed on the top of the page.
2. While the agent is browsing, a message appears that the summary is available. If the agent clicks the banner, the CCP scrolls to the top of the page when the summary is displayed.
3. The banner disappears after the agent clicks on it.

For chat contacts, the summary appears as an **Insights** message at the bottom of the transcript when the chat enters ACW. If the agent chooses the **Summary available** notification, the chat panel scrolls to the summary.

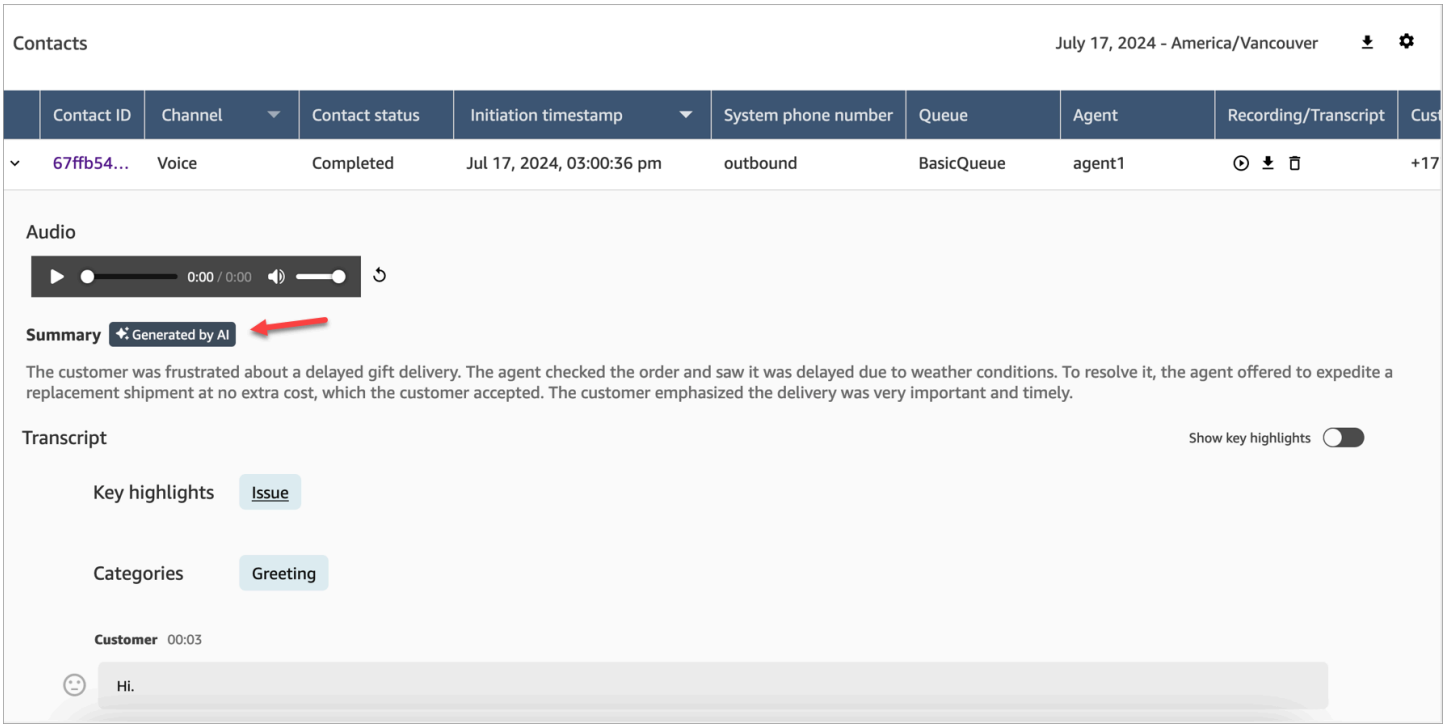
> **Note**
>
> Generative AI-powered post-contact summaries support voice, chat, and email contacts on the CCP.

View post-contact summaries on the Connect Customer admin website

To help managers and other users review contacts, they can view post-contact summaries on the Connect Customer admin website. The following image shows an example of generative AI-powered post-contact summaries on the **Contact details** page.



The following image shows an example of generative AI-powered post-contact summaries on the **Contact search** page.



Each contact has no more than one summary generated. Not all contacts will have a summary generated; for more information, see Why a summary is not generated.

Why a summary is not generated

If a summary is not generated, an error message is displayed on the **Contact details** and **Contact search** pages. In addition, the ReasonCode for the error appears in the `ContactSummary` object in the conversational analytics output file, similar to the following example:

```
"JobDetails": {
    "SkippedAnalysis": [
      {
        "Feature": "POST_CONTACT_SUMMARY",
        "ReasonCode": "INSUFFICIENT_CONVERSATION_CONTENT"
      }
    ]
  },
```

Following is a list of error messages that might be displayed on the Contact details or search pages if a summary is not generated. Also listed is the associated reason code that appears in the conversational analytics output file.

- **Summary could not be generated due to exceeding quota of concurrent summaries**. ReasonCode: `QUOTA_EXCEEDED`.

  If you receive this message, we recommend that you submit a ticket to increase the Concurrent post-contact summary jobs quota.

- **Summary could not be generated due to not enough eligible conversation**. ReasonCode: `INSUFFICIENT_CONVERSATION_CONTENT`.

  For voice, there must be 1 utterance from each participant. For chat, there must be 1 message of supported types from each participant. Supported message types are `text/plain` and `text/markdown`. Messages of other types, such as `application/json`, are not used for the summary.

- **Contact Flow had invalid conversational analytics configuration for PostContact Summary, such as unsupported or invalid language code**. ReasonCode: `INVALID_ANALYSIS_CONFIGURATION`.

  This error is returned if the enabled summary is incompatible with other conversational analytics settings, particularly if it's enabled for an unsupported locale.

- **Summary cannot be provided because it failed to satisfy security and quality guardrails**. ReasonCode: `FAILED_SAFETY_GUIDELINES`.

  This error can occur in Connect Customer for Concurrent post-contact summary jobs. Connect Customer passes contact data to Amazon Bedrock for summary generation. If the contact data contains unredacted Personally Identifiable Information (PII), the safety guidelines of Amazon Bedrock are triggered. As a result, Amazon Bedrock refuses to generate the summary to protect sensitive information, leading to the error in Connect Customer.

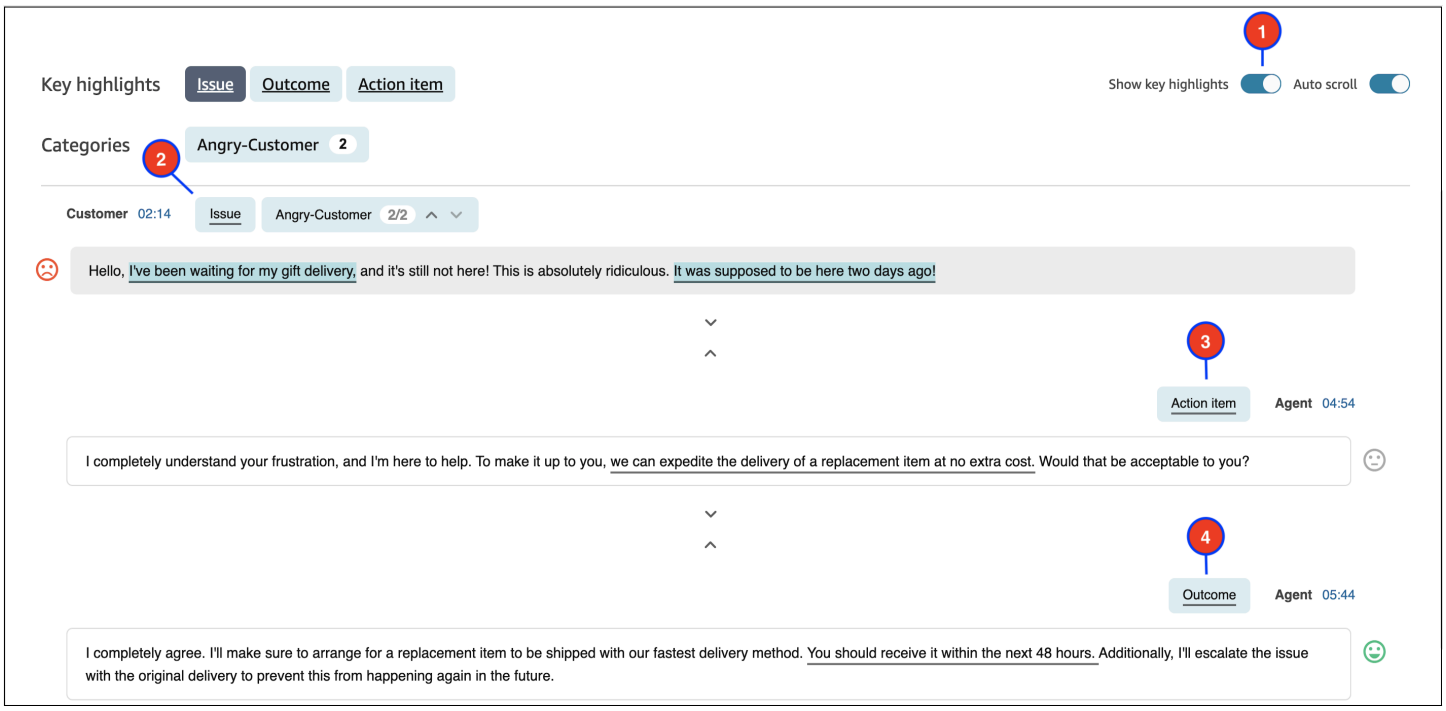
- Internal system error. ReasonCode: `INTERNAL_ERROR`

View key highlights of customer conversations in Connect Customer

It can be time-consuming to review contact transcripts that are hundreds of lines long. To make this process faster and more efficient, conversational analytics automatically identifies and labels key parts of customer conversations, then displays highlights of the conversations. Managers can view those highlights on the **Contact details** page. Agents can view the highlights in the Contact Control Panel (CCP).

After you enable conversational analytics, it identifies key parts of a customer conversation, assigns labels (such as issue, outcome, or action item) to those parts, and displays highlights of the customer conversation. You can expand the highlights to view the full transcript of the contact.

The following example shows the key highlights on the **Contact details** page.



1. Toggle **Show key highlights** on and off as needed.
2. **Issue** represents the contact driver. For example, "I'm thinking of upgrading to your online subscription plan."
3. **Action item** represents the action item the agent takes. For example, "Please keep an eye out for an email with a price quote. I will send it to you shortly."
4. **Outcome** represents the likely conclusion or outcome of the contact. For example, "Based on your current plan I would recommend our online essentials plan."

Contacts have only one issue, one outcome, and one action item. It's possible for some contacts to not have all three.

> **Note**
>
> You see this message **There are no key highlights for this transcript** when conversational analytics can't identify an issue, outcome, or action item.

To learn about the agent's experience—what part of the transcript is displayed in the Contact Control Panel (CCP), and when—see Design a flow for key highlights.

Use theme detection in Connect Customer conversational analytics to discover issues with contacts

Use theme detection to discover previously unknown or emerging contact themes from thousands of customer interactions. For example, you can spot common reasons for customer outreach such as "cancel reservation" or "delayed order." You can then take appropriate actions to improve the customer experience by expediting issue resolution, and improving IVR options, knowledge base articles, and agent training.

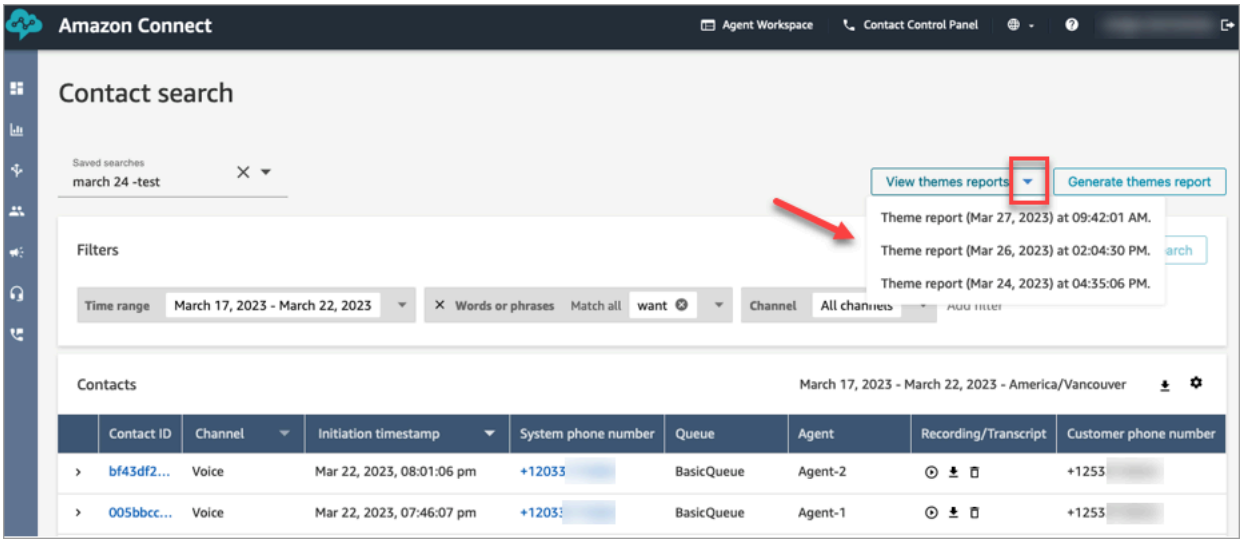
Important things to know

- Theme detection is available in the following languages supported by Connect Customer conversational analytics:

Language (country)	Language code
English (United States)	en-US
English (United Kingdom)	en-GB
English (Australia)	en-AU
English (India)	en-IN
English (Ireland)	en-IE
English (Scotland)	en-AB
English (Wales)	en-WL
English (New Zealand)	en-NZ
English (South Africa)	en-ZA

- Theme detection is supported on contacts that were created on or after January 30, 2023.
- The **Generate themes report** button is enabled only when your saved search contains at least 300 contacts with issues detected by conversational analytics.

- The theme detection report is generated for the 3,000 most recent contacts.
- Theme detection reports are available for 30 days after they are created. After 30 days, the reports are deleted from the database and cannot be retrieved.
- The most recent 20 theme reports for a saved search are available in the **View theme reports** dropdown menu, as shown in the following image.



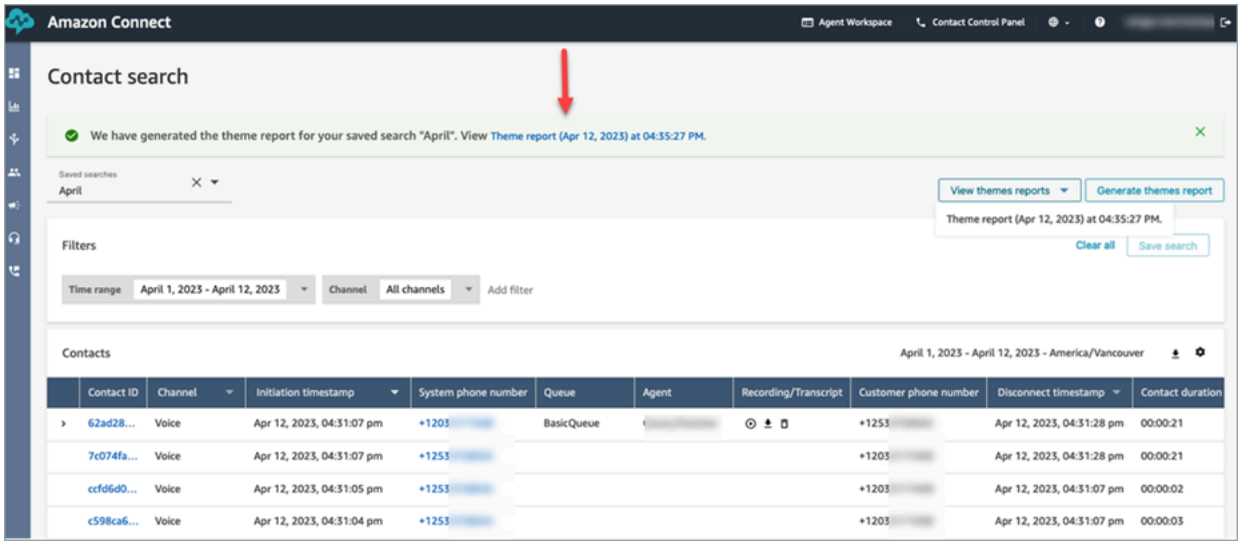
How to generate a theme report

1. Login to Connect Customer using an account that has the following security profile permissions:
   - **Contact search - View**
   - **conversational analytics - theme detection - Create**
   - **conversational analytics - theme detection - View**
2. In Connect Customer, on the left navigation menu, choose **Analytics and optimization**, **Contact search**.
3. On the **Contact search** page, apply filters to select a group of contacts that have been analyzed by conversational analytics.

> **Important**
>
> Your search query must return at least 300 contacts with issues detected by conversational analytics. Otherwise, the **Generate themes report** button is not enabled.

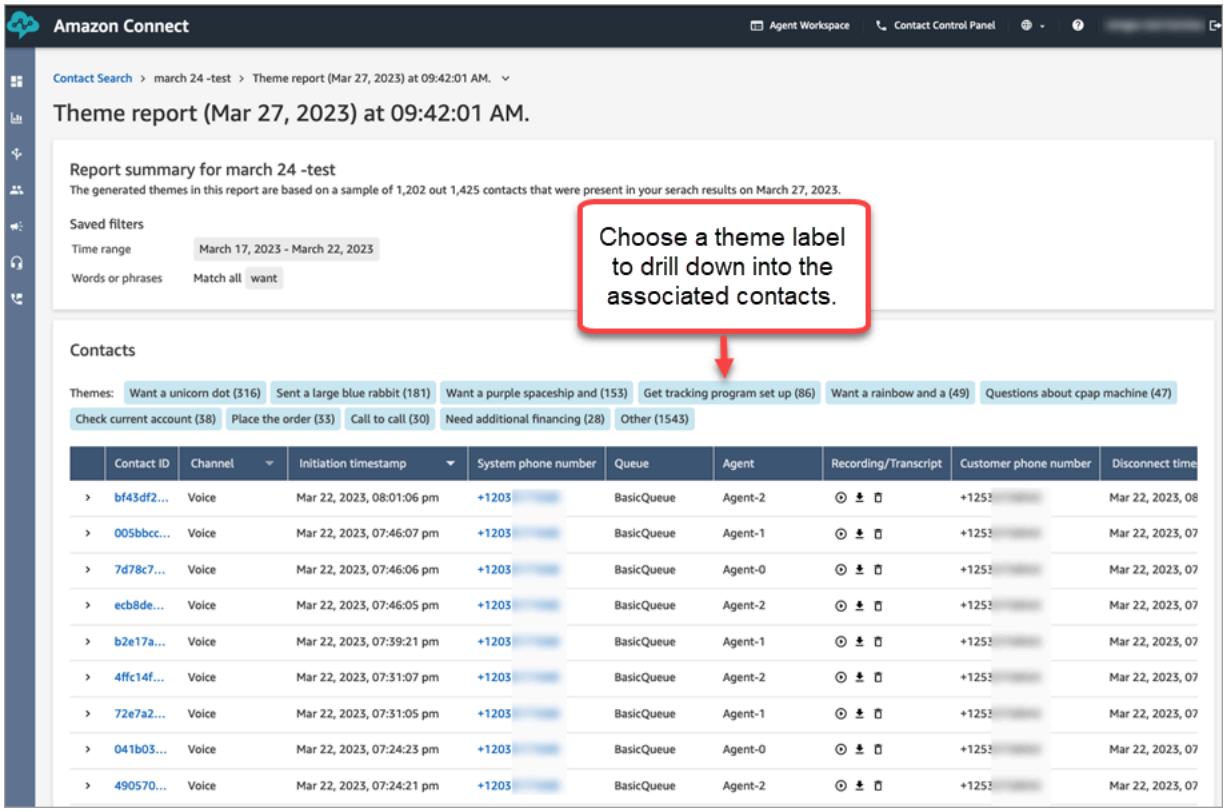
4. Choose **Save search** to save your results. Assign a name to your search.
5. Choose **Generate themes report**.

   Conversational analytics applies machine learning to automatically group contacts with similar issues. When the report is generated, a banner displays a link to the theme report. An example banner is shown in the following image.



6. Choose the link for the theme report.

   The theme report is displayed. It includes theme labels and a list of contacts, as shown in the following image.



7. Choose the theme labels to view associated contacts, listen to specific recordings, and read transcripts for deeper analysis.

Investigate sentiment scores during contact conversations using conversational analytics

What are sentiment scores?

A sentiment score is an analysis of text, and a rating of whether it includes mostly positive, negative, or neutral language. Supervisors can use sentiment scores to search conversations and identify contacts that are associated with varying degrees of customer experiences, positive or negative. It helps them identify which of their contacts to investigate.

You can view a sentiment score for the entire conversation, as well as sentiment trend across whole contact.

How to investigate sentiment scores

When working to improve your contact center, you might want to focus on the following:

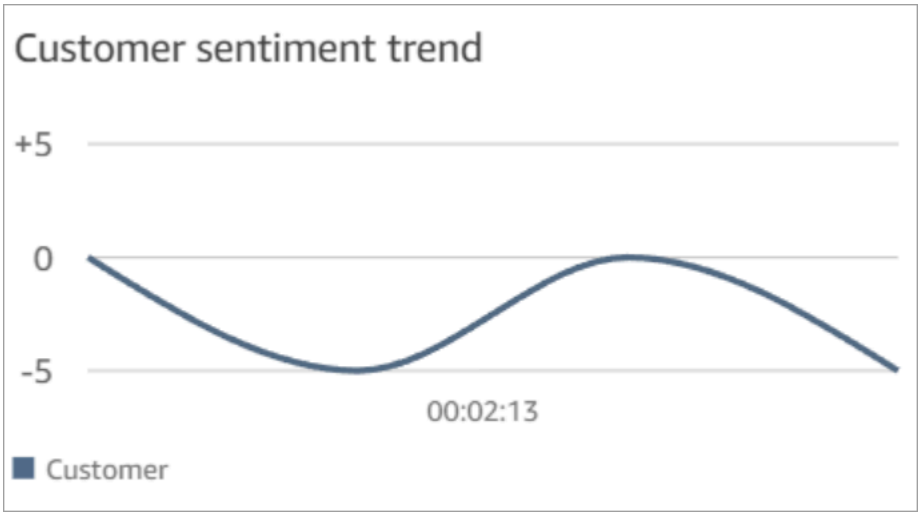
- Contacts that start with a positive sentiment score but end with a negative score.

  If you want to focus on a limited set of contacts to sample for quality assurance, for example, you can look at contacts where you know the customer had a positive sentiment at the start but ended with a negative sentiment. That shows you they left the conversation unhappy about something.

- Contacts that start with a negative sentiment score but end positive.

  Analyzing these contacts will help you identify what experiences you can recreate in your contact center. You can share successful techniques with other agents.

An additional way of looking at sentiment progression is to check the sentiment trendline. You can see the variation in the customer's sentiment as the contact progresses. For example, the following image shows a conversation with a very low sentiment score in the beginning of the conversation, it goes up, and then back down at the end.



For more information, see Search for sentiment score or evaluate sentiment shift.

How sentiment scores are determined

Connect Customer conversational analytics analyzes the sentiment of each speaker turn in a conversation as positive, negative, or neutral. It then considers two factors for each participant turn to assign a score that ranges from -5 to +5 for each period of the call:

- Frequency. The number of times the sentiment is positive, negative or neutral.
- Sentiment streaks. The consecutive turns with same sentiment.

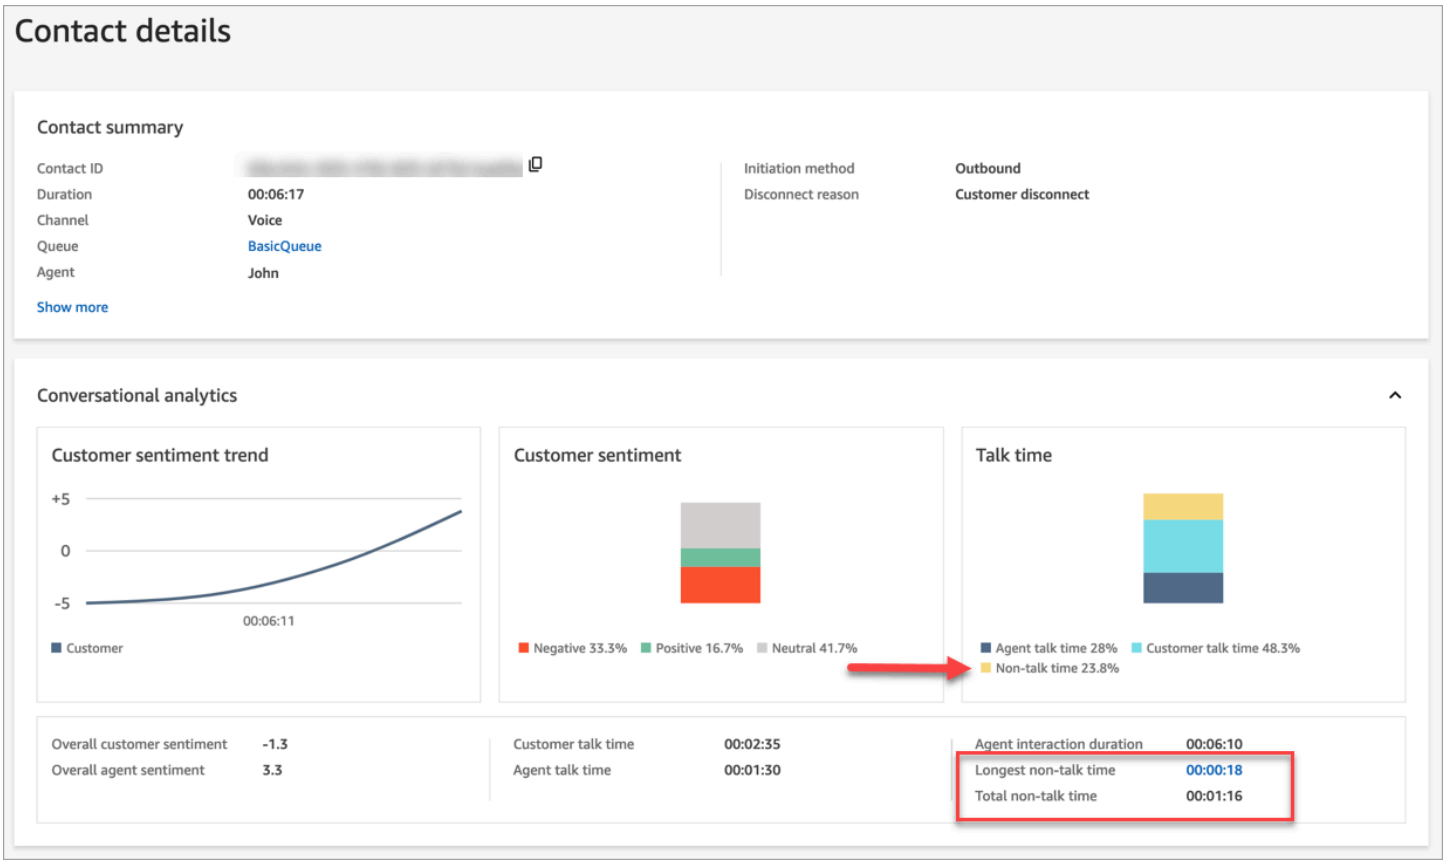
The overall sentiment score is the average of the scores assigned during each portion of the call.

Investigate non-talk time during calls using Connect Customer conversational analytics

What is non-talk time?

Connect Customer conversational analytics also identifies the amount of *non-talk time* in a call. Non-talk time equals hold time, plus any silence where both participants aren't talking for more than 3 seconds. This duration can't be customized.

The following image shows the location of non-talk time data on the **Contact details** page.



How to investigate non-talk time

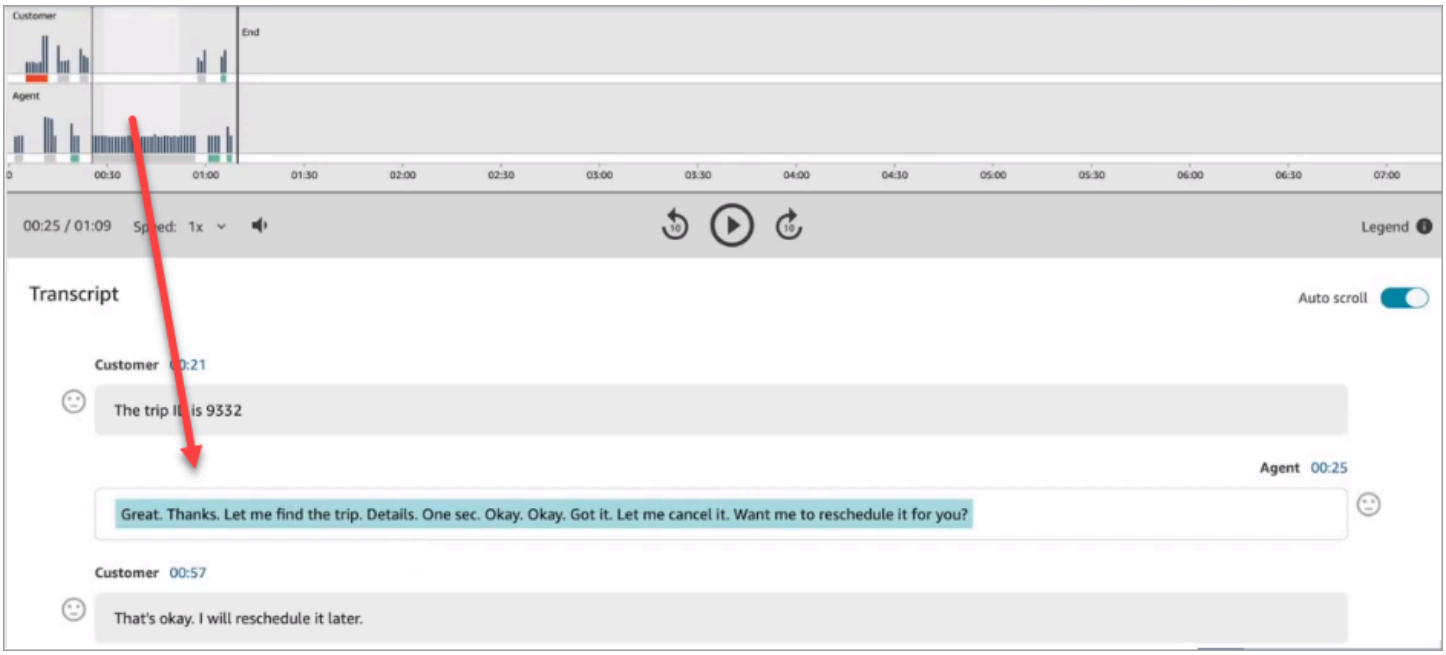
Non-talk time can help you identify calls that have gone poorly. This might be because:

- The customer was asking a question that's new for your contact center.

- It's taking the agent a long time to do something but they are well-trained. This indicates there might be an issue with the tools the agent is using. For example, the tools aren't responsive enough or aren't easy to use.
- The agent didn't have a ready answer, but they are fairly new. This indicates they need more training.

You can decide whether to focus on these contacts to improve your contact center. For example, you can go to that section of the audio, and then look at the transcript to see what was going on.

In the following example, the non-talk time occurred when the agent was searching for the caller's trip ID. This could indicate there's an issue with the agent's tools. Or if the agent is new, they need more training.



For more information, see Search for non-talk time.

Investigate response time during chats in conversational analytics

Use the response time metric to understand the responsiveness of the agent or customer during a chat contact.

Conversational analytics calculates the following metrics:

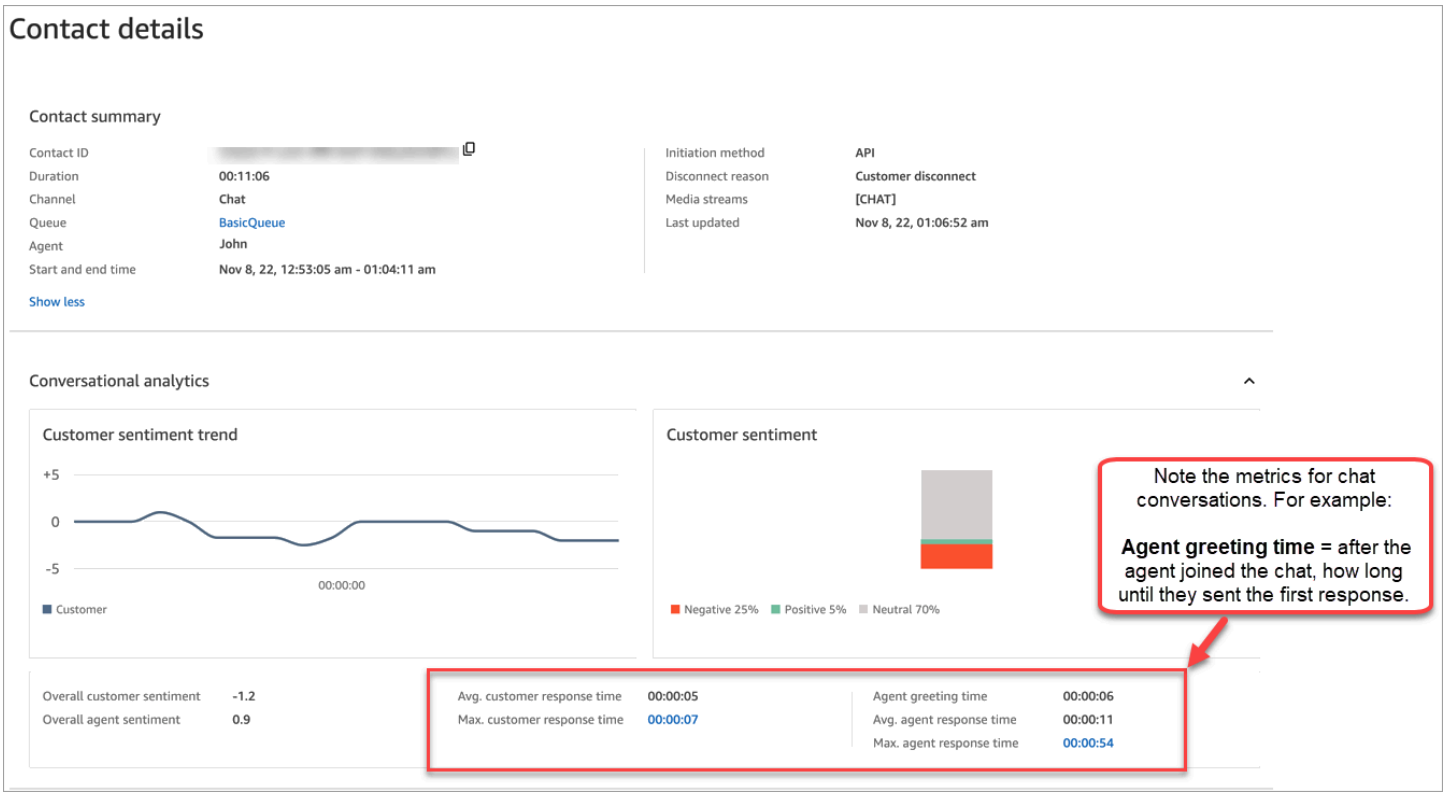
- **Agent greeting time**. This is the first response time for the agent, which is how fast the agent engaged with the customer after the agent joined the chat. A long first response time might explain, for example, if a customer has a negative sentiment in the beginning of conversation.
- **Avg agent response time** and **Avg customer response time**. The agent response time helps you check an agent's performance against your organization's base line.
- **Max agent response time** and **Max customer response time**.

  The customer's max response time might explain an agent's response time. For example, if a customer didn't reply for five minutes and then sent a message, it's possible the agent took longer than usual to respond because they were handling other chats at the same time.

We recommend examining the response time metrics in conjunction with the interactions graph that shows gaps in conversation and participant sentiment.

You can click or tap the longest response time value on the graph to be directed to the associated message in the transcript.

The following image of the **Contact details page** shows metrics for chat conversations. Note that **Agent greeting time** = after the agent joined the chat, how long until they sent the first response.



For more information, see Search by response time for chat conversations.

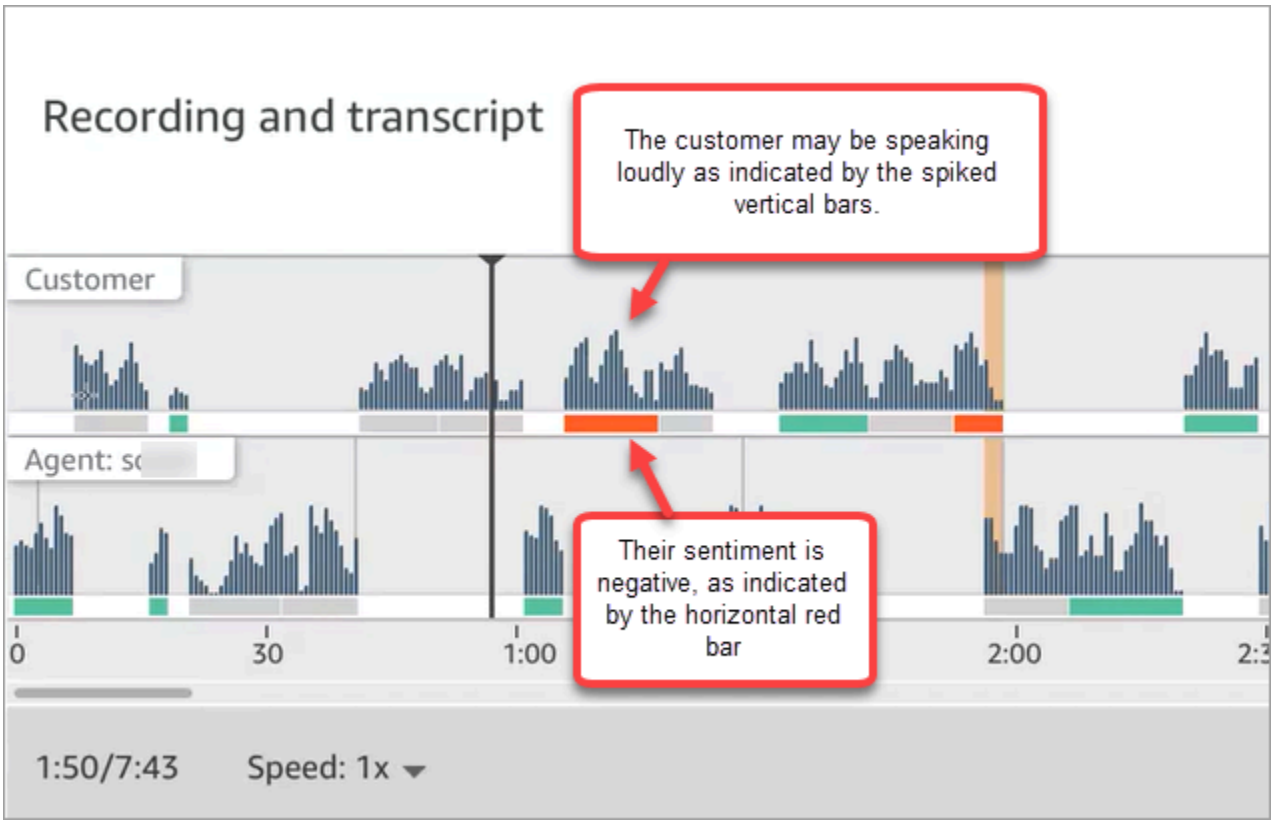
Investigate the loudness of agents and customers in calls using conversational analytics

A loudness score measures how loudly the customer or agent are speaking during a call. conversational analytics displays an analysis of the conversation that you can use to identify where the customer or agent might be talking loudly and have a negative sentiment.

How to use loudness scores

We recommend using loudness scores together with sentiments. Look for areas of the conversation where the loudness score is high and the sentiment is low. Then read that portion of the transcript or listen to that section of the call.

For example, the following is an image of a recording and transcript analysis. Spiked vertical bars indicate where the customer is talking loudly. The horizontal red bars indicate their sentiment is negative.



Use sensitive data redaction to protect customer privacy using conversational analytics

To help you protect your customer's privacy, you can use conversational analytics to automatically redact sensitive data from conversation transcripts, audio files, and email transcripts. It redacts sensitive data, such as name, address, and credit card information using Natural Language Understanding.

When you enable conversational analytics on the **Set recording and analytics behavior** block, you then have the option to enable redaction. For more information, see Enable redaction of sensitive data.

For voice contacts, sensitive data redaction is applied after a call disconnects. For email contacts, redaction is applied after the email contact ends.

> **Important**
>
> The redaction feature is designed to identify and remove sensitive data. However, due to the predictive nature of machine learning, it may not identify and remove all instances of sensitive data in a transcript generated by conversational analytics. We recommend you review any redacted output to ensure it meets your needs.
> The redaction feature does not meet the requirements for de-identification under medical privacy laws like the U.S. Health Insurance Portability and Accountability Act of 1996 (HIPAA), so we recommend you continue to treat it as protected health information after redaction.

For a list of the languages supported by conversational analytics redaction, see Languages supported by Connect Customer features.

About redacted files

Redacted voice files are stored in your Voice Amazon S3 bucket, for example: connect-*instanceARN*/Analysis/Voice.

Redacted chat files are stored in your chat Amazon S3 bucket, for example: connect-*instanceARN*/Analysis/Chat

Redacted email files are stored in your email Amazon S3 bucket, for example: connect-*instanceARN*/Analysis/Email

You can access all files (redacted, unredacted, raw) through the AWS console, by using the Amazon S3 console.

Following is a list of what you can access by using the Connect Customer admin website (such as on the **Contact details** page), assuming you have the appropriate security profile permissions:

- Access redacted voice, chat, and email files.
- Download redacted voice recordings.

> **Note**
>
> Currently, you cannot download redacted chat files and voice transcripts.

When redaction is enabled, conversational analytics generates the following files:

- A redacted file. This file is generated by default when Redaction is enabled. It's the output schema, with sensitive data redacted. For an example file, see Example redacted file for a call analyzed by conversational analytics.
- An original (raw), analyzed file. This file is generated only when you choose **Get redacted and original transcripts with redacted audio** in the Set recording and analytics behavior block. For an example file, see Example original file for a call analyzed by conversational analytics.

  > **Important**
  >
  > For voice contacts, the original analyzed file is the only place where the complete conversation is stored. If you delete it, there will be no record of the sensitive data that was redacted.

- A redacted audio file (wav) for voice contacts. Sensitive data in audio files is redacted as silence. These silent times are not flagged in the Connect Customer admin website or elsewhere as non-talk time.

Use your file retention policies to determine how long to keep these files.

Use conversational analytics APIs for chat analytics

Conversational analytics includes two APIs that support conversational analytics. Use these APIs to build solutions that make your contact center more efficient.

- ListRealtimeContactAnalysisSegments: Use for voice contacts.
- ListRealtimeContactAnalysisSegmentsV2: Use for chat contacts.

These conversational analytics APIs are polling APIs, with a standard request/response exchange, where you don't need to integrate with any other service. However, there are rate limitations. If needed, you can eliminate these limitations by using the streaming API. It requires integration with Amazon Kinesis Data Streams.

Following are two use cases for the call and chat analytics API.

Better contact transfers

When a contact is transferred from one agent to another agent, you can transfer a transcript of the conversation to the new agent. The new agent then has context for why the customer is contacting your contact center. The customer doesn't need to repeat information they already provided. Use the ListRealtimeContactAnalysisSegments API for voice contacts and the ListRealtimeContactAnalysisSegmentsV2 API for chats to get the entire transcript of the conversation up to a certain point, and share it with the new agent.

Highlight key parts of the conversation as labels, issues, action items, and outcomes

With key highlights agents can quickly makes notes after the contact ends, and supervisors can quickly identify contacts for quality and agent performance management. This makes agents and supervisors more productive at their jobs.

Access conversational analytics for voice and chat contacts using Amazon Kinesis Data Streams

With contact analysis segment streams, you can access conversational analytics for voice and chat contacts. Streaming overcomes the scaling limitations of existing call and chat analytics APIs. For voice contacts, it also provides access to a data segment called `Utterance` that you can use to

access partial transcripts. This helps you meet ultra-low latency requirements to assist agents on live calls.

This section explains how to integrate with Amazon Kinesis Data Streams for streaming.

Through streaming, you can receive the following event types:

- STARTED events published at the beginning of a contact analysis session.
- SEGMENTS events published during the contact analysis sessions. These events contain a list of segments with analyzed information.
- COMPLETED or FAILED events published at the end of a contact analysis session.

Topics

- Enable contact analysis segment streams to analyze conversational analytics conversations
- Data model for conversational analytics segment streams to analyze voice contacts in conversational analytics
- Data model for conversational analytics segment streams to analyze chats in conversational analytics
- Sample conversational analytics segment streams to analyze calls using conversational analytics
- Sample conversational analytics streams to analyze chats in conversational analytics

Enable contact analysis segment streams to analyze conversational analytics conversations

Contact analysis segment streams are not enabled by default. This topic explains how to enable them.

Step 1: Create a Kinesis stream

Create the data stream on the same account and Region where your Connect Customer instance resides. For instructions, see Step 1: Create a Data Stream in the *Amazon Kinesis Data Streams Developer Guide*.

> **Tip**
>
> We recommend creating a separate stream for each type of data. While it's possible to use the same stream for contact analysis segment streams, agent events, and contact records,

it is much easier to manage and get data from the stream when you use a separate stream for each one. For more information, see the Amazon Kinesis Data Streams Developer Guide.

Step 2: Set up server-side encryption for the Kinesis stream (optional but recommended)

There are several ways you can do this.

- Option 1: Use the Kinesis AWS managed key (`aws/kinesis`). This works with no additional setup from you.
- Option 2: Use the same customer managed key for call recordings, chat transcripts, or exported reports in your Connect Customer instance.

  Enable encryption, and use a customer managed key for call recordings, chat transcripts, or exported reports in your Connect Customer instance. Then choose the same KMS key for your Kinesis data stream. This key already has the permission (grant) required to be used.
- Option 3: Use a different customer managed key.

  Use an existing customer managed key or create a new one and add required permissions for Connect Customer role to use the key. To add permissions using AWS KMS grants, see the following example:

```
aws kms create-grant \
    --key-id your key ID \
    --grantee-principal arn:aws:iam::your AWS account ID:role/aws-service-role/
connect.amazonaws.com/AWSServiceRoleForAmazonConnect_1111111111111111111 \
    --operations GenerateDataKey \
    --retiring-principal arn:aws:iam::your AWS account ID:role/adminRole
```

  Where `grantee-principal` is the ARN of the service-linked role associated to your Connect Customer instance. To find the ARN of the service-linked role, in the Connect Customer console, choose **Overview**, **Distribution settings**, **Service-linked role**.

Step 3: Associate the Kinesis stream

Use the Connect Customer AssociateInstanceStorageConfig API to associate the following resource types:

- For voice contacts, use `REAL_TIME_CONTACT_ANALYSIS_VOICE_SEGMENTS`

- For chat contacts, use `REAL_TIME_CONTACT_ANALYSIS_CHAT_SEGMENTS`

> **Note**
>
> `REAL_TIME_CONTACT_ANALYSIS_SEGMENTS` is deprecated, but it is still supported and applies to voice contacts only. Use `REAL_TIME_CONTACT_ANALYSIS_VOICE_SEGMENTS` for voice contacts moving forward.
> If you have previously associated a stream with `REAL_TIME_CONTACT_ANALYSIS_SEGMENTS`, no action is needed to update the stream to `REAL_TIME_CONTACT_ANALYSIS_VOICE_SEGMENTS`.

Specify the Kinesis stream where real-time contact analysis segments will be published. You'll need the instance ID and the Kinesis stream ARN. The following code shows an example:

```
// Build request
  const request: Connect.Types.AssociateInstanceStorageConfigRequest = {
    InstanceId: 'your Amazon Connect instance ID',
    ResourceType: 'REAL_TIME_CONTACT_ANALYSIS_VOICE_SEGMENTS or
 REAL_TIME_CONTACT_ANALYSIS_CHAT_SEGMENTS',
    StorageConfig: {
      StorageType: 'KINESIS_STREAM',
      KinesisStreamConfig: {
        StreamArn: 'the ARN of your Kinesis stream',
      },
    }
  };
```

AWS CLI

The following example is for chat contacts.

> **Tip**
>
> If you don't include the AWS Region (`--region`) it uses the default Region based on the CLI profile.
> The `--storage-config` parameter value must not be include within single quote ('). Otherwise it raises an error.

```
aws connect associate-instance-storage-config \
--region "us-west-2" \
--instance-id your Connect Customer instance ID \
--resource-type REAL_TIME_CONTACT_ANALYSIS_CHAT_SEGMENTS \
--storage-config StorageType=KINESIS_STREAM,KinesisStreamConfig={StreamArn=the ARN of
 your Kinesis stream}
```

AWS SDK

The following example is for voice contacts.

```
import { Connect } from 'aws-sdk';

async function associate (): Promise <void> {
  const clientConfig: Connect.ClientConfiguration = {
    region: 'the Region of your Connect Customer instance',
  };

  const connect = new Connect(clientConfig);

  // Build request
  const request: Connect.Types.AssociateInstanceStorageConfigRequest = {
    InstanceId: 'your Connect Customer instance ID',
    ResourceType: 'REAL_TIME_CONTACT_ANALYSIS_VOICE_SEGMENTS',
    StorageConfig: {
      StorageType: 'KINESIS_STREAM',
      KinesisStreamConfig: {
        StreamArn: 'the ARN of your Kinesis stream',
      },
    }
  };

  try {
    // Execute request
    const response: Connect.Types.AssociateInstanceStorageConfigResponse = await
 connect.associateInstanceStorageConfig(request).promise();

    // Process response
    console.log('raw response: ${JSON.stringify(response, null, 2)}');
  } catch (err) {
    console.error('Error calling associateInstanceStorageConfig. err.code:
 ${err.code},' +
```

```
      'err.message: ${err.message}, err.statusCode: ${err.statusCode}, err.retryable:
 ${err.retryable}');
  }
}

associate().then(r => console.log('Done'));
```

Step 4: Enable conversational analytics for your Connect Customer instance

For instructions, see Enable conversational analytics in Connect Customer conversational analytics.

Step 5 (Optional): Review a sample segment stream

We recommend you review a voice or chat sample segment stream to familiarize yourself with what it looks like.

Data model for conversational analytics segment streams to analyze voice contacts in conversational analytics

Real-time contact analysis segment streams are generated in JSON. Event JSON blobs are published to the associated stream for every contact that has real-time conversational analytics enabled. The following types of events can be published for a conversational analytics session for a voice contact:

- STARTED events—Each conversational analytics session publishes one STARTED event at the beginning of the session.
- SEGMENTS events—Each conversational analytics session might publish zero or more SEGMENTS events during the session. These events contain a list of segments with analyzed information. For voice contacts, the list of segments might include "`Utterance`", "`Transcript`", "`Categories`", or "`PostContactSummary`" segments.
- COMPLETED or FAILED events—Each conversational analytics session publishes one COMPLETED or FAILED event at the end of the session.

Common properties included in all events for voice contacts

Every event includes the following properties:

Version

The version of the event schema.

Type: String

Channel

The type of channel for this contact.

Type: String

Valid values: `VOICE`, `CHAT`, `TASK`

For more information about channels, see Channels and concurrency for routing contacts in Connect Customer.

AccountId

The identifier of the account where this contact takes place.

Type: String

ContactId

The identifier of the contact being analyzed.

Type: String

InstanceId

The identifier of the instance where this contact takes place.

Type: String

LanguageCode

The language code associated to this contact.

Type: String

Valid values: the language code for one of the supported languages for conversational analytics real-time call analytics.

EventType

The type of event published.

Type: String

Valid values: `STARTED`, `SEGMENTS`, `COMPLETED`, `FAILED`

STARTED event

STARTED events include only the common properties:

- Version
- Channel
- AccountId
- ContactId
- LanguageCode
- EventType: STARTED

SEGMENTS event

SEGMENTS events include the following properties:

- Version
- Channel
- AccountId
- ContactId
- LanguageCode
- EventType: SEGMENTS
- Segments: In addition to the common properties, SEGMENTS events include a list of segments with analyzed information.

  Type: Array of Segment objects
- PostContactSummary: Information about the post-contact summary for a voice contact segment.

  Type: PostContactSummary objects

  Required: No

Segment

An analyzed segment for a real-time analysis session.

Each segment is an object with the following optional properties. Only one of these properties is present, depending on the segment type:

- Utterance
- Transcript
- Categories
- PostContactSummary

Utterance

The analyzed utterance.

Required: No

- **Id**

  The identifier of the utterance.

  Type: String
- **TranscriptId**

  The identifier of the transcript associated to this utterance.

  Type: String
- **ParticipantId**

  The identifier of the participant.

  Type: String
- **ParticipantRole**

  The role of participant. For example, is it a customer, agent, or system.

  Type: String
- **PartialContent**

  The content of the utterance.

  Type: String
- **BeginOffsetMillis**

  The beginning offset in the contact for this transcript.

Type: Integer

- **EndOffsetMillis**

  The end offset in the contact for this transcript.

  Type: Integer

Transcript

The analyzed transcript.

Type: Transcript object

Required: No

Categories

The matched category rules.

Type: Categories object

Required: No

PostContactSummary

Information about the post-contact summary for a voice contact segment.

Type: PostContactSummary object

Required: No

COMPLETED event

`COMPLETED` events include only the following common properties:

- Version
- Channel
- AccountId
- ContactId
- LanguageCode

- EventType: COMPLETED

FAILED event

FAILED events include only the following common properties:

- Version
- Channel
- AccountId
- ContactId
- LanguageCode
- EventType: FAILED

Data model for conversational analytics segment streams to analyze chats in conversational analytics

Conversational analytics segment streams for chat contacts are generated in JSON. Event JSON blobs are published to the associated stream for every contact that has real-time conversational analytics enabled. The following types of events can be published for a conversational analytics session for a chat contact:

- STARTED events—Each conversational analytics session publishes one STARTED event at the beginning of the session.
- SEGMENTS events—Each conversational analytics session might publish zero or more SEGMENTS events during the session. These events contain a list of segments with analyzed information. For chat contacts, the list of segments might include "`Attachments`," "`Transcript`," "`Categories`," "`Events`," "`Issues`," or "`PostContactSummary`" segments.
- COMPLETED or FAILED events—Each conversational analytics session publishes one COMPLETED or FAILED event at the end of the session.

Common properties included in all events for chat contacts

Every event includes the following properties:

Version

The version of the event schema. For chat contacts, this is 2.0.0.

Type: String

Channel

The type of channel for this contact.

Type: String

Valid values: `VOICE`, `CHAT`, `TASK`

For more information about channels, see Channels and concurrency for routing contacts in Connect Customer.

AccountId

The identifier of the account where this contact takes place.

Type: String

InstanceId

The identifier of the instance where this contact takes place.

Type: String

ContactId

The identifier of the contact being analyzed.

Type: String

StreamingEventType

The type of event published.

Type: String

Valid values: `STARTED`, `SEGMENTS`, `COMPLETED`, `FAILED`

StreamingSettings

The conversational analytics settings for this contact

Type: StreamingSettings object

StreamingSettings object

LanguageCode

The language code associated to this contact.

Type: String

Valid values: the language code for one of the supported languages for conversational analytics real-time call analytics.

Output

The conversational analytics output type enabled for this contact.

Type: String

Valid values: `Raw`, `Redacted`, `RedactedAndRaw`

RedactionTypes

The type of redaction enabled for this contact.

Type: Array of Strings

Valid values: `PII`

RedactionTypesMetadata

The redaction metadata for each redaction type.

Type: RedactionType string to RedactionMetadata object

Valid values: `PII`

RedactionMetadata object

Provides information on redaction settings.

RedactionMaskMode

The data redaction replacement setting

Type: String

Valid values: `PII`, `EntityType`

STARTED event

`STARTED` events include only the common properties:

- Version
- Channel
- AccountId
- ContactId
- StreamingEventType: STARTED
- StreamingSettings

SEGMENTS event

`SEGMENTS` events include the following properties:

- Version
- Channel
- AccountId
- OutputType
  - The conversational analytics output type of the current segment
  - Type: String
  - Valid values: `Raw`, `Redacted`
- ContactId
- StreamingEventType: SEGMENTS
- StreamingSettings
- Segments
  - A list of segments with analyzed information.
  - Type: Array of Segment objects

Segment

An analyzed segment for a real-time analysis session.

Each segment is an object with the following optional properties. Only one of these properties is present, depending on the segment type:

- Attachments
- Categories
- Event
- Issues
- Transcript
- PostContactSummary

Attachments

The analyzed attachments.

Required: No

Type: RealTimeContactAnalysisSegmentAttachments object

Categories

The matched category rules.

Type: RealTimeContactAnalysisSegmentCategories object

Required: No

Event

Segment type describing a contact event.

Type: RealTimeContactAnalysisSegmentEvent object

Required: No

Issues

Segment type containing a list of detected issues.

Type: RealTimeContactAnalysisSegmentIssues object

Required: No

Transcript

The analyzed transcript segment.

Type: RealTimeContactAnalysisSegmentTranscript object

Required: No

PostContactSummary

Information about the post-contact summary for a real-time contact segment for chat.

Type: RealTimeContactAnalysisSegmentPostContactSummary object

Required: No

COMPLETED event

`COMPLETED` events include only the following common properties:

- Version
- Channel
- AccountId
- InstanceId
- ContactId
- StreamingEventType: COMPLETED
- StreamingSettings

FAILED event

`FAILED` events include only the following common properties:

- Version
- Channel
- AccountId
- InstanceId
- ContactId
- StreamingEventType: FAILED
- StreamingSettings

Sample conversational analytics segment streams to analyze calls using conversational analytics

This topic provides sample segment streams for STARTED, SEGMENTS, COMPLETED, and FAILED events that can occur during a voice contact.

Sample STARTED event

- EventType: STARTED
- Published at the beginning of the conversational analytics session.

```
{
    "Version": "1.0.0",
    "Channel": "VOICE",
    "AccountId": "123456789012", // your AWS account ID
    "InstanceId": "a1b2c3d4-5678-90ab-cdef-EXAMPLE11111",  // your Connect Customer
 instance ID
    "ContactId": "a1b2c3d4-5678-90ab-cdef-EXAMPLE22222", // the ID of the contact
    "LanguageCode": "en-US", // the language code of the contact
    "EventType": "STARTED"
}
```

Sample SEGMENTS event

- EventType: SEGMENTS
- Published during a conversational analytics session. This event contains a list of segments with analyzed information. The list of segments might include "`Utterance`," "`Transcript`," "`Categories`" or "`PostContactSummary`" segments.

```
{
    "Version": "1.0.0",
    "Channel": "VOICE",
    "AccountId": "123456789012", // your AWS account ID
    "InstanceId": "a1b2c3d4-5678-90ab-cdef-EXAMPLE11111",  // your Connect Customer
 instance ID
    "ContactId": "a1b2c3d4-5678-90ab-cdef-EXAMPLE22222", // the ID of the contact
    "LanguageCode": "en-US", // the language code of the contact
    "EventType": "SEGMENTS",
    "Segments": [
```

```
        {
            "Utterance": {
                "Id": "7b48ca3d-73d3-443a-bf34-a9e8fcc01747",
                "TranscriptId": "121d1581-905f-4169-9804-b841bb4df04a",
                "ParticipantId": "AGENT",
                "ParticipantRole": "AGENT",
                "PartialContent": "Hello, thank you for calling Example Corp. My name
is Adam.",
                "BeginOffsetMillis": 19010,
                "EndOffsetMillis": 22980
            }
        },
        {
            "Utterance": {
                "Id": "75acb743-2154-486b-aaeb-c960ae290e88",
                "TranscriptId": "121d1581-905f-4169-9804-b841bb4df04a",
                "ParticipantId": "AGENT",
                "ParticipantRole": "AGENT",
                "PartialContent": "How can I help you?",
                "BeginOffsetMillis": 23000,
                "EndOffsetMillis": 24598
            }
        },
        {
            "Transcript": {
                "Id": "121d1581-905f-4169-9804-b841bb4df04a",
                "ParticipantId": "AGENT",
                "ParticipantRole": "AGENT",
                "Content": "Hello, thank you for calling Example Corp. My name is Adam.
How can I help you?",
                "BeginOffsetMillis": 19010,
                "EndOffsetMillis": 24598,
                "Sentiment": "NEUTRAL"
            }
        },
        {
            "Transcript": {
                "Id": "4295e927-43aa-4447-bbfc-8fccc2027530",
                "ParticipantId": "CUSTOMER",
                "ParticipantRole": "CUSTOMER",
                "Content": "I'm having trouble submitting the application, number
AX876293 on the portal. I tried but couldn't connect to my POC on the portal. So, I'm
calling on this toll free number",
                "BeginOffsetMillis": 19010,
```

```
                "EndOffsetMillis": 22690,
                "Sentiment": "NEGATIVE",
                "IssuesDetected": [
                    {
                        "CharacterOffsets": {
                            "BeginOffsetChar": 0,
                            "EndOffsetChar": 81
                        }
                    }
                ]
            }
        },
        {
            "Categories": {
                "MatchedCategories": [
                    "CreditCardRelated",
                    "CardBrokenIssue"
                ],
                "MatchedDetails": {
                    "CreditCardRelated": {
                        "RuleId": "6e4a9c1b-3d7f-5e2a-8b0c-1f9d2a4e7c6b",

                        "RuleId": "7f5b0d2c-4e8a-6f3b-9c1d-2a0e3b5f8d7c",
                        "PointsOfInterest": [
                            {
                                "BeginOffsetMillis": 25000,
                                "EndOffsetMillis": 29690
                            }
                        ]
                    }
                }
            }
        },
        {
            "PostContactSummary": {
                "Content": "Customer contacted Example Corp because of an issue with
their application",
```

```
                "Status": "COMPLETED"
            }
        }
    ]
}
```

Sample COMPLETED event

- EventType: COMPLETED
- Published at the end of the conversational analytics session if the analysis completed successfully.

```
{
    "Version": "1.0.0",
    "Channel": "VOICE",
    "AccountId": "123456789012", // your AWS account ID
    "InstanceId": "a1b2c3d4-5678-90ab-cdef-EXAMPLE11111",  // your Connect Customer
 instance ID
    "ContactId": "a1b2c3d4-5678-90ab-cdef-EXAMPLE22222", // the ID of the contact
    "LanguageCode": "en-US", // the language code of the contact
    "EventType": "COMPLETED"
}
```

Sample FAILED event

- EventType: FAILED
- Published at the end of the conversational analytics session if the analysis failed.

```
{
    "Version": "1.0.0",
    "Channel": "VOICE",
    "AccountId": "123456789012", // your AWS account ID
    "InstanceId": "a1b2c3d4-5678-90ab-cdef-EXAMPLE11111",  // your Connect Customer
 instance ID
    "ContactId": "a1b2c3d4-5678-90ab-cdef-EXAMPLE22222", // the ID of the contact
    "LanguageCode": "en-US", // the language code of the contact
    "EventType": "FAILED"
}
```

Sample conversational analytics streams to analyze chats in conversational analytics

This topic provides sample segment streams for STARTED, SEGMENTS, COMPLETED, and FAILED events that occur during a chat contact.

Sample STARTED event

- EventType: STARTED
- Published at the beginning of the conversational analytics session.

```
{
    "Version": "2.0.0",
    "Channel": "CHAT",
    "AccountId": "123456789012", // your AWS account ID
    "InstanceId": "a1b2c3d4-5678-90ab-cdef-EXAMPLE11111",  // your Connect Customer
 instance ID
    "ContactId": "a1b2c3d4-5678-90ab-cdef-EXAMPLE22222", // the ID of the contact
    "StreamingEventType": "STARTED",
    "StreamingSettings": {
      "LanguageCode": "en-US", // the language code of the contact
      "Output": "RedactedAndRaw",
      "RedactionTypes": [
          "PII"
      ],
      "RedactionTypesMetadata": {
        "PII": {
            "RedactionMaskMode": "PII"
        }
       }
    }
}
```

Sample SEGMENTS event

- EventType: SEGMENTS
- Published during a conversational analytics session. This event contains a list of RealtimeContactAnalysisSegment objects with analyzed information. The list of segments might include `"Transcript"`, `"Categories"`, `"Issue"`, `"Event"`, `"Attachment"`, or "PostContactSummary" segments.

```
{
    "Version": "2.0.0",
    "Channel": "CHAT",
    "AccountId": "123456789012", // your AWS account ID
    "InstanceId": "a1b2c3d4-5678-90ab-cdef-EXAMPLE11111",  // your Connect Customer
 instance ID
    "ContactId": "a1b2c3d4-5678-90ab-cdef-EXAMPLE22222", // the ID of the contact
    "OutputType": "Redacted",
    "StreamingEventType": "SEGMENTS",
    "StreamingSettings": {
        "LanguageCode": "en-US", // the language code of the contact
        "Output": "RedactedAndRaw",
        "RedactionTypes": [
            "PII"
        ],
        "RedactionTypesMetadata": {
            "PII": {
                "RedactionMaskMode": "PII"
            }
        }
    },
    "Segments": [{
        "Transcript": {
            "Id": "07a2d668-5c9e-4f69-b2fe-986261b0743a",
            "ParticipantId": "a309ac1e-ca87-44ca-bb5d-197eca8ed77a",
            "ParticipantRole": "AGENT",
            "DisplayName": "[PII]",
            "Content": "Hello, thank you for contacting Example Corp. My name is Ray.",
            "ContentType": "text/markdown",
            "Time": {
                "AbsoluteTime": "2024-03-14T19:39:26.715Z"
            },
            "Sentiment": "NEUTRAL"
        }
    }, {
        "Categories": {
            "MatchedDetails": {
                "Hi": {
                    "RuleId": "8a6c1e3d-5f9b-7a4c-0d2e-3b1f4c6a9e8d",
                    "PointsOfInterest": [{
                        "TranscriptItems": [{

Output file locations for files analyzed by conversational analytics

Following are examples of what the path looks like for conversational analytics output files when they are stored in the Amazon S3 bucket for your instance.

> **Timestamp in the file path**
>
> The date and timestamp in the output file path correspond to the `ConnectedToAgentTimestamp`, not the `InitiationTimestamp`. If the contact spans a UTC day boundary, the file appears under the date when the agent connected, not the date when the contact started.

- Original analyzed transcript file (JSON)

- /connect-instance- bucket/**Analysis/Voice**/2020/02/04/*contact's_ID*_analysis_2020-02-04T21:14:16Z.json
- /connect-instance- bucket/**Analysis/Chat**/2020/02/04/*contact's_ID*_analysis_2020-02-04T21:14:16Z.json
- /connect-instance- bucket/**Analysis/Email**/2026/03/10/*contact's_ID*_analysis_20260310T22:35_UTC.json

- Redacted analyzed transcript file in (JSON)
  - /connect-instance- bucket/**Analysis/Voice/Redacted**/2020/02/04/*contact's_ID*_**analysis_redacted**_2020-02-04T21:14:16Z.json
  - /connect-instance- bucket/**Analysis/Chat/Redacted**/2020/02/04/*contact's_ID*_**analysis_redacted**_2020-02-04T21:14:16Z.json
  - /connect-instance- bucket/**Analysis/Email/Redacted**/2026/03/10/*contact's_ID*_**analysis_redacted**_20260310T22:35_UTC.json
- Redacted audio file
  - /connect-instance- bucket/**Analysis/Voice/Redacted**/2020/02/04/*contact's_ID*_**call_recording_redacted**_2020-02-04T21:14:16Z.**wav**

> ⚠ **Deleting recordings**
>
> To fully remove a recording, you must delete both the redacted and unredacted files. If you delete only one version, the other version remains accessible.

Example conversational analytics output files for a call

The following sections provide examples of the output that results when conversational analytics detects issues, matches categories, indicates loudness, redacts sensitive data, and skipped analysis.

Expand each section to learn more.

Example original file for a call analyzed by conversational analytics

The following example shows the schema for a call that conversational analytics has analyzed. The example shows loudness, issue detection, call drivers, and the information that will be redacted.

Note the following about the analyzed file:

- It doesn't indicate which sensitive data were redacted. All data are referred to as PII (personally identifiable information).
- Each turn includes a `Redaction` section only if it includes PII.
- If a `Redaction` section exists, it includes the offset in milliseconds. In a .wav file, the redacted portion will be silence. If desired, you can use the offset to replace the silence with something else, such as a beep.
- If two or more PII redactions exist in a turn, the first offset applies to the first PII, the second offset applies to the second PII, and so on.

Example redacted file for a call analyzed by conversational analytics

This section shows an example redacted file for a call after it's been analyzed by conversational analytics. It's a twin of the original analyzed file. The only difference is that sensitive data are redacted. In this example, three entities were selected for redaction: "CREDIT_DEBIT_NUMBER", "NAME", "USERNAME".

In this example, `RedactionMaskMode` is set to PII. When an entity is redacted, conversational analytics replaces it with `[PII]`. If it were set to `ENTITY_TYPE`, conversational analytics would replace the data with the name of the entity, for example, `[CREDIT_DEBIT_NUMBER]`.

Example conversational analytics output files for a chat analyzed by conversational analytics

This section shows an example schema for a chat conversation that has been analyzed by conversational analytics. The example shows inferred sentiment, matched categories, contact summary, and response time.

The original, analyzed file contains the full chat transcript. The same content that is present in the chat **Transcript** field on the **Contact details** page is present in `Transcript` field in the original conversational analytics analysis file. In addition, the analyzed file might contain more fields, such as a `Redaction` section to indicate that there is redacted data in the redacted analysis file.

> **Note**
>
> Some `ConversationCharacteristics` include `DetailsByParticipantRole` maps, with participant roles as keys. However, not all roles from the `Participants` list (such as `CUSTOMER` or `AGENT`) are guaranteed to have corresponding keys in the `DetailsByParticipantRole` objects. The presence of a key for a participant depends on whether there was eligible data for conversational analytics analysis.

Categories

`PointsOfInterest` differs between post-chat and post-call categories:

- Post-call `PointsOfInterest` has milliseconds offset.
- Post-chat `PointsOfInterest` has an array of `TranscriptItems`; each item has an `id` and `CharacterOffset`.

There is an array of `PointsOfInterest`. Each array has an array of `TranscriptItems`: each `PointOfInterest` is for a Category match, but each match can span across multiple transcript items.

For both calls and chats, the `PointsOfInterest` array can be empty. This means that the category is matched for the whole contact. For example, if you create a rule to match the category when `Hello` is not mentioned in the contact, there would be no portion of the transcript to pinpoint for this condition.

> **Note**
>
> Currently, category is inferred for `text/plain`, `text/markdown` chat messages only.

Key highlights

Key highlights are located in the `ConversationCharacteristics.ContactSummary.SummaryItemsDetected` array. No more than one item can be in that array, emphasizing that only one set of `Issue`, `Outcome`, and `Action` item can be found.

Each object in the array has following fields: `IssuesDetected`, `OutcomesDetected`, `ActionItemsDetected`.

Each of the fields has an array of `TranscriptItems` that has `Id` and `CharacterOffsets`. They describe `TranscriptItems` and specific parts that were identified to contain that contact summary: issue, outcome, or action item.

> **Note**
>
> Currently, key highlights are inferred for `text/plain` chat messages only.

Sentiment

Overall sentiment

The `DetailsByParticipantRole` field sentiment score for contact participants is similar to the conversational analytics for speech analytics file.

`DetailsByInteraction` field has `CUSTOMER` sentiment score for parts of chat interaction `WithAgent` and `WithoutAgent`. If there were no customer messages in those parts of interaction, the respective field will be absent.

> **Note**
>
> Currently, sentiment is inferred for `text/plain`, `text/markdown` chat messages only.

Sentiment shift

The `DetailsByParticipantRole` field contains an object that describes the sentiment shift for contact participants (that is, `AGENT`, `CUSTOMER`): `BeginScore` and `EndScore`.

The `DetailsByInteraction` field has `CUSTOMER` sentiment shift for parts of the chat interaction `WithAgent` and `WithoutAgent`. If there were no customer messages in those parts of the interaction, the respective field will be absent.

Sentiment shift provides information about how the participant's sentiment changed throughout the chat interaction.

Response time

`AgentGreetingTimeMillis` measures the time between when the `AGENT` joined the chat and the moment when they ended their first message to customer.

`DetailsByParticipantRole` has following characteristics for each of participant:

- `Average`: What is average response time for a participant.
- `Maximum`: What is the longest response time for a participant. If there are multiple transcript items with the same maximum response time, which ones are they.

To calculate the `Average` and `Maximum` response times for a given participant, they need to respond to a message from another participant (`AGENT` needs to respond to the `CUSTOMER`, or vice versa).

For example, if there was only one message from `CUSTOMER` and then only one message from `AGENT` before the chat ended, conversational analytics will calculate a response time for the `AGENT`, but not for the `CUSTOMER`.

> **Note**
>
> Currently, response time is inferred for `text/plain`, `text/markdown` chat messages only.

Redaction

Note the following about the original analysis file for chats:

- Transcript item includes a `Redaction` section only if it there is data to be redacted. The section contains character offsets for the data that is redacted in the redacted analysis file.
- If two or more pieces of a message are redacted, the first offset applies to the first redacted piece, the second offset applies to the second redacted piece, and so on.

`DisplayNames` for `AGENT` and `CUSTOMER` are redacted because they contain PII. This applies to `AttachmentName`, too.

`CharacterOffsets` take into consideration redaction changes of the `Content` length in the redacted analysis file. `CharacterOffsets` describe redacted content, not original content.

Example conversational analytics output files for an email analyzed by conversational analytics

This section shows an example schema for an email contact that has been analyzed by conversational analytics. The example shows matched categories and a contact chain summary.

Note the following about email analytics output files:

- The `Channel` field is set to `EMAIL`.
- The `Version` field uses the `EMAIL` prefix (for example, `EMAIL-2026-01-01`).
- Email output files do not include sentiment scores, sentiment shift, loudness, or non-talk time data.
- The `Categories` section includes an `EventSource` field set to `OnEmailAnalysisAvailable`.
- Contact summaries use `ContactChainSummary` instead of `PostContactSummary`, because email analytics summarizes the full email thread (contact chain).
- The `CustomerMetadata.InputFiles` section references the email message and plain text files stored in Amazon S3.

Example email analytics output file

The following example shows the output for an email contact with categorization, redaction, and contact chain summary enabled.

```

Troubleshoot issues in Connect Customer conversational analytics

Why don't I see or hear unredacted content?

If your organization is using the conversational analytics redaction feature, by default only redacted content appears in the Connect Customer admin website.

You must have permissions to view unredacted content. For more information, see Assign permissions to use conversational analytics in Connect Customer.

Information extraction

Information extraction uses generative AI to extract information from conversations. That information could be verbatim — such as preferred name, invoice number, or reservation ID. Alternatively, it could be derived – such as reason for contact, resolution provided, or next steps promised. Information can be extracted from chat contacts or voice contacts with human agents. The extracted information is associated with the contact as structured data.

> **Note**
>
> Information extraction is only available in Amazon Connect Customer instances.

Extracted information is available in the following locations:

- **Contact Control Panel (CCP)** — During after-call work.
- **Contact details page** — After the contact ends.
- **Contact search** — Extracted information is displayed in the contact search results table.
- **S3 files** — Extracted data is included in the conversational analytics output files stored in Amazon S3.
- **API** — Via ListRealtimeContactAnalysisSegments (voice) and ListRealtimeContactAnalysisSegmentsV2 (chat).
- **Amazon Kinesis** — Extracted information events are delivered to your Kinesis data stream in real time.
- **Rule actions** — Extracted information can be injected as variables into other rule actions, such as sending emails, creating tasks, creating cases, or sending notifications.

How it works

Information extraction uses a large language model (LLM) to extract information from contacts — either verbatim information mentioned in the conversation, or derived information inferred from the conversation. You define what to extract by creating extraction definitions (Step 1), and when to extract by configuring rules (Step 2). When a rule fires, the LLM processes the contact content and returns the extracted information.

Note

If a single extraction definition matches multiple times within a contact, all matches are returned as a list of results. For example, if you create an extraction definition for "Flight Number" and the conversation is about a round-trip, all flight numbers mentioned are returned: "XX123, YY567".

Prerequisites

Before you configure information extraction, verify the following:

- **Contact with conversational analytics** — Your flow must include a Set recording and analytics behavior block with conversational analytics enabled.
- **Security profile permissions** — Information extraction requires explicit permissions configured in the Security Profiles under **Analytics and Optimization**:

  For users that manage information extraction definitions:

  - **Conversational analytics** = View
  - **Information extraction - definitions** = All
  - **Rules** = All
  - **Rules - Generative AI** = All

  For users to view information extracted for a contact:

  - **Conversational analytics** = View
  - **Information extraction - results** = View

Important

Information extraction operates on the raw contact content, before redaction is applied. This means you can extract sensitive data, wholly or in part. For example, you can redact the credit card number from a call recording and transcript while using information extraction to extract the last 6 digits of the credit card number.

Known limitations

- Maximum information extraction definitions per instance: 100
- Maximum information extractions per contact with after-call work analytics rules: 20
- Maximum information extractions per contact with post-contact analytics rules: 20

Pricing

Information extraction is available in Amazon Connect Customer at no additional cost for voice and chat contacts.

Configure voice and chat information extraction

Configuring information extraction requires two steps:

- **Create information extraction definitions** – Define what information to extract from contacts
- **Create a rule with the Extract Information action** – Define when to trigger extraction for matching contacts

Step 1: Create information extraction definition

Extraction definitions are instance-level resources that define what to extract from a contact. However, they only take effect when you add them to a rule (Step 2).

To create an extraction definition

1. In the Connect Customer navigation pane, choose **Rules**.
2. On the **Rules** page, choose the **Information extraction** tab.
3. Choose **Create information extraction definition**.
4. Configure the information extraction criteria:

Field	Description
Name	The name of the information to extract. The name is included as input to the extraction process and appears as the label for the

Field	Description
	extracted information (unless you specify a display label). For example: `Reservation ID` or `Next steps promised`.
Display Label (optional)	The label for the extracted information. The display label is not used as input to the extraction process.
Prompt Hint	Provide contextual cues or guidelines to identify the specific information you want to extract. Example: `A reservation identifier should be six characters long and only include letters A-Z and digits 0-9.`
If information is not found	What to display when the information is not found in the contact. **Omit** hides the field entirely. **Replace with alternate word** to specify a fixed value (for example, "Not provided").

> **Tip**
>
> Do not over-engineer the **Prompt Hint** — prompt engineering is already handled by conversational analytics. Keep hints brief and descriptive.

5. Choose **Save**.

You can edit extraction definitions at any time. Changes apply to contacts processed after the edit.

Repeat this process for each piece of information you want to extract. You can create multiple extraction definitions and selectively use them in different rules.

Examples of verbatim information extraction criteria:

Name	Prompt hint
Preferred name	The name the customer used when introducing themself to the agent.
Invoice number	The unique identifier assigned to a specific invoice which starts with "I-", then a four-digit year, then "-", and then eight digits.

Name	Prompt hint
Reservation ID	The unique identifier assigned to a specific reservation and is comprised of six characters and only includes letters A-Z and digits 0-9.

Examples of derived information extraction criteria:

Name	Prompt hint
Reason for contact	The primary reason or issue that led the customer to contact the agent as stated by the customer at the start of the conversation.
Resolution provided	What actions did the agent take during the contact to address the customer's concerns or issues.
Next steps promised	What next steps, if any, that the agent told the customer would happen after the conversation.

Step 2: Create a rule with the Extract Information action

Rules are used to trigger the information extraction process. Add information extraction definitions to a rule to activate extraction for matching contacts.

To create a rule with information extraction

1. In the Connect Customer navigation pane, choose **Rules**.
2. Choose **Create a rule**, then select **Conversational analytics**.
3. For **When** (event source), choose one of the following:

Event source	When processed	Where results appear
After-call work analysis is available	During after-contact work.	CCP (Extracted Informati on widget), Contact details page

Event source	When processed	Where results appear
After chat analysis is available	During after-contact work.	Contact details page
Post-call analysis is available	After the contact is closed and after-contact work is complete.	Contact search, Contact details page
Post-chat analysis is available	After the contact is closed and after-contact work is complete.	Contact search, Contact details page

> **Note**
>
> If a post-contact analysis rule triggers an information extraction that was already completed by an after-call work analysis rule, the extraction is skipped and does not process a second time.

> **Note**
>
> Information extraction is not available for real-time call analysis or real-time chat analysis event sources.

4. Define your rule conditions. Choose **Next**.

> **Tip**
>
> If you want information extraction to occur on most contacts, set the condition to match on **Agents** or **Queues** rather than specific keywords. This provides broad coverage while still providing the flexibility to limit extraction to relevant contact types.

5. Under **Actions**, choose **Extract Information**.
6. Select the information extraction definitions to include in this rule. You can select multiple definitions.

7. (Optional) Add additional actions. Extracted information is available as injectable variables in the following actions:

   - **Send email** — Insert extracted information into the email subject or body.
   - **Create task** — Include extracted information in the task name or description.
   - **Create case** — Map extracted information to case fields.
   - **Send notification** — Include extracted information in notification messages.

   To insert extracted information, use the variable picker (or type `@`) and select from the available information names.

8. Choose **Save**.

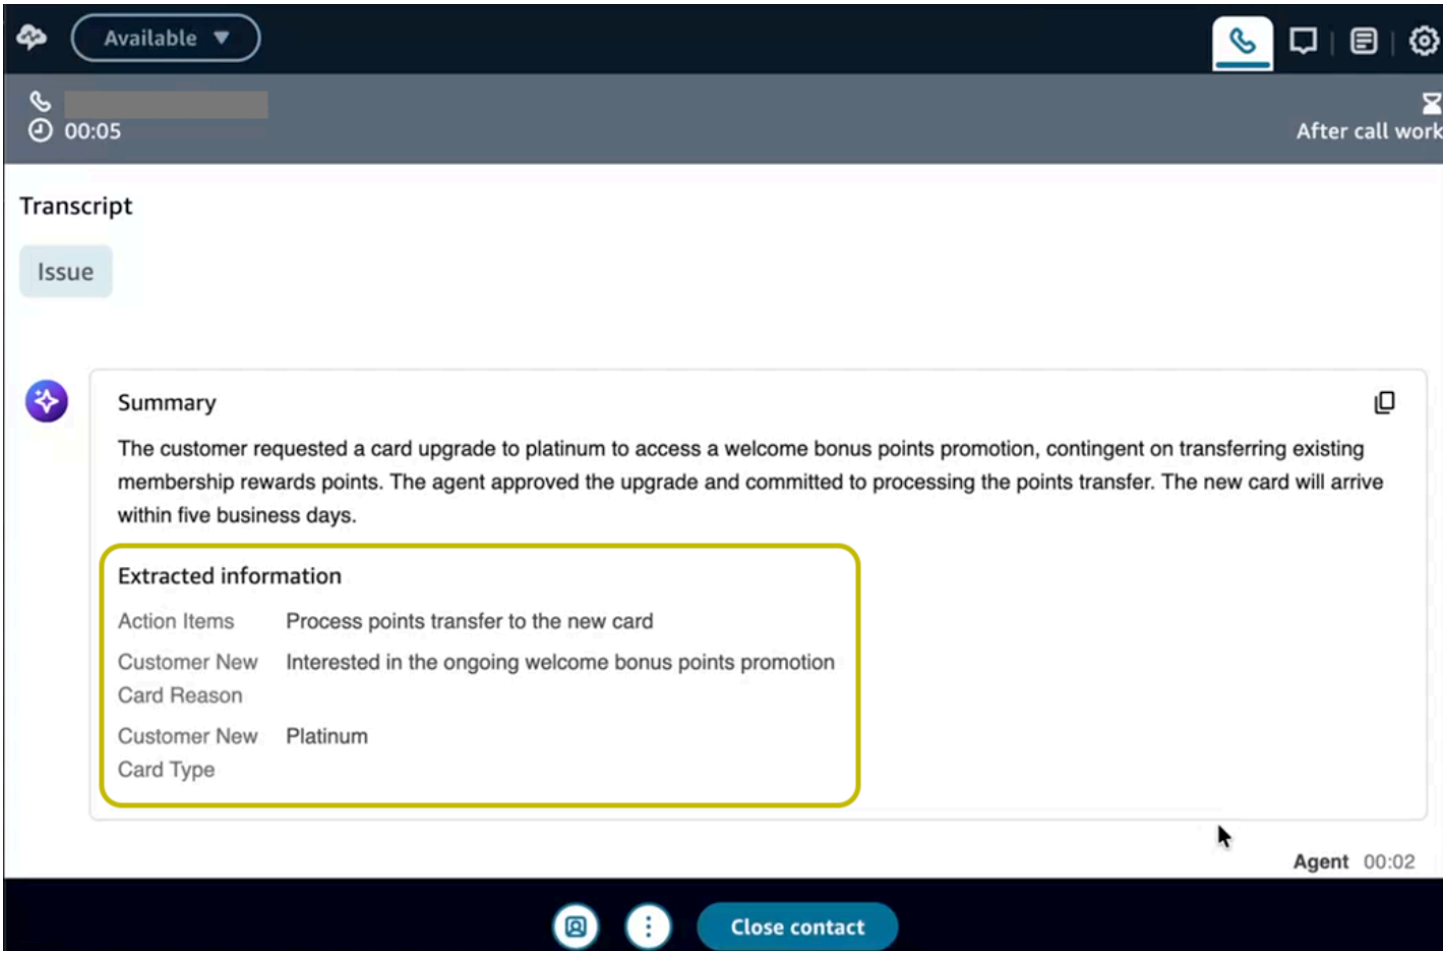
View extracted information

Extracted information appears in alphabetical order by display label, and is available in the following locations:

- **Contact Control Panel (CCP)** – During after-call work
- **Contact details page** – After the contact ends
- **Contact search** – Displayed in the contact search results table

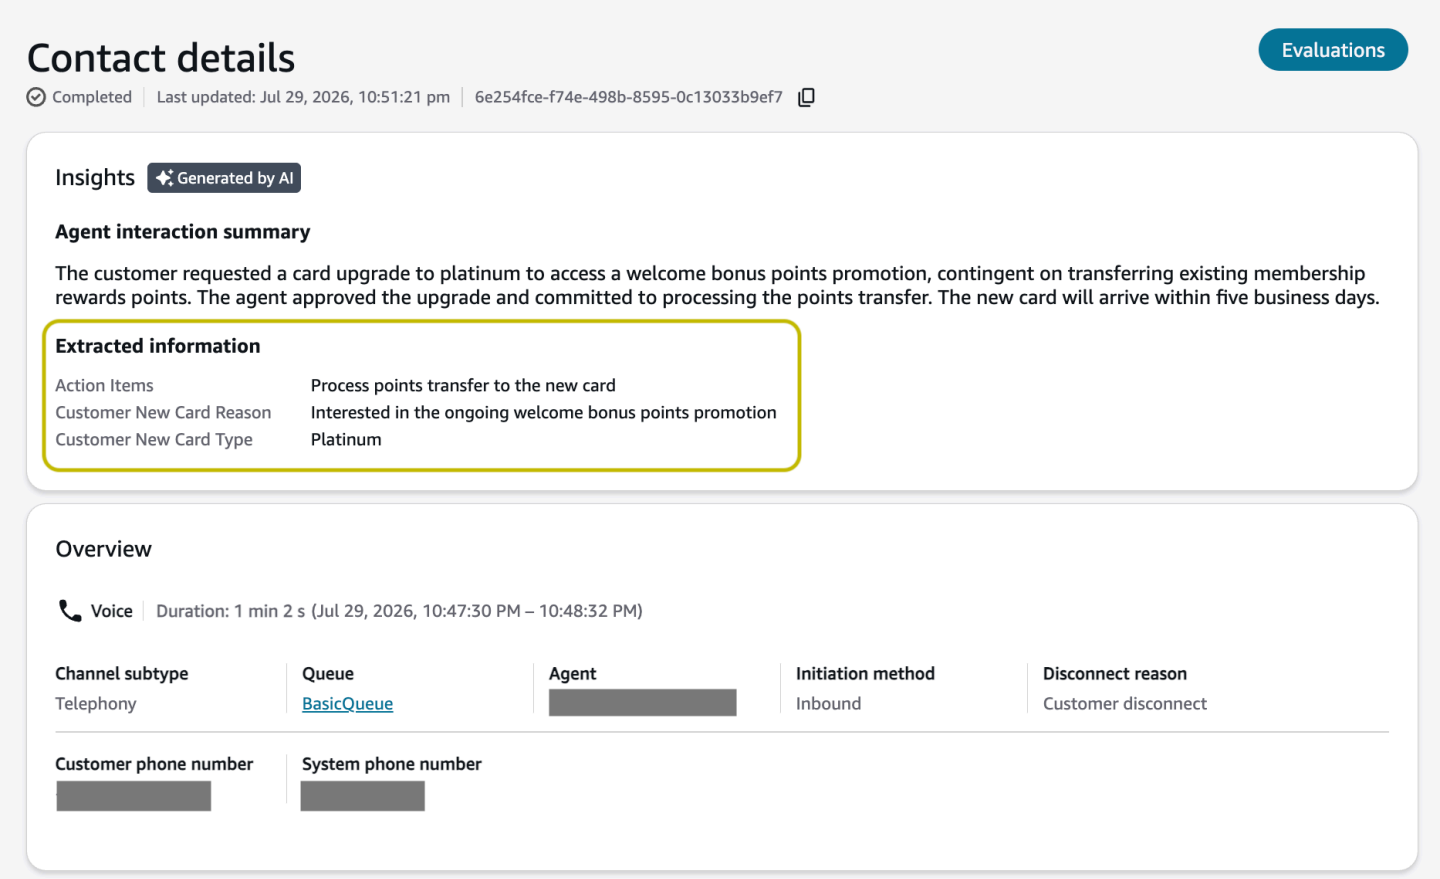
Contact Control Panel (CCP)

During the after-call work process, any information extracted with an ACW analysis event source is displayed in the **Extracted Information** widget in the CCP.



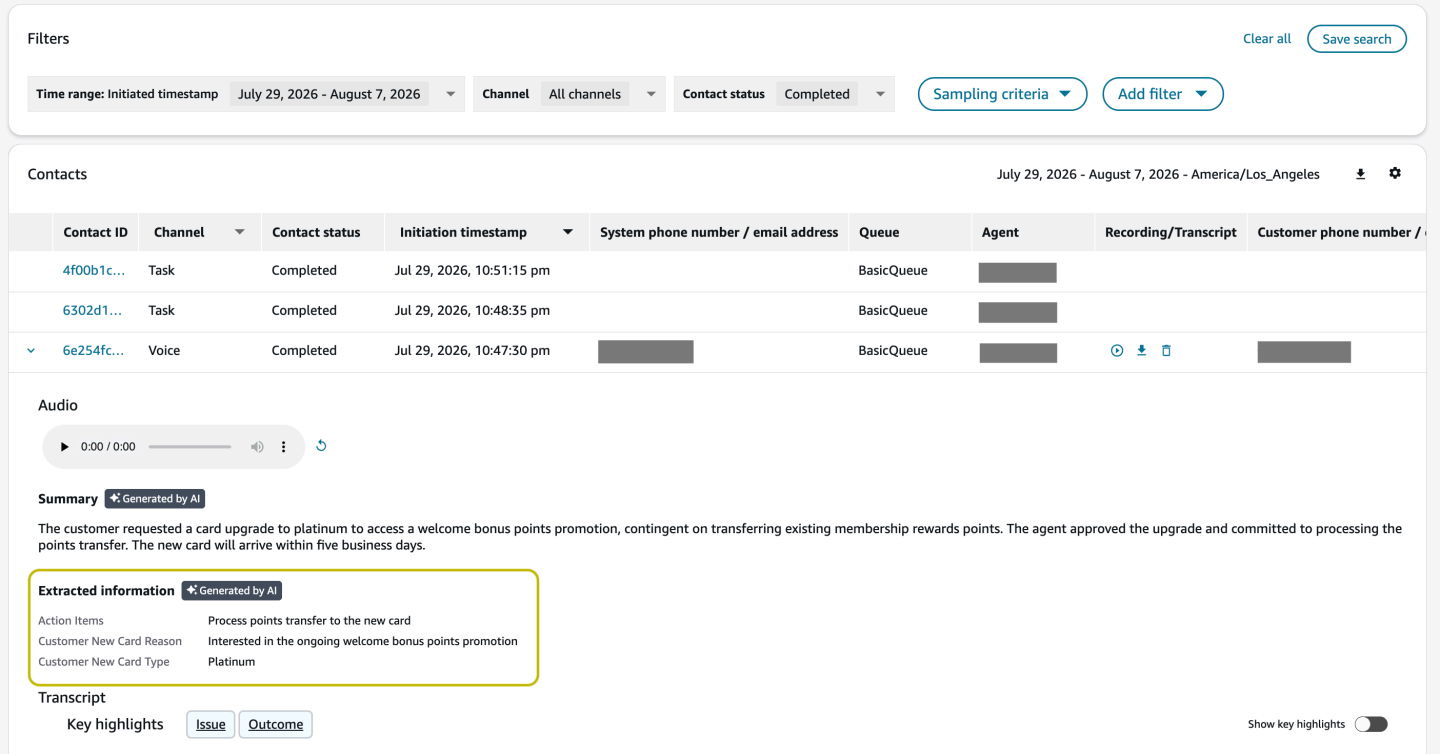
Contact details page

After the contact ends, all extracted information appears in the **Extracted Information** section of the **Contact details** page.



Contact search

Extracted information is displayed in the **Contact search** results table.



Errors

If information extraction fails with a runtime error, the failure is displayed similarly to a category error.

In the UI (Contact details page)

Failed extractions are displayed with dashed borders, transparent backgrounds, and an error icon. Pausing on a failed extraction shows why it failed.

In the S3 analysis output file

Failed extractions appear under `JobDetails.SkippedAnalysis` with the feature `INFORMATION_EXTRACTION` and a reason code:

```
"SkippedAnalysis": [
    {
        "Feature": "INFORMATION_EXTRACTION",
        "ReasonCode": "QUOTA_EXCEEDED",
        "SkippedEntities": [
            { "ExtractionName": "Flight Number", "RuleId": "a113..." }
        ]
    },
```

```
    {
        "Feature": "INFORMATION_EXTRACTION",
        "ReasonCode": "FAILED_SAFETY_GUIDELINES",
        "SkippedEntities": [
            { "ExtractionName": "Credit Card Type", "RuleId": "cccc..." }
        ]
    }
]
```

Common failure reasons

Reason code	Meaning
QUOTA_EXCEEDED	The AI actions service quota was exceeded at the time of execution.
FAILED_SAFETY_GUIDELINES	Extraction processing did not satisfy security or quality guardrails.
FEATURE_UNAVAILABLE	The instance is an Amazon Connect Customer Basic instance, which does not support information extraction.
SYSTEM_ERROR	An unexpected system error occurred during extraction.

Programmatic access to extracted information

Extracted information can be accessed programmatically through the following channels:

- **Amazon S3** – Contact analysis output files (after-call work and post-contact processing)
- **API** – Real-time contact analysis segments (after-call work only)
- **Amazon Kinesis** – Real-time event delivery (after-call work only)

Extracted information in Amazon S3

Extracted information is included in the contact analysis output written to Amazon S3. This includes information extracted during after-call work and during post-contact processing.

The following is an example of the extracted information structure in the JSON output:

```
{
  "ExtractedInformation": {
    "Extractions": [
      {
        "Name": "Flight number",
        "DisplayLabel": "Flight #",
        "Value": "XX123",
        "PointsOfInterest": [
          {
            "BeginOffsetMillis": 15230,
            "EndOffsetMillis": 18450
          }
        ]
      },
      {
        "Name": "Next steps promised",
        "Value": "Refund to be processed within 7 days",
        "PointsOfInterest": [
          {
            "BeginOffsetMillis": 19010,
            "EndOffsetMillis": 22690
          }
        ]
      }
    ]
  }
}
```

Each extraction includes:

- **Name** — The extraction definition name.
- **DisplayLabel** — The display label, if configured.
- **Value** — The extracted information from the contact.
- **PointsOfInterest** — The timestamp offsets in the recording where the information was mentioned (voice contacts only).

Extracted information through API

You can retrieve extracted information generated during after-call work programmatically using the following APIs:

- **ListRealtimeContactAnalysisSegments** — Returns extracted information segments for **voice** contacts during after-contact work.
- **ListRealtimeContactAnalysisSegmentsV2** — Returns extracted information segments for **chat** contacts during after-contact work.

Extracted information through Amazon Kinesis

If your Connect Customer instance is configured to send conversational analytics to Amazon Kinesis Data Streams, extracted information events generated during after-call work are delivered to your Kinesis stream as they are produced.

For more information, refer to Use streaming for contact analysis.

Evaluate agent and self-service interaction performance in Connect Customer

> **Tip**
>
> **New user?** Check out the Connect Customer Contact Lens Workshop. This online course includes guidance on creating evaluation forms.
> **IT administrators**: To enable Connect Customer evaluation capabilities, navigate to the Connect Customer console, choose your instance alias, choose **Data storage**, **Content evaluations**, **Edit**. You'll be prompted to create or choose an S3 bucket. After the bucket is created, you can store evaluations and export them.

With Connect Customer performance evaluations, you can define custom performance evaluation criteria to assess, monitor and improve how agents and automated systems (bots, AI agents) interact with customers and resolve issues. You can then monitor performance by reviewing aggregated insights in dashboards, and drill-down into individual contacts where you can see evaluations alongside recordings, transcript, conversation summaries and analytics in a single view. With integrated coaching, you can provide feedback to agents highlighting their strengths and opportunities to improve.

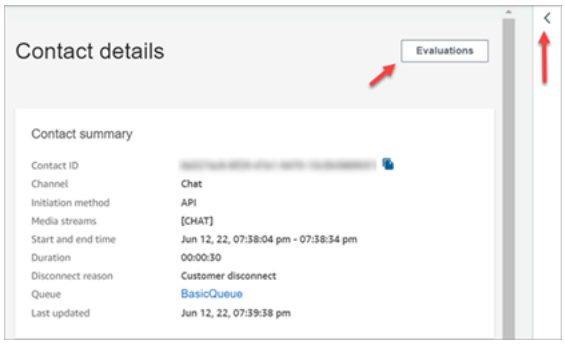
You can perform manual evaluations for all contact types (voice, chat, email, and task). You can perform automated interactions for voice and chat contacts analyzed by Connect Customer conversational analytics. You can perform automated evaluations of both agent interactions and

automated interactions (handled by bots or AI agents). For more details on automated evaluations, see Step 6: Enable automated evaluations.

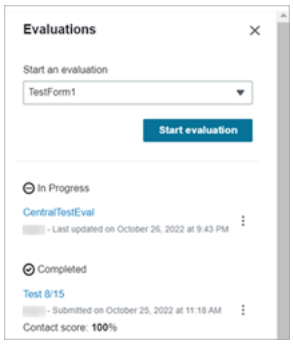
To perform manual evaluations, you can search for a contact, choose the appropriate evaluation form, review the contact audio, screen recording or transcript, and then evaluate how the human, AI agent, or bot interacted with the customer. You can then use those insights to improve the customer experience by providing agent coaching feedback and optimizing bots, AI agents and self-service workflows.

To evaluate performance

1. Log in to Connect Customer with a user account that has permissions to perform evaluations.
2. Access the contact that you want to evaluate. There are a few ways you can do this. For example, someone might have shared the contact URL with you, or assigned you a task that has the URL. Or, you might have the contact ID, which you can use to search for the contact record by doing the following: on the navigation pane, choose **Analytics and optimization**, **Contact search**, and then search for the contact that you want to evaluate.
3. On the **Contact details** page, choose **Evaluations** or the **<** icon.

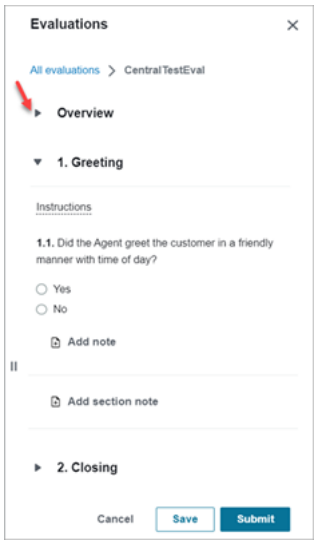


4. The **Evaluations** panel lists any evaluations that are in progress or completed for the contact.

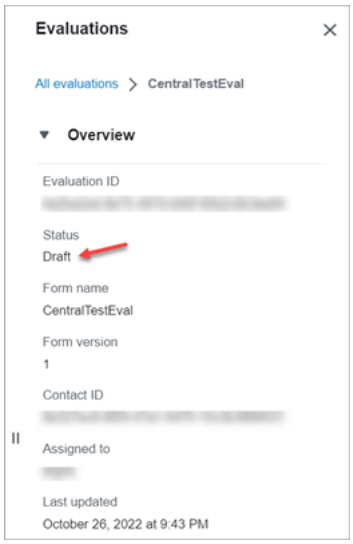


5. To start an evaluation, choose an evaluation form from the dropdown menu, and then choose **Start evaluation**. If you have not set up an evaluation form yet, then you will need to do so beforehand. For more information, see Create an evaluation form.

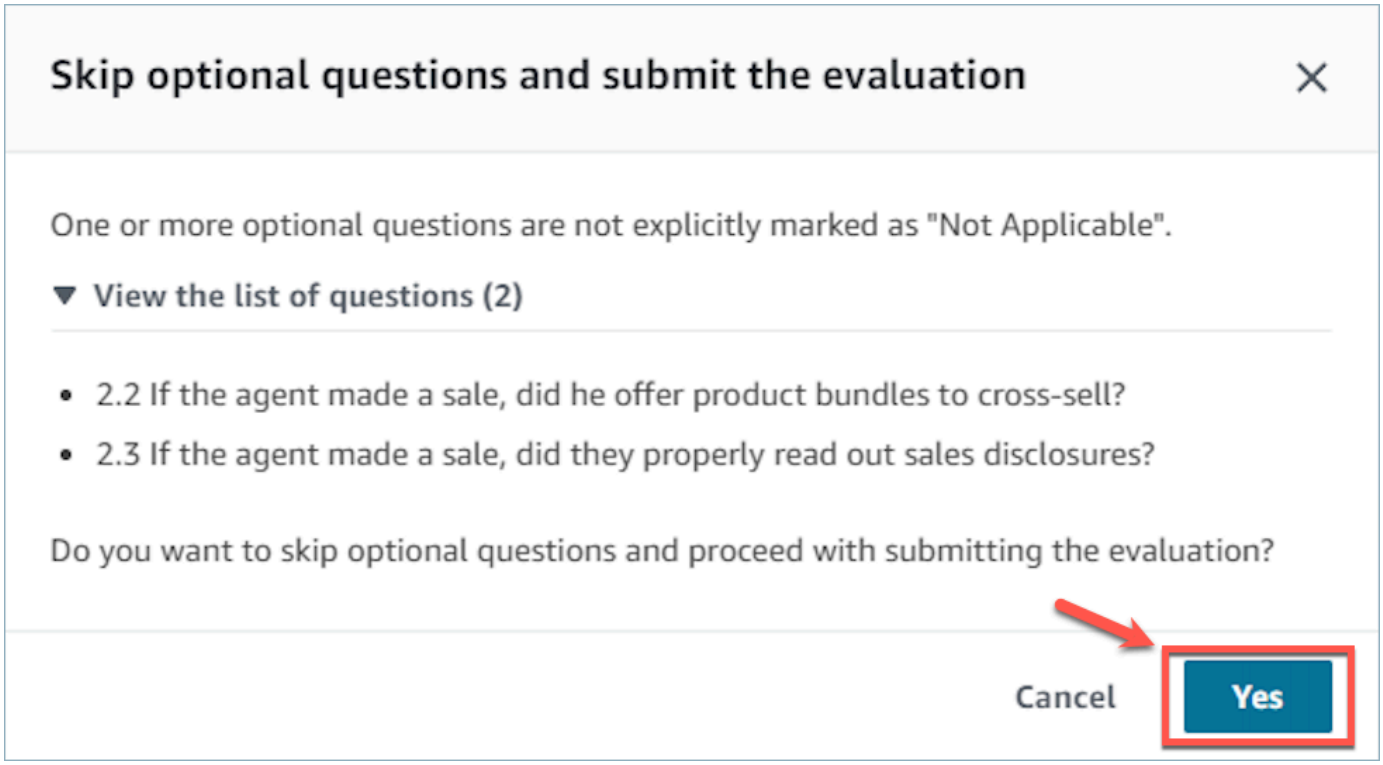
6. To navigate an especially long evaluation form, use the arrows next to each section to collapse or expand it.



7. Choose **Save** to save a form in progress. The status of the form becomes **Draft**. You can return to it any time to continue, or you can delete it and start over.



8. When you're done, choose **Submit**. If you have skipped optional questions in the form, you will see a warning asking you to confirm that you want to submit the evaluation. Choose **Yes**. The evaluation is now **Completed**.



Assign security profile permissions for performance evaluations and coaching

To allow users to create, automate, and access evaluation forms, assign the following **Analytics and optimization** security profile permissions:

- **Evaluation forms - manage form definitions**: Allows admins and managers to create and manage evaluation forms.
- **Evaluation forms - perform contact evaluations**: Allows a user, such as a Quality Assurance team member, to use an evaluation form to review a contact. For an example image, see Evaluate agent and self-service interaction performance in Connect Customer.

  This permission allows users to search evaluations by evaluation form, score, last updated date/range, evaluator, and status. It also allows them to view the evaluation form audit trail.

  - **View** permission enables users to view submitted evaluations. This permission enables users to see evaluations on any contacts they have access to (unless restricted by tag-based access control). You can grant this permission to users who perform evaluations (such as managers).
  - **Create** permission enables users to create new evaluations, view and edit draft evaluations.
  - **Edit** permission enables users to edit submitted evaluations.

  - **Delete** permission enables users to delete both draft and submitted evaluations.
- **Evaluation forms - view my received evaluations**: Allows agents to search for and view completed evaluations that they have received. This does not grant access to evaluations in draft, under review or part of calibrations. Access to an evaluation will be subject to tag-based access control .
- **Rules**: Permissions to create, view, edit, and delete rules are required to automatically categorize contacts based on certain agent behaviors and customer outcomes. These contact categories can be used to configure automation on evaluation forms. In addition, rules permissions are needed to create a rule to submit automated evaluations.
- **Evaluation forms - ask AI assistant**: Provides access to the **Ask AI** button while performing evaluations. With the **Ask AI** button, you can get generative AI-powered recommendations for answers to questions in evaluation forms.
- **Evaluation forms - manage calibration sessions**: Allows admins to create and manage calibration sessions to drive consistency and accuracy in how managers evaluate agent performance.
- **Sample contacts**: Allows managers to randomly sample agents' contacts for evaluation. For example, a manager can select all agents in his hierarchy, and get 5 random contacts per agent from the last week for evaluation.

To allow users to manage or access coaching sessions, assign the following **Analytics and optimization** security profile permissions:

- **Coaching - my coaching sessions**: Access coaching sessions where you are assigned as a coach or a participant.
  - **View**: View coaching sessions where you are the coach or the participant. If you are the participant, you can acknowledge the coaching session with this permission.
  - **Create**: Create new coaching sessions with yourself as the coach.
  - **Edit**: Edit coaching sessions where you are the coach.
  - **Delete**: Delete coaching sessions where you are the coach.
- **Coaching - manage coaching sessions**: Access coaching sessions performed by yourself or others. This permission is for admins or quality managers.
  - **View**: View any coaching session.
  - **Create**: Create new coaching sessions. You can choose yourself as the coach or assign other users as the coach.

- **Edit**: Edit any coaching session.
- **Delete**: Delete any coaching session.

- **Contact Search - View** and **Evaluation forms - perform evaluations - View** permissions: Receive automated suggestions of evaluations to coach on after selecting a specific evaluation criteria as a coaching topic.

The **Admin** security profile has these permissions by default.

For information about how to add more permissions to an existing security profile, see Update security profiles in Connect Customer.

View an evaluation audit trail in Connect Customer

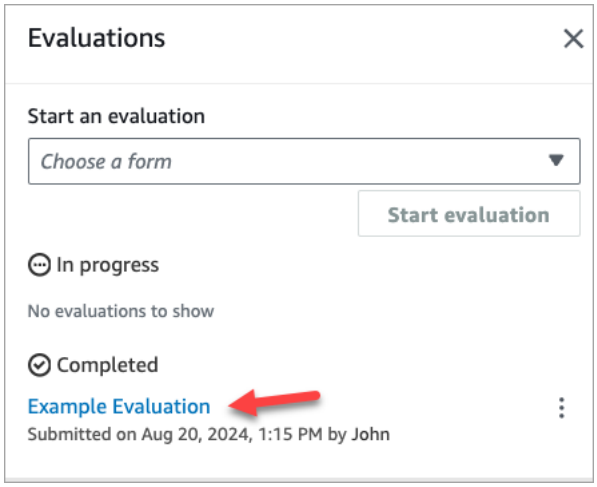
An evaluation can be amended and submitted multiple times. When an evaluator submits changes to an existing evaluation, managers can view an audit trail that records:

- Who submitted the original evaluation
- Who re-submitted the evaluation
- What changes they made (for example, changing answers or answer notes in an evaluation)

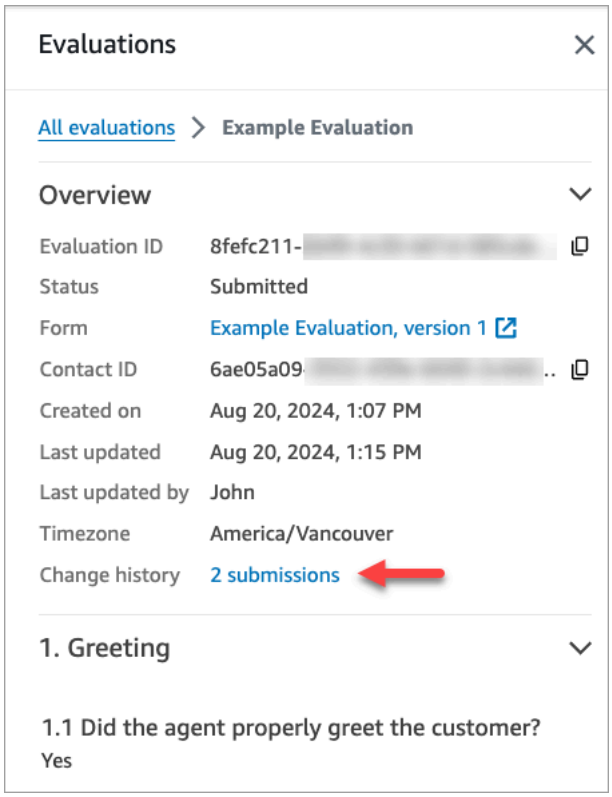
Contact center managers can use this information to perform internal audits and uncover opportunities to improve consistency across evaluators.

To view an evaluation audit trail

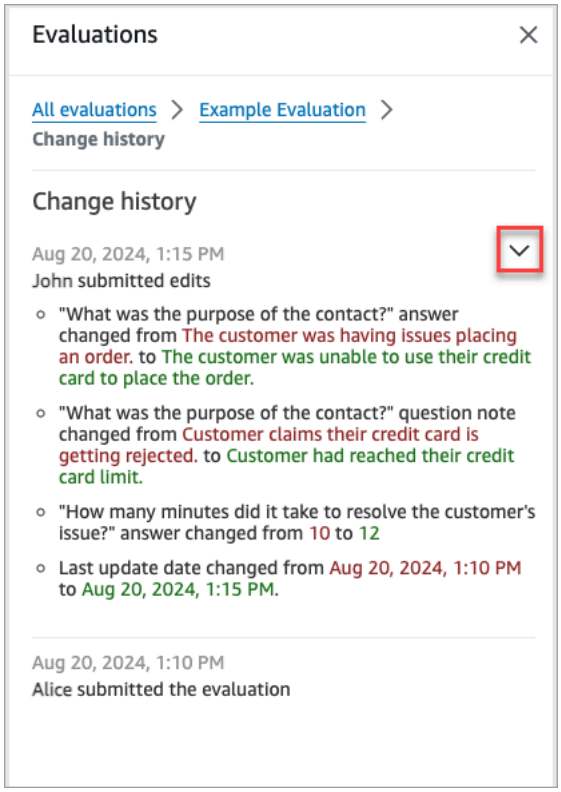
1. Log into Connect Customer with a user account that has **Analytics and optimization - Evaluation forms - perform evaluations** permission on their security profile.
2. Access a contact with an evaluation that was edited after it was submitted.
3. Choose the evaluation you want to investigate. The following image shows the **Evaluations** page with a link to a completed evaluation.



4. The **Overview** section of the evaluation contains **Change history**. It indicates the number of times the evaluation has been submitted. Choose the link as shown in the following image.



5. You can view the audit trail of subsequent submissions after the initial submission. Choose the arrow next to a re-submission to view details of the edits. The following image shows an example of an audit trail of the edits that were made to an evaluation after it was submitted.



Create an evaluation form in Connect Customer

In Connect Customer, you can create many different evaluation forms. For example, you might need a different evaluation form for each business unit, and for different queues. You can also create different evaluation forms for evaluating the agent interaction and the self-service interaction with a Lex bot or AI agent.

Each form can contain multiple sections and questions.

- You can assign weights to each question and section to indicate how much their score impacts the overall score of the evaluation form.
- You can configure automation on each question so that answers to those questions are automatically filled using insights and metrics from conversational analytics.

This topic explains how to create a form and configure automation using the Connect Customer admin website. To create and manage forms programmatically, see Evaluation actions in the *Connect Customer API Reference*.

Contents

- Step 1: Create an evaluation form
  - Create a form from a sample template
  - Import an evaluation form from a PDF using AI
  - Create a blank form and set a title
  - Import an evaluation form from another instance
- Step 2: Add sections and questions
- Step 3: Add answers
- Step 4: Conditionally enable questions
- Step 5: Assign scores and ranges to answers
  - Step 5.1: Percentage-based scoring
  - Step 5.2: Point-based scoring
  - Step 5.3: Assign performance thresholds
- Step 6: Enable automated evaluations
  - Choose a Gen AI model version for automated evaluations
- Step 7: Preview the evaluation form
- Step 8: Assign weights for final score
  - Weight distribution mode
- Step 9: Validate the evaluation form
- Step 10: Activate an evaluation form

Before you begin, make sure you have the required security profile permissions. For more information, see Assign security profile permissions for performance evaluations and coaching.

Step 1: Create an evaluation form

There are several ways to create an evaluation form. Choose the method that best fits how you work — each method opens the form in the editor, where you can refine it to fit your needs, then preview, validate, and activate it:

- **Sample form** – Start from a pre-built template whose sections, questions, scoring, and automation are already configured, including questions mapped to business outcomes. See Create a form from a sample template.

- **Import from a PDF using AI** – Migrate a form from another quality management system by uploading a PDF. See Import an evaluation form from a PDF using AI.
- **Blank form** – Build a form from scratch, adding every section, question, and score yourself. See Create a blank form and set a title.
- **Import from another instance** – Copy a form between Connect Customer instances (for example, from a test instance to a production instance) using JSON. See Import an evaluation form from another instance.

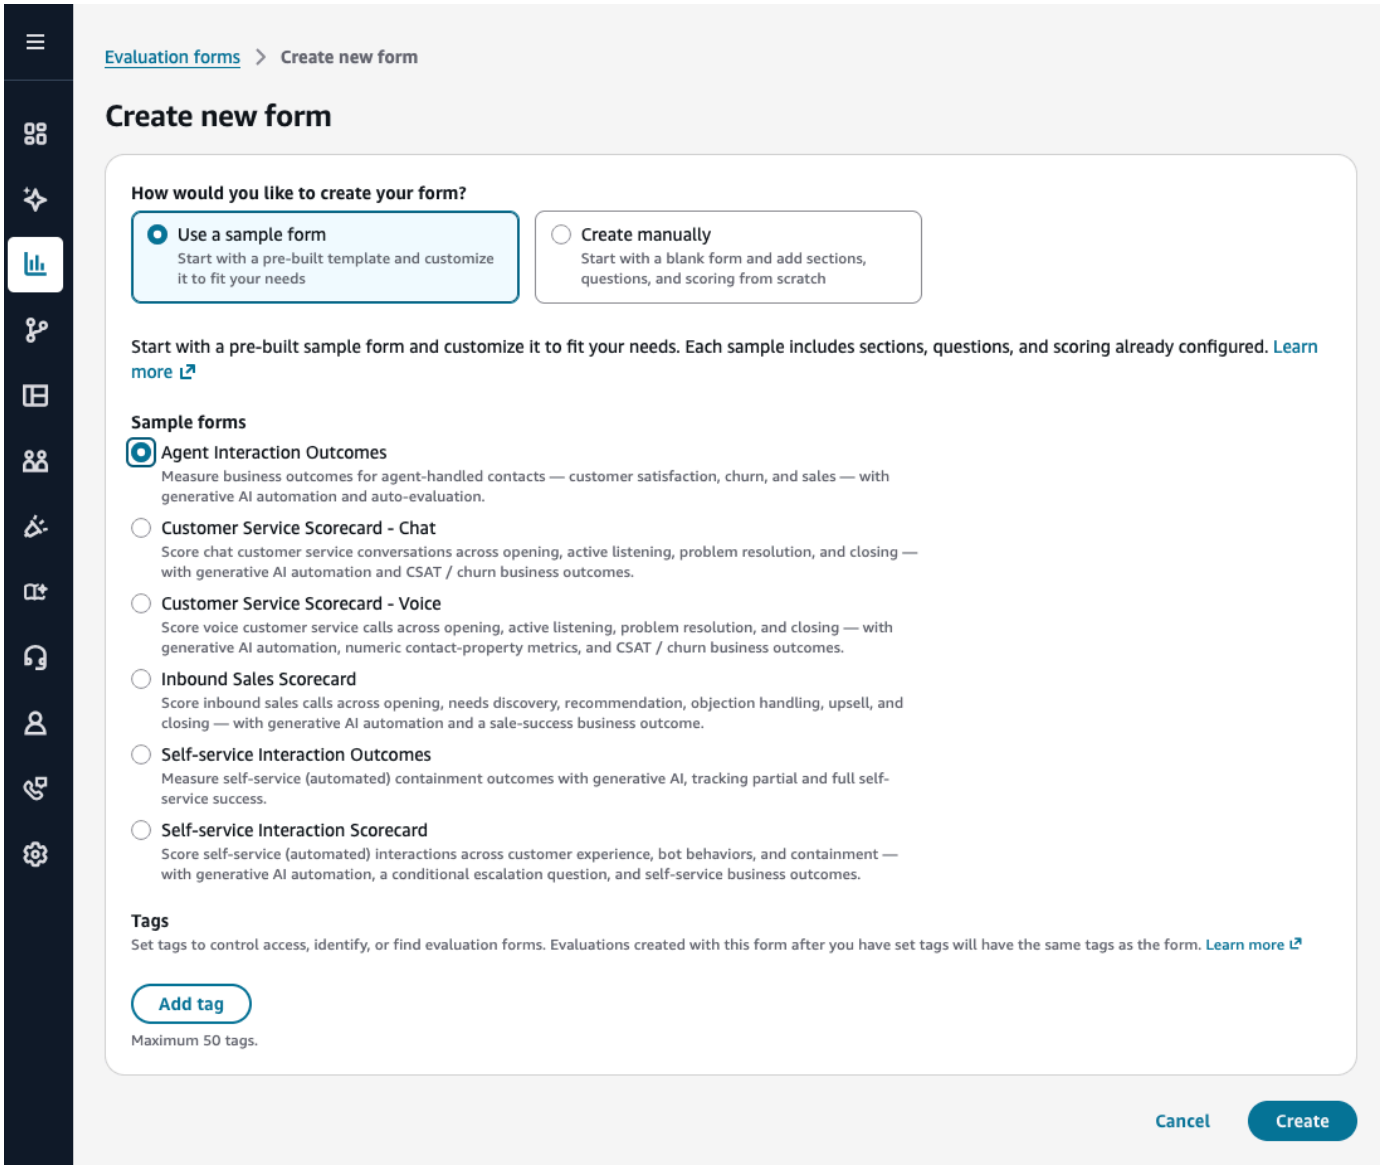
Whichever method you choose, start by navigating to the **Evaluation forms** page:

1. Log in to Connect Customer with a user account that has the following security profile permission: **Analytics and Optimization** - **Evaluation forms - manage form definitions** - **Create**.
2. Choose **Analytics and optimization**, then choose **Evaluation forms**.

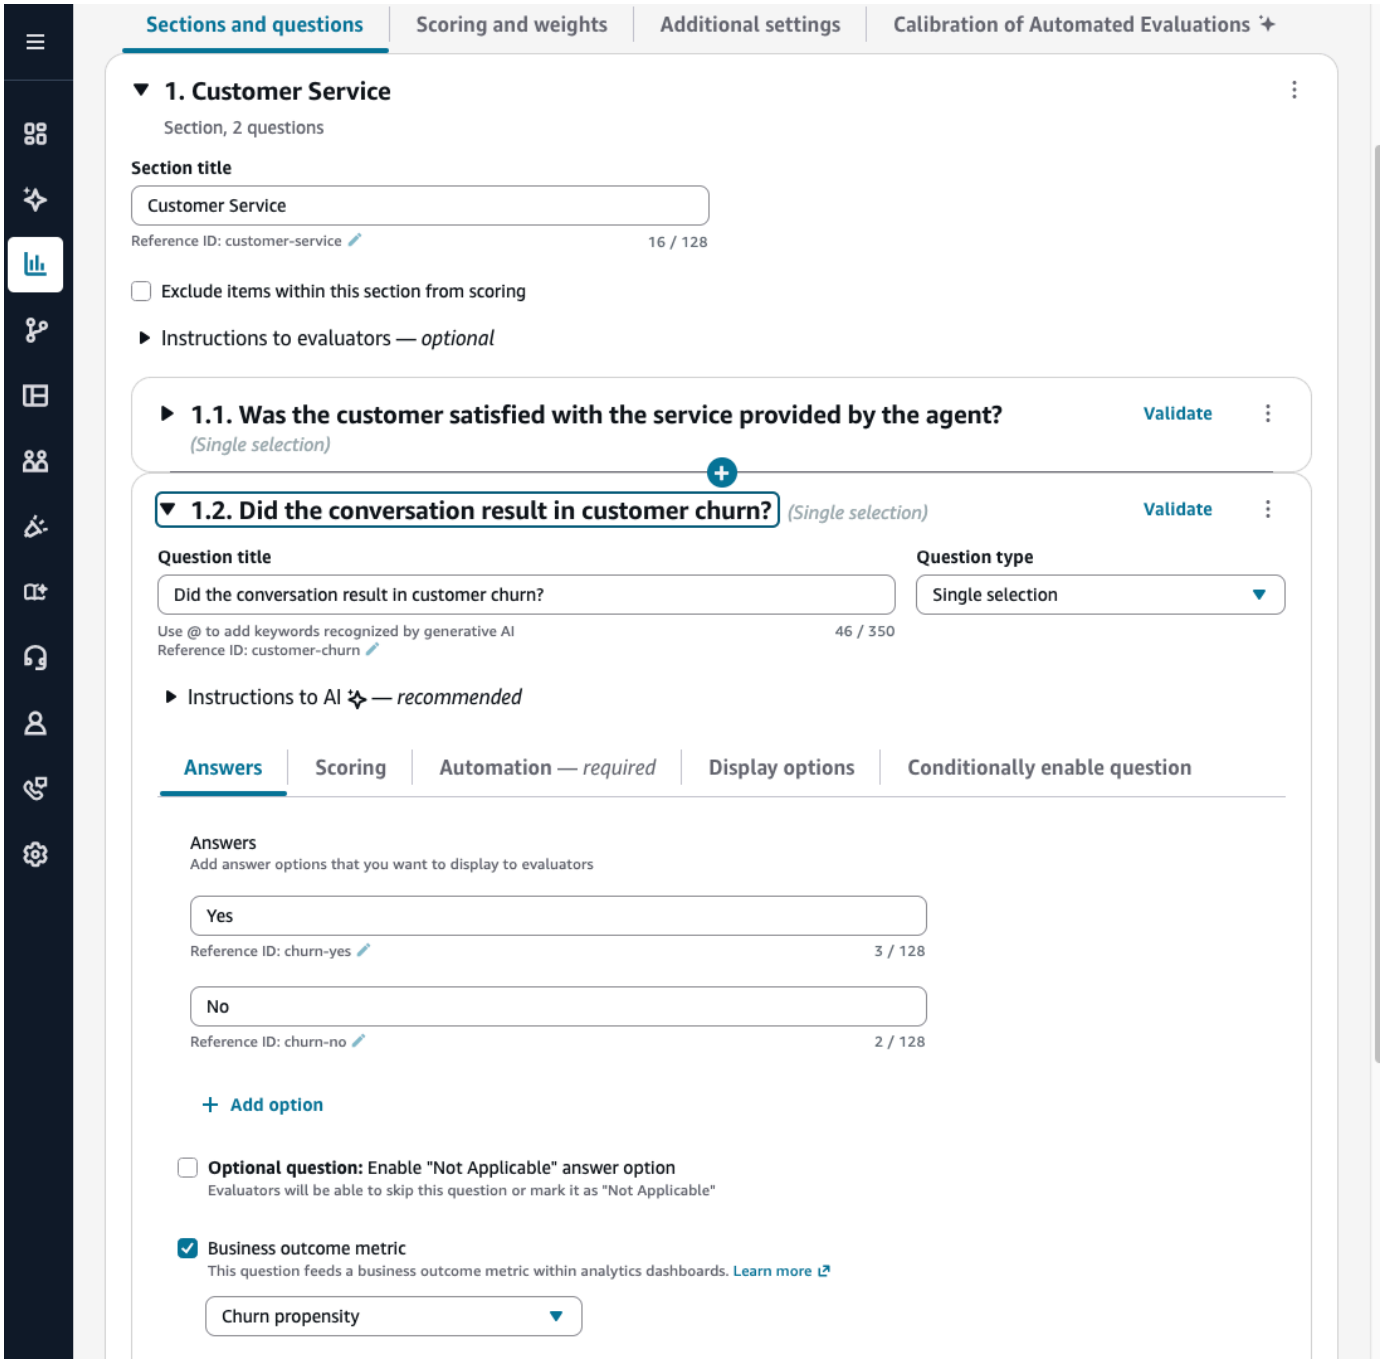
Create a form from a sample template

Start from a sample form — a pre-built template with sections, questions, answers, scoring, and automation already configured. Sample forms cover both agent-handled and self-service interactions, and include questions that map to standard business outcomes so you can measure them without building the scoring from scratch.

1. On the **Evaluation forms** page, choose **Create new form**.
2. Choose **Use a sample form**, then select a template, such as **Agent Interaction Outcomes**. (Optional) Add tags to control access to the form. Choose **Create**.



The form opens fully configured. Its sections, questions, and scoring are already set up, and questions that measure a business outcome are flagged as a **Business outcome metric**.



3. Review the form and edit it as needed. Because a sample form is already fully configured, you can typically skip ahead to Step 7: Preview the evaluation form.

A business outcome metric maps an evaluation question to a standard, normalized outcome. Sample forms use five industry-standard outcome metrics: customer satisfaction (CSAT), churn propensity, and successful sale for agent-handled interactions, and full and partial self-service

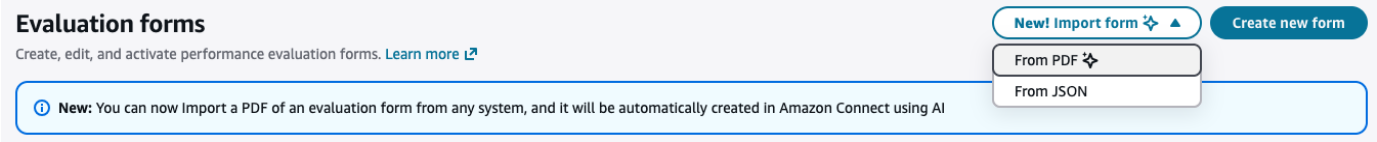
success for self-service interactions. These outcomes roll up into analytics dashboards, where they are summarized across evaluations and broken down by agent.

Import an evaluation form from a PDF using AI

You can import an evaluation form from any quality management system by uploading a PDF. Connect Customer uses AI to extract the sections, questions, answer options, and scoring from the PDF and create a draft evaluation form that you can review and edit.

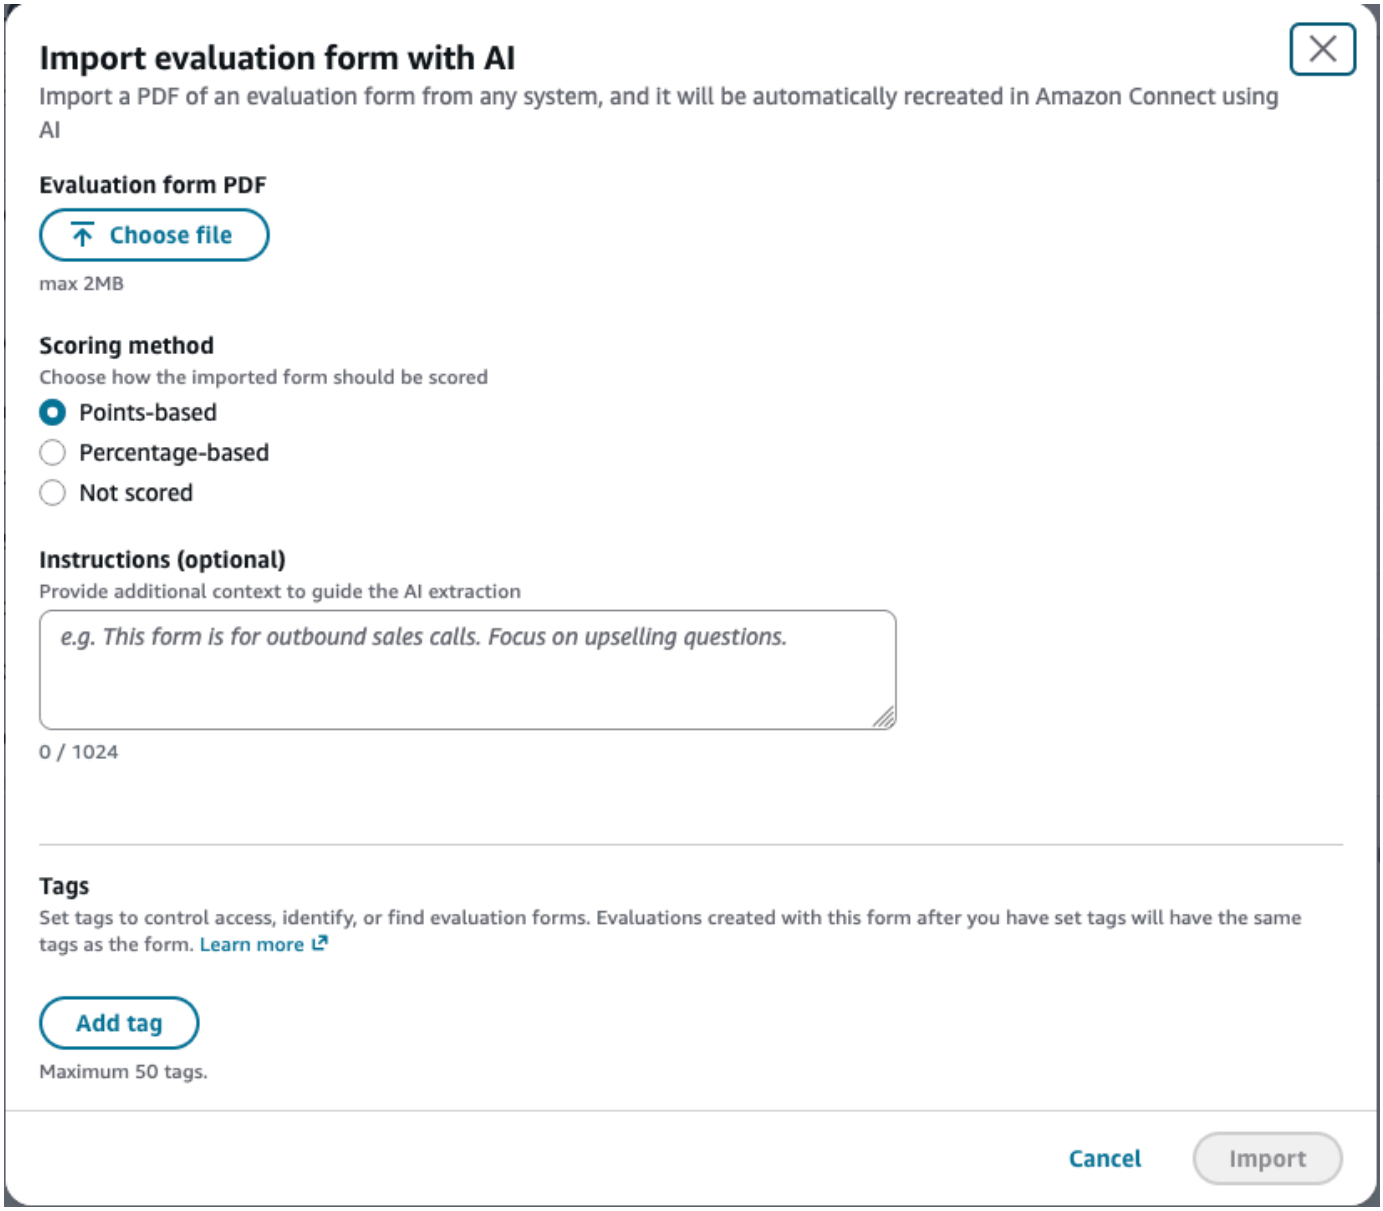
1. On the **Evaluation forms** page, choose **Import form**, then choose **From PDF**.

   The following image shows the **Import form** menu with the **From PDF** option.



2. In the **Import evaluation form with AI** dialog:

   - **Evaluation form PDF** – Choose a PDF file (max 2 MB).
   - **Scoring method** – Choose **Points-based**, **Percentage-based**, or **Not scored**.
   - **Instructions (optional)** – Provide context to guide the extraction, for example: "This form is for outbound sales calls. Focus on upselling questions."



3. Choose **Import**. The import typically completes within one minute.
4. After the import completes, the form appears as a draft. Open it to review that the sections, questions, and scoring were extracted correctly.
5. Edit the form as needed, then activate it.

Create a blank form and set a title

The following steps explain how to create a blank evaluation form (or duplicate an existing form) and set a title, then build it up using the remaining steps in this topic.

1. On the **Evaluation forms** page, choose **Create new form**, choose **Create manually**, and then choose **Create**.

   —or—

   Select an existing form and choose **Duplicate**.

2. Enter a title for the form, such as *Sales evaluation*, or change the existing title. Add any tags to the form for controlling access to the form (see Set up tag-based-access controls on performance evaluations) When finished, choose **Ok**.

   The following tabs appear at the top of the evaluation form page:

   - **Sections and questions**. Add sections, questions, and answers to the form.
   - **Scoring**. Enable scoring on the form. You can also apply scoring to sections or questions.

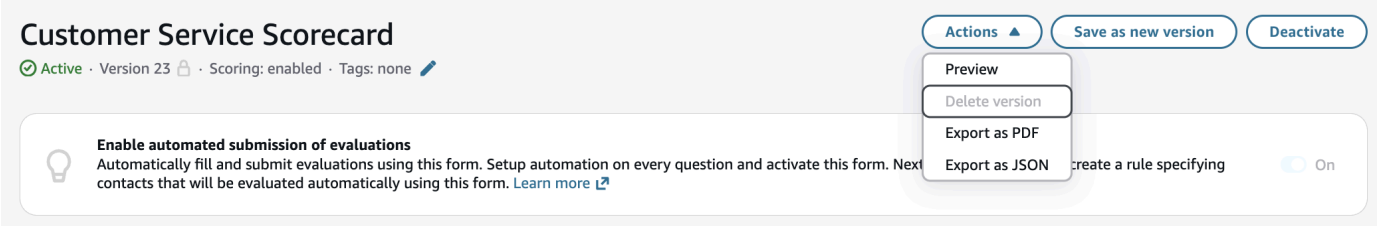
3. Choose **Save** at any time while creating your form. After you save, you can navigate away from the page and return to the form later.
4. Continue to the next step to add sections and questions.

Import an evaluation form from another instance

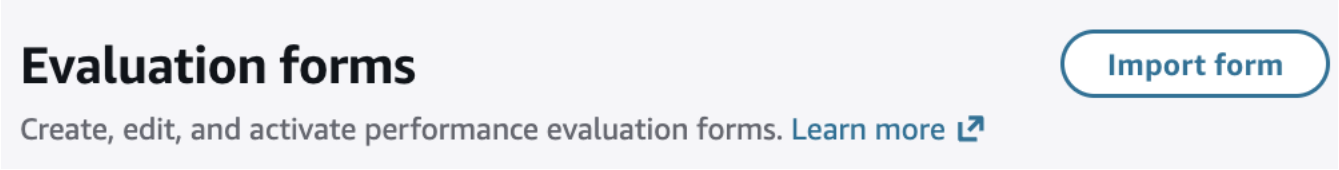
You can export an evaluation form from one Connect Customer instance (say a test instance) and import it into another instance (say a production instance).

To import an evaluation form from JSON

1. While viewing an existing evaluation form, choose **Actions**, **Export as JSON**.



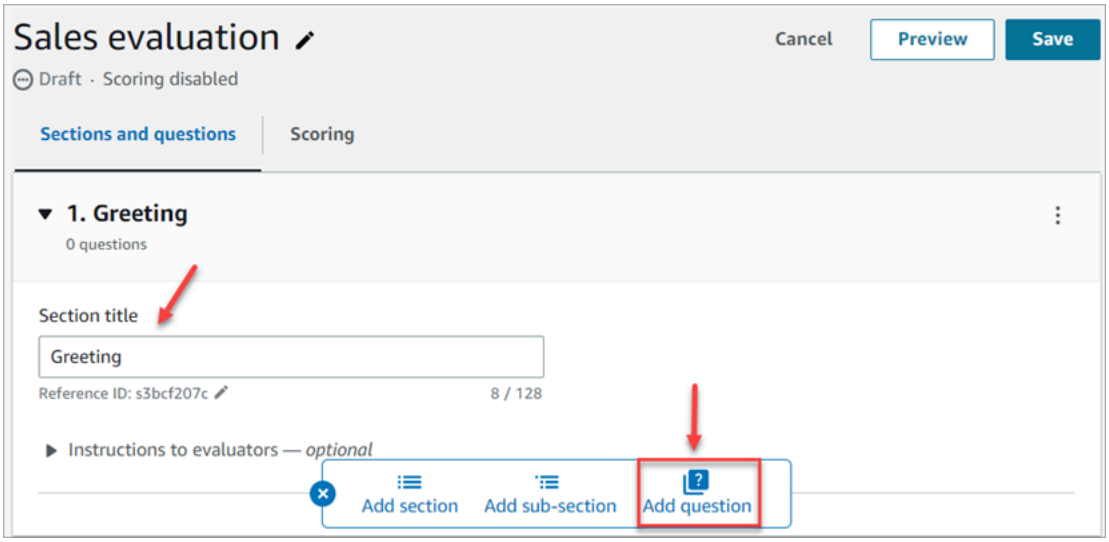
2. Open the instance where you want to import this form.
3. On the **Evaluation forms** page, choose **Import form**. Choose **Choose File** to upload the previously exported JSON, then choose **Import**.



The form is created including questions, instructions, answers, scoring, and automation configuration. Instance-specific settings such as rule categories and tags are not present in the exported file.

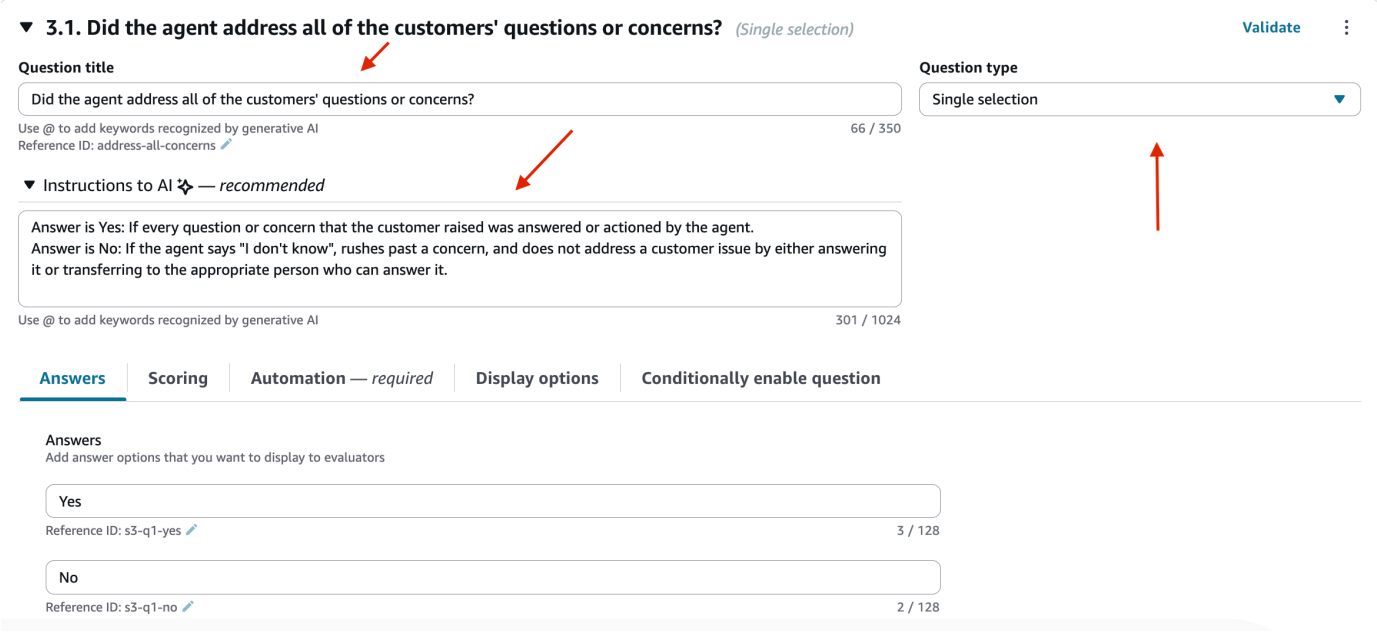
Step 2: Add sections and questions

1. While on the **Sections and questions** tab, add a title to the section 1, for example, *Greeting*.



2. Choose **Add question** to add a question.

3. In the **Question title** box, enter the question that will appear on the evaluation form. For example, *Did the agent address all of the customer's questions or concerns?*



4. In the **Instructions to evaluators** box, add information to help the evaluators or generative AI to answer the question.

   For example, for the question *Did the agent try to validate the customer identity?* you might provide additional instructions such as, *The agent is required to always ask a customer their membership ID and postal code before addressing the customer's questions*.

5. In the **Question type** box, choose one of the following options to appear on the form:

   - **Single selection**: The evaluator can choose from a list of options, such as **Yes**, **No**, or **Good**, **Fair**, **Poor**.
   - **Multiple selection**: The evaluator can choose multiple answers from a list of options, such as list of products that the customer was interested in purchasing, or non-compliant agent behaviours.
   - **Text field**: The evaluator can enter free form text.
   - **Number**: The evaluator can enter a number from a range that you specify, such as 1-10.
   - **Date**: The evaluator can choose a date as an answer.

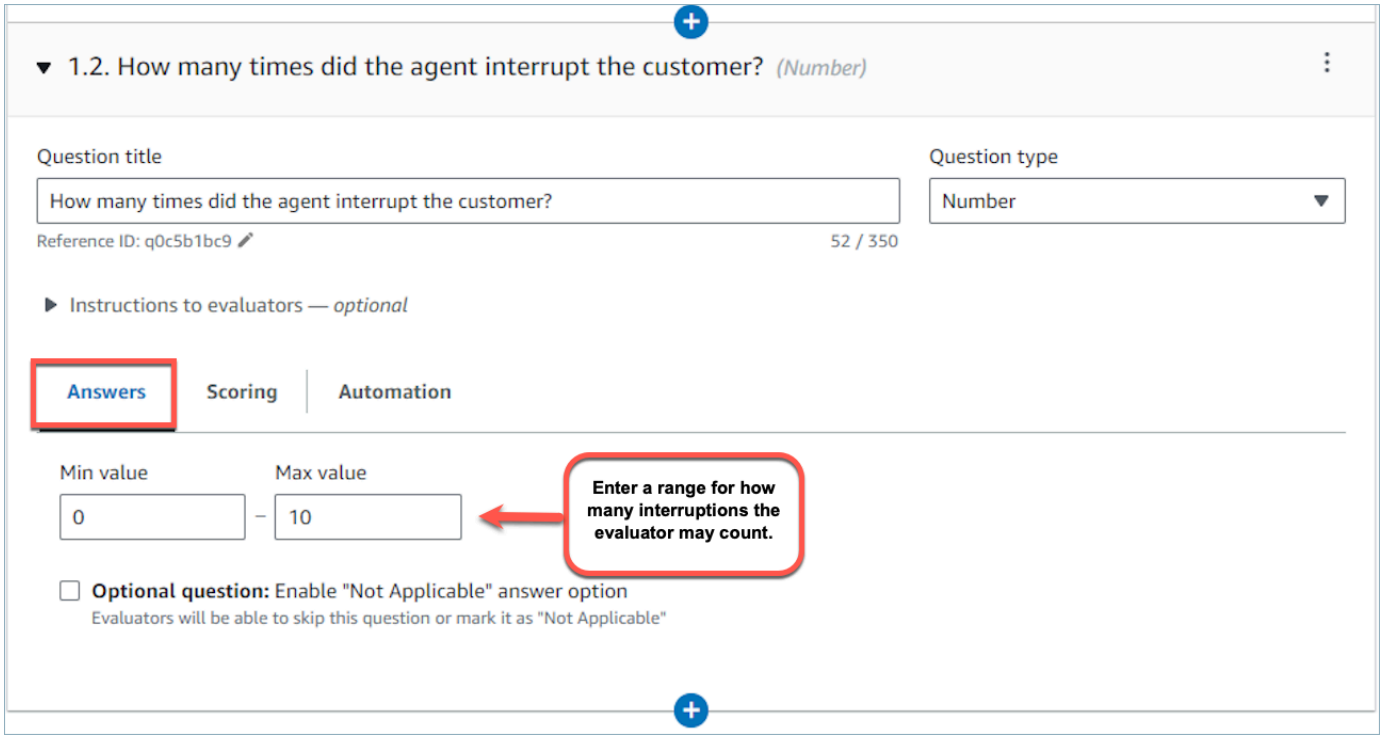
6. Continue to the next step to add answers.

Step 3: Add answers

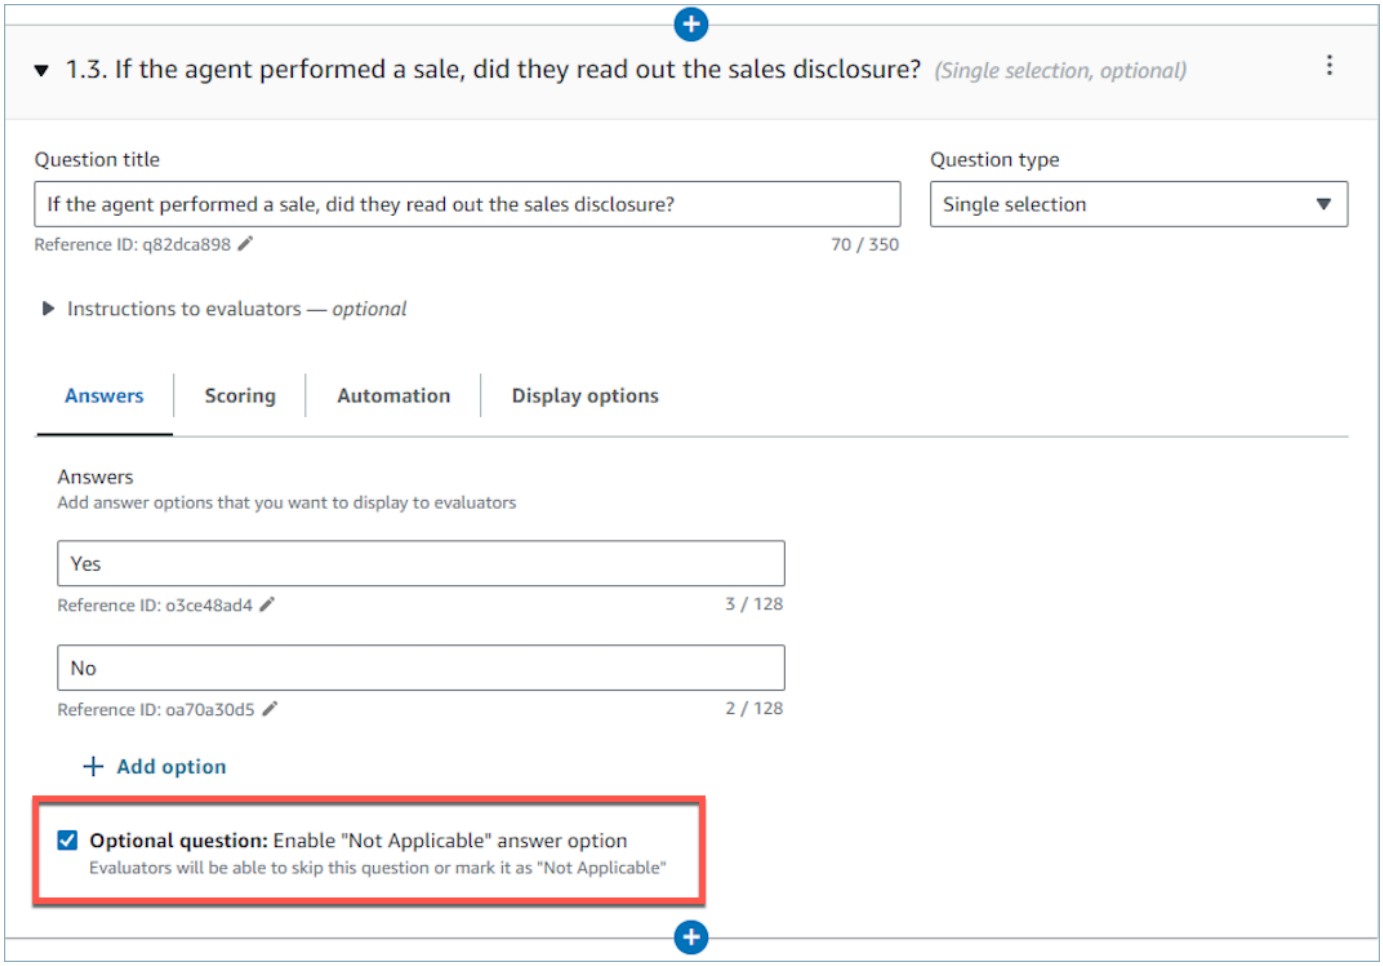
1. On the **Answers** tab, add answer options that you want to display to evaluators, such as **Yes**, **No**.
2. To add more answers, choose **Add option**.

   The following image shows example answers for a **Single selection** question.

   The following image shows an answer range for a **Number** question.



3. You can also mark a question as optional. This enables managers to skip the question (or mark it as **Not applicable**) while performing an evaluation.

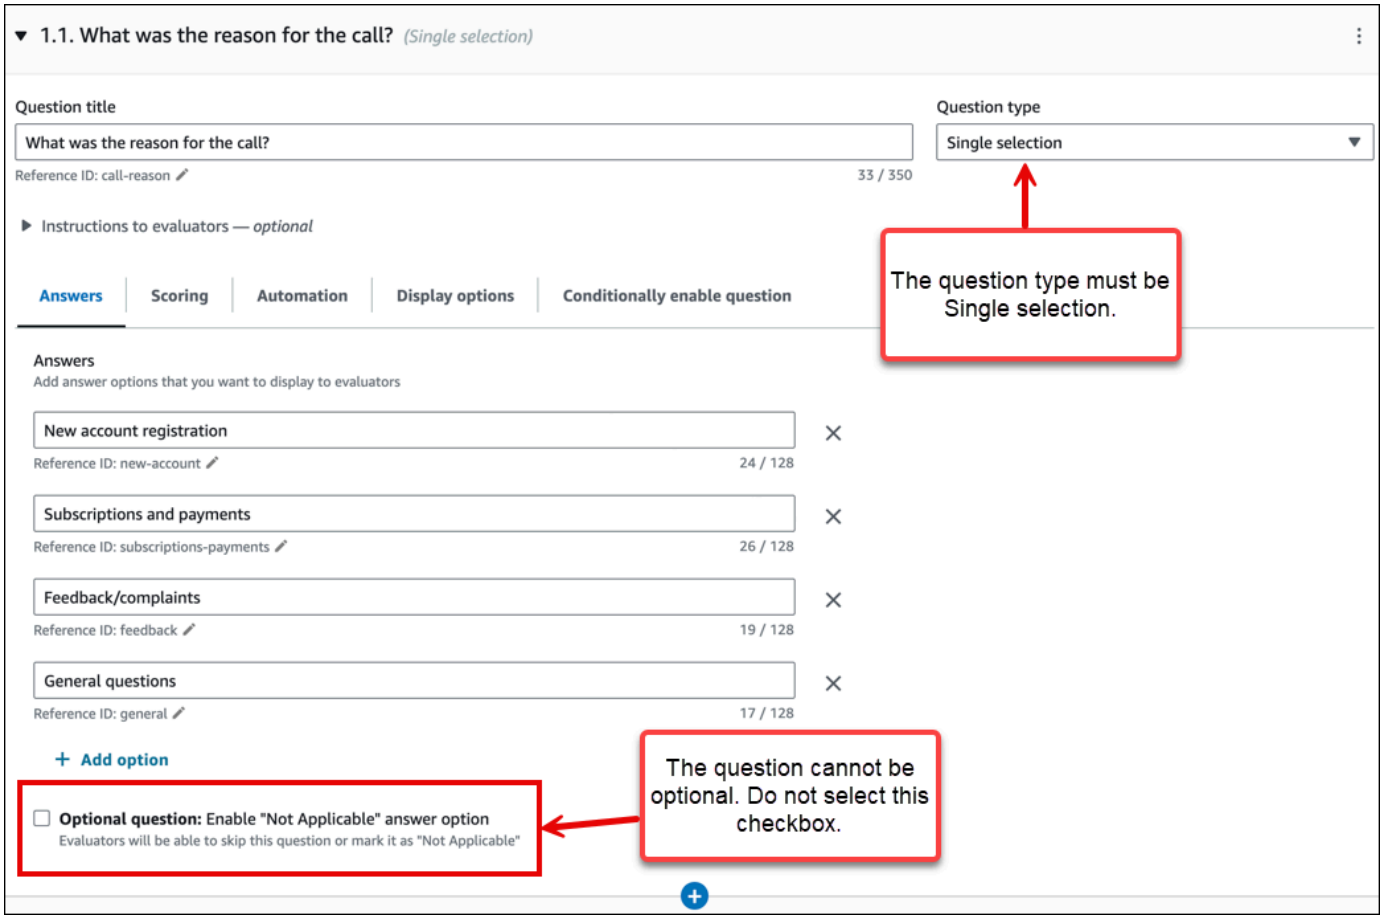


Step 4: Conditionally enable questions

Evaluation forms can have questions that are conditionally enabled or disabled, based on answers to other questions. For example, you can configure a follow-up question to appear in the form only if it is needed.

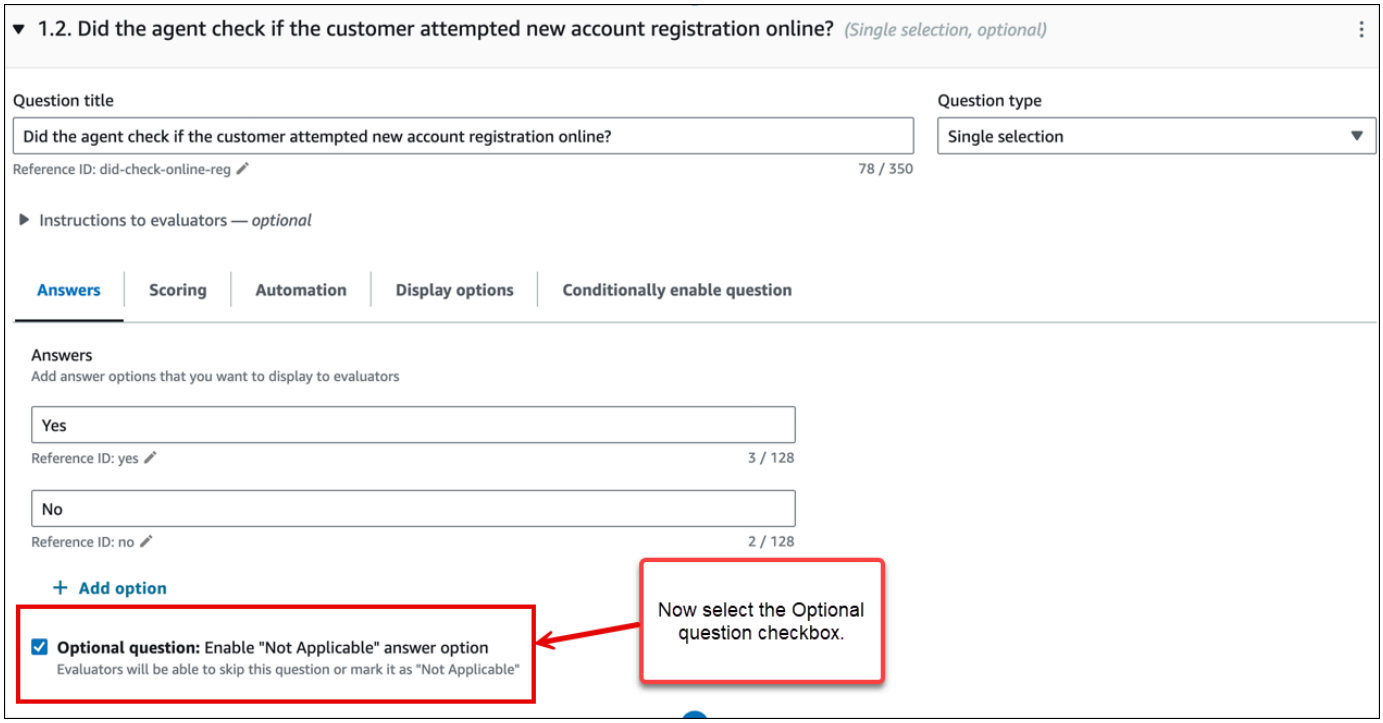
1. Choose a question that needs a follow-up question. The question type must be **Single selection** or **Multiple selection**, and it must not be an optional question (do not select the **Optional question** checkbox).

   For example, in the following image, question 1.1 is *What was the reason for the call?* and the **Optional question** checkbox is not selected.



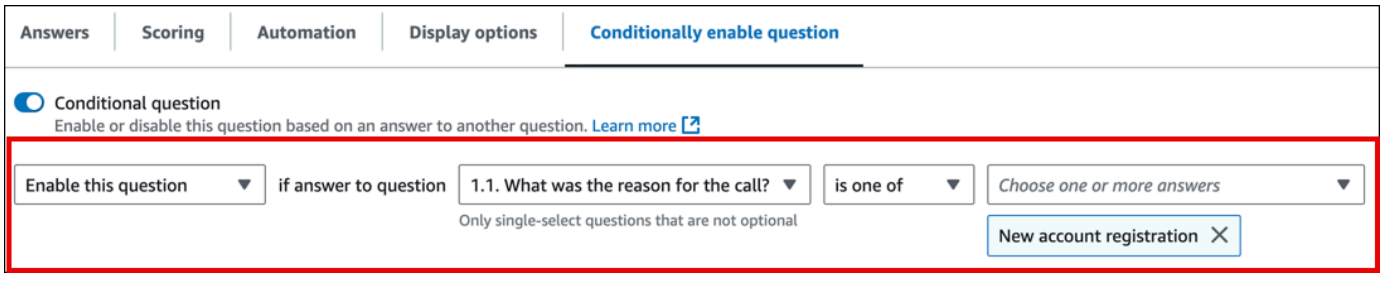
2. Add a follow-up question and now select the **Optional question** checkbox.

   In the following image, the follow-up question is question 1.2 *Did the agent check if the customer attempted new account registration online?* and the **Optional question** checkbox is selected.



3. Choose the **Conditionally enable question** tab and then turn on **Conditional question**. The toggle is shown in the following image.

4. Configure the follow-up question to be enabled only if answer to question 1.1. *What was the reason for the call?* is **New account registration**. These options are shown in the following image.



With this configuration, the follow-up question *Did the agent check if the customer attempted new account registration online?* is dynamically added to the form only if the answer to *What*

was the reason for the call? is **New account registration**. In all other cases this question is not present in the form and does not need to be answered.

5. To verify that this configuration works as expected, use the **Preview** action.

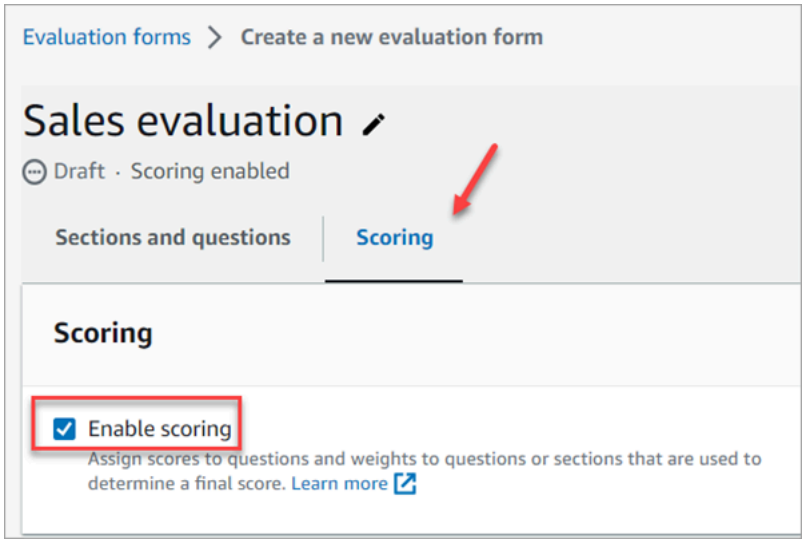
Following are a few things to keep in mind when creating conditional questions:

- When a question is conditionally enabled, it is by default disabled.
- When a question is conditionally disabled, it is by default enabled.
- You can only use **Single selection** or **Multiple selection** questions to conditionally enable or disable other questions. The question cannot be optional.
- You can choose one or more answer options to trigger the condition of a conditional question.

> **Note**
>
> If generative AI-powered automation is enabled on a question that is conditionally enabled, then the use of generative AI on that question counts towards the usage limit of questions that can be evaluated on a contact using generative AI. It counts even if the question was conditionally disabled.
> For the default limit of the **Number of evaluation questions that can be answered automatically on a contact using generative AI**, see Conversational analytics service quotas.

Step 5: Assign scores and ranges to answers

1. Navigate to the top of the form. Choose the **Scoring** tab, and then select the **Enable scoring** checkbox.

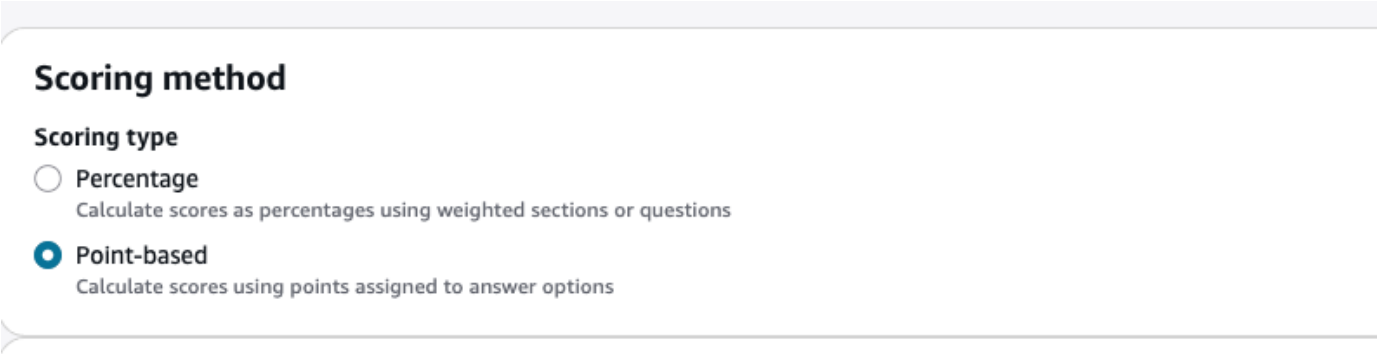


This enables scoring for the entire form. You can also use it to add ranges for answers to **Number** question types.

2. For **Scoring mode**, choose one of the following options:

- **Percentage** – Calculate scores as percentages using weighted sections or questions.
- **Point-based** – Calculate scores using points assigned to answer options.

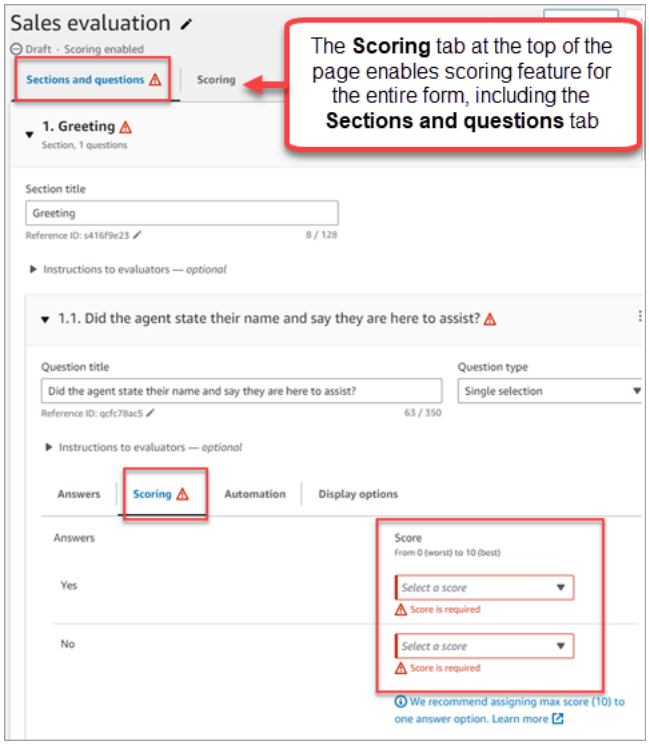
> **Important**
>
> We recommend creating a new evaluation form rather than switching the scoring mode on an existing form. Changing the scoring mode resets all previously configured scoring values, and historical evaluations completed with the previous scoring mode cannot be directly compared with evaluations using the new mode.



Step 5.1: Percentage-based scoring

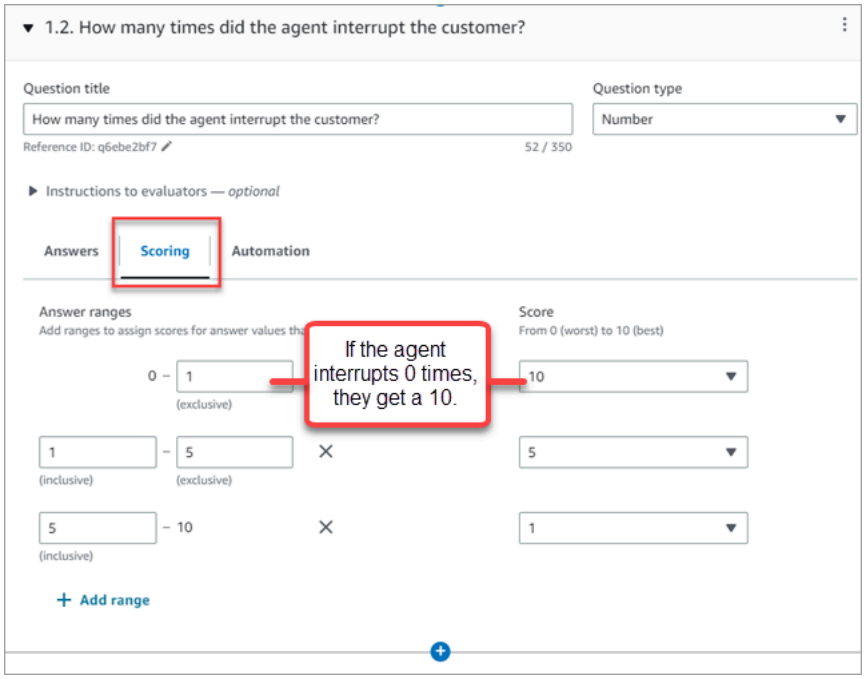
If you selected **Percentage** scoring mode, follow these steps to configure scoring for your evaluation form.

1. Return to the **Sections and questions** tab. You can assign scores to **Single selection**, **Multiple selection**, and add ranges for **Number** question types.



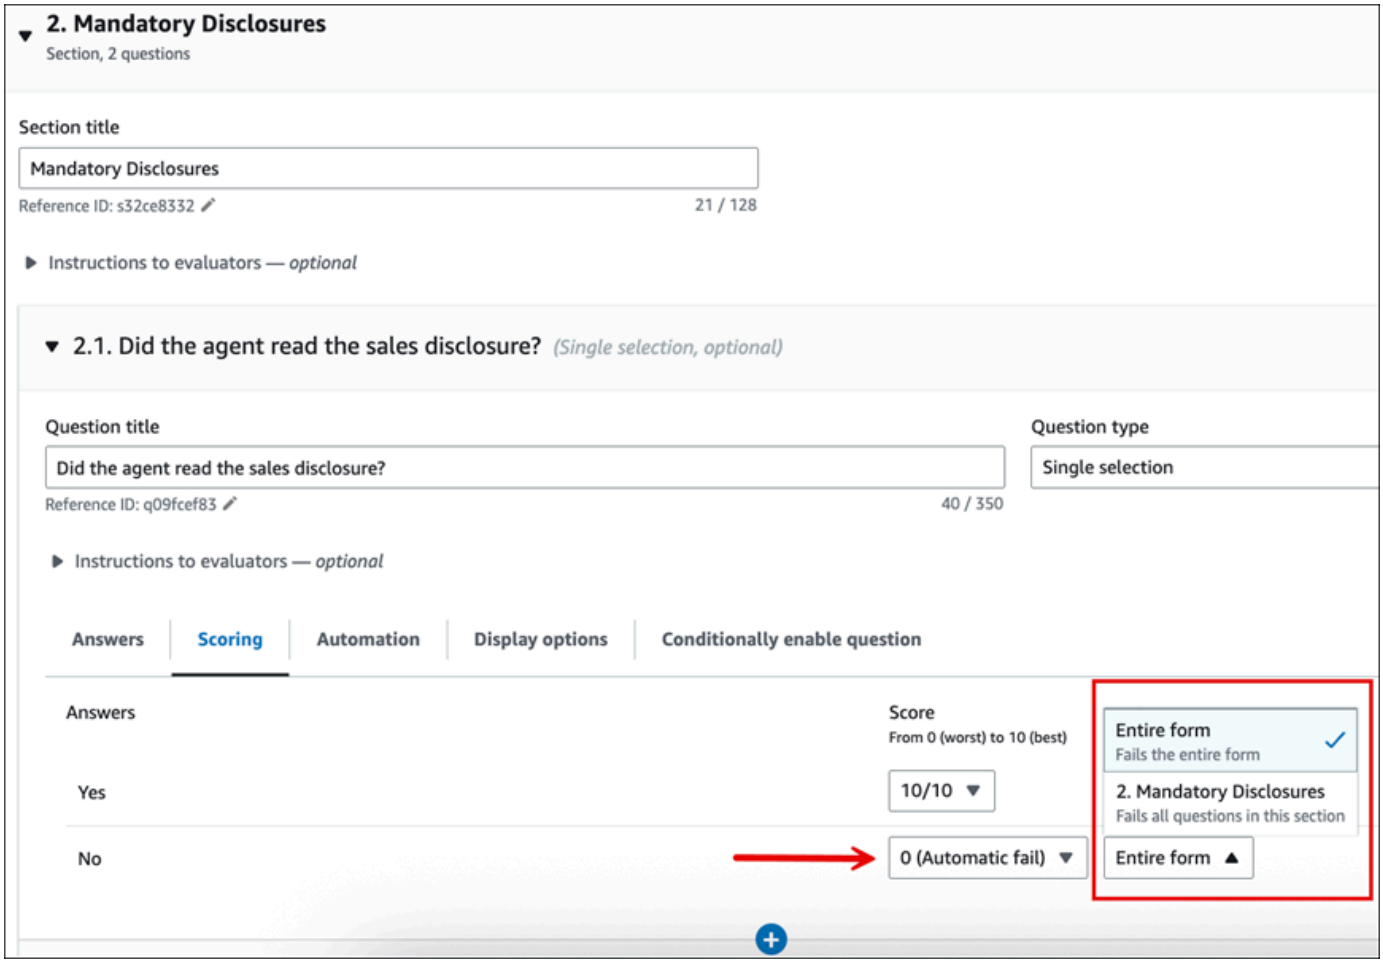
2. When you create a **Number** type question, on the **Scoring** tab, choose **Add range** to enter a range of values. Indicate the worst to best score for the answer.

   The following image shows an example of ranges and scoring for a **Number** question type.

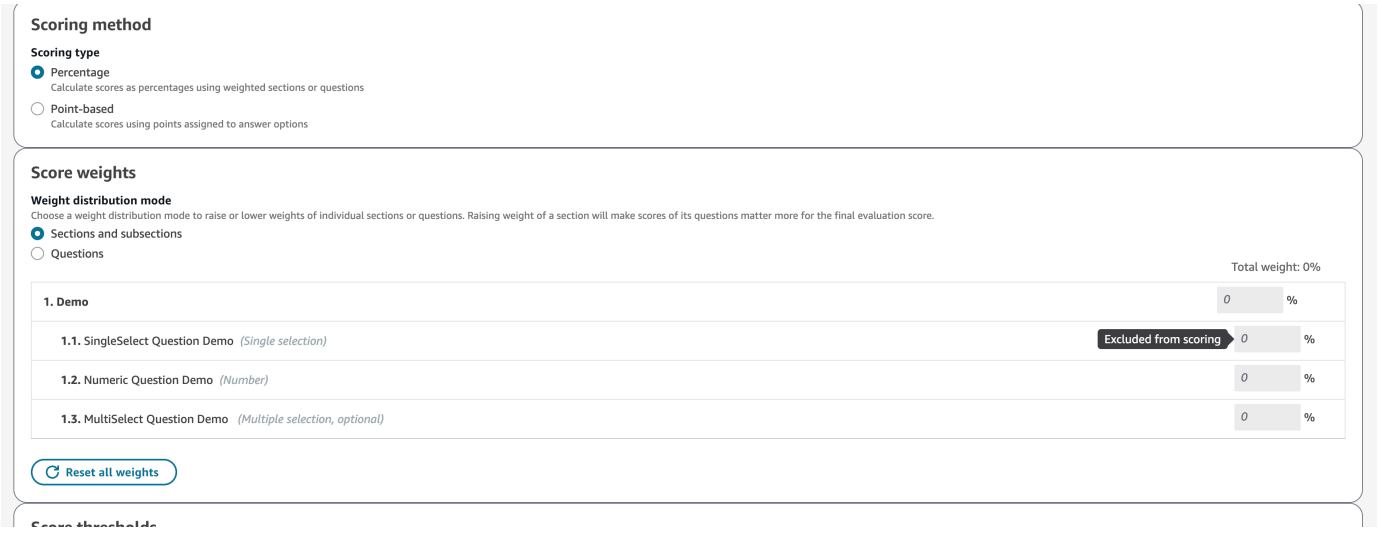


- If the agent interrupted the customer 0 times, they get a score of 10 (best).
- If the agent interrupted the customer 1-4 times, they get a score of 5.
- If the agent interrupted the customer 5-10 times, they get a score of 1 (worst).

3. For **Multiple selection** questions, assign a score value (0-10) to each option. When multiple options are selected, the total score is the sum of selected options' scores, capped at 10.
4. (Optional) Configure **Automatic fail** for an answer option. You can choose to apply automatic fail to the section, the subsection, or the entire form. When the evaluator selects this answer during an evaluation, the score for the affected scope is set to zero.



5. (Optional) Exclude individual questions or entire sections from scoring. When a question or section is excluded, it is automatically assigned a weight of 0%, similar to a non-scorable question. The remaining weight is redistributed among the other scored items.



6. After you assign scores to all the answers, choose **Save**.

Updating existing forms with multiple selection questions

If you have existing evaluation forms that were created with multiple selection questions before scoring support was added, you will receive a validation error when creating a new version or activating the form. To resolve this, follow these steps:

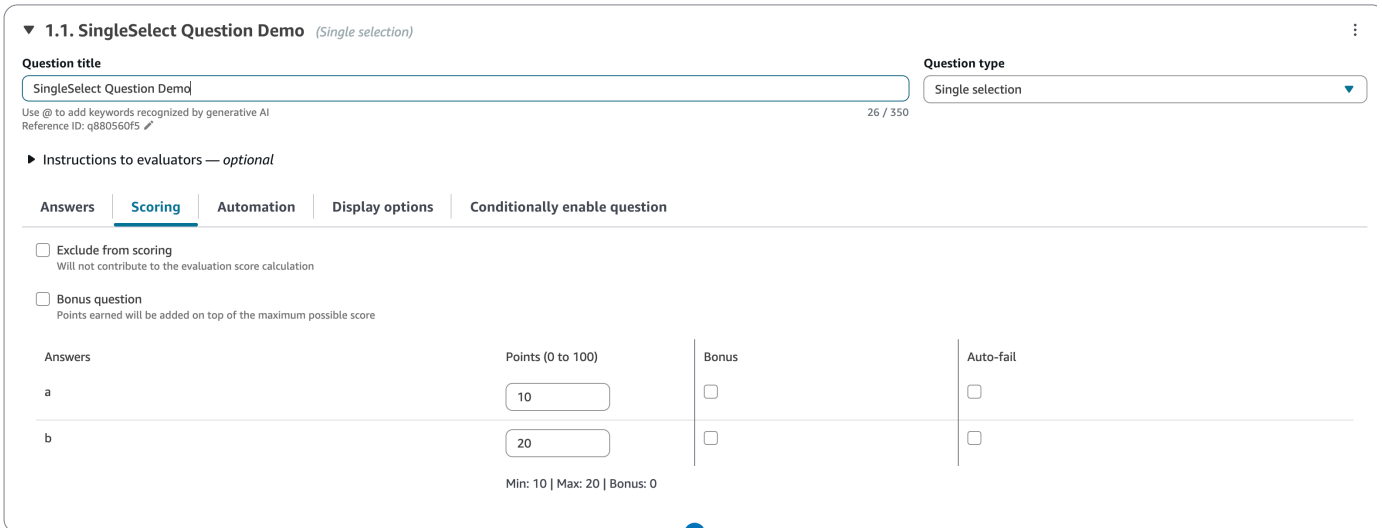
1. Open the evaluation form and navigate to the multiple selection question.
2. Choose the **Scoring** tab for the question.
3. Do one of the following:
   - Assign score values to each answer option (0-10), or
   - Select the **Exclude from scoring** checkbox to remove the question from the scoring calculation.
4. Choose **Save** and then activate the form.

Step 5.2: Point-based scoring

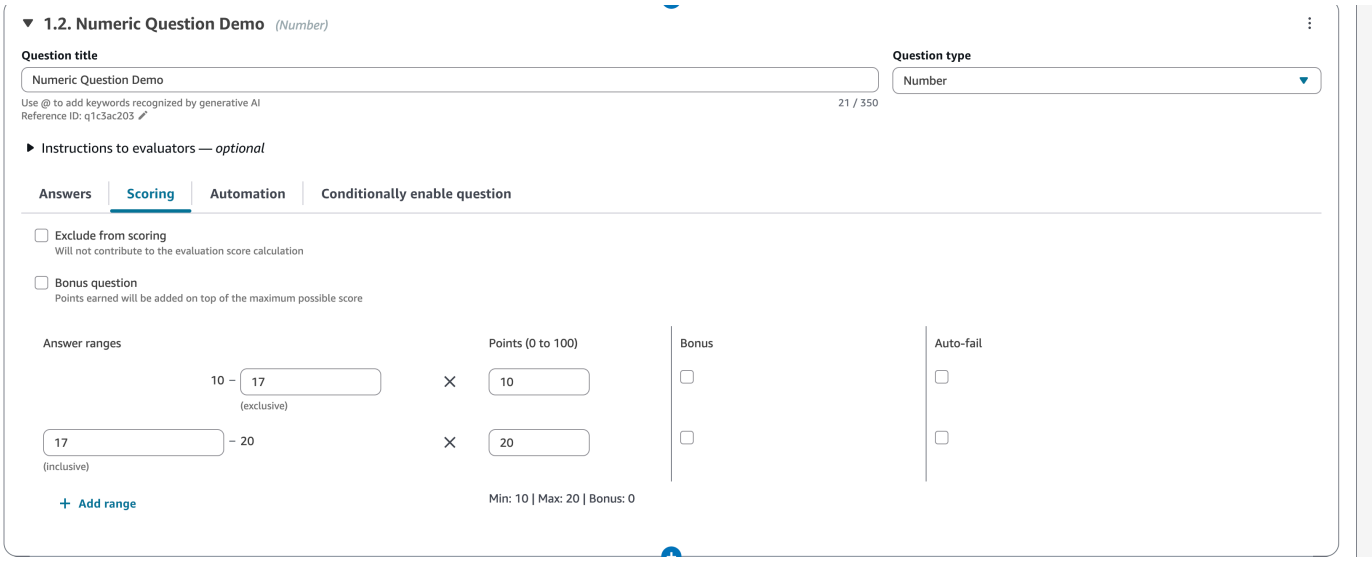
If you selected **Point-based** scoring mode, follow these steps to configure scoring for your evaluation form.

1. Return to the **Sections and questions** tab. For each question, choose the **Scoring** tab and assign point values to each answer option. Point values can range from **0 to 100**.

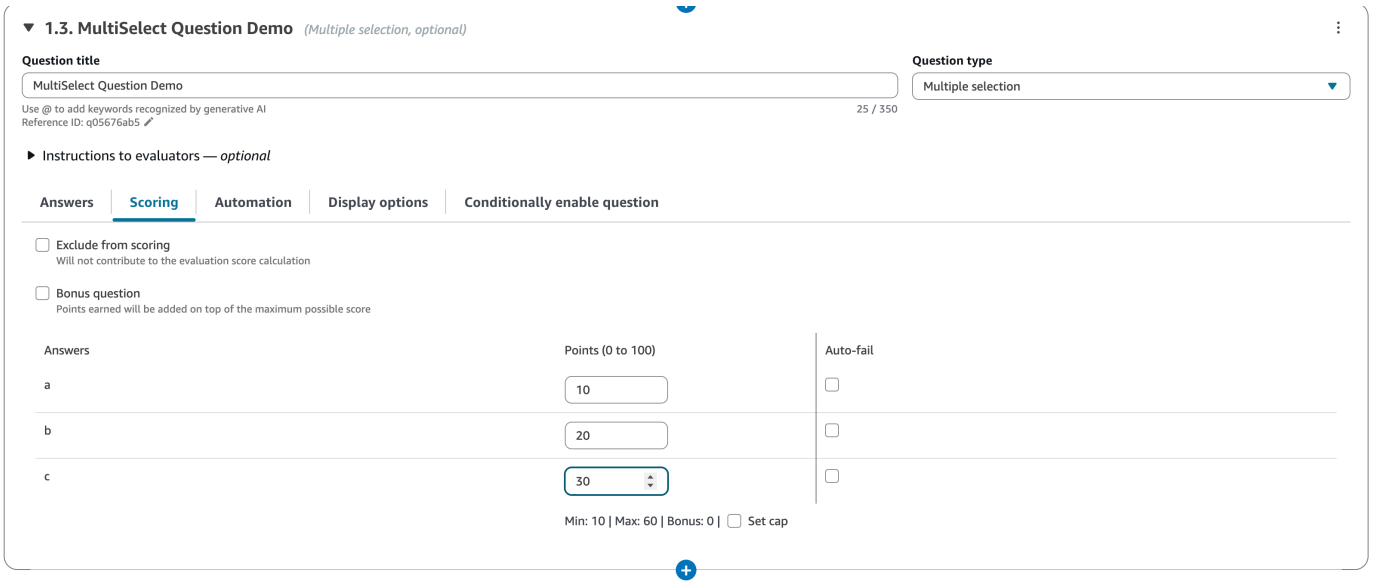
   The following image shows an example of point values assigned to a **Single selection** question.



2. For **Number** type questions, choose **Add range** to define answer ranges and assign a point value to each range.



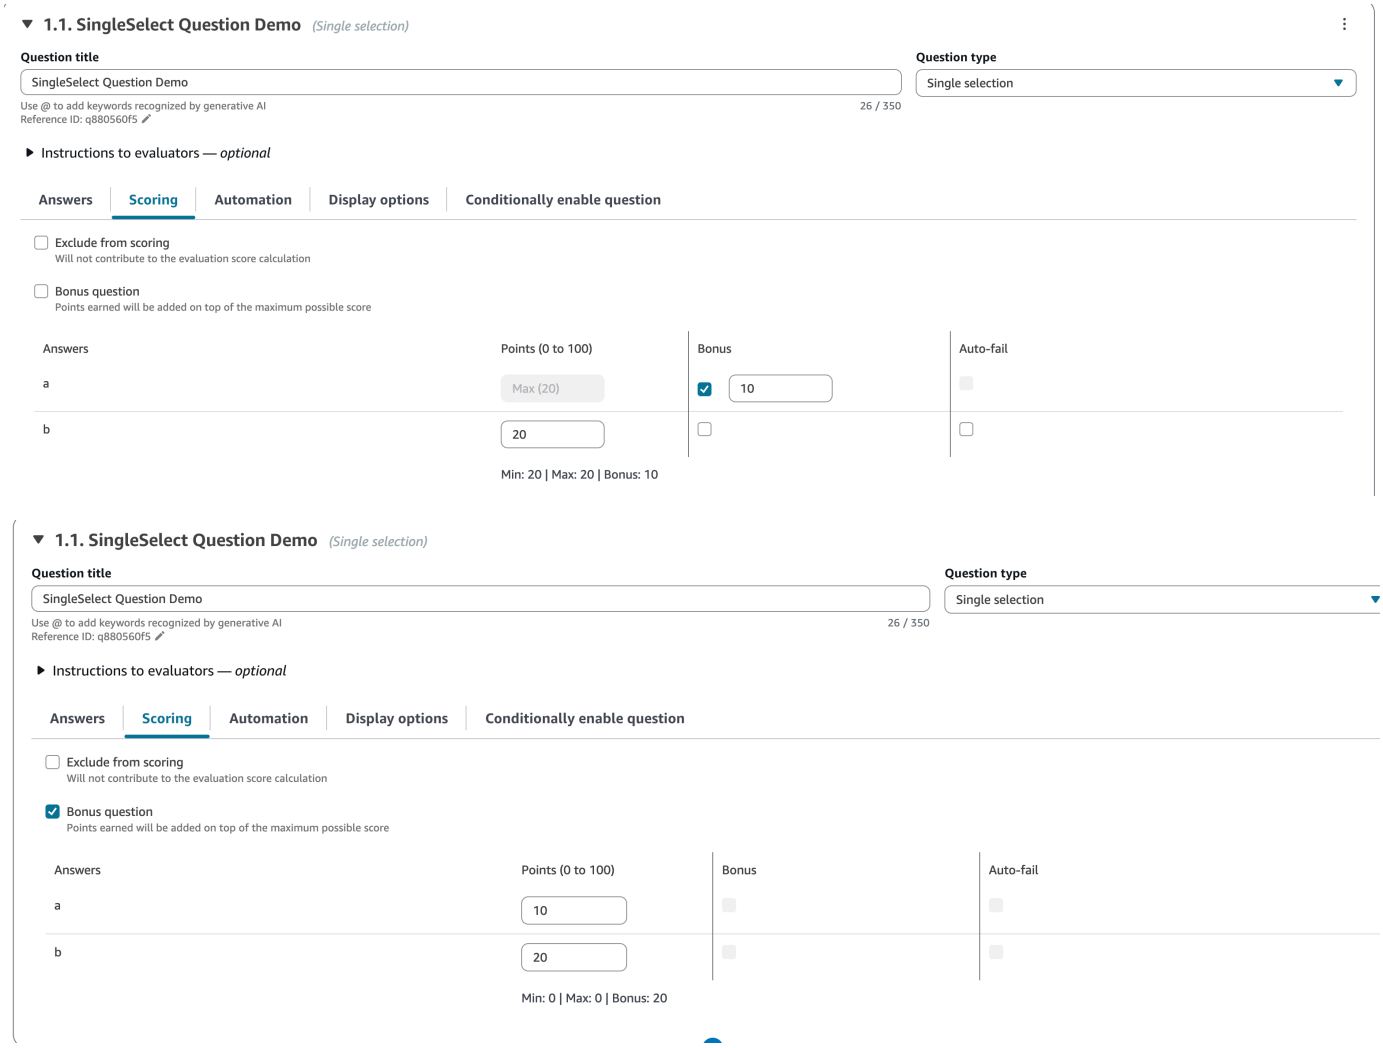
3. For **Multiple selection** questions, assign point values to each option. When multiple options are selected, their point values are summed. Optionally, select **Set cap** to configure a maximum point value cap for the question.



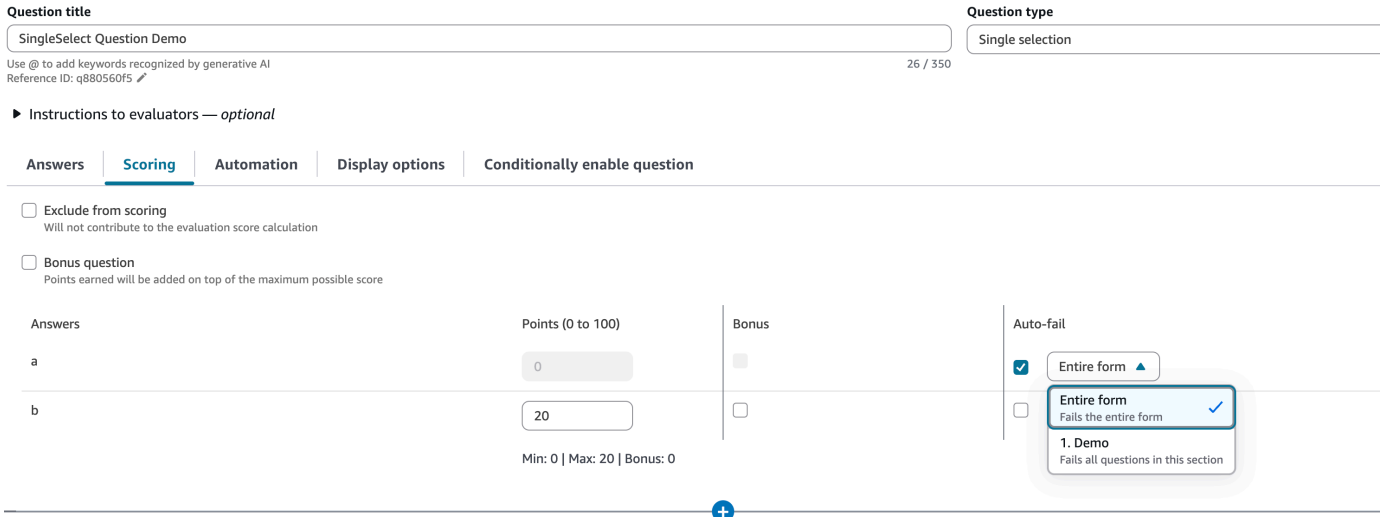
4. (Optional) Configure bonus options or bonus questions. With bonus points, you can award extra credit without increasing the maximum possible score.

   - **Bonus options** – An individual answer option that awards extra points on top of the question's maximum base score. When a bonus option is selected, the earned points can exceed the question's normal maximum. Bonus options are only supported on single selection and numeric questions.

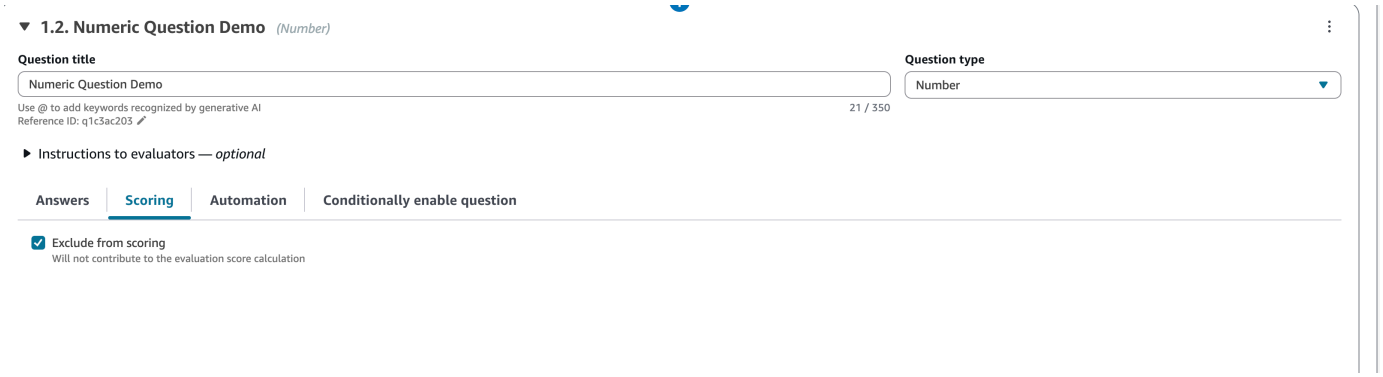
- **Bonus questions** – An entire question that does not contribute to the maximum possible score. The earned points from a bonus question are added to the total, but the question's maximum points are not counted in the base total. Bonus questions cannot have automatic fail options.



5. (Optional) Configure automatic fail. When an automatic fail option is selected during an evaluation, the score for the affected scope is set to zero. You can choose to apply automatic fail to the **Section** or **Entire form**. Automatic fail is supported on single selection, numeric, and multiple selection questions. Bonus questions and bonus options cannot have automatic fail.



6. (Optional) Exclude individual questions or entire sections from scoring. Excluded items do not contribute to the total score or the maximum possible score.



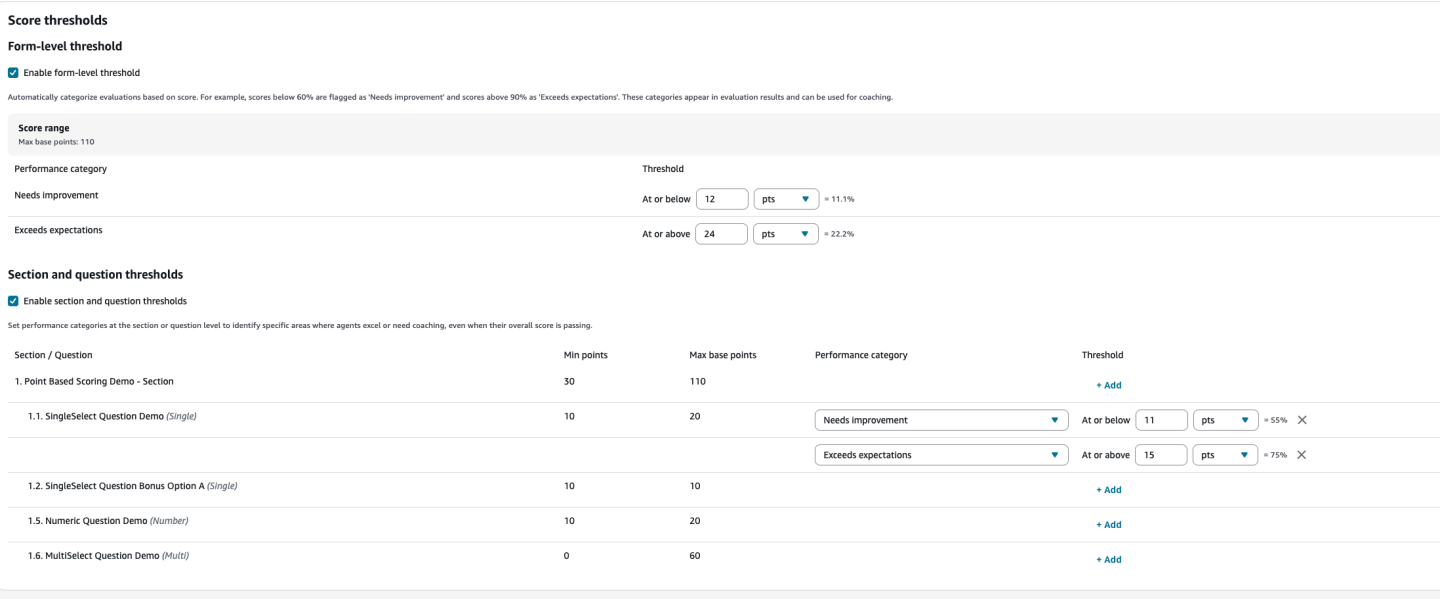
7. After you assign scores to all the answers, choose **Save**.
8. When you're finished assigning scores, continue to the next step to automate the answer of certain questions, or continue to preview the evaluation form.

Step 5.3: Assign performance thresholds

With performance thresholds, you can classify evaluation results into categories such as "Needs Improvement" or "Exceeds Expectations" based on score thresholds. This feature is supported in both percentage-based and point-based scoring modes.

You can configure performance thresholds at the form level, section level, or question level.

Performance thresholds are not inherited. If you set thresholds at the form level, those thresholds apply only to the overall form score. Sections and questions do not automatically inherit the form-level thresholds. You must explicitly configure thresholds at each level where you want them to apply.



Step 6: Enable automated evaluations

With Connect Customer, you can automatically answer questions within evaluation forms (for example, did the agent adhere to the greeting script?) using insights and metrics from conversational analytics. Automation can be used to:

- **Assist evaluators with performance evaluations**: Evaluators receive automated answers to questions on evaluation forms while performing evaluations. Evaluators can override automated answers before submission.
- **Automatically fill and submit evaluations**: Administrators can configure evaluation forms to automate responses to all questions within an evaluation form and automatically submit evaluations for up to 100% of customer interactions. Evaluators can edit and re-submit evaluations (if needed).

The ways of automation vary by whether you are evaluating the agent interaction or automated interaction (for example, self-service while interacting with a Lex bot or AI agent). You can choose between agent and automated interaction by choosing the **Additional settings**, under **Contact interaction type**.

Both for assisting evaluators, and for automated submission of evaluations, you need to first set up automation on individual questions within an evaluation form. Connect Customer provides three ways of automating evaluations:

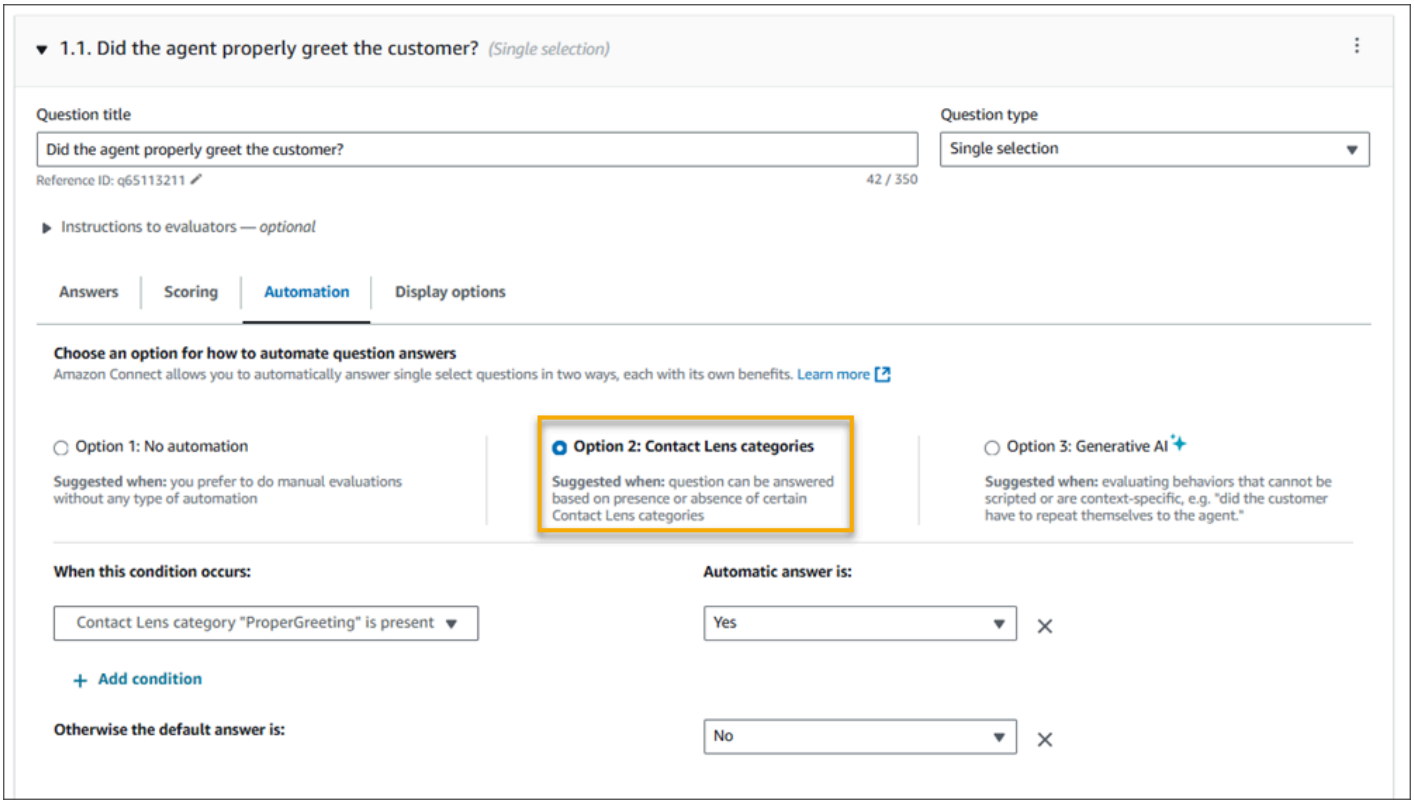
- **Contact categories**: *Single selection* questions (for example, did the agent properly greet the customer (Yes/ No)?), and *Multiple selection* questions (for example, what parts of the greeting script did the agent state correctly?) can be automatically answered using contact categories defined with rules. For more information, see Create conversational analytics rules using the Connect Customer admin website.
- **Generative AI**: Both *Single selection* and *Text field* questions can be automatically answered using generative AI.

  For information about automating evaluations of self-service (automated) interactions, see Performance evaluations of self-service interactions in Connect Customer.
- **Metrics**: *Numeric* questions (for example, what was the longest that the customer was put on hold?) can be automatically answered using metrics such as longest hold time, sentiment score.

Following are examples of each type of automation for each type of question.

Example automation for a Single selection question using conversational analytics categories

- The following image shows that the answer to the evaluation question is yes when conversational analytics has categorized the contact with a label **ProperGreeting**. To label contacts as **ProperGreeting**, you must first set up a rule that detects the words or phrases expected as part of a proper greeting, for example, the agent mentioned "Thank you for calling" in the first 30 seconds of the interaction. For more information, see Automatically categorize contacts.

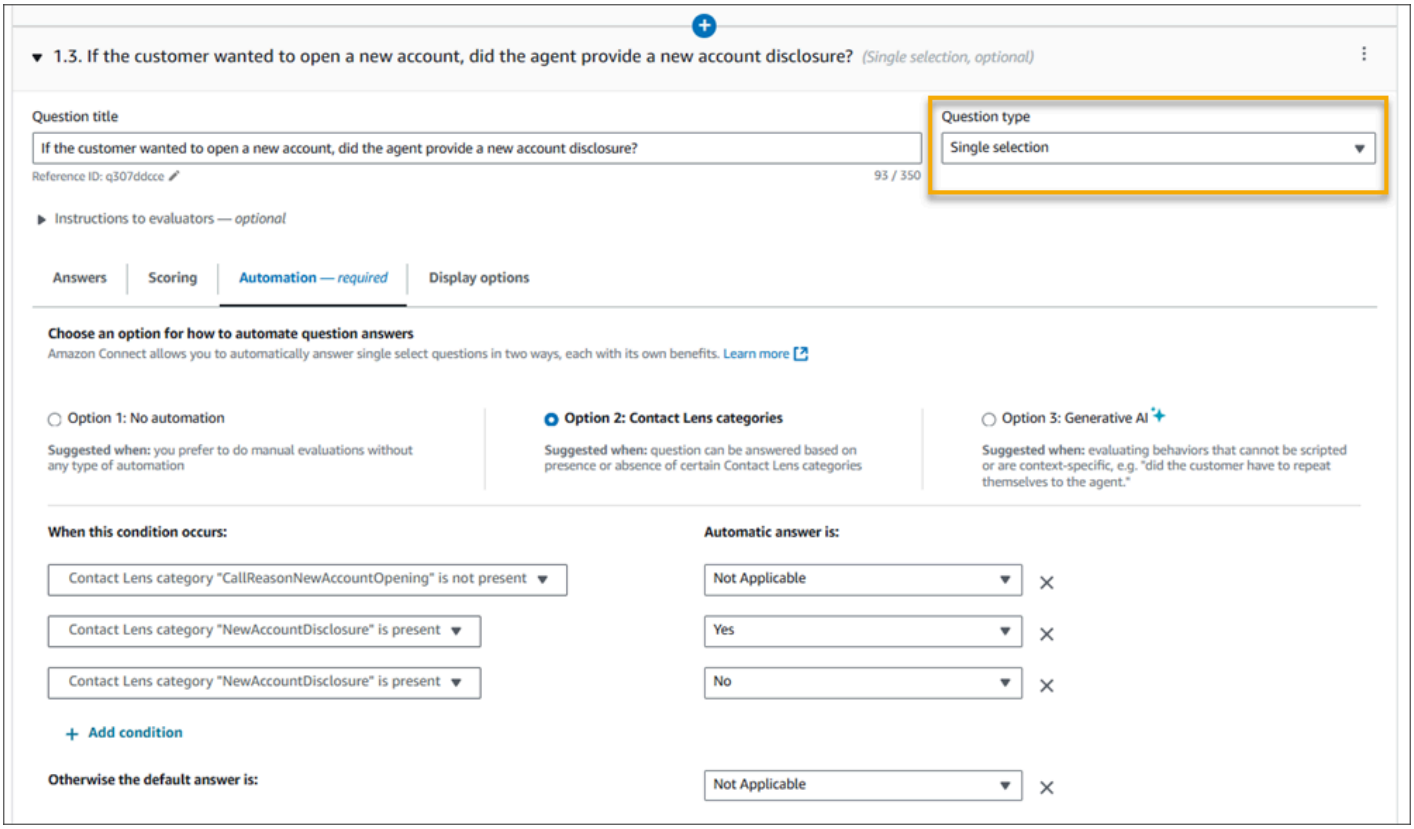


For information about setting up contact categories, see Automatically categorize contacts.

Example automation for an *optional* Single selection question using contact categories

- The following image shows example automation of an optional Single selection question. The first check is whether the question is applicable or not. A rule is created to check whether the contact is about opening a new account. If so, the contact is categorized as **CallReasonNewAccountOpening**. If the call is not about opening a new account, the question is marked as **Not Applicable**.

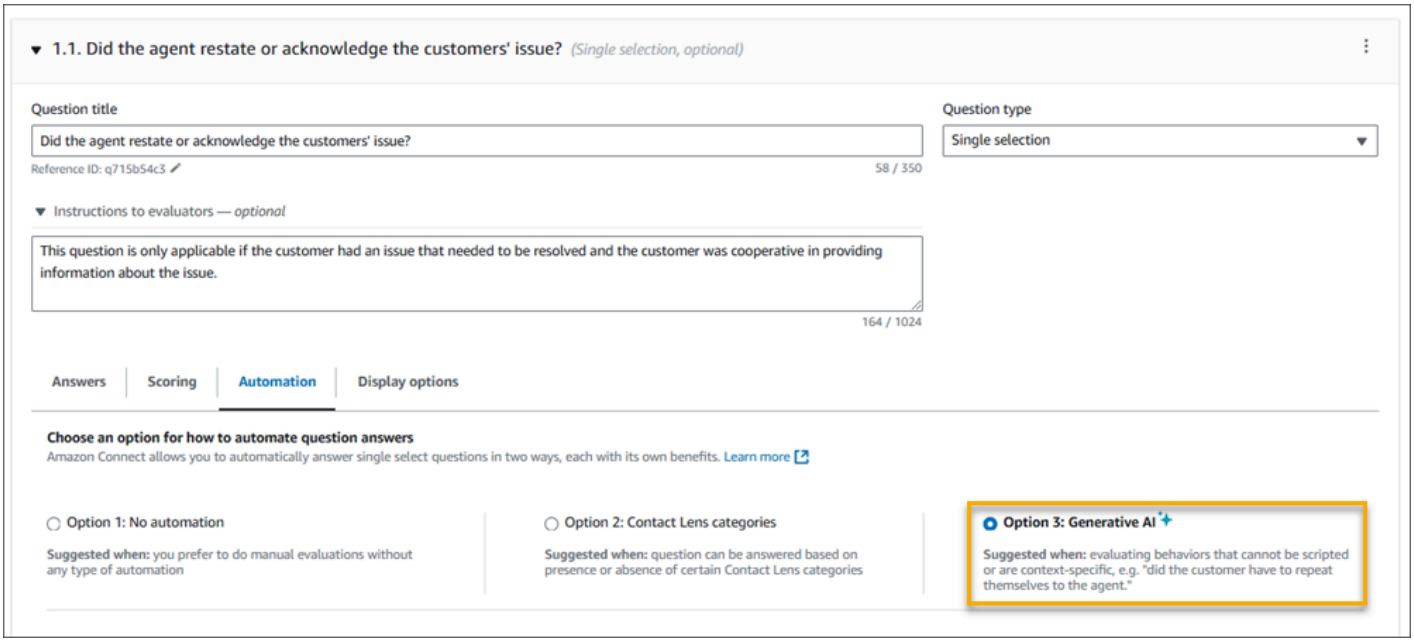
  The subsequent conditions run only if the question is applicable. The answer is marked as **Yes** or **No** based on the contact category **NewAccountDisclosures**. This category checks whether the agent provided the customer with disclosures about opening a new account.



For information about setting up contact categories, see Automatically categorize contacts.

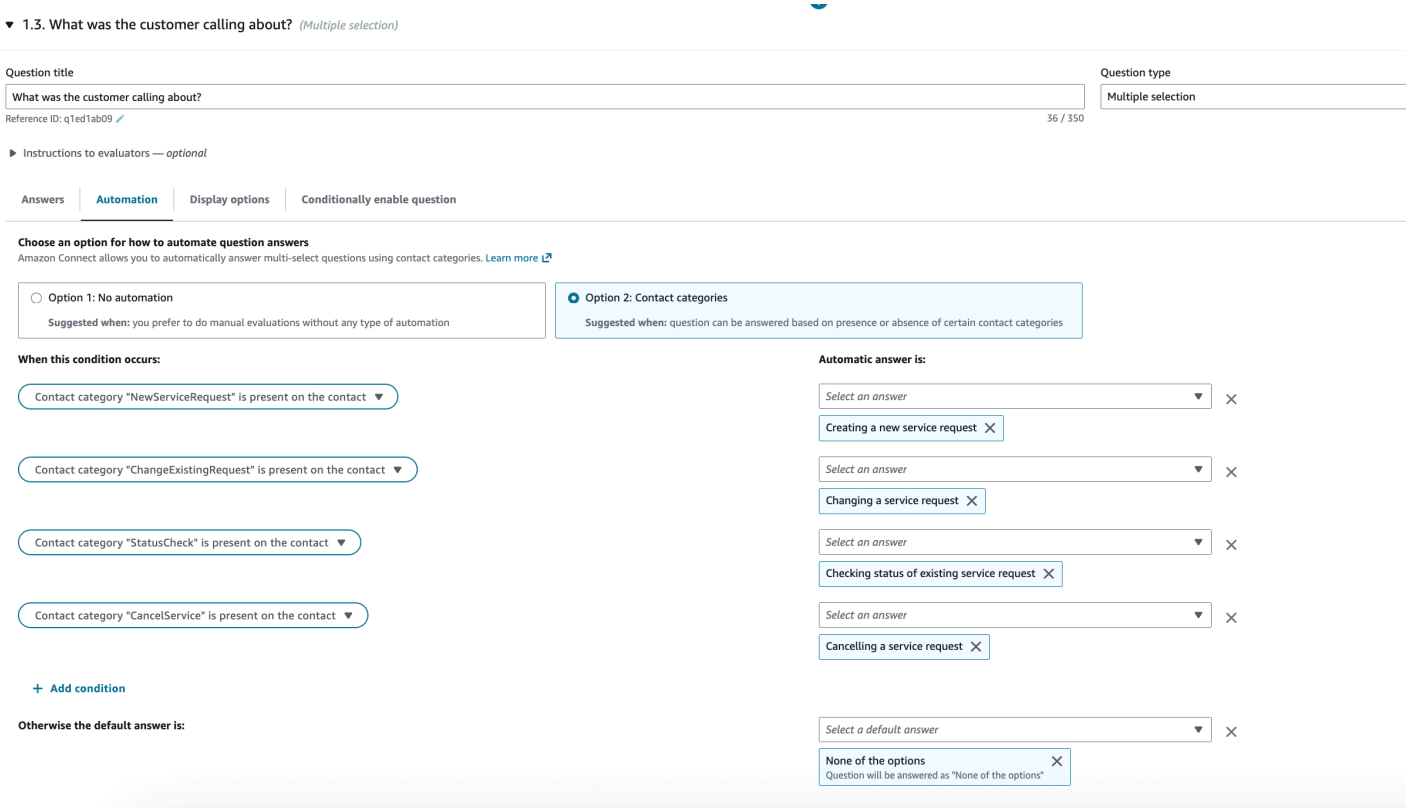
Example automation for an *optional* Single selection question using Generative AI

- The following image show example automation using Generative AI. Generative AI will automatically answer the evaluation question by interpreting the question title and evaluation criteria specified in the instructions of the evaluation question, and using it to analyze the conversation transcript. Using complete sentences to phrase the evaluation question and clearly specifying the evaluation criteria within the instructions improves accuracy of generative AI. For information, see Evaluate agent performance in Connect Customer using generative AI.



Example automation for a Multiple selection question using conversational analytics categories

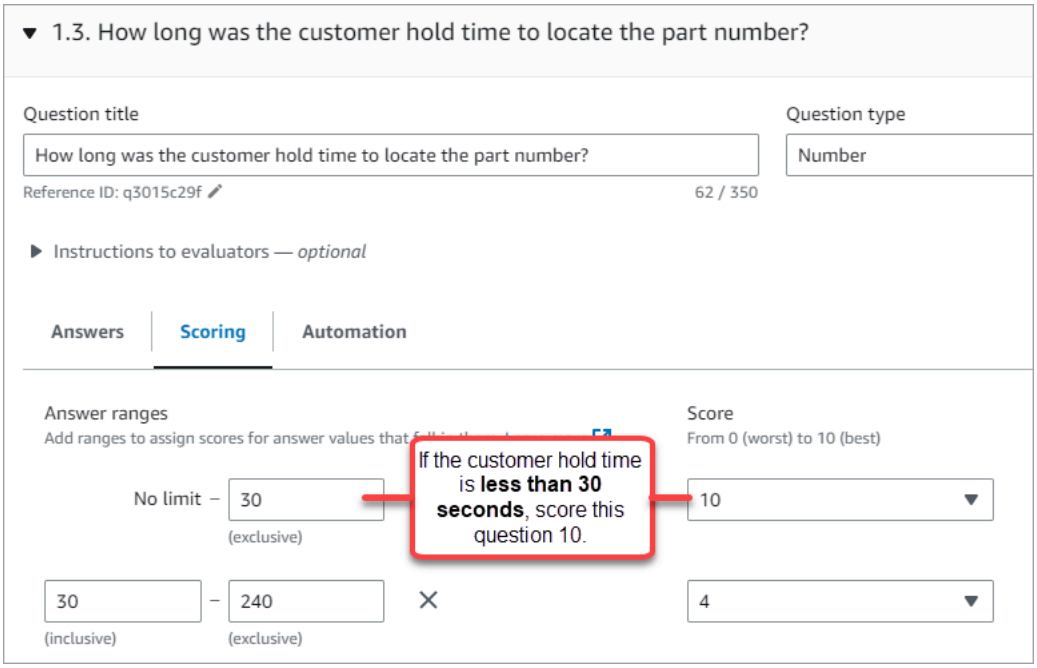
- Multiple selection questions can be used to capture answer reasoning for a single select question. It can also be used to trigger conditional questions, by checking for customer scenarios, such as call reasons. The following example shows how you can use rules that capture customer call reasons to automatically fill answers to a multiple selection question. Unlike single select questions, all of the conditions are executed sequentially to answer a multiple selection question. In the following example, if the categories **StatusCheck** and **ChangeExistingRequest** are both present on the contact, then the answer would be both "Checking status of existing service request" and "Changing a service request".



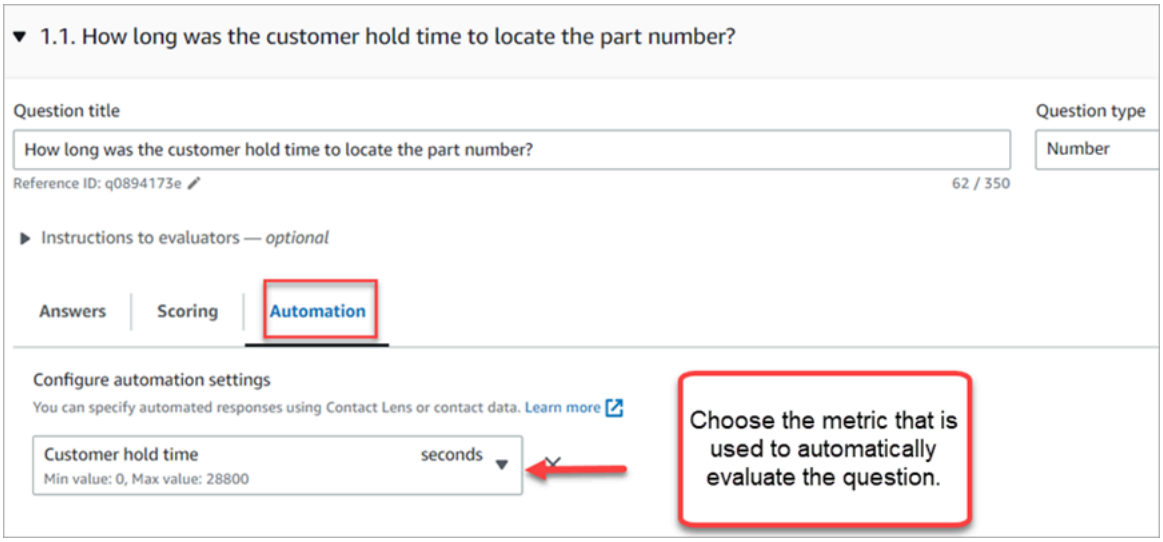
For information about setting up contact categories, see Automatically categorize contacts.

Example automation for a Numeric question

- If the agent interaction duration was less than 30 seconds, score the question as a 10.



- On the **Automation** tab, choose the metric that is used to automatically evaluate the question.

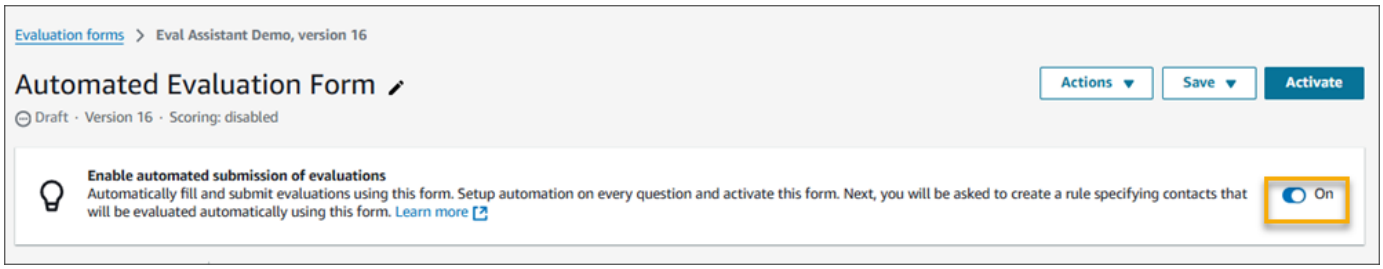


- You can automate responses to numeric questions using conversational analytics metrics (such as sentiment score of the customers, non-talk time percentage, and number of interruptions) and contact metrics (such as longest hold duration, number of holds, and agent interaction duration).

After an evaluation form is activated with automation configured on some of the questions, then you will receive automated responses to those questions when you start an evaluation from within the Connect Customer admin website.

To automatically fill and submit evaluations

1. Set up automation on every question within an evaluation form as previously described.
2. Turn on **Enable fully automated submission of evaluations** before activating the evaluation form. This toggle is shown in the following image.

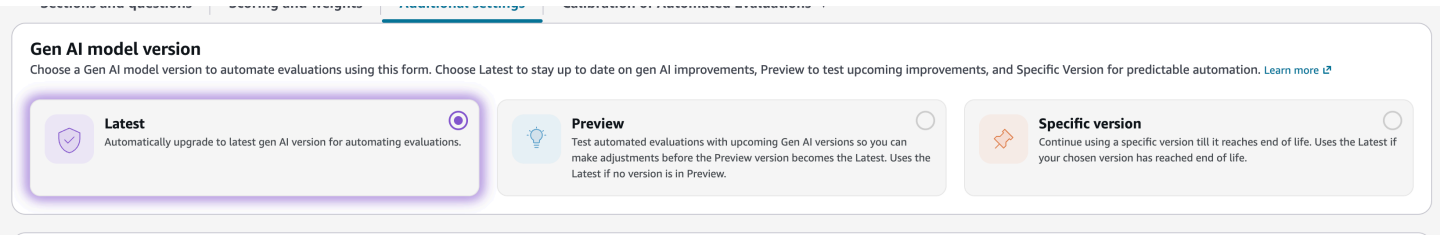


3. Activate the evaluation form.
4. Upon activation you will be asked to create a rule in conversational analytics that submits an automated evaluation. For more information, see Create a rule in conversational analytics that submits an automated evaluation. With the rule, you can specify which contacts should be automatically evaluated using the evaluation form.

Choose a Gen AI model version for automated evaluations

When you enable automated evaluations, Connect Customer uses generative AI to automatically fill answers to questions on the form. Each automated evaluation uses a specific Gen AI model version — the generative AI model, the prompts, or any other configurations. By default, an evaluation form uses the latest generally available Gen AI model version, so your automated evaluations benefit from the latest models and optimal configurations, without requiring any action on your part.

If you want more control, choose the Gen AI model version the form uses. On the evaluation form builder, choose the **Additional settings** tab. In the **Gen AI model version** section, choose one of the following options.



Latest

Automatically upgrade to the latest Gen AI model version for automating evaluations. This is the default. When Connect Customer promotes a new model version to latest, forms set to **Latest** move to it automatically so you always benefit from the most recent improvements.

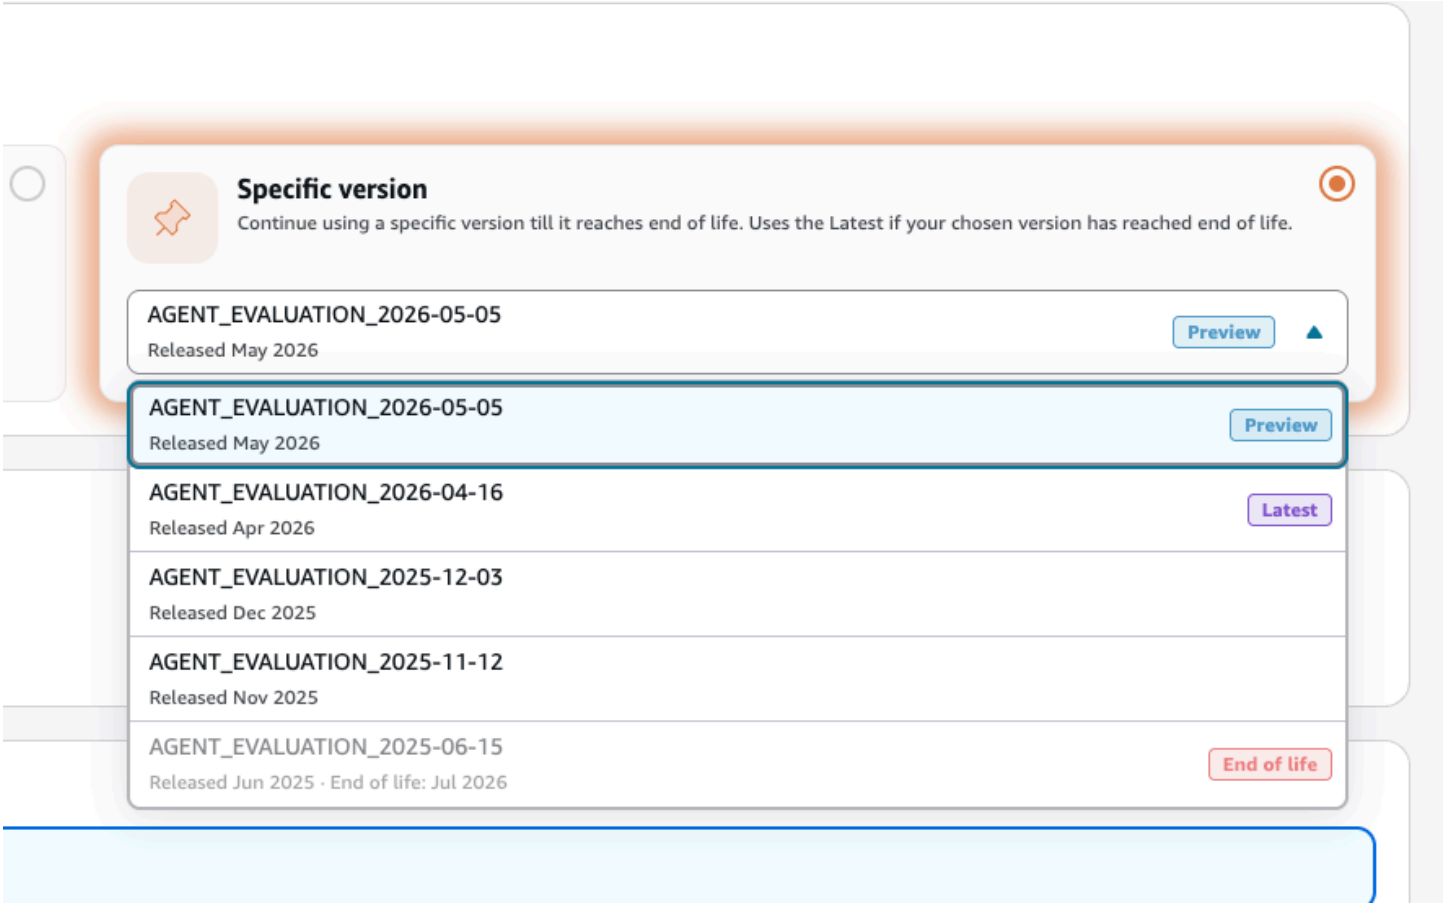
Preview

Try automated evaluations with an upcoming Gen AI model version. This enables you to check if your evaluation criteria is being correctly interpreted by the upcoming Gen AI model version, and make adjustments to your evaluation forms if needed, before the Preview model version becomes the Latest. If no Preview version is available, then this uses the Latest version.

Specific version

Continue using a specific model version until it reaches end of life. Choose this option for predictable automation. If your chosen version reaches end of life, the form automatically uses the latest version.

When you choose **Specific version**, choose a version from the dropdown list. Each entry shows the version name and the date it was released, and a badge indicates the version's state. The versions that are available depend on your form type, your AWS Region, and your account's enrollment in cross-Region inference. The following tables describe the available versions.



Versions that have reached end of life appear dimmed and cannot be selected for a new form version.

The following agent evaluation model versions are available for agent evaluation forms when your account is enrolled in cross-Region inference.

Agent evaluation model versions

Version	State	What changed
`AGENT_EVALUATION_2026-05-05`	**Preview**	Adjusts how strictly the model scores answers, to make automated suggestions less strict where earlier versions were too harsh.
`AGENT_EVALUATION_2026-04-16`	**Latest**	Reduces the rate of automated evaluations that fail to generate a suggested answer, so more questions receive an automated suggestion.

Version	State	What changed
AGENT_EVALUATION_2025-12-03	**Active**	The first version with the model upgrade.

The following in-Region model versions for agent evaluations are available only to customers that have disabled cross-Region inference for Connect Customer generative AI capabilities. These model versions are offered in the Europe (London) and Asia Pacific (Singapore) Regions.

In-Region model versions for agent evaluations

Version	State	What changed
AGENT_EVALUATION_IN_REGION_2026-10-08	**Latest**	Latest in-Region version. Adjusts how strictly the model scores answers, so that automated suggestions are less strict where earlier versions were too harsh, improving agreement with human evaluators on borderline answers.
AGENT_EVALUATION_IN_REGION_2026-10-07	**Active**	Reduces the rate of automated evaluations that fail to generate a suggested answer, so more questions receive an automated suggestion and fewer are left unanswered.
AGENT_EVALUATION_IN_REGION_2026-10-06	**Active**	The first in-Region version. Introduces agent evaluation on an in-Region model so accounts not enrolled in cross-Region inference can use Gen AI automated evaluations.

In the Canada (Central) Region, in-Region model versions for agent evaluations are available to customers that have disabled cross-Region inference for Connect Customer generative AI capabilities. The two **Preview** versions use an upgraded generative AI model that processes your data only within Canada. If you choose **Preview**, your form uses the most recent Preview version (AGENT_EVALUATION_IN_REGION_2026-11-07). To use the other Preview version, choose **Specific version** and select AGENT_EVALUATION_IN_REGION_2026-11-06. The following table lists the in-Region model versions available in Canada (Central).

In-Region model versions for agent evaluations in Canada (Central)

Version	State	What changed
`AGENT_EVALUATION_IN_REGION_2026-11-07`	**Preview**	Upgraded model that processes data within Canada. Adjusts how strictly the model scores answers, so that automated suggestions are less strict where earlier versions were too harsh.
`AGENT_EVALUATION_IN_REGION_2026-11-06`	**Preview**	Upgraded model that processes data within Canada.
`AGENT_EVALUATION_IN_REGION_2025-11-12`	**Latest**	The current in-Region version in Canada (Central) . This version is scheduled to reach end of life on November 27, 2026.

The following automated interaction (self-service) evaluation model versions are available for automated interaction evaluation forms when your account is enrolled in cross-Region inference.

Automated interaction (self-service) evaluation model versions

Version	State	What changed
`SELF_SERVICE_EVALUATION_2026-04-24`	**Preview**	Adjusts how strictly the model scores answers, making automated suggestions less strict than the previous version.
`SELF_SERVICE_EVALUATION_2026-03-18`	**Latest**	The initial Gen AI version for automated interaction evaluations.

Note

The Gen AI model versions available to you depend on your form type, your AWS Region, and your account's enrollment in cross-Region inference. If only one version is available for your form's context, the version selector does not list any versions, and the form uses the latest version that Connect Customer provides.

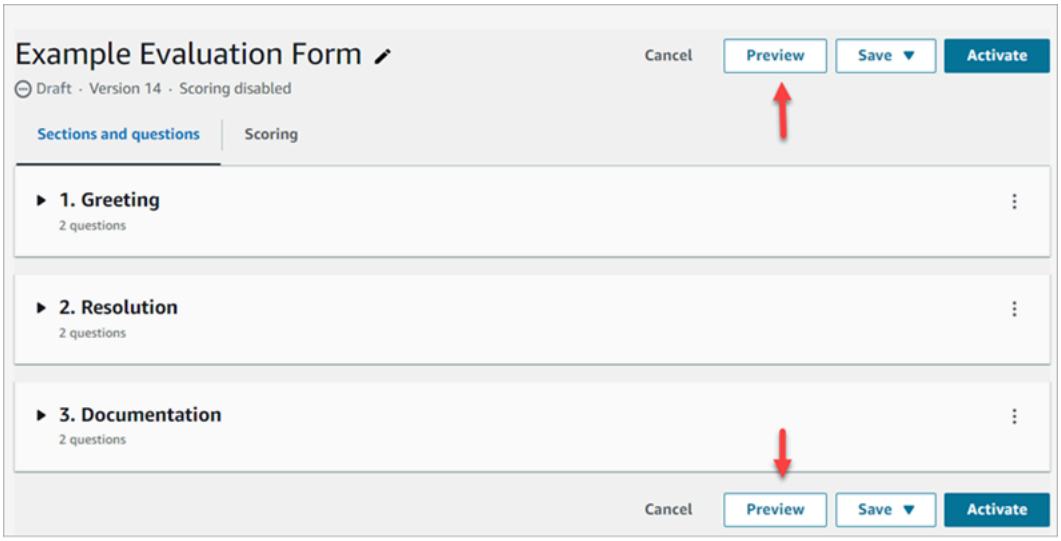
The Gen AI version you choose is saved on the form version when you save the form, and it applies to that form version for its lifetime. You can change the selection while a form version is in **Draft**; after a form version is activated, its Gen AI version selection is fixed. To move a form to a different version, create a new form version and choose the version you want. Forms created before this feature was available do not have a selection, and Connect Customer uses the latest version for them at evaluation time.

Each Gen AI version has a state, shown as a badge in the version selector: **Latest** is the current default; **Preview** is an upcoming version you can try before it becomes the default; **Active** is a stable version that is not the default but is still available to select; and **End of life** means the version is being retired and can no longer be selected for a new form version.

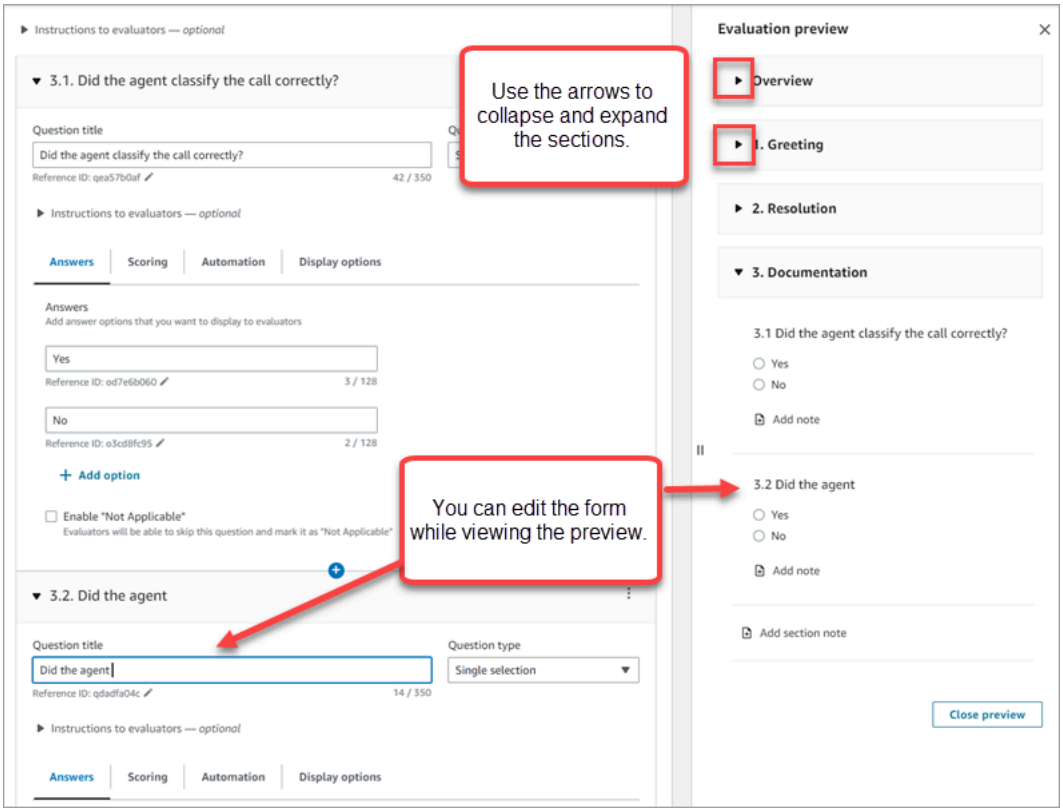
When a version that one of your forms uses is approaching end of life, Connect Customer notifies you in advance through the AWS Health Dashboard and a warning banner on each affected form version's detail page. You do not need to take action to keep your evaluations running: if a form's selected version reaches end of life before you move the form, Connect Customer automatically uses the latest available version for that form's automated evaluations rather than failing them, so there are no gaps in your evaluations. We recommend that you review your form against the newer version to confirm accuracy, because a newer version can behave differently from the version your form was originally set to.

Step 7: Preview the evaluation form

The **Preview** button is active only after you have assigned scores to answers for all of the questions.

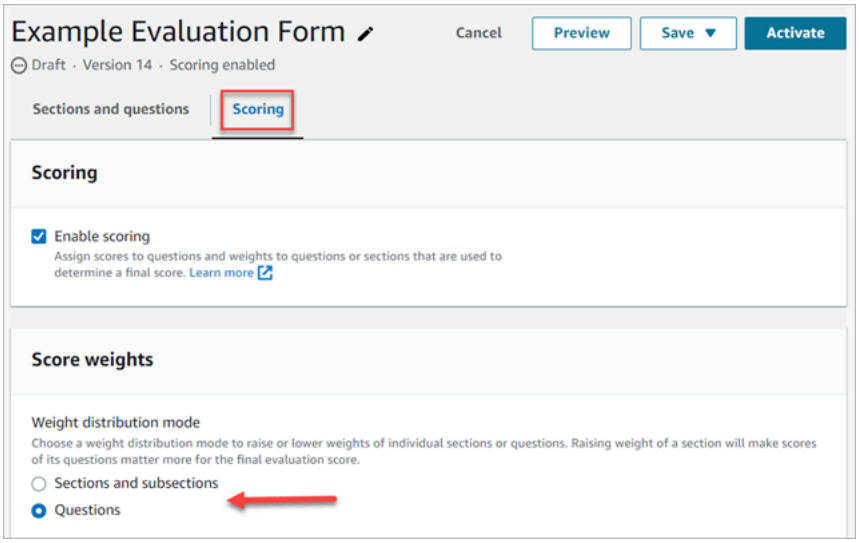


The following image shows the form preview. Use the arrows to collapse sections and make the form easier to preview. You can edit the form while viewing the preview, as shown in the following image.



Step 8: Assign weights for final score

When percentage-based scoring is enabled for the evaluation form, you can assign *weights* to sections or questions. The weight raises or lowers the impact of a section or question on the final score of the evaluation. This step applies only to the **Percentage** scoring mode. If you selected **Point-based** scoring, weights are not used; instead, the score is calculated from earned points versus maximum possible points.



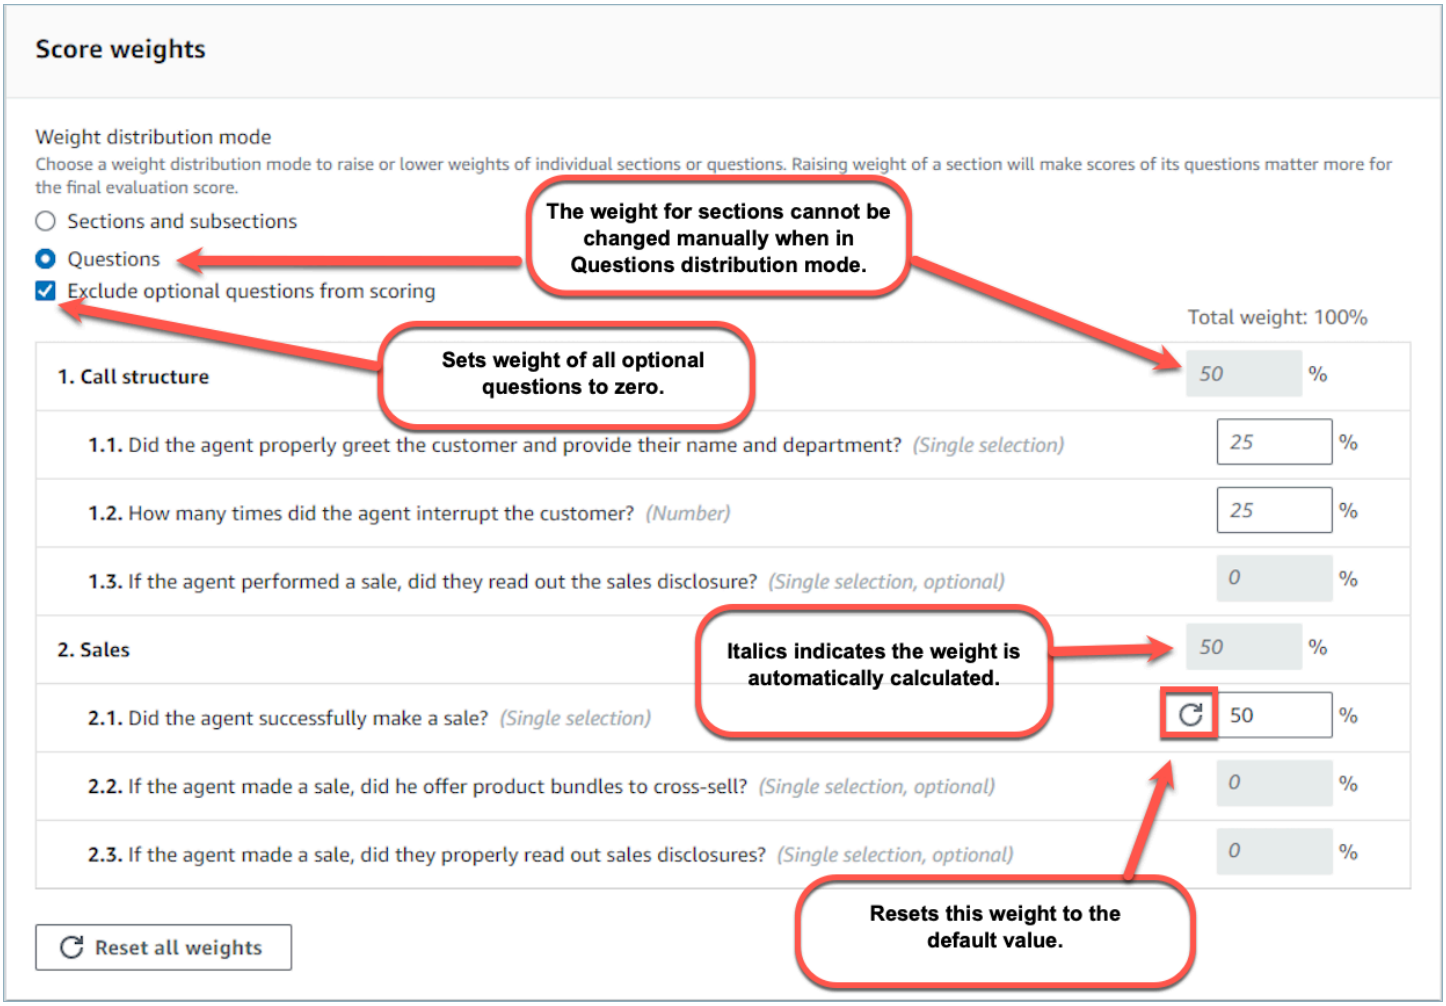
Weight distribution mode

With **Weight distribution mode**, you choose whether to assign weight by section or question:

- **Weight by section**: You can evenly distribute the weight of each question in the section.
- **Weight by question**: You can lower or raise the weight of specific questions.

When you change a weight of a section or question, the other weights are automatically adjusted so the total is always 100 percent.

For example, in the following image, question 2.1 was manually set to 50 percent. The weights that display in italics were adjusted automatically. In addition, you can turn on **Exclude optional questions from scoring**, which assigns all optional questions a weight of zero and redistributes the weight among the remaining questions.



Step 9: Validate the evaluation form

Choose **Save and validate** to save the evaluation form and run it through the validation pipeline. Results appear in a side panel. Validation happens in two stages. First, the validation pipeline checks the form against the same structural and configuration rules that govern activation—for example, section and question limits, weight and scoring consistency, and unique identifiers. The pipeline reports any issues found here as **Errors**, because they would prevent the form from being activated and you must resolve them before you can proceed.

If the pipeline finds no structural **Errors** and the form contains Gen AI–automated questions, validation moves to a second stage. This stage evaluates the content of those questions against best practices for Gen AI automation. The pipeline reports anything identified here as a **Warning**. Warnings do not block activation, but we recommend addressing them to improve the quality and reliability of automated answers.

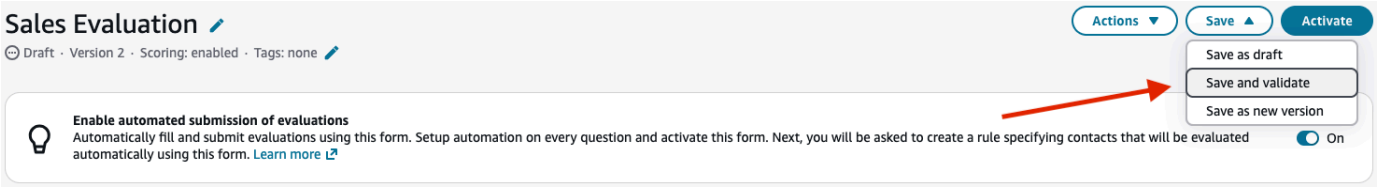
Validation checks each Gen AI–automated question against the following best practices:

- **Question phrasing** – The question title reads as a complete question (ending in a question mark), not a statement or heading.
- **Instructions present** – Every Gen AI–answered question includes instructions telling the AI how to evaluate and answer it.
- **Answer option language** – Answer options use plain, everyday language with no acronyms or abbreviations.
- **Answer option conciseness** – Answer options are short labels only, with no extra commentary or conditions.
- **Transcript answerability** – The question can be answered from the transcript and instructions alone, without external data or system lookups.
- **Positive action framing** – The question asks what the agent did rather than asking the AI to detect the absence of an action.
- **Plain language** – Instructions avoid abbreviations, acronyms, and company-specific jargon.
- **Spelling** – Question titles, instructions, and answer options are free of misspelled words.
- **No external system references** – Instructions don't reference actions or states in external systems the AI can't see in the transcript.
- **No non-textual cues** – Questions don't require assessing audio-only qualities (volume, pitch, speaking speed, vocal tone). Text-assessable qualities like professionalism or empathy are fine.
- **No PII references** – Questions and instructions don't contain specific PII values. Evaluating the agent's PII-handling behavior is fine.

> **Note**
>
> Gen AI validation is rate limited per Connect Customer instance: no more than 3 Gen AI validations can run in parallel, and no more than 30 can run per hour. If you exceed either limit, an error message appears in the side panel. Try again later. These limits don't affect structural validation.

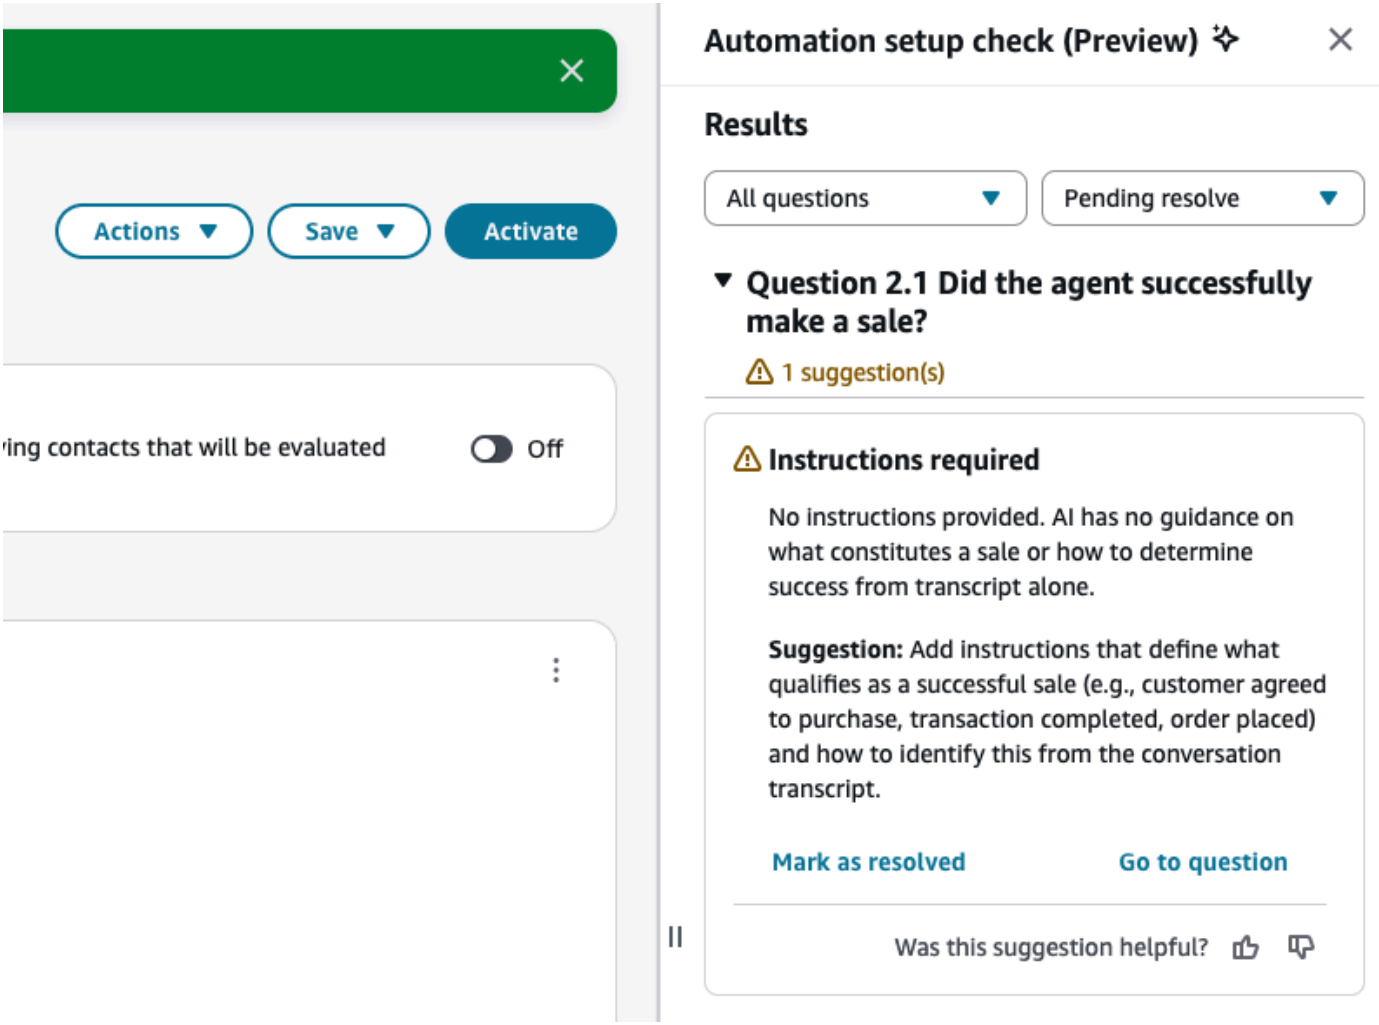
To validate an evaluation form

1. Choose **Save**, **Save and validate**.

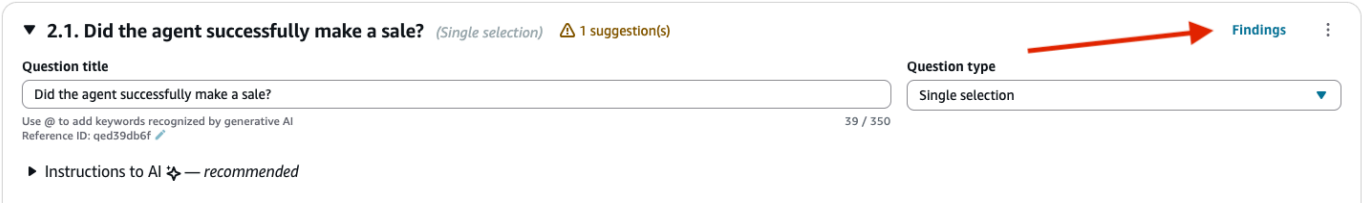


2. When validation completes, the results appear at the top of the form:

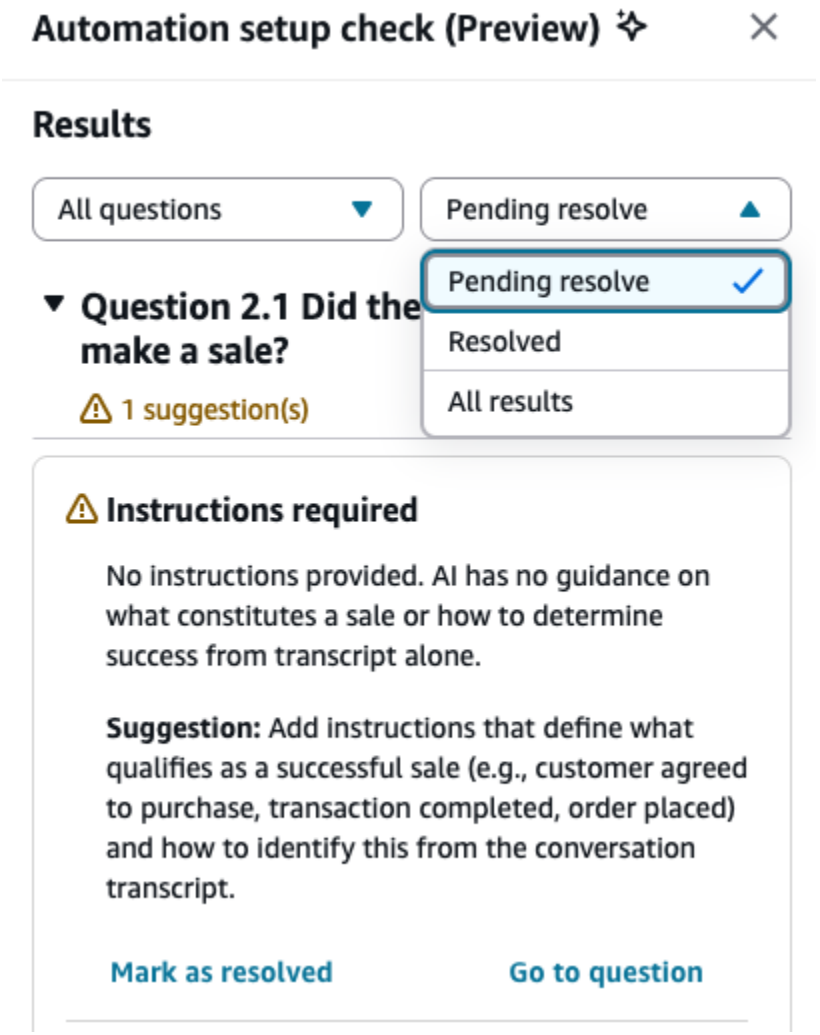
   - If no recommendations are found, a green banner appears at the top of the form confirming that validation passed.
   - If recommendations are found, they are listed in the side panel, grouped as **Errors** or **Warnings**.



3. You can close the side panel at any time. To reopen it, either choose the **Findings** button next to a question, or choose **Save and validate** again.



4. On the side panel, you can mark each finding as resolved after you have addressed it. Choose the **Pending resolve** filter to focus on the findings that still need attention.



> **Note**
>
> Marking a finding as resolved only visually hides it on the panel so you can clearly see which findings are left to address. It does not re-run validation or change the form's activation state.

Step 10: Activate an evaluation form

Choose **Activate** to make the form available to evaluators. Evaluators will no longer be able to choose the previous version of the form from the dropdown list when starting new evaluations. For any evaluations that were completed using previous versions, you will still be able to view the version of the form on which the evaluation was based on.

> **Important**
>
> After you activate a new version, evaluators can no longer start new evaluations with the previous version.

If you are still working on setting up the evaluation form and want to save your work at any point you can choose **Save**, **Save draft**.

If you want to check whether the form has been correctly set up, but not activate it, select **Save**, **Save and validate**.

Set up tag-based-access controls on performance evaluations

Connect Customer enables businesses to restrict access to specific performance evaluation forms, preventing unauthorized access to evaluation form templates and completed evaluations. Businesses can provide managers access to modify or use only the evaluation form templates that are relevant to their business line or function, improving security and making it easier for managers to select the right form while completing evaluations. Additionally, both managers and agents can be restricted from viewing certain completed evaluations. For example, you can restrict agents from viewing test evaluations filled with a form template that is yet to be finalized.

You can start by tagging evaluation forms, for example "Department: New customer". When you tag an evaluation form, all subsequent evaluations filled with the evaluation form also carry the same tag. You can then enable tag-based access controls to evaluation forms and evaluations within the security profiles of users for whom you wish to restrict access to specific evaluation forms and evaluations. Once tag-based-access control on evaluation forms is enabled, users will be able to modify only specific evaluation forms on the **Evaluation forms** page. On Contact Search, users will only be able to search for evaluation forms for which they have access, and use the evaluation forms to start evaluations. Similarly within Connect Customer **Dashboards**, users will only be able to view aggregated scores for evaluation forms for which they have access. Tag-

based access control on evaluations restricts users to only be able to view specific evaluations on the **Contact Details** page. For example, if a specific evaluation should only be visible to certain personas, such as fraud investigation, then you can restrict agents from viewing those evaluations on the Contact Details page.

⚠ Important Notes

- After you enable tag based access control on evaluations, users will lose access to any evaluations before tagging the evaluation form. If you are already using performance evaluations, we recommend that you first tag evaluation forms and accumulate evaluations over several months, before enabling tag based access to evaluations.
- We recommend using a single tag on an evaluation form (for example, "Department: New customer") while configuring tag-based access. While assigning and permitting access on multiple tags is possible, it creates complexity. This is discussed in more detail below.

Tagging evaluation forms

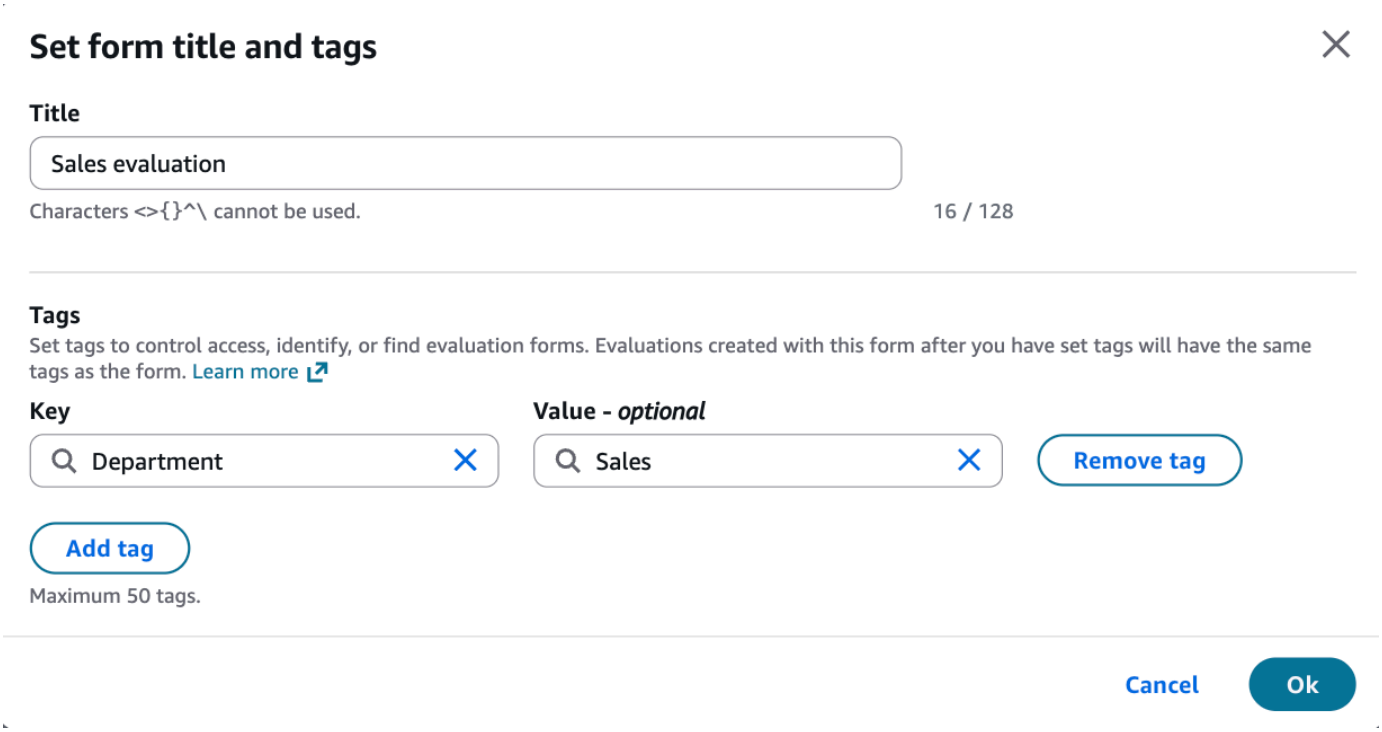
You can tag evaluation forms while creating a new evaluation form, or by updating an existing evaluation form. The tags that you can add to an evaluation form will depend on tag-based-access control granted on your security profile(s):

- If your security profile has no tag-based access controls configured for evaluation forms, then you can create or update a form with any tag(s).
- If you have one security profile with tag-based-access control enabled on an evaluation forms, then evaluation form tags from your security profile will be added automatically while creating evaluation forms through the Connect Customer UI. You will not be able to update tags on evaluation forms in this scenario.
- If you have multiple security profiles, you must add all the tags from one of your security profiles to the evaluation form while creating or updating an evaluation form. For example, if one of your security profile grants you access to "Department: Sales" and another grants you access to "Department: Retention", then you must add either the "Department: Sales" or "Department: Retention" tag on the evaluation form. While creating an evaluation form, tags from one of your security profiles will be automatically added.

Below are the steps to add tags to an evaluation form.

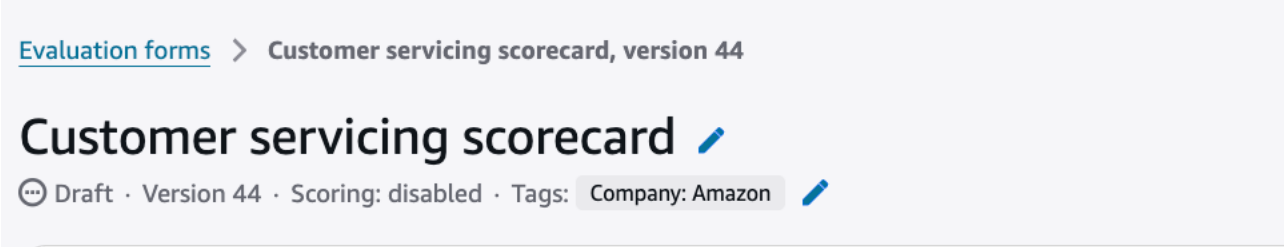
While creating an evaluation form

- You will be prompted to add tags to an evaluation form when you create it (see Create an evaluation form).

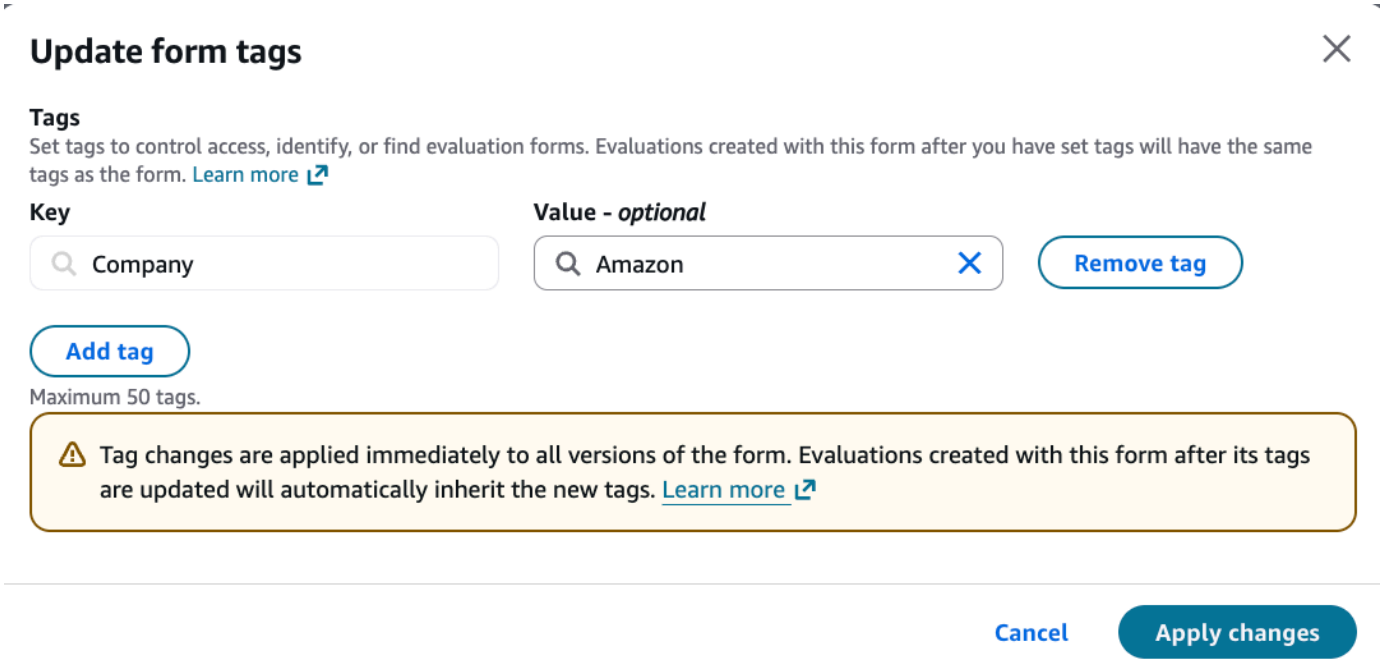


While editing an evaluation form

1. Open the evaluation form with a security profile that has the permission **Evaluation forms - manage form definitions - Edit**.
2. Choose the edit icon next to the Tags.



3. Update the tags.



Note

Tag changes are applied immediately to all versions of the form. Updating tags does not require you to save or activate the form.

Tag inheritance from evaluation forms to evaluations

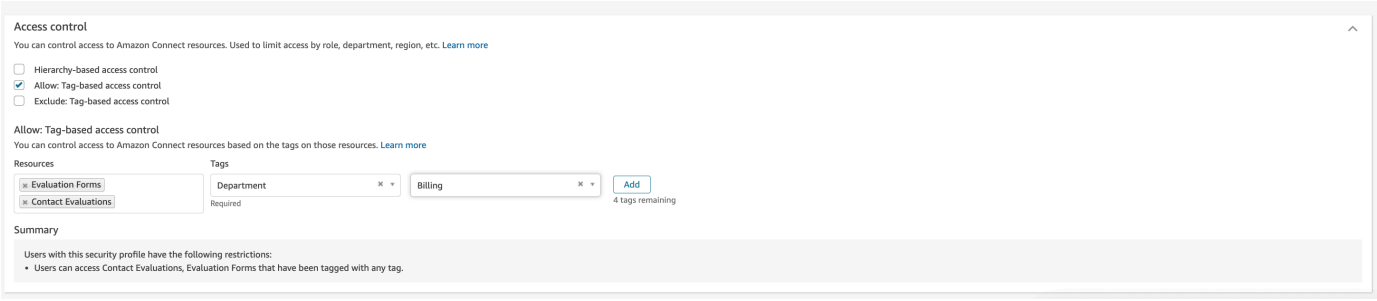
While creating an evaluation from the Connect Customer UI, the tags from the evaluation form are copied over to the evaluation upon creation. For example, if the evaluation form is tagged as "Department: Sales" then the evaluation created with this evaluation will also carry the same tag. If the evaluation form contains multiple tags (Department: Sales, Product: Dishwasher) then those will also be carried over to the evaluation provided you have access to create an evaluation with those tags (discussed in more detail in the next section).

Note

Tags are copied over only to new evaluations. If you have existing evaluations, then adding or updating tags on evaluation forms will not change evaluations on historically completed evaluations.

Set up tag-based access to evaluation forms and evaluations

1. Login to **Connect Customer** with a user profile that has access to **Security Profiles - View** and **Edit** permissions.
2. Choose **Users > Security Profiles** within security profiles, and select a security profile that you want to modify.
3. Choose **Show advanced options**.
4. Select **Allow: Tag-based access control**.
5. Under resources, select **Evaluation forms** and **Contact Evaluations**.
6. Enter the tag that you want to use for restricting access.



If you have existing evaluations, then enabling tag-based access to contact evaluations will result in individuals who already have access to evaluations losing access to historical evaluations. To retain access to historical evaluations you can:

- Start by tagging forms. This would result in any evaluations performed subsequently carrying the same tag. After you have accumulated several months' evaluations you can enable tag-based-access.
- Your technical administrator can use the TagResource API to tag any historical evaluations.
- Enable tag-based access on **evaluation forms** but not **contact evaluations**. This might be desirable in situations where there is already security that limits access to which contacts are accessible. For example, supervisors might already be restricted to access contacts within their own hierarchy, and you might want to grant your supervisors access to all evaluations on those contacts.

If you have enabled tag-based access control on **Contact Evaluations**, it is recommended to have consistency with tag-based-access on the **Evaluation Forms**. It is also recommended that users' security profiles have access to all tags on the form(s) that they need to use. For example, if a

user needs to use a form with tags "Department: New customer", "Product: Auto Insurance", their security profile should have access control enabled for both these tags across both **Evaluation Forms** and **Contact Evaluations**. If they have only one of the tags, then creating an evaluation manually in the UI will fail.

Restricting access to automated evaluation forms under testing

Tag-based-access-control can be used to run automated evaluation tests in production, without revealing evaluation results to agents and supervisors. This is useful if you are already using evaluation forms in production. An example setup is as follows:

- On the **Evaluation forms** page, tag evaluation forms that are live and should be visible to agents and supervisors as "Live: Yes"
- On **Users > Security Profiles**, you can turn on tag-based access control on **Evaluation Forms** and **Evaluations**, restricting agent and supervisors access to forms with the tag "Live:Yes"

> **Note**
>
> Before enabling tag-based-access-control, you might want sufficient history to accumulate, for example, 2 months of evaluations, as this would result in a loss in historical evaluations

- Automated evaluation forms that are still under testing can be tagged as "Live:No", preventing them from being visible by agents and supervisors
- Quality managers responsible for creating evaluation forms can be granted access to evaluation forms without tag-based restrictions. Alternatively, you can assign two security profiles to quality managers:
  - The first would grant them access to **Evaluation Forms** and **Evaluations** with the tag "Live: No"
  - The second would grant them access to **Evaluation Forms** and **Evaluations** with the tag "Live: Yes"
- After you are ready to go live with automated evaluations, you can duplicate the form, and change the tag to "Live: Yes". The original form when it was under testing should continue carrying the tag "Live: No". This makes sure that supervisors and agents cannot see historical aggregated evaluation scores in **Dashboards** when the form was under testing.

Tag Based Access Control while setting up rules to submit automated evaluations

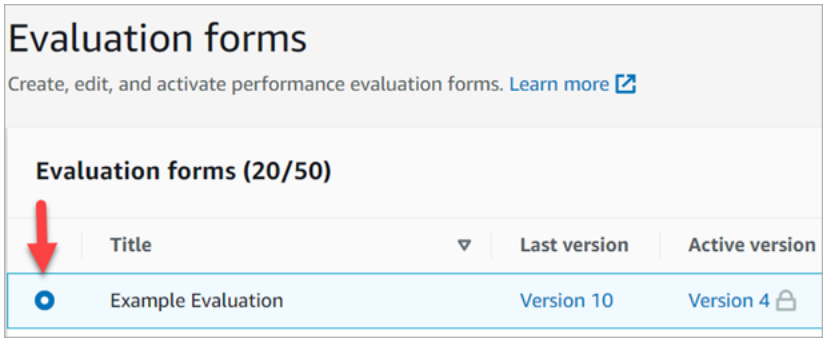
You can only create a rule to submit automated evaluations using a form that you have access to. For example, suppose there is an automated evaluation form **Auto Insurance Sales Scorecard** with the tags "Department: New customer", "Product: Auto Insurance", and your security profile grants you access to the tag "Department: New customer" for evaluation forms. Then you would be able to set up a rule to auto-submit evaluations using the form **Auto Insurance Sales Scorecard**.

Tag Based Access Control while setting up Calibration Sessions

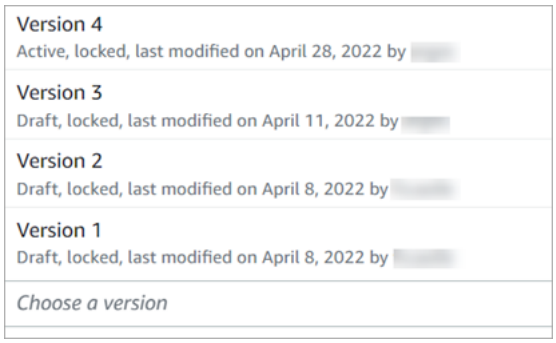
As an administrator of a calibration session, you can only create a calibration session with evaluation forms that you have access to.

View an evaluation form audit trail in Connect Customer

1. Select the evaluation form that you want to research.



2. At the bottom of the page, under **Example Evaluation**, use the dropdown menu to view previous versions, who accessed them, and when. The following image shows an example audit trail.



3. Optionally, choose one of the forms to open it.

What do Active, Draft, and Locked mean?

A form is in one of the following states:

- **Active**. A published version of the form that is available to evaluators.
- **Draft**. An inactive, locked version of the form. A draft is unlocked only when you are working on it.
- **Locked**. An evaluation form is locked when you activate or publish it. Even after you deactivate the form, it stays locked, and becomes a historical version of the form. However, you can activate the historical version to save it as a new version.

Evaluate agent performance in Connect Customer using generative AI

> **Note**
>
> **Powered by Amazon Bedrock**: AWS implements automated abuse detections. Because generative AI features in conversational analytics are built on Amazon Bedrock, users can take full advantage of the controls implemented in Amazon Bedrock to enforce safety, security, and the responsible use of artificial intelligence (AI).

Managers can specify their evaluation criteria in natural language, and use generative AI for automating evaluations of up to 100% of customer interactions. With generative AI, you can automate evaluations of additional agent behaviors (for example, was the agent able to resolve the customer's issue?), enabling managers to comprehensively monitor and improve regulatory compliance, agent adherence to quality standards and sensitive data collection, while reducing the time spent on evaluating agent performance. Along with answers, you are also provided with context and justification, and references to specific points in the transcript that you can use to provide agent coaching.

You can use generative AI to assist managers with filling evaluations or use it to automatically fill and submitting evaluations. For more information about setting up automated evaluations, see Step 6: Enable automated evaluations.

Evaluations questions are answered using generative AI by interpreting the question title and evaluation criteria specified within the instructions to evaluators associated with each question, and using these to analyze the conversation transcript. For more information, see Step 2: Add sections and questions.

Process to automate evaluations using generative AI

The following is the overview of the automation process:

1. Get a high-level understanding of which of the evaluation questions should be answered with generative AI by reading Guidelines to improve generative AI accuracy.
2. Assign permissions to select users within your quality management team to use Ask AI assistant. These users will start seeing the Ask AI button next to each question, while performing evaluations and can use that to get answer recommendations. These users can provide feedback on which questions are receiving accurate answers using generative AI. For more information, see Assign security profile permissions for performance evaluations and coaching.
3. To improve accuracy, you can provide additional evaluation criteria within instructions to evaluators. For more information, see Guidelines to improve generative AI accuracy.
4. After you have a good understanding of which questions can be accurately answered with generative AI, you can do a broader rollout by pre-configuring on the evaluation form, whether a question will receive an automated answer using generative AI.
5. After you have set up automation, any user performing evaluations using the evaluation form will get automated generative AI answers to the pre-configured questions (without requiring additional permissions). For more information, see Step 6: Enable automated evaluations.
6. You can set up automation such that an evaluator first reviews the generative AI answers before submission or you can automatically fill and submit evaluations.

> **Note**
>
> AI-generated evaluations are not 100% accurate. Before acting on AI outputs (such as providing rewards, agent coaching, and so on), we recommend that you review a sample of evaluations. This helps confirm the performance trends that AI provides. You can override AI-filled evaluations and make any corrections before sharing them with the agent or using them for performance reviews. We also recommend keeping a manual evaluation process in place. This helps you catch any drift between AI-filled evaluations and manager-filled evaluations over time.

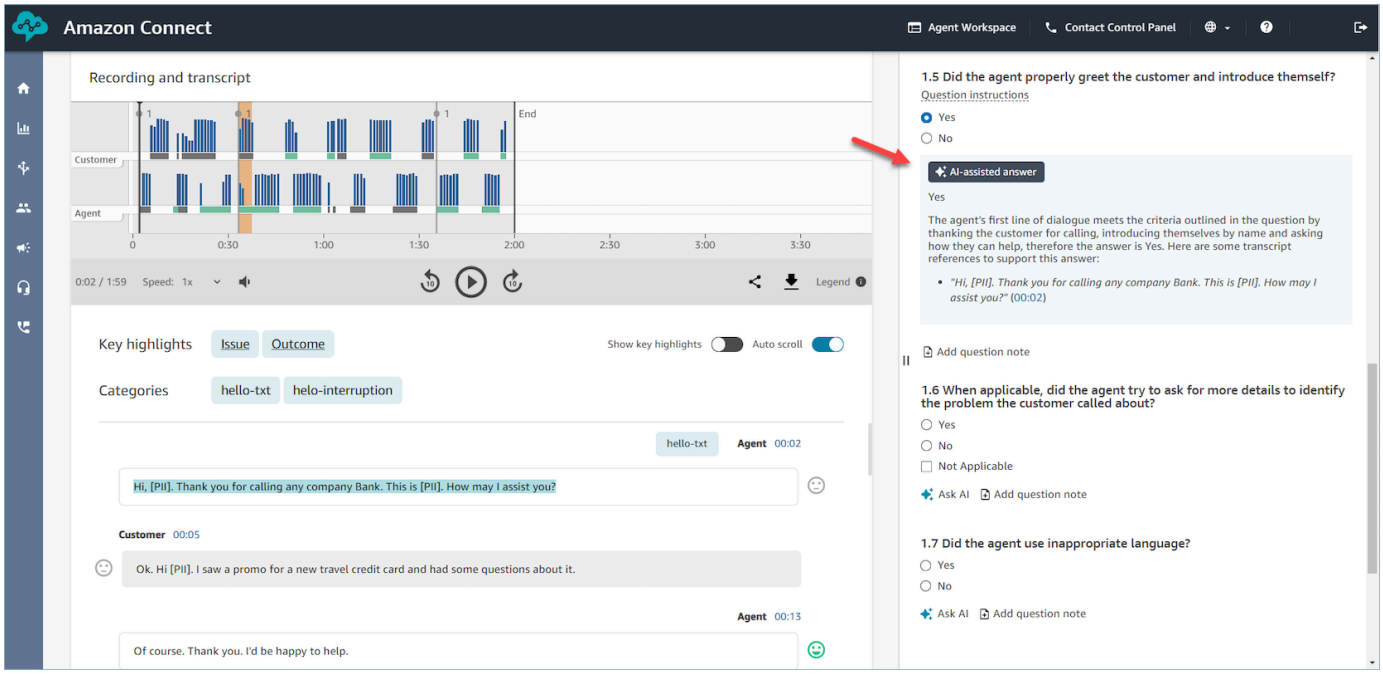
Limitations of generative AI-powered performance evaluations

Transcription accuracy affects the accuracy of generative AI-powered evaluations. Conversational analytics cannot accurately transcribe conversations that include more than one language. It also cannot accurately transcribe conversations in which multiple parties speak at the same time. Examples include conference calls, warm transfers, and calls where an agent adds a third party. Both scenarios lower the accuracy of generative AI-powered performance evaluations.

You can use rules to filter out conversations where you expect these scenarios to occur, such as conversations in specific queues. For more information, see Create a rule in conversational analytics that submits an automated evaluation.

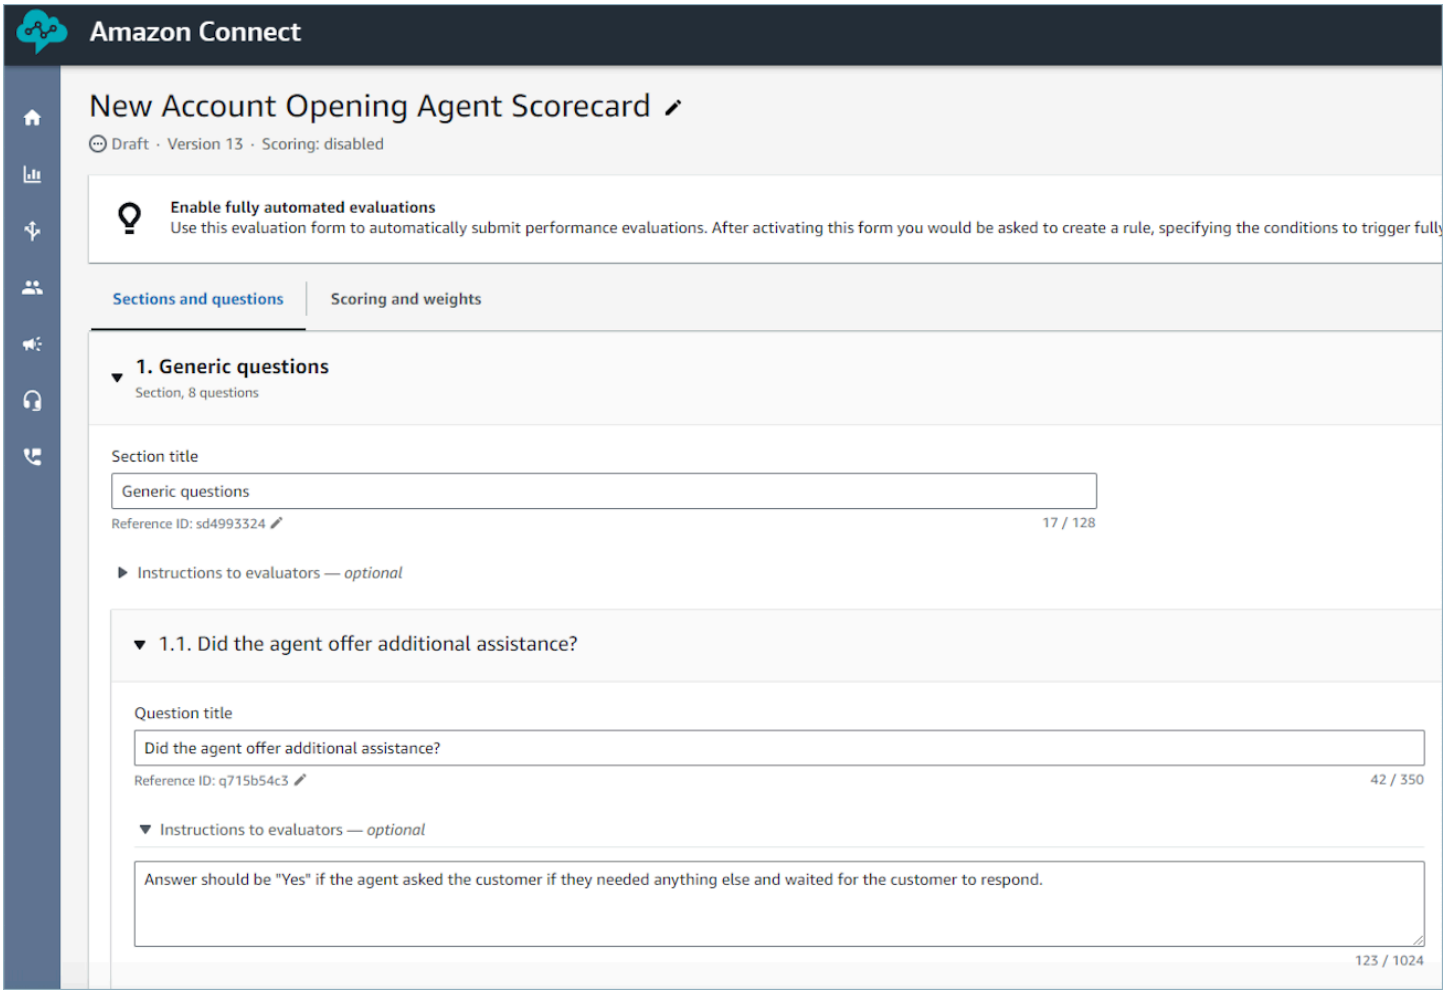
Use Ask AI to get generative AI answer recommendations

1. Log into Connect Customer with a user account that has permissions to perform evaluations and ask AI assistant.
2. Choose the **Ask AI** button below a question to receive a generative AI-powered recommendation for the answer, along with context and justification (reference points from the transcript that were used to provide answers).
    a. The answer is automatically selected based on the generative AI recommendation, but you can change it.
    b. You can get generative AI-powered recommendations by choosing **Ask AI** for up to 30 questions per contact. For more information, see Conversational analytics service quotas.
3. You can choose the time associated with a transcript reference to be directed to the point in the conversation



Provide additional criteria for answering evaluation form questions using generative AI

While configuring an evaluation form, you can provide criteria for answering questions within the **instructions to evaluators** associated with each evaluation form question. Apart from driving consistency in evaluations by evaluators, these instructions are also used to provide generative AI-powered evaluations.



AI answer mapping and scoring

If AI is not able to identify which of the provided answer options is appropriate, then it selects **Not Applicable**, even if the question is not optional. When this happens, the question is excluded from scoring and the weights are redistributed to the other questions. To avoid this, clearly explain each answer option in the **Instructions to evaluators** for the question. For more information, see Guidelines to improve generative AI accuracy.

Set up automated evaluations using generative AI on the evaluation form

You can pre-configure on an evaluation form whether a question will be automatically answered using generative AI. Then, if you start an evaluation using the evaluation form on the Connect Customer UI, answers to these questions will get automatically filled using generative AI (without requiring you to choose Ask AI). You can also use generative AI to automatically fill and submit

evaluations. For automatically submitted evaluations, you can use generative AI to answer up to 10 questions per contact (see Conversational analytics service quotas). This limit does not apply to automation using contact categories or metrics (for example, longest hold duration).

To learn more about setting up automated evaluations using generative AI, see Guidelines to improve generative AI accuracy.

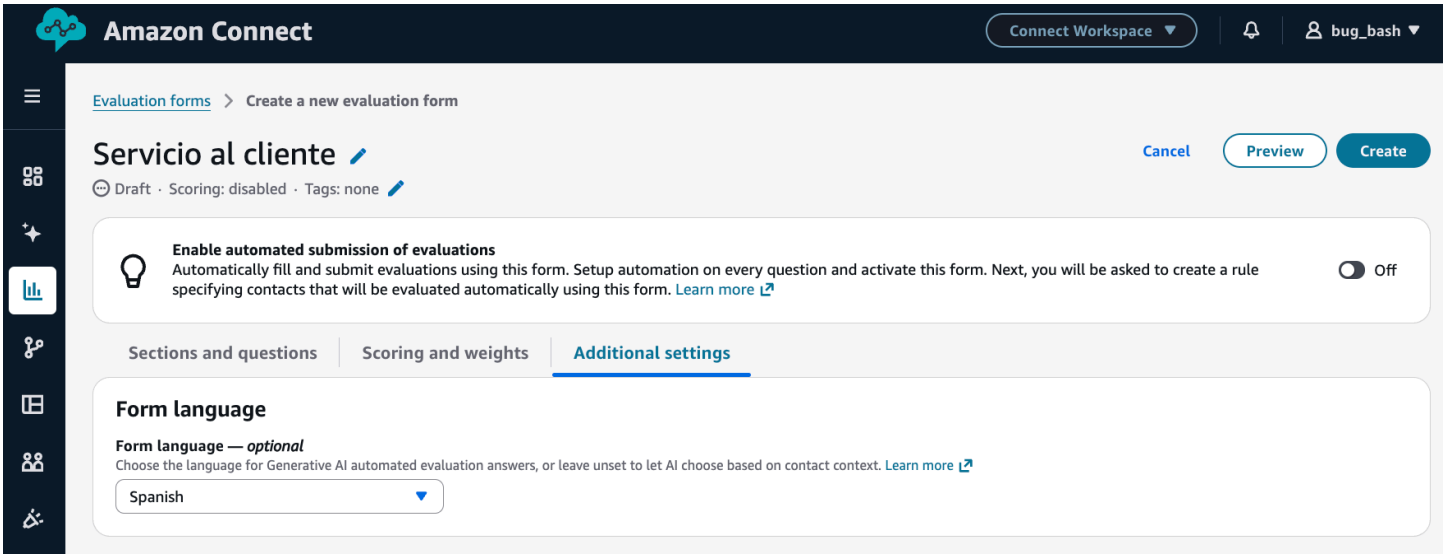
Set up generative AI-powered evaluations in non-English languages

By default, if you do not set the language of an evaluation form, the generative AI model automatically detects the language of your evaluation form questions and tries to provide answers in the same language, if the AI model understands that language. By default, generative AI answer justifications are typically provided in English.

To consistently receive both AI-generated answers and answer justifications in your preferred language, you can set the language of an evaluation form, choosing from **Afrikaans**, **Albanian**, **Amharic**, **Arabic**, **Armenian**, **Basque**, **Belarusian**, **Bengali**, **Bosnian**, **Bulgarian**, **Burmese**, **Catalan**, **Central Kurdish**, **Chinese - Cantonese**, **Chinese - Simplified**, **Chinese - Traditional**, **Croatian**, **Czech**, **Danish**, **Dari**, **Dutch**, **English**, **Estonian**, **Farsi**, **Finnish**, **French**, **Galician**, **Georgian**, **German**, **Greek**, **Gujarati**, **Haitian Creole**, **Hebrew**, **Hindi**, **Hmong**, **Hungarian**, **Icelandic**, **Indonesian**, **Irish**, **Italian**, **Japanese**, **Javanese**, **Kannada**, **Kazakh**, **Khmer**, **Korean**, **Lao**, **Latvian**, **Lithuanian**, **Luganda**, **Macedonian**, **Malay**, **Malayalam**, **Marathi**, **Nepali**, **Norwegian**, **Odia**, **Pashto**, **Polish**, **Portuguese**, **Punjabi**, **Romanian**, **Russian**, **Serbian**, **Sinhala**, **Slovak**, **Slovenian**, **Somali**, **Spanish**, **Sundanese**, **Swahili**, **Swedish**, **Tagalog**, **Tamil**, **Telugu**, **Thai**, **Turkish**, **Ukrainian**, **Uzbek**, **Vietnamese**, **Welsh**, **Xhosa**, and **Zulu**. By explicitly setting the language of an evaluation, you can also perform cross-language evaluations, where generative AI fills an evaluation form in English, even when the conversation transcript is in another language, say Spanish. This enables multilingual contact centers to use a standardized evaluation framework across languages.

To set the language of the evaluation form:

1. Select the **Additional settings** tab while creating or updating an evaluation form.
2. Choose **Form language** from the dropdown.
3. Ensure your form's questions, instructions and answer choices are in the same language as the selected **Form language**, for optimal AI performance.



Guidelines to improve generative AI accuracy

Selecting questions to be answered by generative AI

Dos

- Use generative AI to answer questions that only require the conversation transcript. Examples are questions on soft skills, questions that check for call flow, or compliance statements, among others.
- Split complex questions into multiple simpler ones. For example, instead of "Did the agent exhibit active listening?", ask two questions: "Did the agent understand the customer's problem the first time, without the customer needing to repeat themselves?" and "Did the agent summarize the issue after the customer explained it?".
- Use conditionally enabled questions to enable or disable questions that are only applicable in certain situations. For example, you might have one question, "Did the customer buy a product during the conversation?", and a subsequent conditionally enabled question, "Did the agent provide mandatory fee disclosures before completing the sale?". For more details, see Step 4: Conditionally enable questions.

Don'ts

- Don't use generative AI to answer questions that need information outside the conversation transcript. Generative AI cannot analyze screen recordings, access your internal or third-party systems such as CRM applications, or evaluate conversations across multiple contacts.

- Don't use generative AI to evaluate quantifiable activities such as "Was the customer put on excessive hold?" or "Was the customer frequently interrupted?". Instead, set the question type to **Number** and use metrics such as the longest hold duration or the number of interruptions. For more details, see Step 6: Enable automated evaluations.
- Don't automate questions that assess interactions between multiple parties (another agent, a partner institution, or a second customer). conversational analytics is aware of only two participants at a given time. For example, avoid a question like "If another person other than the primary account holder joined the conversation, did the agent first confirm with the primary account holder before proceeding?".
- Don't ask questions that depend on tone of voice. Generative AI cannot determine the agent's or customer's tone.
- Don't use generative AI for highly subjective questions, such as "Was the agent attentive during the call?".

Improving phrasing of questions and associated instructions

Dos

- Word questions as complete sentences. Instead of "ID validation", ask "Did the agent attempt to validate the customer's identity?".
- Add detailed evaluation criteria in the **Instructions to evaluators** for the question. For "Did the agent try to validate the customer's identity?", add the instruction: *Answer is Yes if the agent asked for the customer's membership number and postal code before addressing their questions. Answer is No otherwise.*
- Define business-specific terms the question depends on. If the agent must name a department in the greeting, list example department names in the instructions.
- Use "agent" and "customer" consistently. Avoid variations like "colleague", "representative", or "associate", and "member", "caller", or "subscriber".
- Make it clear who is being evaluated. "Did the agent avoid the usage of profanity?" can be read as asking whether profanity occurred anywhere, returning "No" even when only the customer used it. Ask "Did the agent use profanity?" instead.
- Phrase questions positively. Use "Did the agent greet the customer?" rather than "Did the agent skip the greeting?". Phrasing questions positively provides better AI-evaluation reasoning and references.

- Specify when the answer is **Not Applicable** (N/A). For example: *The answer is N/A if the call resulted in a transfer.*
- In the **Instructions to evaluators**, explain when AI should select each answer option. For "Did the agent give a resolution timeframe?", add the instruction: *Answer is Yes if the agent gave a resolution timeframe, No otherwise.* Not explaining each option might result in AI selecting **Not Applicable**, even if the question is not optional.
- Clarify whether all or any of the specified agent behaviors is required. "The agent must ask the customer's name and phone number" fails if the agent asked for the name but not the phone number.
- Include examples for non-standard scenarios, not just the standard call flow. If you expect the agent to say "It typically takes 3 to 5 business days" on a standard call, you should also include callback phrasing like "I'll call you back within 30 minutes with an update". Standard-flow-only examples lead to inconsistent answers on callbacks, escalations, and transfers.
- Give auto-fail questions the most attention, since one failing answer affects the whole form's evaluation score. Cover edge cases and non-standard scenarios. For more on scoring, see Step 5: Assign scores and ranges to answers.

Don'ts

- Don't use double quotes unless you need exact wording. If the instruction checks for `"Have a nice day"`, the AI won't match *Have a nice afternoon*. Write instead: `The agent wished the customer a nice day`.
- Don't use acronyms. Spell out the full term, for example "CFPB", so the AI can interpret it correctly.
- Don't use proper nouns likely to be misspelled in the transcript. A product name like *Klarity Pay* might be transcribed differently, preventing a match.
- Don't use vague questions. Instead of "Did the agent use appropriate language?", ask "Did the agent use profanity?".
- Don't use long verbatim scripts. Checking for `"Thank you for calling ABC Bank. How may I assist you?"` rarely matches, since minor transcription differences break the full script.

Improving answer options

Dos

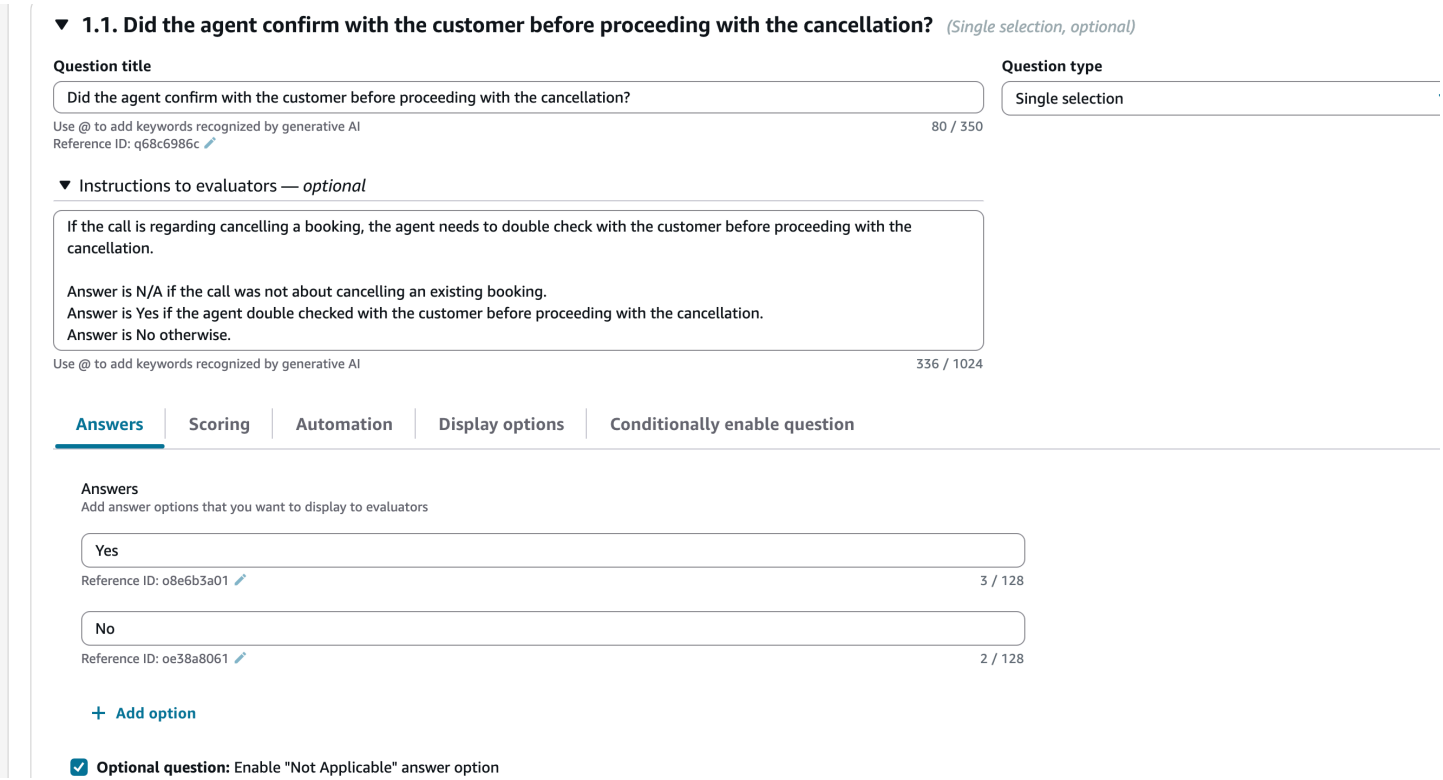
- Use simple, short answer options, such as **Yes**, **No**, and **Partial**.
- Enable the **Optional question** setting when a question might not apply. This lets evaluators skip the question or mark it **Not Applicable**.

Don'ts

- Don't use spelling errors or special characters in answer options, as they can reduce the accuracy of generative AI answers.
- Don't use too many answer options. For "How was the customer experience?", a long list like Great, Good, OK, Poor, Very Poor, and Horrible reduces accuracy. Use a smaller set of distinct options instead.
- Don't use long text in answer options, since the generative AI model might reproduce it incorrectly.

Example implementation following guidelines

The following example shows a generative AI-answered question that follows these guidelines. The question title is a complete sentence, the instructions to evaluators define each answer option and explain the Not Applicable scenario, and the answer options are short.



Performance evaluations of self-service interactions in Connect Customer

Connect Customer provides you with the ability to automatically evaluate the quality of self-service interactions and get aggregated insights to improve customer experience. Managers can define custom criteria to assess the quality of self-service interactions, that can be filled manually or automatically using insights from conversational analytics, and other Connect Customer data. For example, you can automatically assess if the AI agent repeatedly fails to understand the customer, resulting in poor customer sentiment and transfer to a human agent. Managers can review these insights in aggregate and on individual contacts, alongside self-service interaction recordings and transcripts, to identify opportunities to improve bot or AI agent performance.

> **Note**
>
> Performance evaluations of self-service interactions is only available as part of Connect Customer (with unlimited AI). For more information, see Connect Customer pricing.

To automatically evaluate self-service interactions, you need to first the section called “Enable conversational analytics” (automated interactions include self-service and post-call workflows like

surveys). Performance evaluations can evaluate the entire self-service interaction, irrespective of whether it's handled by touch tone, Lex bots, Connect Customer AI agents or custom bots within Connect Customer. The steps to set up automated evaluations of self-service interactions are as follows:

- the section called “Step 1: Create a draft evaluation form”
- the section called “Step 2: Set up automation”
- the section called “Step 3: Set up a rule to automatically submit evaluations of self-service interactions”

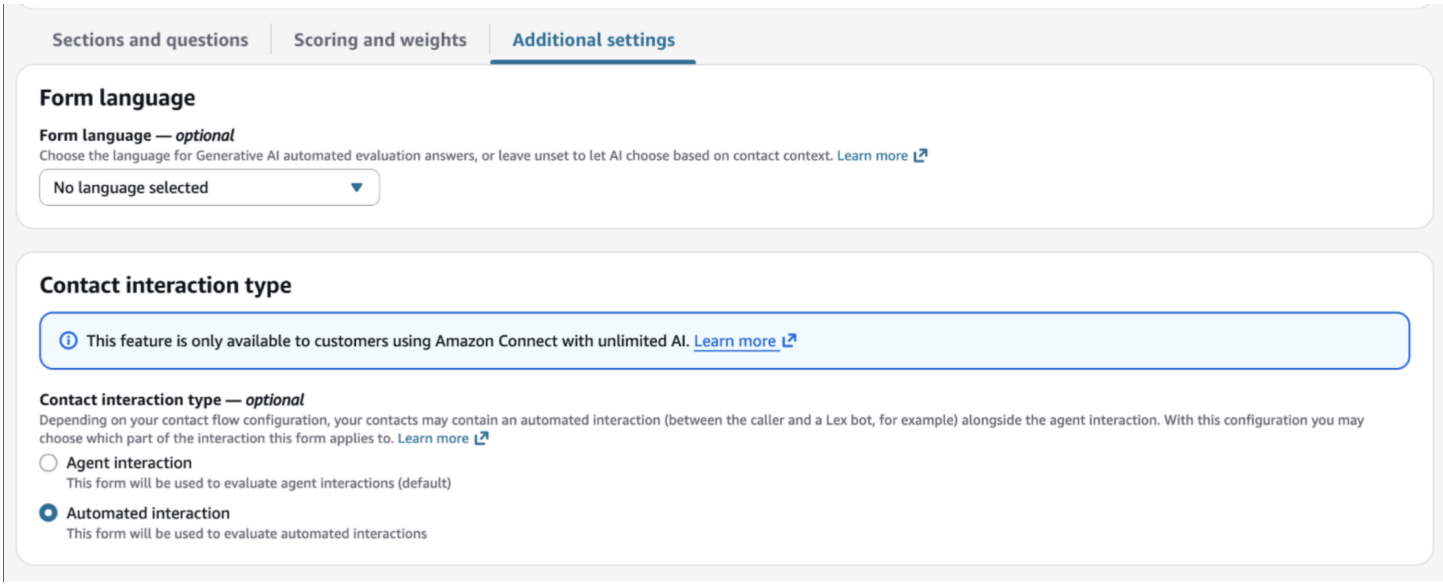
After setting up automation on an evaluation form (step 2), you can use the same form for AI-assisted (human-in-the loop) evaluations. You can manually start an evaluation at which point AI fills the answers automatically. You can then review or revise answers before submission. With this approach, you can also test and optimize automation before you set up rules to automatically submit evaluations (step 3).

Step 1: Create a draft evaluation form

You can define custom criteria to evaluate self-service interactions. These criteria can measure self-service resolution, customer experience or bot/AI agent behaviors. To evaluate self-service interactions, set **Contact interaction type** as automated interaction under additional settings:

How to set the contact interaction type

When creating or editing an evaluation form, choose **Additional settings**, then under **Contact interaction type**, select **Automated interaction**. If you do not set this, the form defaults to agent interaction and cannot be used to evaluate automated (self-service) contacts.



An example evaluation form is as follows:

Section 1: Self-service success

- **1.1** Was the contact handled during self-service, without transferring to a human agent? (Single selection)
- **1.2** Was the customer able to self-serve at least one of their needs? (Single selection)

Section 2: Customer experience

- **2.1** What was the overall customer sentiment score during self-service? (Number)
- **2.2** Did the customer express frustration during self-service? (Single selection)

Section 3: AI agent behaviors

- **3.1** Did the AI agent fail to understand the customer and asked them to repeat themselves? (Single selection)
- **3.2** Was the AI agent rude or aggressive towards the customer at any point? (Single selection)

For additional details, see the section called “Create an evaluation form”.

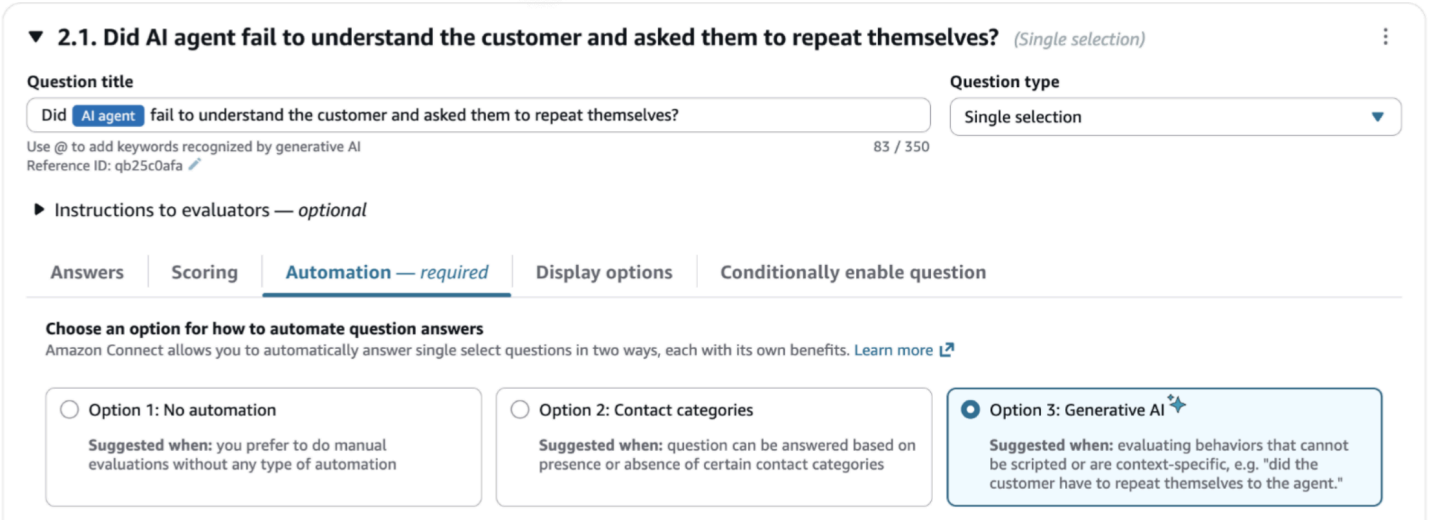
Step 2: Set up automation

You can automatically fill evaluations of self-service interactions using integrated generative AI within evaluation forms, rules and integrated metrics such as customer sentiment.

Automation using integrated generative AI

Type in the question, questions instructions and answer options to be used by AI for evaluating performance of self-service interactions. Under Automation for a question, select **Option 3: Generative AI**. The AI interprets the text of the question, question instructions, and analyzes the self-service interaction transcript to fill one of the answer options.

Use @ to enter keywords that generative AI can understand - the words system, AI agent and bot refer to any non-human participant that is interacting with the customer. You can use these words interchangeably.



Automation using rules

Start with setting up a rule:

1. On the navigation menu, choose **Analytics and optimization**, **Rules**.
2. Select **Create a rule**, **Conversational analytics**.
3. Under **When**, use the dropdown list to choose **post-call analysis** or **post-chat analysis**.

Example rules that you can create:

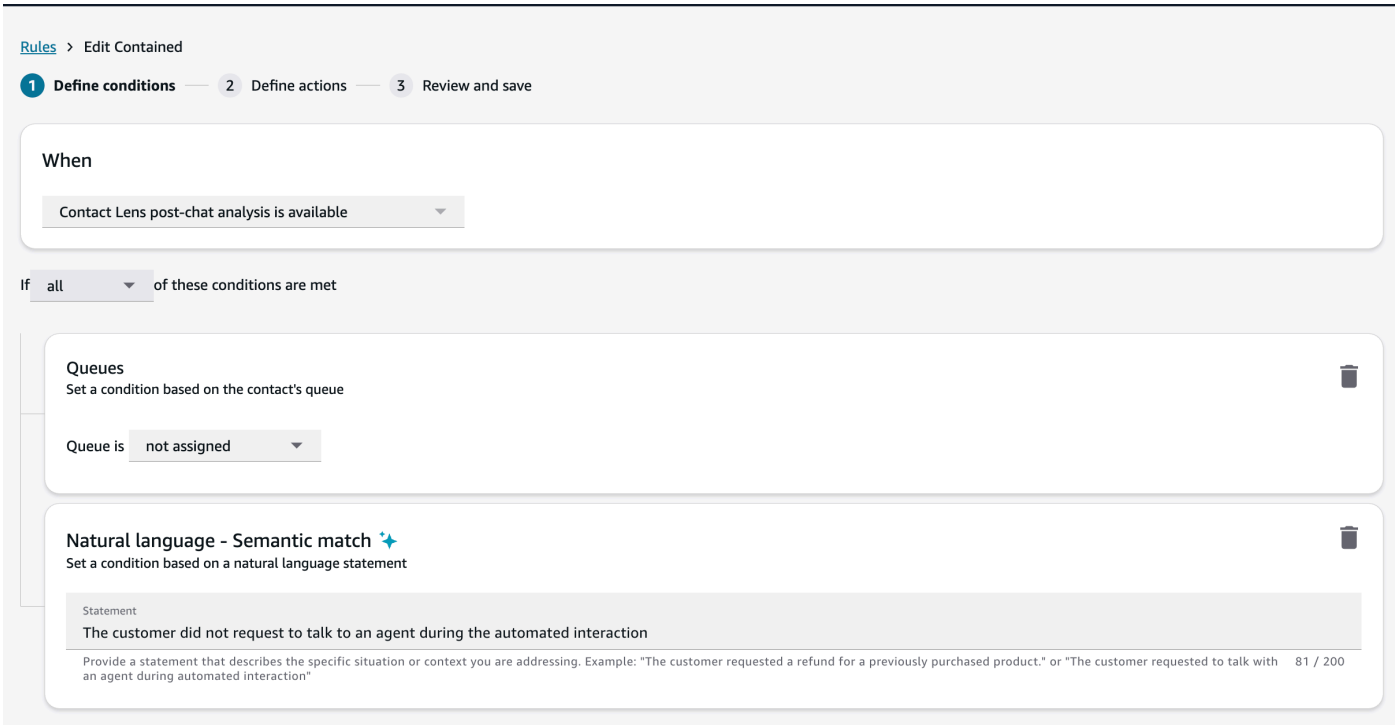
Self-service containment

- Add a new condition checking that the queue was not assigned and the contact was handled during the automated interaction.
- You can also use natural language intent to confirm that the customer did not request for a human agent during the automated interaction with the Lex bot or AI agent.

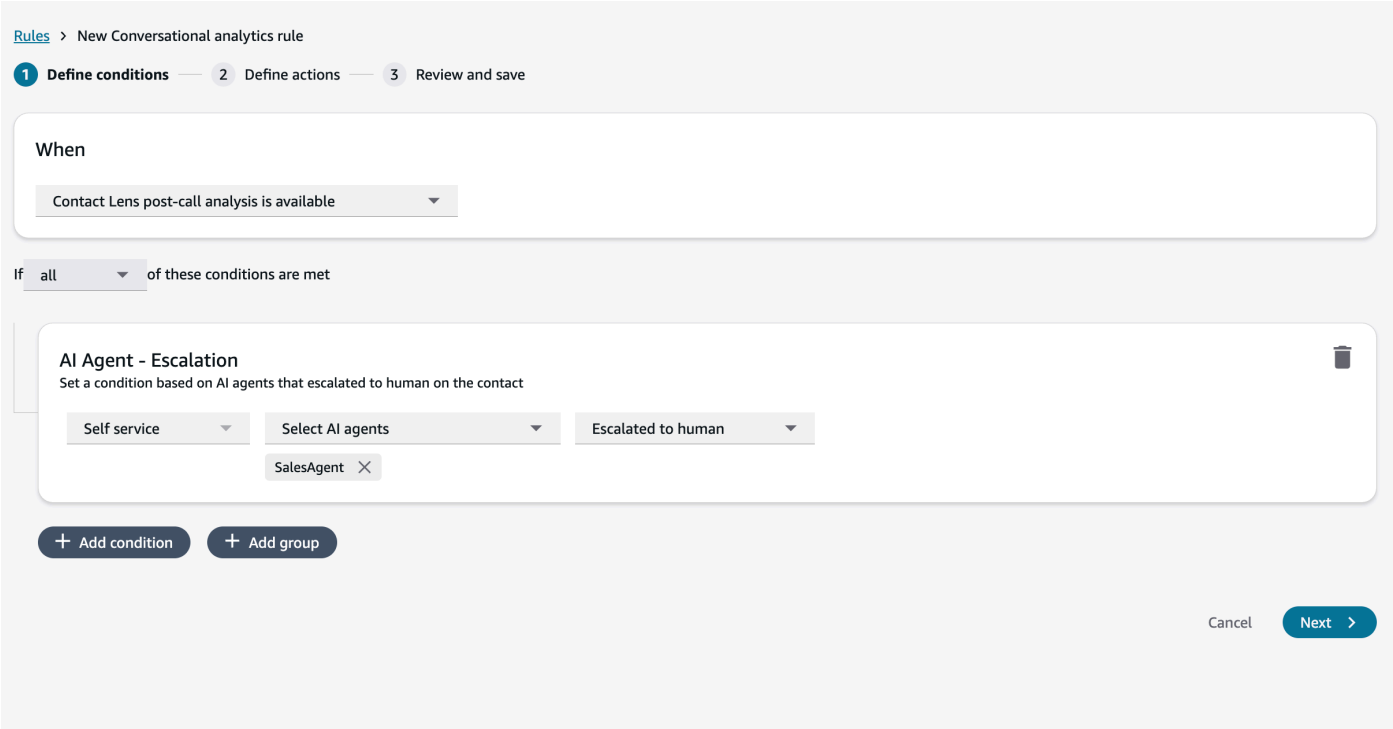
Note

Connect Customer understands the following keywords within semantic match rules:

- **System:** Denotes a bot or AI agent
- **Agent:** Refers to the human agent
- **Customer:** The person interacting with the contact center
- **Automated interaction:** Part of the customer interaction where human agent was not present on the conversation, including self-service interaction with bot or AI agent, and wait time in the queue
- **Human agent interaction:** Customer interaction with the human agent



- If you are using a Connect Customer AI agent, you can also check if the AI agent for self-service escalated to a human or not.



Self-service success for at least one intent

Create a rule using **natural language - semantic match** condition:

"During the automated interaction, the system successfully fulfilled at least one of the customer requests, such as providing information or completing another service request."

Bot/AI agent failing to understand the customer

Create a rule using **natural language - semantic match** condition:

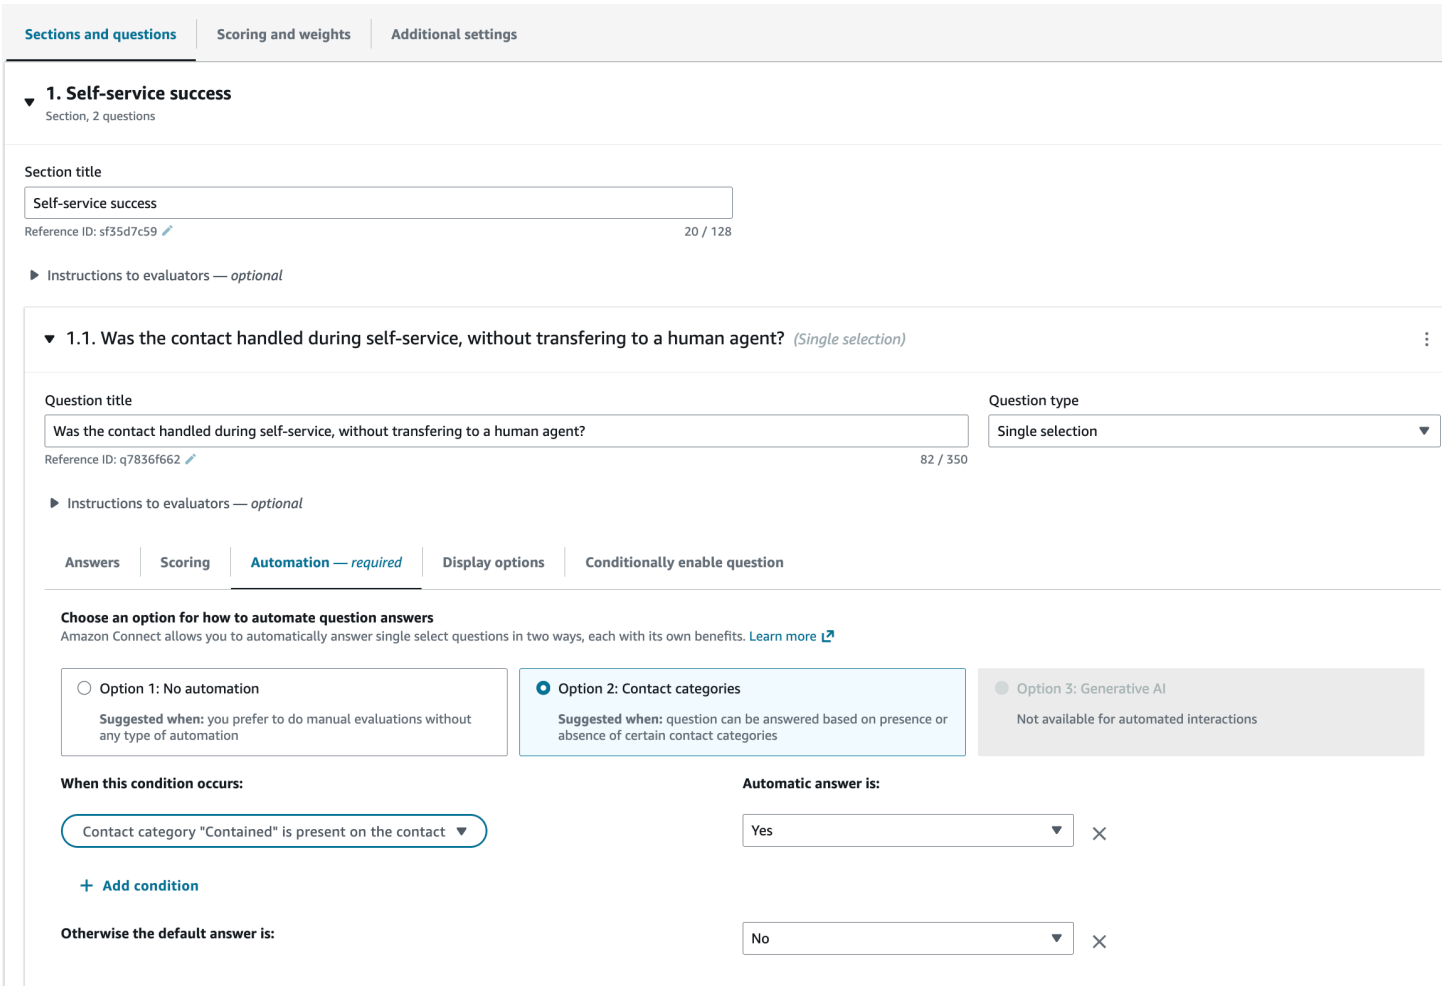
"The system failed to understand the customer and asked the customer to repeat themselves."

Customer expressed frustration

Create a rule using **natural language - semantic match** condition:

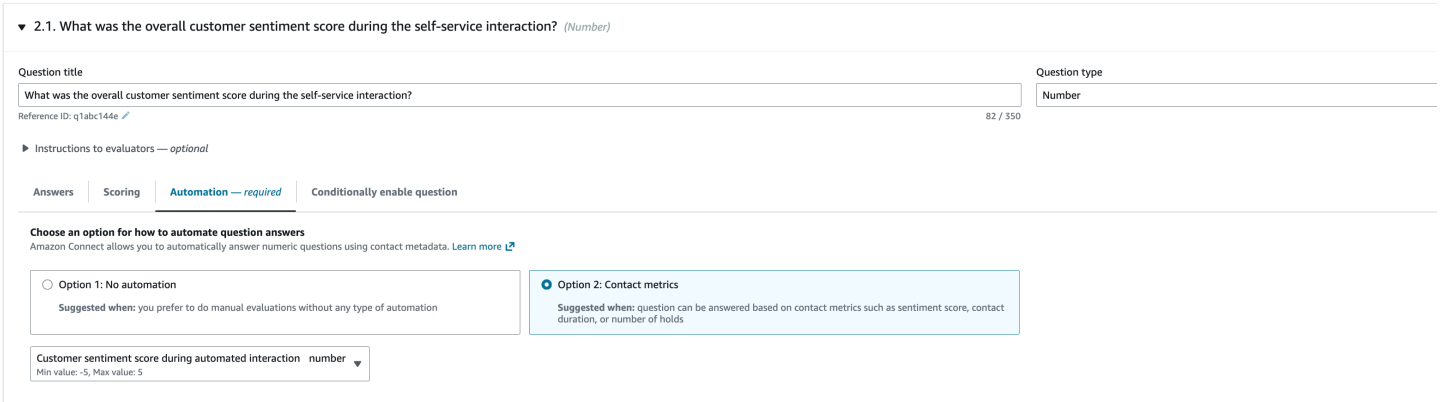
"Customer expressed frustration during the automated interaction."

After you set up a rule you can use it to answer single selection or multiple selection questions in your evaluation form. For example, if you created a rule to check for self-service containment, then you can use that to answer a question on whether the contact was handled during self-service.



Automation using metrics

You can use contact metrics to automatically answer questions on the self-service experience. For example, you can check for customer sentiment during the automated interaction. To use metrics, make sure that the Question Type is chosen as Number.



After you have set up automation on every question, you toggle on **Enable automated submission of evaluations** and activate the form. You would then be guided to create a rule to automatically submit the evaluation form.

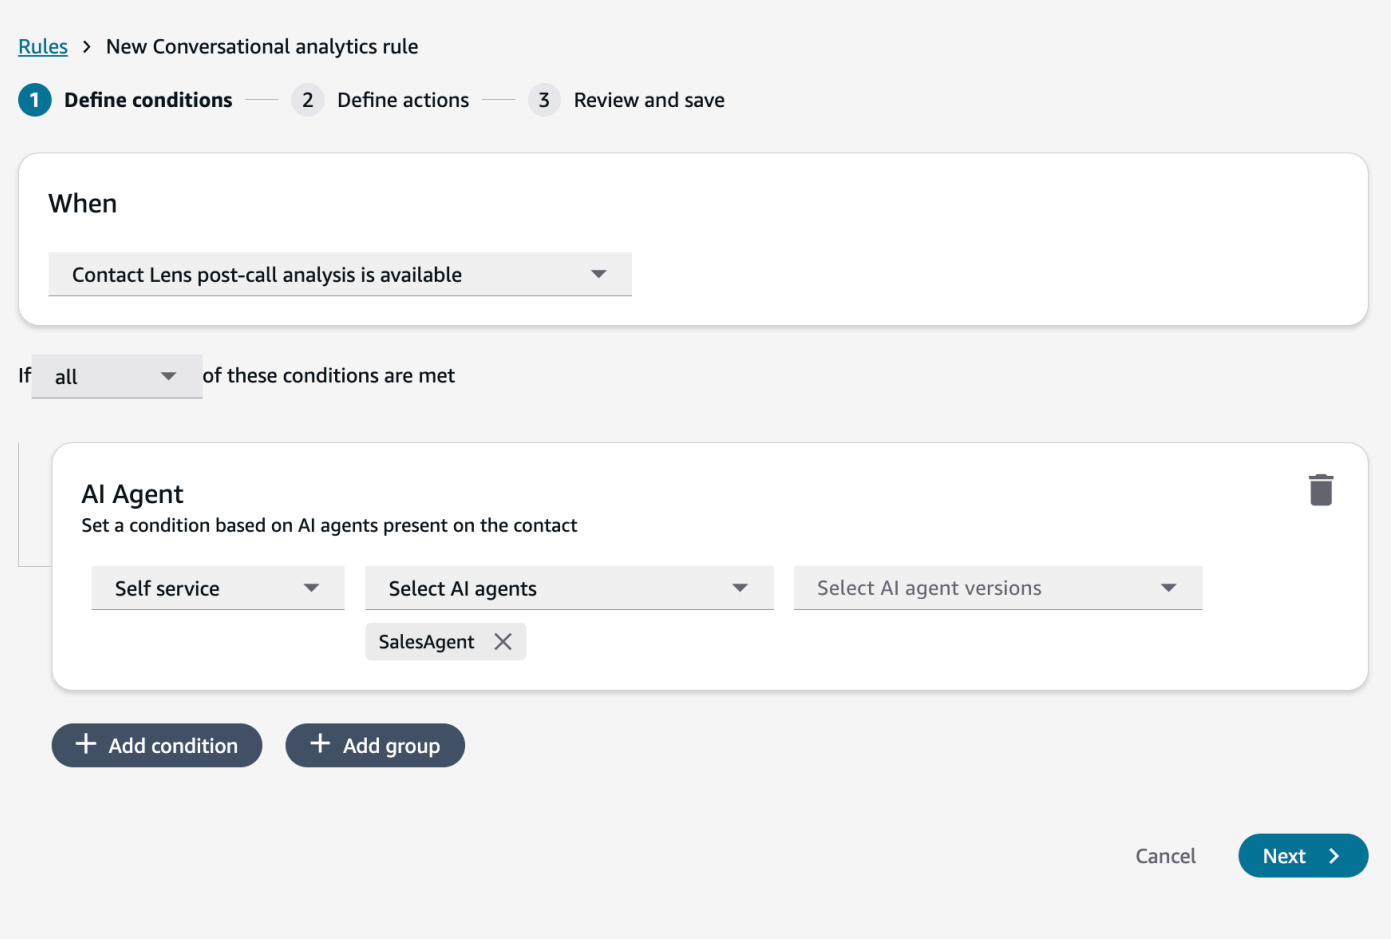
For additional details, see the section called “Enable automated evaluations”.

Step 3: Set up a rule to automatically submit evaluations of self-service interactions

You can use the following conditions to identify specific self-service interactions.

AI Agent

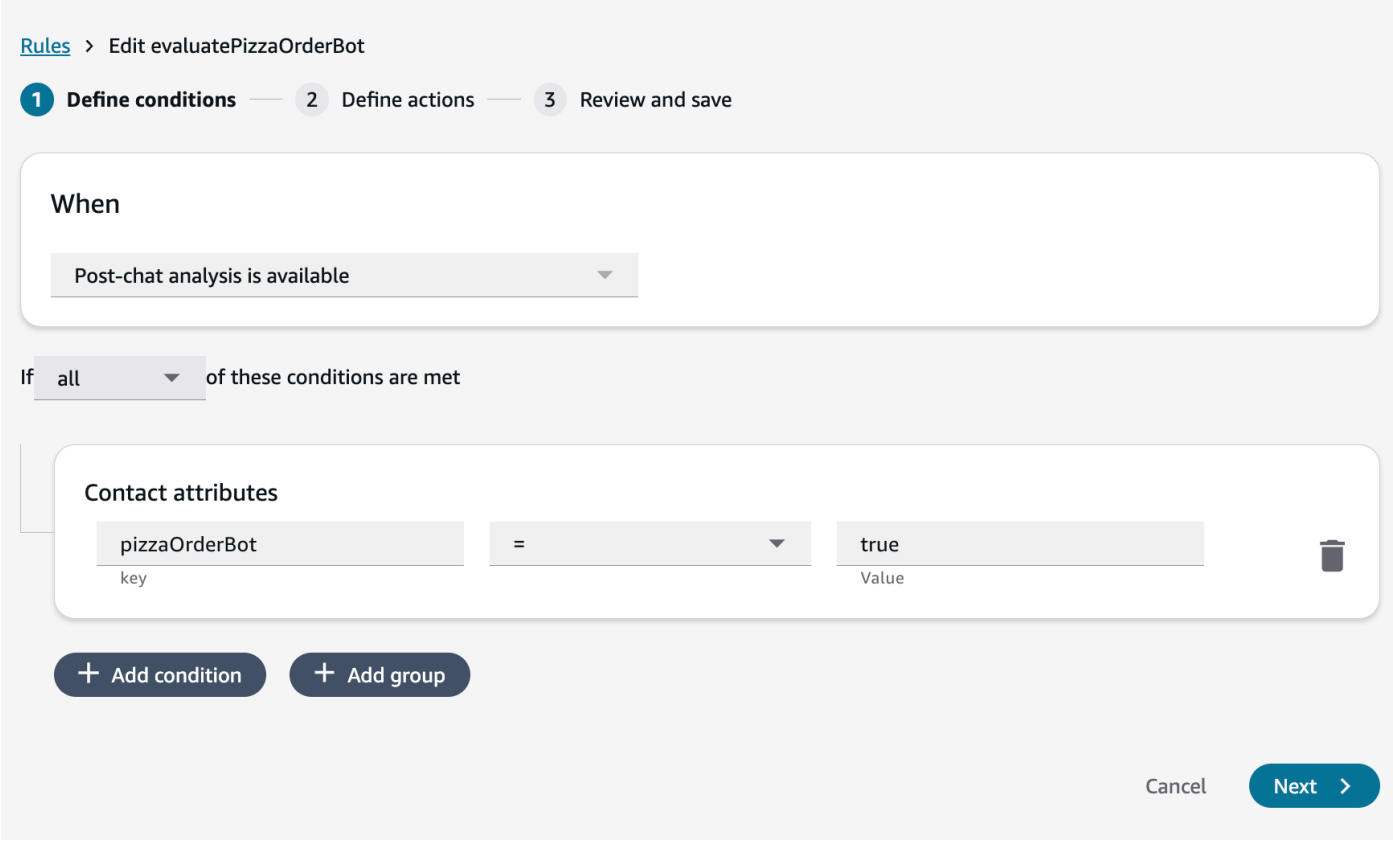
To trigger a self-service interaction evaluation, you can identify if specific AI agent(s) were active on the contact. You can also check for a specific AI agent version.



Custom contact attributes and contact segment attributes

You can also use **custom contact attributes** and **contact segment attributes** set within flows to identify specific workflows, bots, customer intents or outcomes. For example, you might set a

contact attribute within flows, `pizzaOrderBot = true` if a Lex bot called "Pizza Order Bot" is invoked during the conversation.



After you have defined conditions:

1. On the **Define actions** page, provide a category name to identify the rule.
2. Choose **Add action**, select **Submit automated evaluation**, and select the form that you want to use for automatically submitting an evaluation. (This action is already selected on the page if you created the rule when you activate the form.)

For more information, see the section called “Create a rule that submits an automated evaluation”.

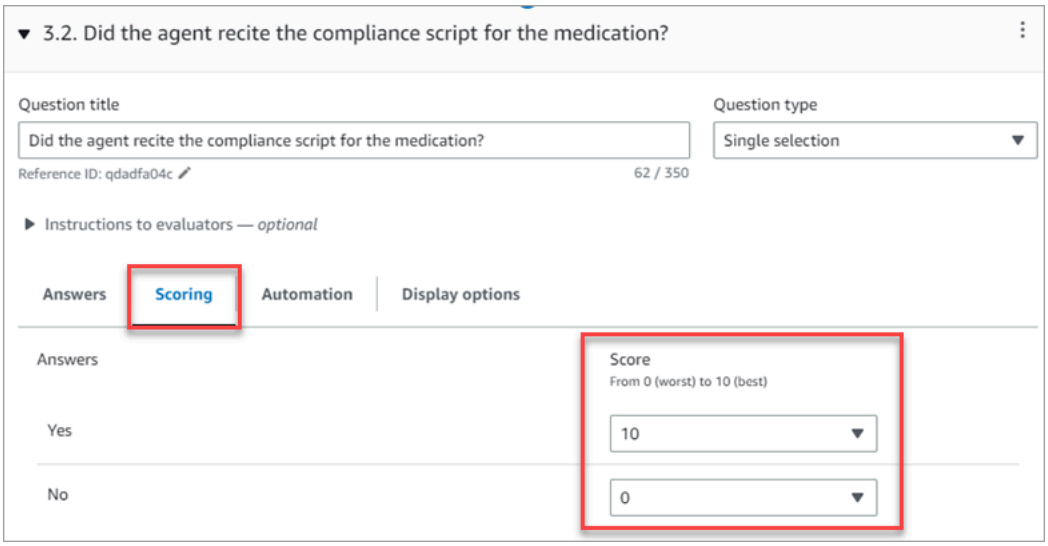
Use scoring and weights on agent evaluation forms in Connect Customer

By using *weights*, you can increase or decrease the impact of a question or section score on the overall evaluation score.

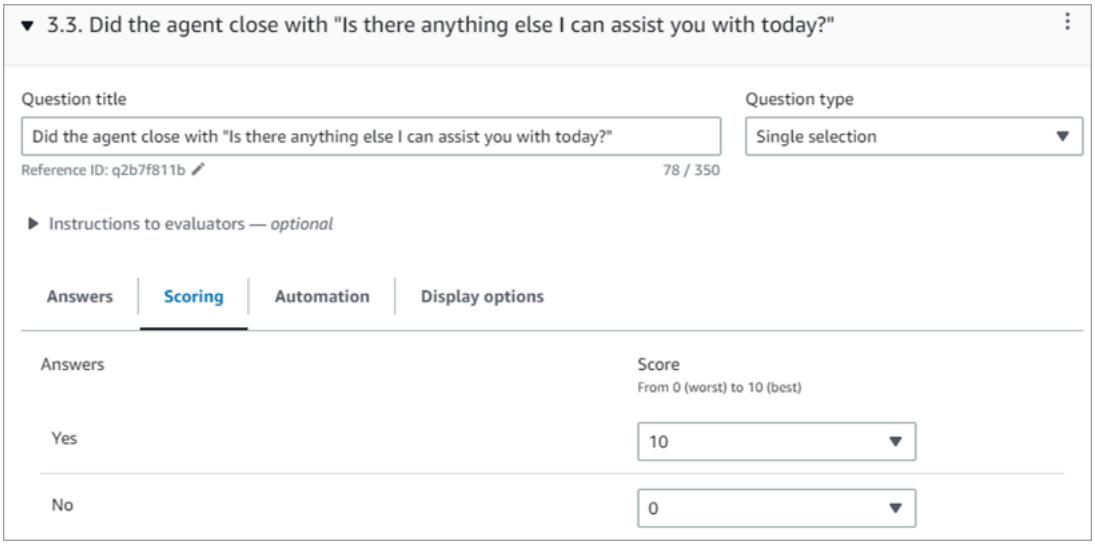
When scoring is enabled for the evaluation form, you can assign *weights* to sections or questions. The weight raises or lowers the impact of a section or question on the final score of the evaluation.

Example score

Let's say you are assigning the score to a question that is critically important to your business. If the answer is a Yes, the agent gets 10 points. For No they get 0 points. This is shown in the following image.

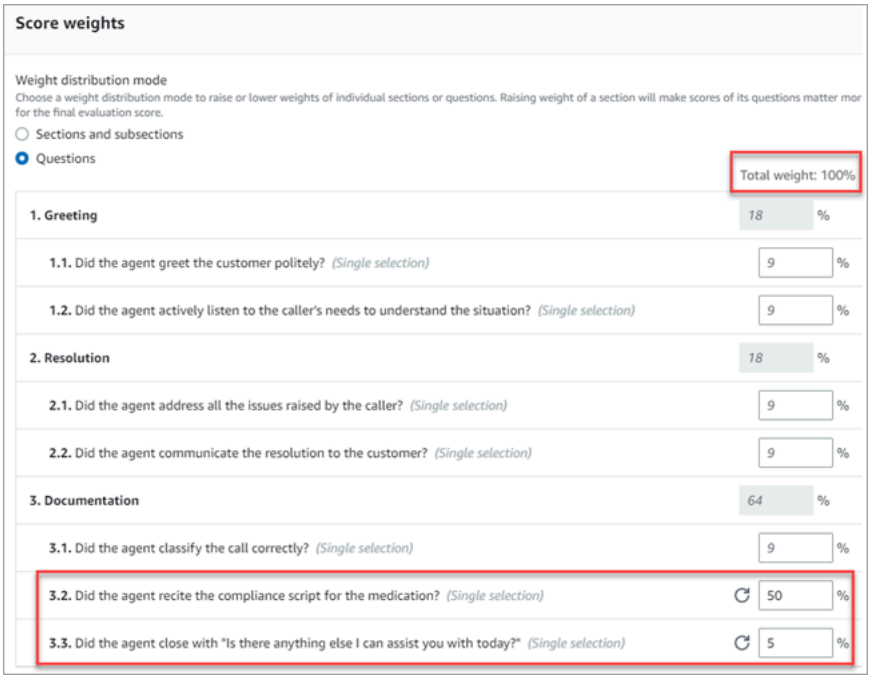


The answer to first question is more important to your business than the answer to *Did the agent close with "Is there anything else I can assist you with today?"*, which is also worth 0-10 points, as shown in the following image.



To differentiate scores of the questions, you indicate that weight of one question is more than the other.

The following image shows that the answer to *Did the agent recite the compliance script for the medication* is 50% of the agent's score. Whereas the answer to *Did the agent close with "Is there anything else I can assist you with today"* weighs only 5% of the score.



The total weight must always equal 100%.

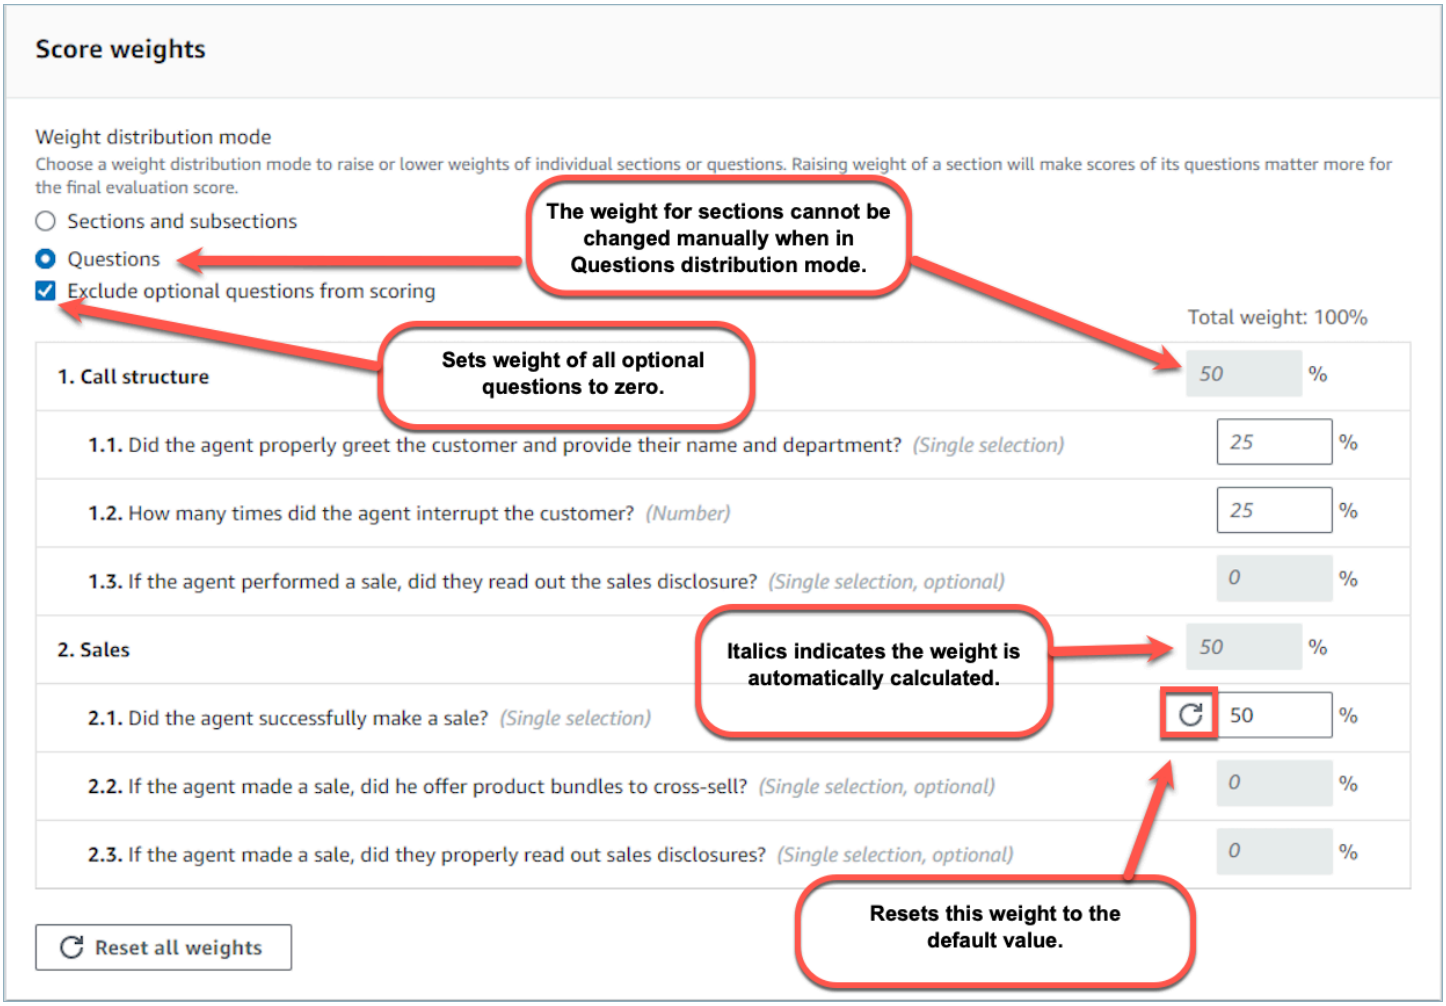
Weight distribution mode

With **Weight distribution mode**, you choose whether to assign weight by section or question:

- **Weight by section**: You can evenly distribute the weight of each question in the section.
- **Weight by question**: You can lower or raise the weight of specific questions.

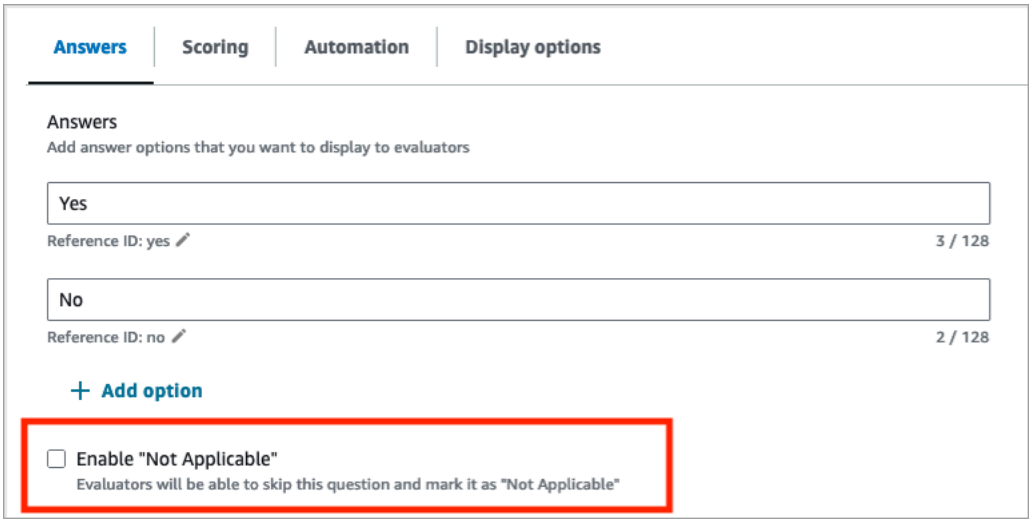
When you change a weight of a section or question, the other weights are automatically adjusted so the total is always 100 percent.

For example, in the following image, three of the questions were manually set to 10 percent. The weights that display in italics were adjusted automatically.



Weights of optional questions

When a question is optional or applicable only in certain scenarios, choose **Enable "Not Applicable"** as an answer option to the question. The following image shows this setting on the **Answers** tab.



After an evaluation is completed, Connect Customer calculates the evaluation score:

- Questions that are answered as **Not Applicable** do not count toward the form's final score.
- Their weight is redistributed proportionally among the remaining questions so that the total sum of weights across all questions remains 100%.

For example, consider the following table. It represents a form with four questions (Q1, Q2, Q3, and Q4) that have weights of 40%, 20%, 20%, and 20% respectively. Each question has three answer options (A1, A2, and A3) with scores of 10, 5, and 0. An evaluation with answers Q1:A1, Q2:A2, Q3:A2, Q4:A3 would be scored as shown in the table.

Question	Question weight	Answer	Answer score	Weighted answer score
Q1	40%	A1	10	40%
Q2	20%	A2	5	10%
Q3	20%	A2	5	10%
Q4	20%	A3	0	0%

The form's evaluation score = 40% + 10% + 10% + 0% = 60%.

However, if the answer to question Q4 is changed to **Not Applicable**, then the evaluation is scored as follows:

Question	Question weight	Answer	Additional question weight	Redistributed question weight	Answer score	Weighted answer score
Q1	40%	A1	10%	50%	10	50%
Q2	20%	A2	5%	25%	5	12.5%
Q3	20%	A2	5%	25%	5	12.5%
Q4	20%	Not Applicable	-	-	-	-

Here's what's going on:

- Question Q4 is effectively removed from the calculation. Its weight (20%) is distributed among the remaining 3 questions in proportion to their weights.
- Question Q1 has double the weight of questions Q2 and Q3, so it receives double the amount of added weight.
- The form's evaluation score = 50% + 12.5% + 12.5% = 75%.

How point-based scoring is calculated in Connect Customer

The overall evaluation score in point-based mode is calculated as follows:

```
Score Percentage = (Total Earned Points / Total Maximum Base Points) x 100
```

- **Earned Points** – The sum of point values for all selected answers across all scored questions.
- **Maximum Base Points** – The sum of the highest achievable point values for each non-bonus question.

Example: Point-based score calculation

Consider a form with one section containing six questions:

Question	Type	Answer	Earned Points	Max Base Points
1.1	Single select (Regular)	b	20	20
1.2	Single select with Bonus Option	a (bonus)	30	20
1.3	Bonus Question	b	20	0 (bonus)
1.4	Excluded from Scoring	a	N/A	N/A
1.5	Numeric (Regular)	5	20	20
1.6	Multiple selection	c, b, a	60	60

Calculation:

- Total Earned Points: 20 + 30 + 20 + 20 + 60 = 150
- Total Max Base Points: 20 + 20 + 0 + 20 + 60 = 120
- Score Percentage: (150 / 120) x 100 = **125%**

The score exceeds 100% because Q1.2 has a bonus option (which adds 10 extra points beyond the question's max of 20) and Q1.3 is a bonus question (its earned points of 20 contribute to the numerator but its max does not contribute to the denominator). Q1.4 is excluded from scoring and does not affect the calculation at all.

The following image shows this evaluation with all maximum scores achieved.

Question-level scoring details

- **Single selection questions** – The earned points equal the point value of the selected option. The max base points equal the highest non-bonus option value.
- **Numeric questions** – The same logic applies as single selection, but the "option" is the range that the numeric answer falls into.
- **Multiple selection questions** – The earned points equal the sum of all selected options' point values. If a cap is configured, the sum is clamped at the cap value. The max base points equal the sum of all option values (or the configured cap).
- **Bonus options** – When a bonus option is selected, the earned points include the bonus value on top of the question's normal maximum. The max base points remain unchanged. This means the earned points for that question can exceed its max.
- **Bonus questions** – The earned points from a bonus question are added to the total earned points, but the question's max base points are 0 (not counted in the denominator). This allows the overall score to exceed 100%.
- **Excluded questions** – Excluded questions do not contribute to either earned points or max base points. They are completely removed from the score calculation.
- **Automatic fail** – If an automatic fail option is selected, the earned points for the affected scope (section or entire form) are set to zero. The max base points remain unchanged.
- **"None of the options" (multiple selection)** – When the evaluator selects "None of the options" on a multiple selection question, the earned points for that question are zero. The question still contributes its maximum base points to the denominator.

Notify supervisors and agents about performance evaluations

You can create rules that automatically send emails or tasks to supervisors and agents based on evaluation results.

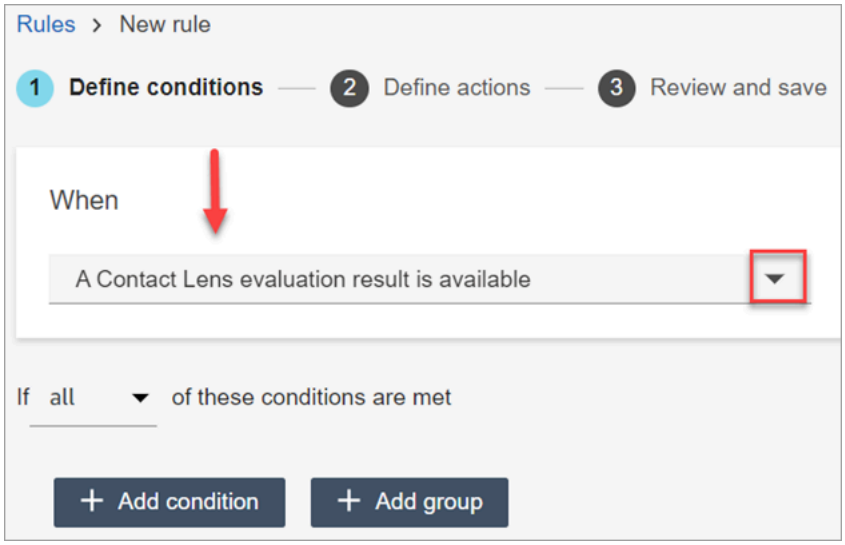
- Supervisor notifications can drive timely coaching based on performance evaluations. For example, you can notify supervisors if an agent receives an evaluation score below a certain threshold.
- Agent notifications can be used to prompt agents to review and acknowledge their evaluations.

Topics

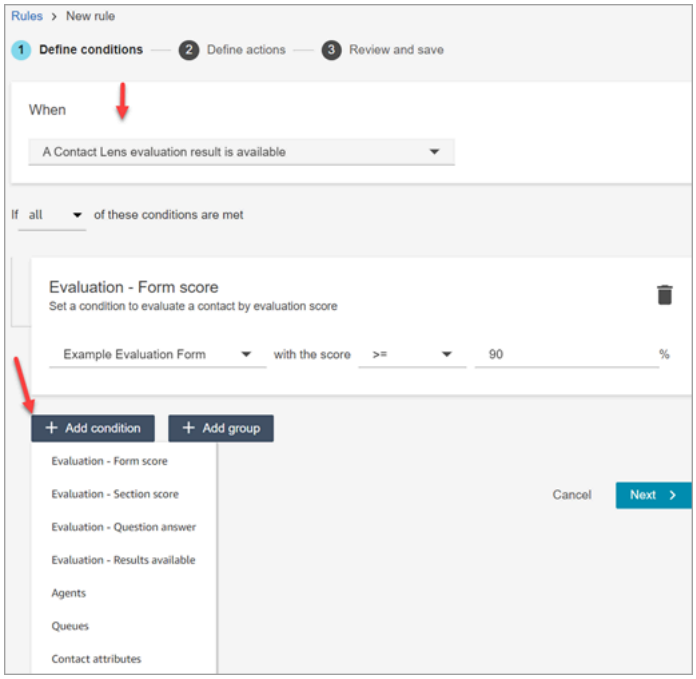
- Step 1: Define rule conditions for evaluation forms
- Step 2: Define rule actions
- Example rule with multiple conditions

Step 1: Define rule conditions for evaluation forms

1. On the navigation menu, choose **Analytics and optimization**, **Rules**.
2. Select **Create a rule**, **Evaluation forms**.
3. Under **When**, use the dropdown list to choose **A conversational analytics evaluation result is available**, as shown in the following image.



4. Choose **Add condition**.



You can combine criteria from a set of conditions to build very specific conversational analytics rules. The following are some of the available conditions:

- **Evaluation - Form score**: Build rules that run when the score for a specific evaluation form is met.
- **Evaluation - Section score**: Build rules that run when the score for a specific section is met.
- **Evaluation - Question answer**: Build rules that run when the score for a specific question and answer is met.
- **Evaluation - Results available**: Build rules that run on any evaluation submissions.
- **Agent hierarchy**: Build rules that run on a specific agent hierarchy. Agent hierarchies might represent geographical locations, departments, products, or teams.

  To see list of agent hierarchies so you can add them to rules, you need **Agent hierarchy - View** permissions in your security profile.
- **Agent**: Build rules that run on a subset of agents. For example, receive notifications on agents belonging to your team.

  To see agent names so you can add them to rules, you need **Users - View** permissions in your security profile.

- **Queues**: Build rules that run on a subset of queues. Often organizations use queues to indicate a line of business, topic, or domain. For example, you could build rules specifically for the evaluations of those agents assigned to sales queues.

  To see the queue names so you can add them to rules, you need **Queues - View** permissions in your security profile.

- **Contact attributes**: Build rules that run on the values of custom contact attributes. For example, you can build rules for agent evaluations for a particular line of business or for specific customers, such as based on their membership level, their current country of residence, or if they have an outstanding order.

- **Contact segment attributes**: You can identify contacts within rules using custom contact segment attributes with values populated from other systems or using custom logic. You can define an attribute and set its value in flows. Custom segment attributes are only present on that specific contact ID, and not the entire contact chain. For example, you can build a rule that identifies that the customer closed their account during the conversation.

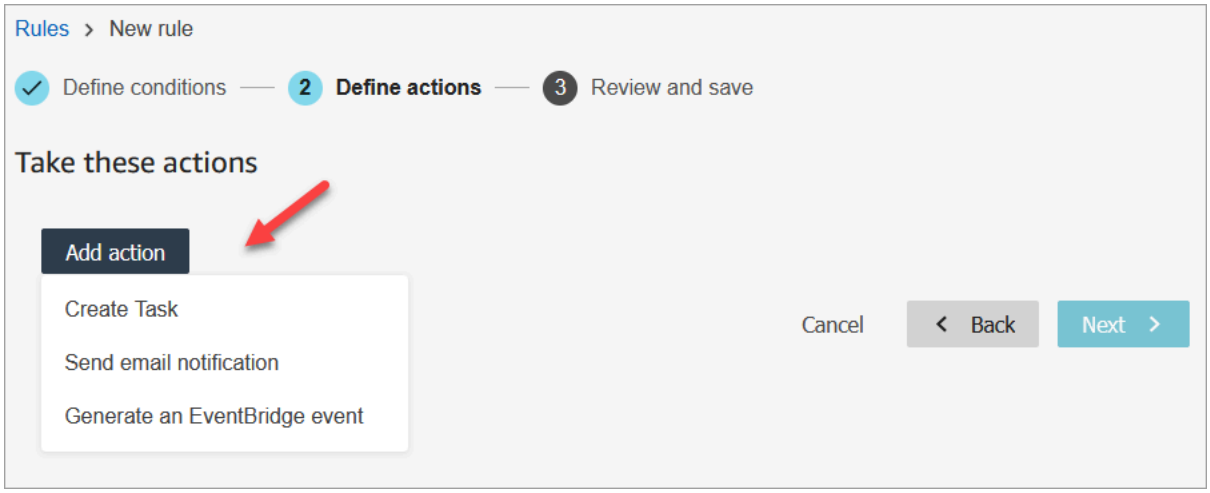
  To see the list of contact segment attributes to add to a rule, you need **Predefined attributes - View** permission.

5. Choose **Next**.

Step 2: Define rule actions

1. Choose **Add action**. You can choose the following actions:

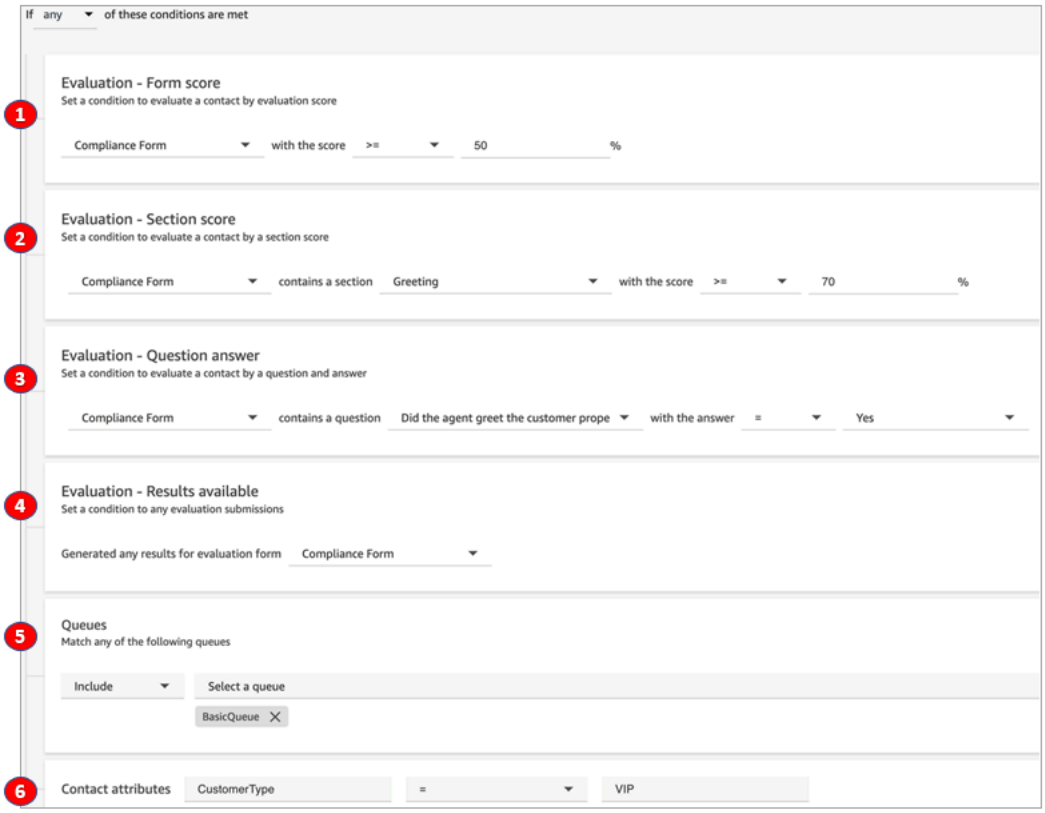
   - Create Task
   - Send email notification
   - Send in-app notification
   - Generate an EventBridge event



2. Choose **Next**.
3. Review and make any edits, then choose **Save**.
4. After you add rules, they are applied to new evaluation submissions that occur after the rule was added. You cannot apply rules to past, stored evaluations.

Example rule with multiple conditions

The following image shows a sample rule with six conditions. If any of these conditions are met, the action is triggered.



1. **Evaluation - Form score**: Does the Compliance Form have a score greater than or equal to 50%?
2. **Evaluation - Section score**: In a Compliance Form, does the Greeting section have a score greater than or equal to 70%?
3. **Evaluation - Question score**: Does the Compliance Form question *Did the agent greet the customer properly* equal **Yes**?
4. **Evaluation - Results available**: Have any results been generated for the Compliance Form?
5. **Queues**: Is this for the **BasicQueue**?
6. **Contact attributes**: Does CustomerType equal VIP?

Provide agent coaching in Connect Customer

Connect Customer provides integrated coaching tools that help supervisors deliver structured, data-driven feedback to agents based on performance evaluations. For upcoming one-on-one sessions with agents, supervisors can share detailed coaching feedback with concrete examples, and set performance goals directly within Connect Customer. Quality management teams can also assign coaching to supervisors with due dates when they identify improvement opportunities, such as showing greater empathy towards customer issues. After coaching is completed, agents

can acknowledge the feedback in Connect Customer, making sure that they understand next steps for improvement. Past coaching feedback is centrally accessible, making it easier for agents, supervisors, and quality managers to track agent progress over time.

> **Note**
>
> This feature is available as part of Connect Customer performance evaluations.

Assign permissions for coaching

Permissions can be configured as follows:

1. **Admins and quality managers**: Provide **coaching – manage coaching sessions** permissions. These permissions grant them access to all coaching sessions in your Connect Customer instance. With this permission, they can assign agent coaching to agents' supervisors.
2. **Supervisors**: Provide **coaching – my coaching sessions** (View, Create, Delete, Edit) permissions. These permissions enable them to create and manage agent coaching with themselves as the coach.
3. **Agents**: Provide **coaching – my coaching sessions – View** permission. This permission enables the agent to view and acknowledge coaching where they are the participant.

In addition, admins, quality managers and supervisors can be granted **Contact Search - View** and **Evaluation forms - perform evaluations - View** permissions. With these permissions enabled, users will see automated suggestions of evaluations to coach on, based on the selected coaching topic.

For more information, see Assign security profile permissions for performance evaluations and coaching.

Provide coaching to agents

You can start coaching in two ways:

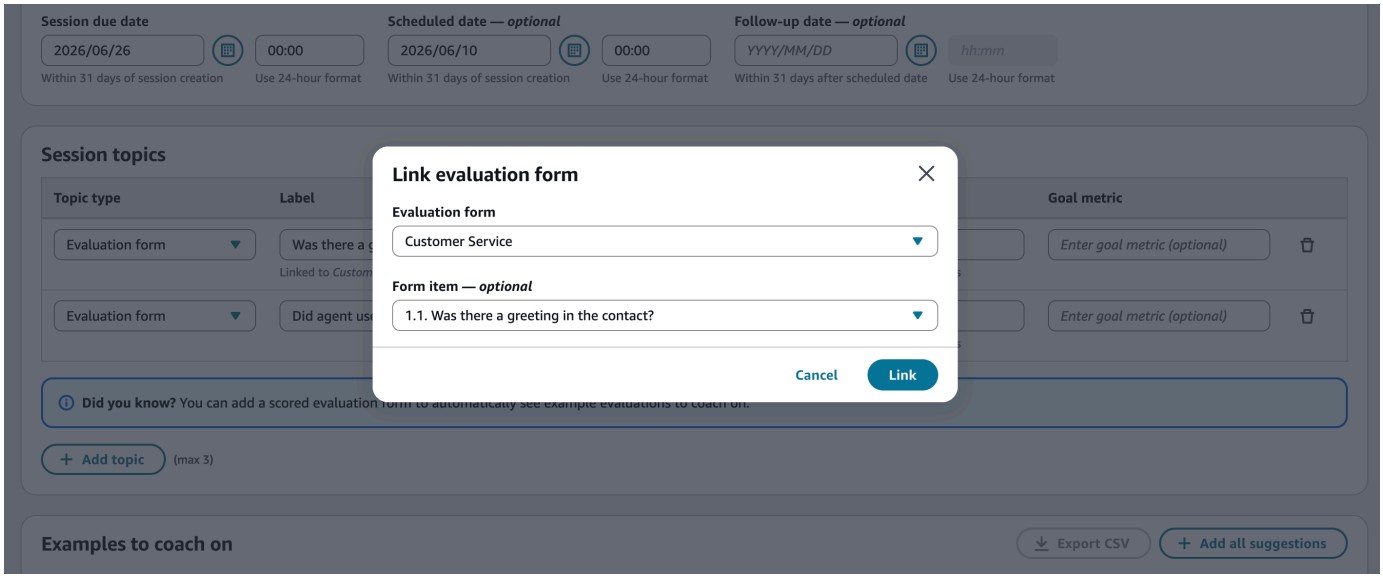
- **Coach based on aggregated performance insights**: If you already know topics to coach on by reviewing average evaluation scores within the Agent performance evaluations dashboard, you can navigate to the coaching sessions page, create a new coaching session, and select the corresponding evaluation criteria as a topic. You will then receive automated suggestions of evaluations to coach on, which you can use to draft detailed feedback.

- **Coach on individual evaluations**: While reviewing an evaluation on the Contact Details page, you can start a coaching session to provide detailed feedback based on that specific evaluation. You can link multiple evaluations to a coaching session.

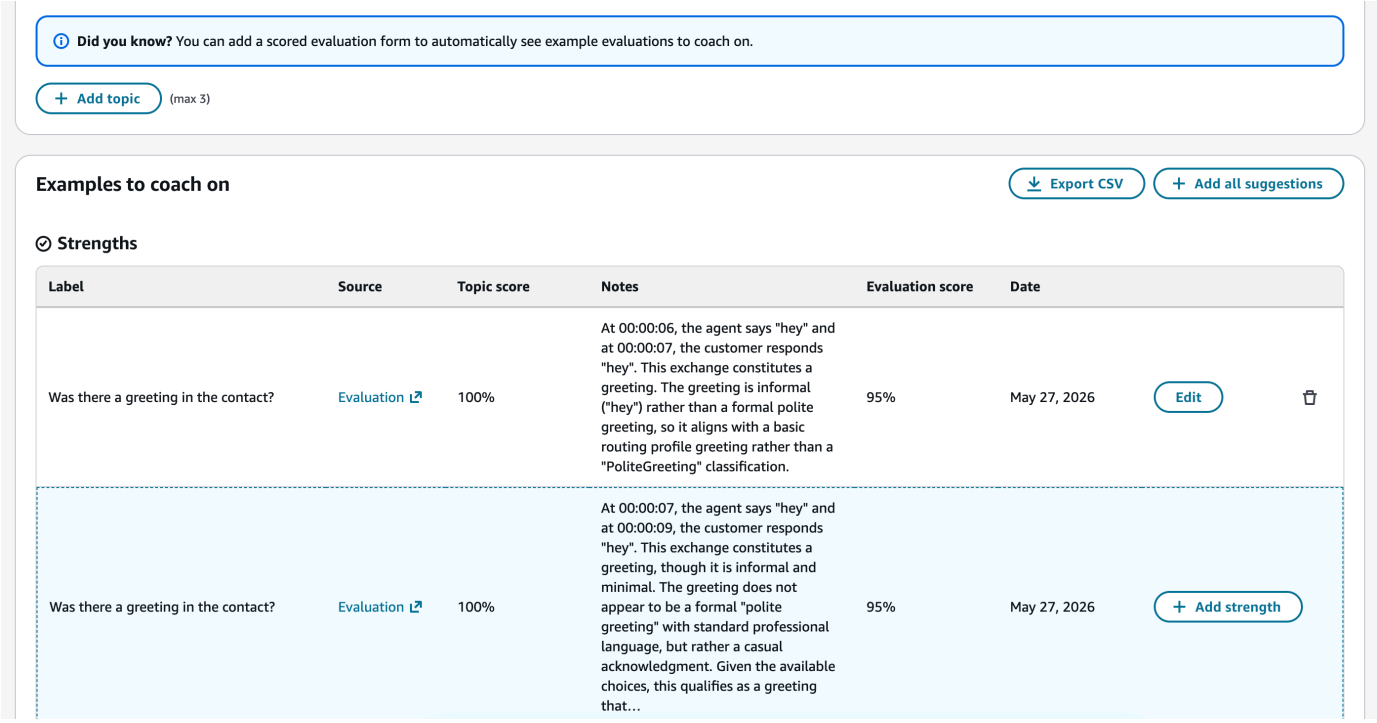
Coach based on aggregated performance insights

For example, if you notice in your Agent performance evaluations dashboard that an agent has been scoring low on empathy, you can navigate to the coaching sessions page and create a new coaching session to address that trend.

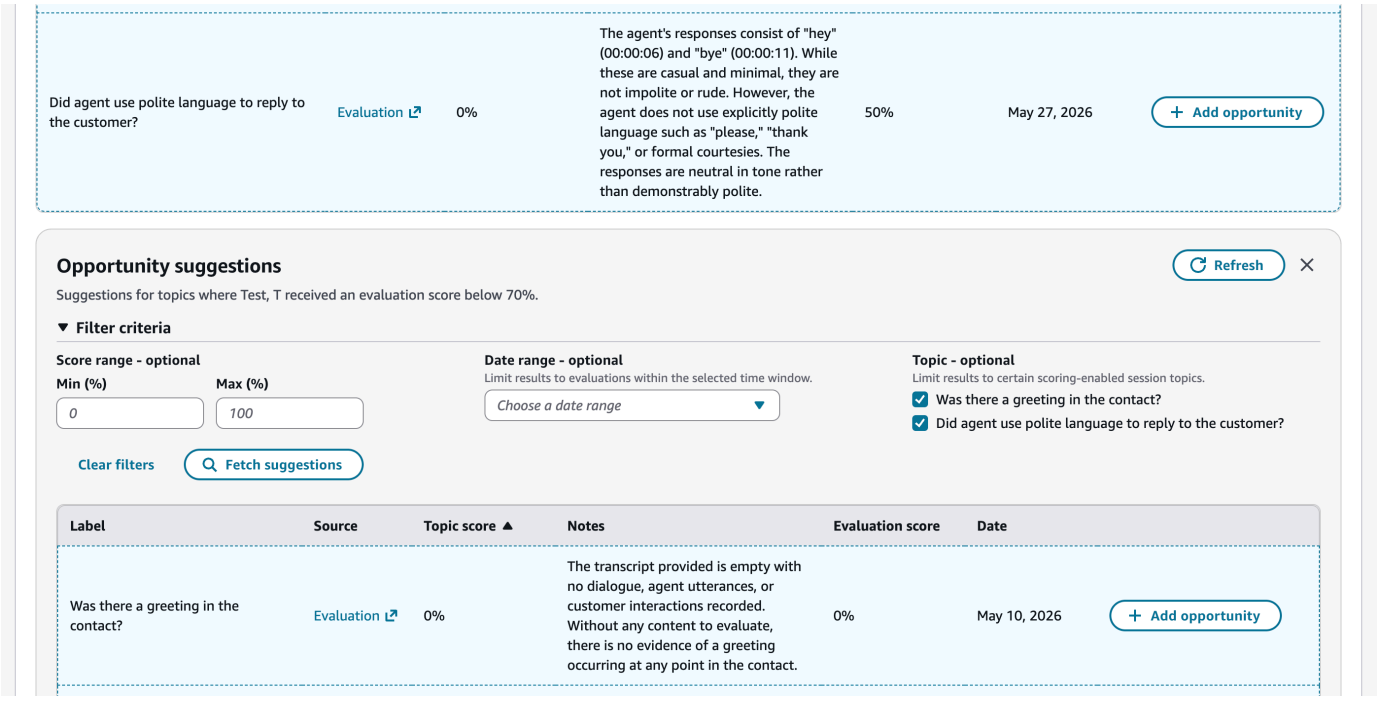
1. Log in to Connect Customer with a security profile that has required permissions to create coaching, search for contacts and view evaluations.
2. Navigate to **Analytics and Optimization** > **Coaching sessions**.
3. When creating a new coaching session, first select a participant.
4. Add scored evaluation forms as session topics. For example, select the evaluation form, section, or question that contains the empathy criteria the agent scored low on. Suggestions are based on these evaluation forms.



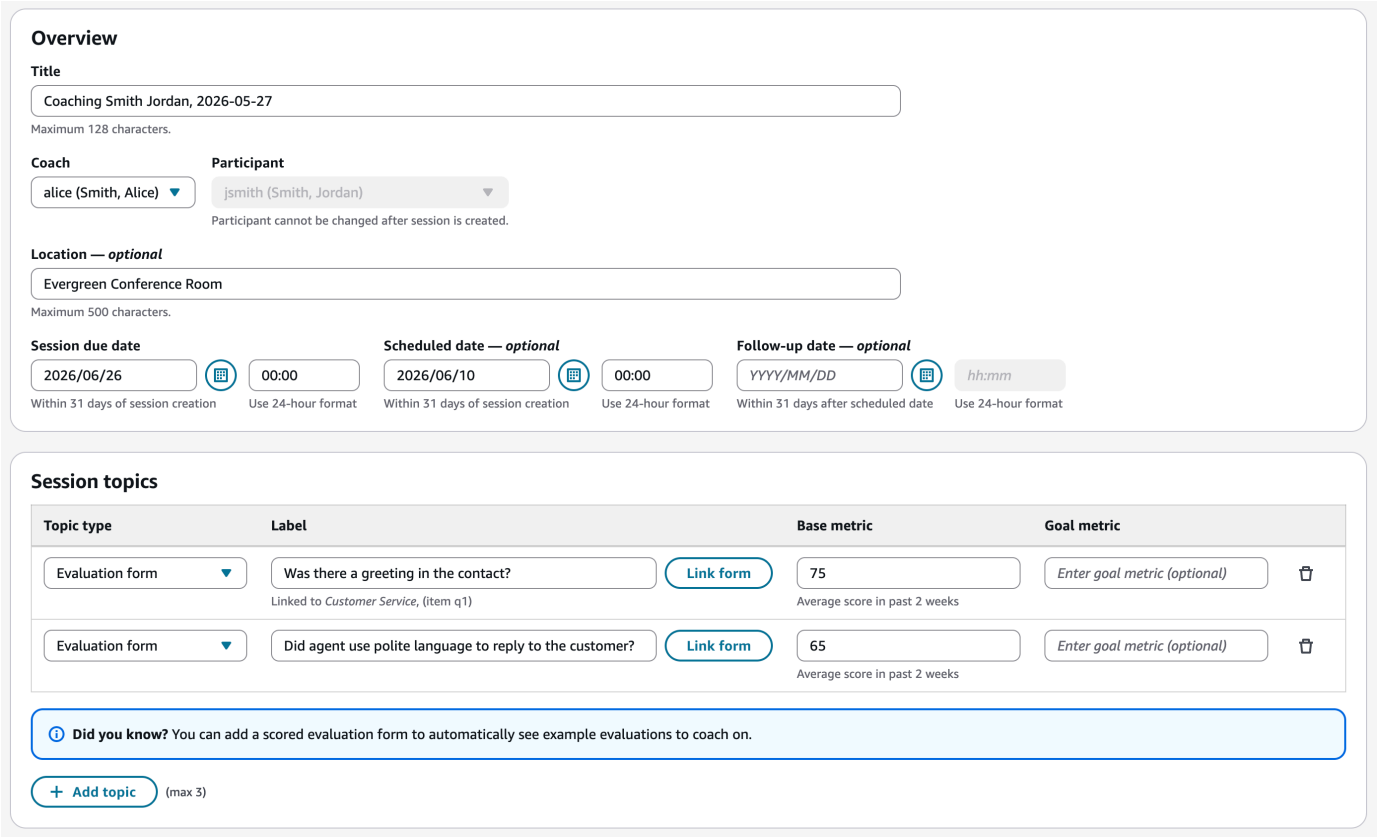
5. Connect Customer automatically suggests evaluations for this participant. You can choose to add suggestions as strengths or opportunities.



6. Select **Show strength suggestions** or **Show opportunity suggestions** to view more suggestions, or filter suggestions based on different criteria, such as score range, date range, or certain topics.



7. You can edit the coaching session by specifying dates, times, and location, providing detailed feedback, and setting improvement goals on coaching topics.

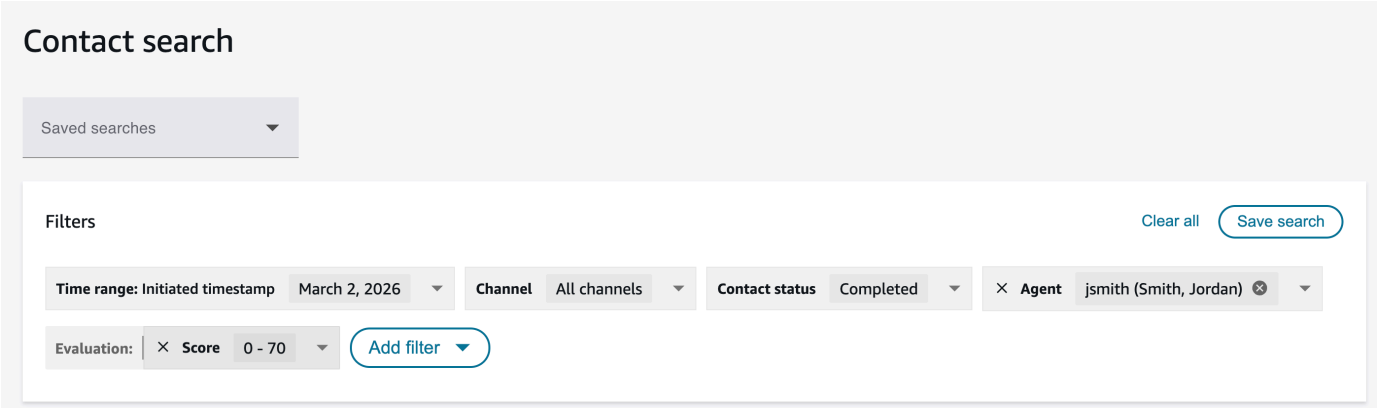


> **Note**
>
> **Session due date** is mandatory.

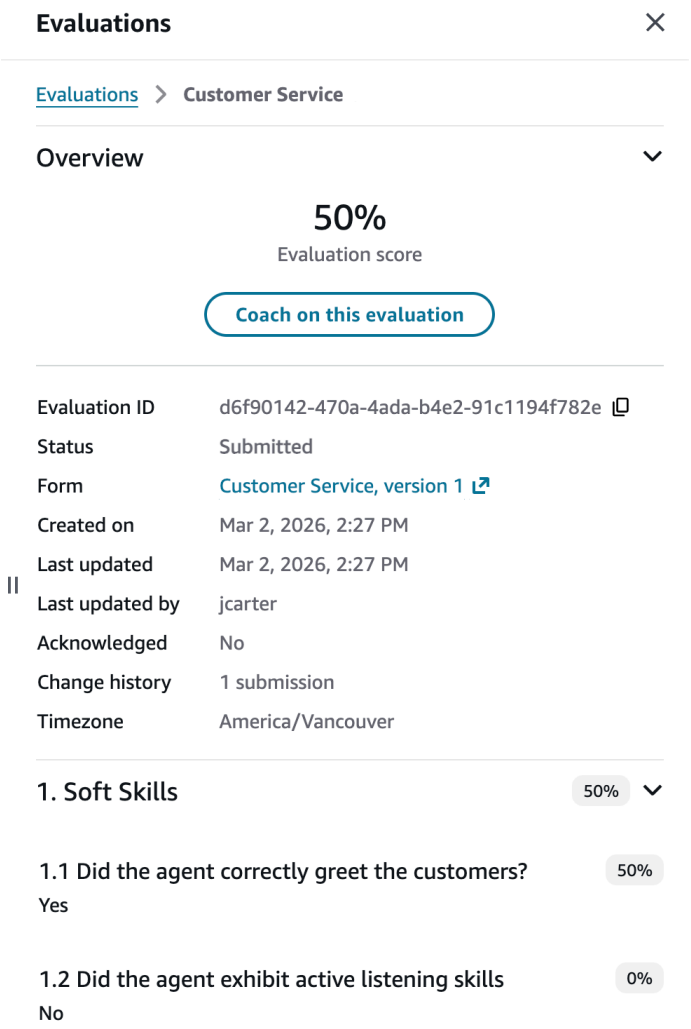
8. Choose **Submit** to save the coaching session as a draft.
9. When the coaching session is ready, choose **Share** to make the coaching session visible to the agent. If the agent has an email configured within Connect Customer (or has a secondary email for a SAML instance), they will receive an email notification with a link to view the coaching session.
10. At the time of coaching, you can access the coaching session on **Analytics and Optimization** > **Coaching sessions**. This page displays all past and upcoming coaching sessions.
11. After the coaching session is finished, choose **Mark as Complete** and optionally add a note.
12. Agents can acknowledge the coaching along with their own coaching notes.

Coach on individual evaluations

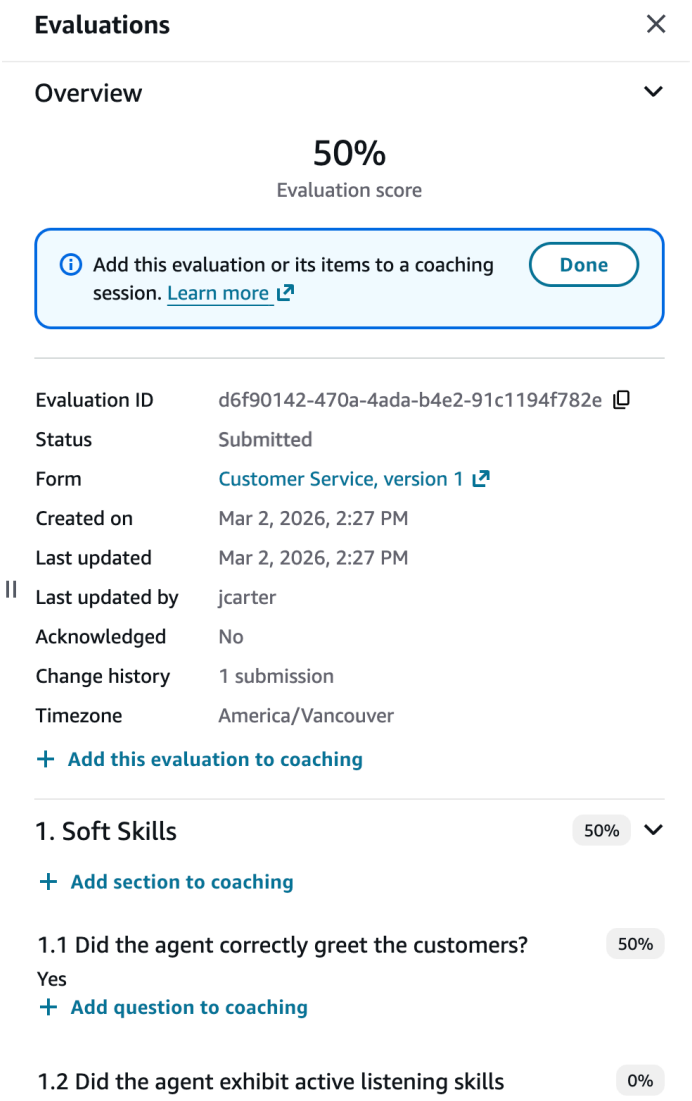
1. Log in to Connect Customer with a security profile that has required permissions to create coaching, search for contacts and view evaluations.
2. Select **Analytics and Optimization** > **Contact search** from the navigation bar on the left.
3. From **Contact Search**, find contacts that have been evaluated for the agent that you want to coach. For example, you can find contacts where the evaluation score is less than 70%:



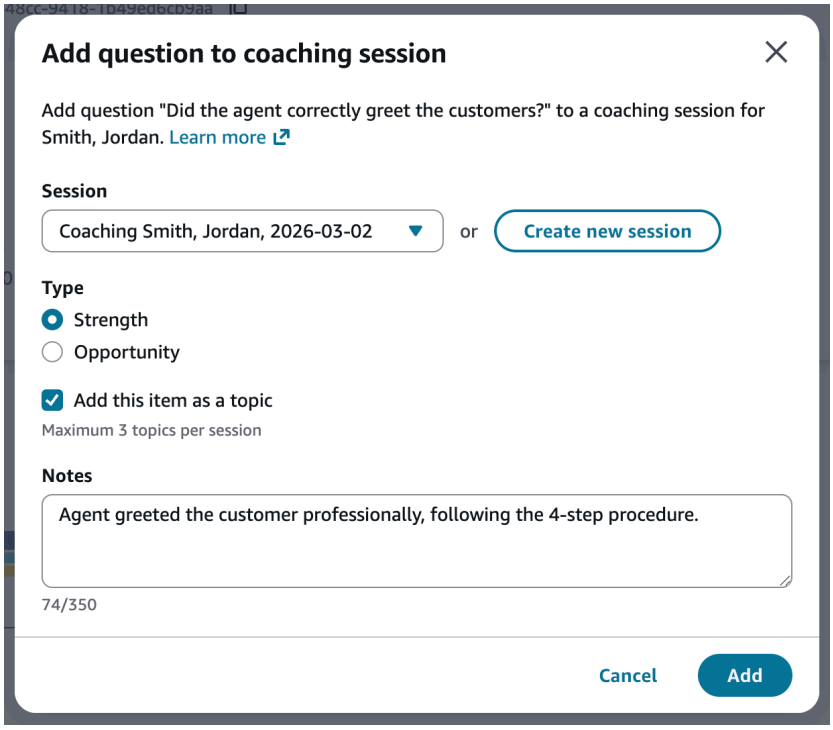
4. Open a contact that has been evaluated, and view the evaluations on the right pane.
5. Open an evaluation and choose **Coach on this evaluation**.



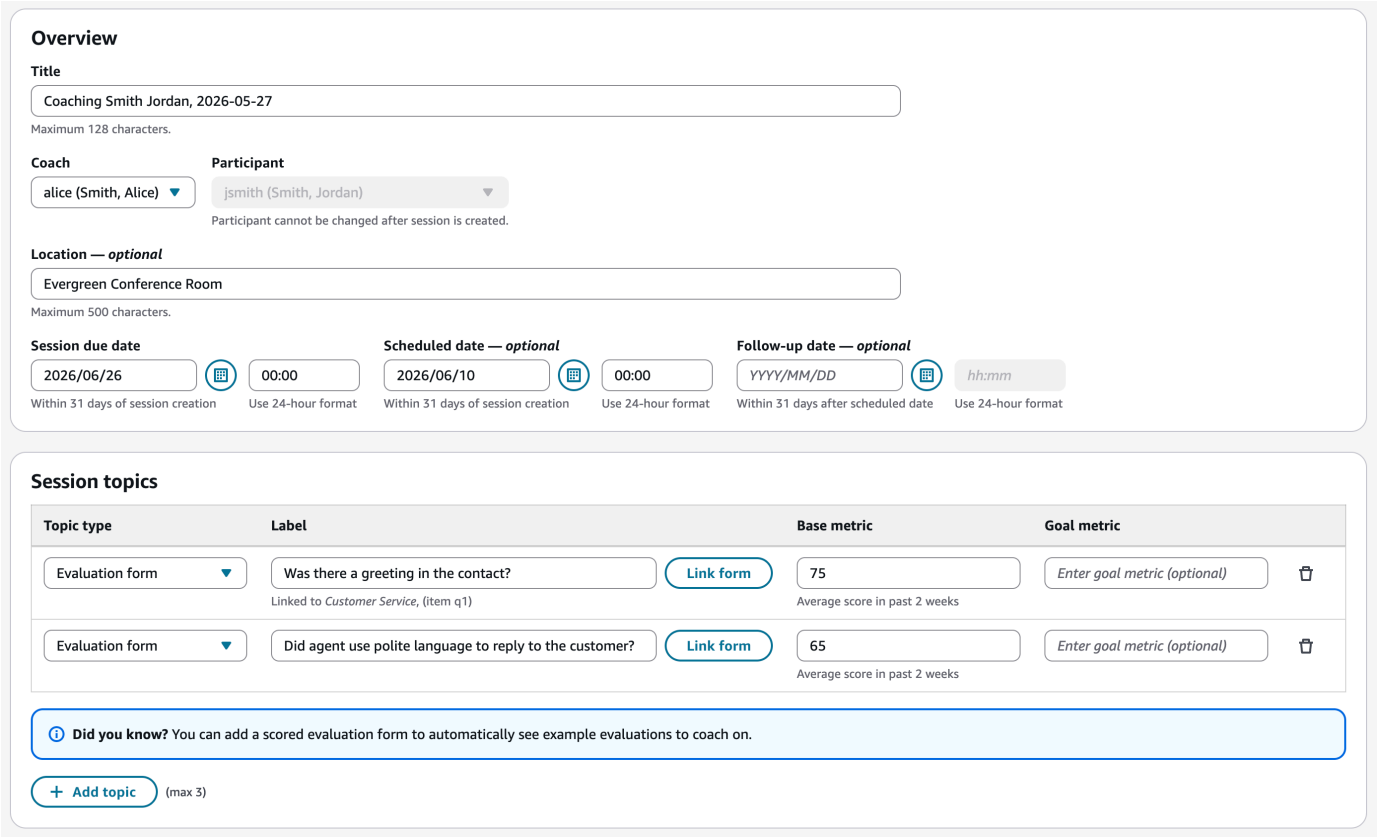
6. You can add the entire evaluation, a specific section or question to a coaching session:



7. You can link the evaluation, its sections or questions to an existing coaching session, or create a new session. Items can be linked as strength or growth opportunities.



8. After you add an evaluation or its items for coaching, a link will be provided to view the coaching session.
9. You can link up to 10 evaluations or evaluation items to a single coaching session as examples of agent strength or growth opportunities. To link additional evaluations, repeat steps 2 through 7
10. You can edit the coaching session by specifying dates, times, and location, providing detailed feedback, and setting improvement goals on coaching topics.



> **Note**
>
> **Session due date** is mandatory.

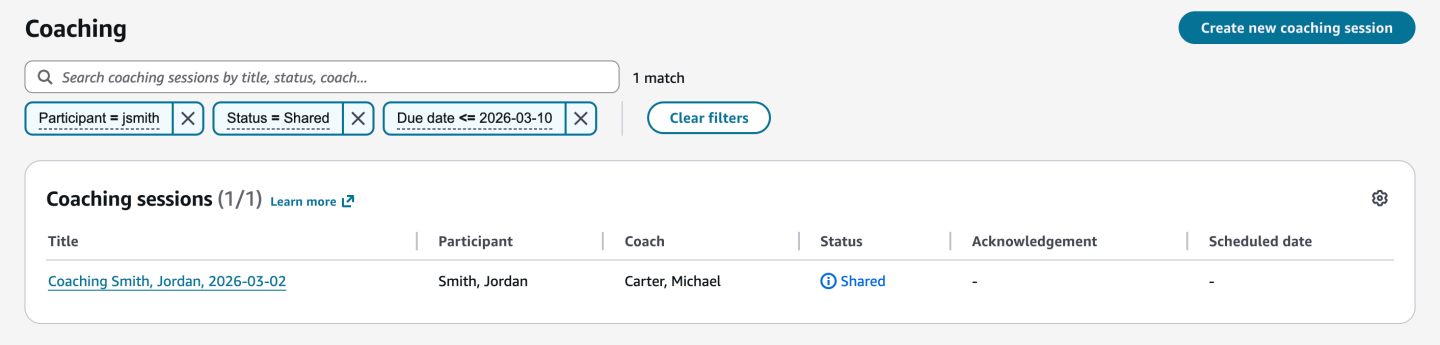
11. Choose **Submit** to save the coaching session as a draft.
12. When the coaching session is ready, choose **Share** to make the coaching session visible to the agent. If the agent has an email configured within Connect Customer (or has a secondary email for a SAML instance), they will receive an email notification with a link to view the coaching session.
13. At the time of coaching, you can access the coaching session on **Analytics and Optimization** > **Coaching sessions**. This page displays all past and upcoming coaching sessions.
14. After the coaching session is finished, choose **Mark as Complete** and optionally add a note.
15. Agents can acknowledge the coaching along with their own coaching notes.

Search for coaching sessions

You can view all past and upcoming coaching sessions from the **Analytics and Optimization** > **Coaching sessions** page.

This page provides advanced search capabilities. You can search for coaching sessions:

- Performed by a particular coach
- Where a specific agent was the participant
- Created by a specific quality manager
- On a specific topic
- That are past due date but not completed
- That are pending completion (shared or draft status)
- That are completed, but not yet acknowledged by the participant
- And more



Acknowledge performance evaluations in Connect Customer

When an agent performance evaluation is submitted, you can automatically notify the agent to review their evaluation. For example, you can set up a rule to send an email to the agent when an evaluation is available. You can also walk an agent through their evaluation during coaching.

After the agent has reviewed the performance evaluation, they can acknowledge their review of the evaluation and write an optional note in the Connect Customer admin website. This acknowledgement enables managers to track whether agents are reviewing the feedback provided on their performance evaluations.

This topic explains the steps for agents to view and acknowledge an evaluation.

To acknowledge an evaluation

1. After you have received a performance evaluation for a contact, use your agent account to log in to the Connect Customer admin website at https://*instance name*.my.connect.aws/.
2. Access the contact evaluation that you want to acknowledge. There are a few ways you can do this:

   - Someone might have shared the contact URL with you.

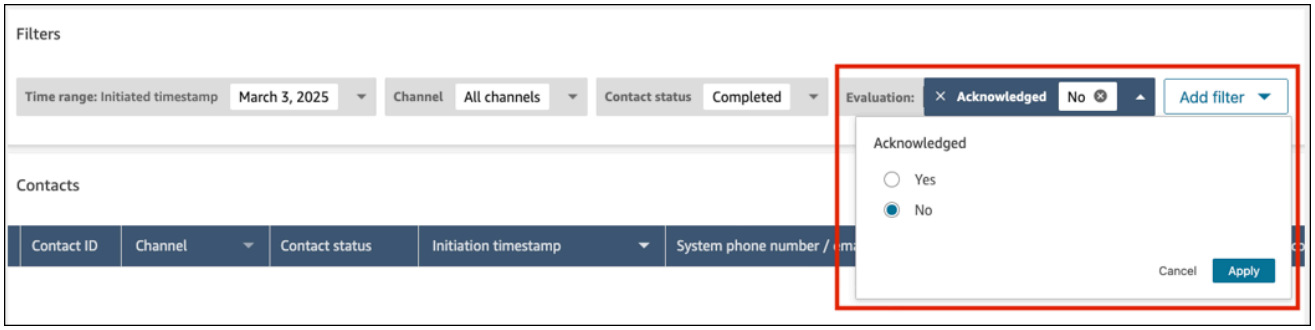
   - OR -

   - You might have been assigned a task or received an email notification containing the URL for the contact that received an evaluation.

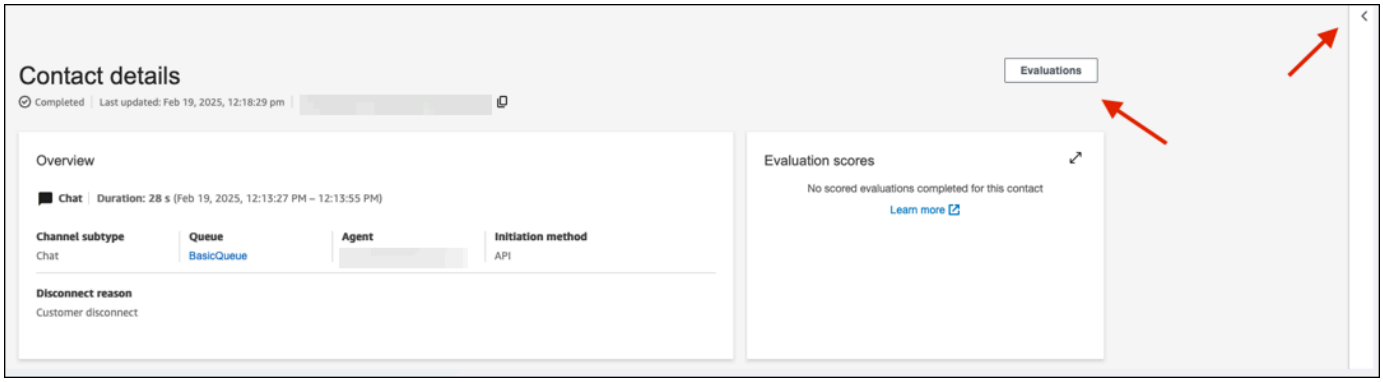
   - OR -

   - You might have the contact ID and evaluation form name. You can use this information to search for the contact that received the evaluations using the following steps.

     1. On the navigation pane, choose **Analytics and optimization**, **Contact search**.
     2. Search for the contact which was evaluated, but is not yet acknowledged. The following image shows the filters to search for **Acknowledged** = **No**.



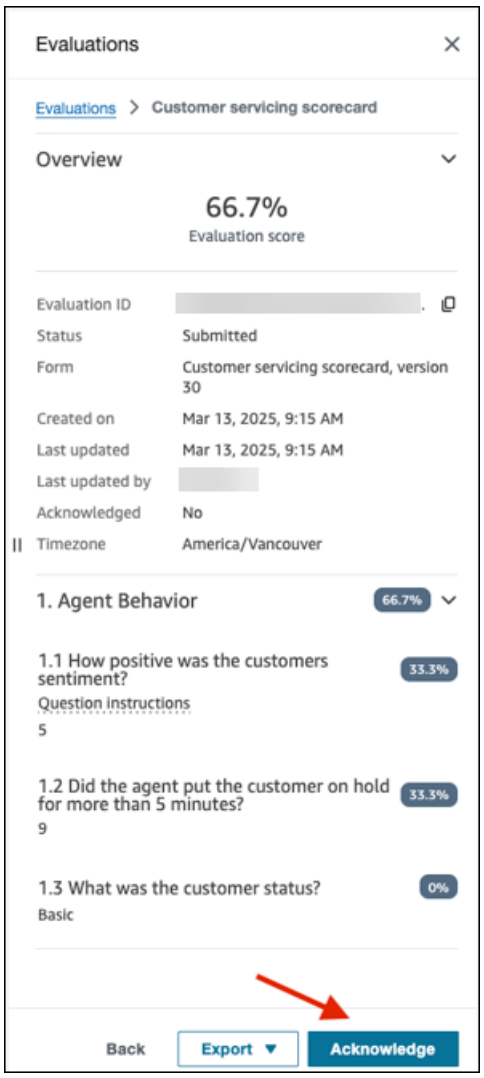
3. On the **Contact details** page, choose **Evaluations** or expand the evaluation panel by choosing the **<** icon, as shown in the following image.



4. The **Evaluations** panel lists any evaluations that are in progress or completed for the contact. To acknowledge an evaluation, choose an evaluation from the list of **Completed evaluations**. The following image shows one evaluation that has been completed: **Customer servicing scorecard**.

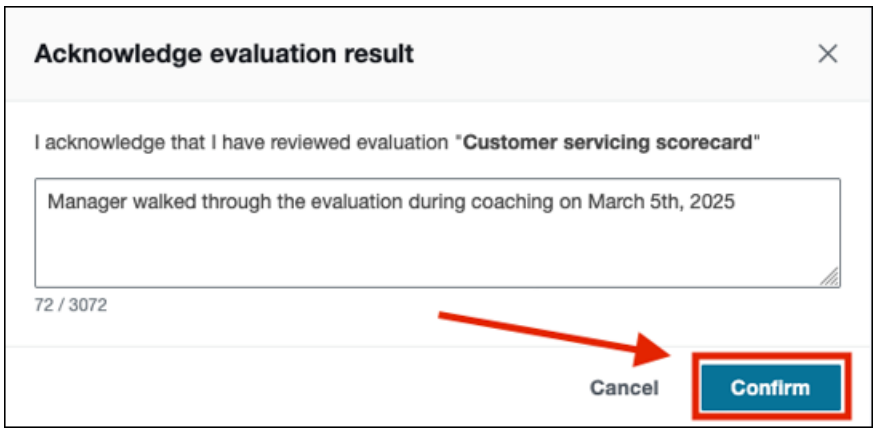
5. Choose the evaluation you want to review. At the bottom of the evaluation, choose **Acknowledge**, as shown in the following image.

> **Note**
>
> Only the agent who was evaluated can acknowledge the evaluation.

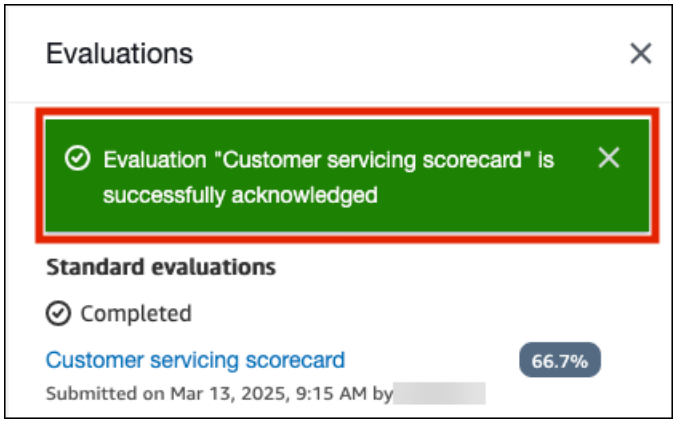


6. In the **Acknowledge evaluation result** dialog box, provide an optional comment. For example, *Manager walked through the evaluation during coaching on March 5th, 2025*.

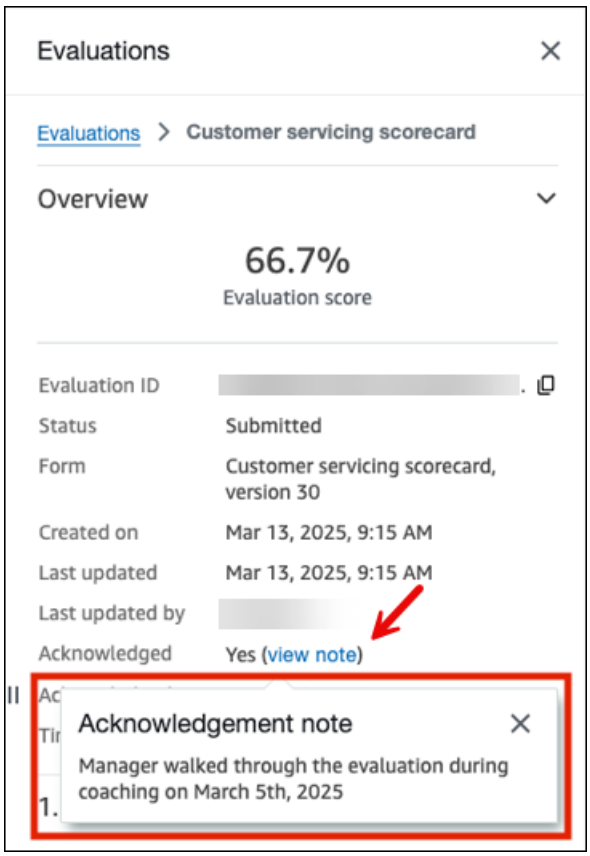
   When you're finished, choose **Confirm**.



7. A message is displayed that the evaluation acknowledgement is **Completed**, as shown in the following image.



8. You can only acknowledge an evaluation after it is submitted. If an evaluation is re-submitted, it again becomes eligible for acknowledgement.
9. To view the acknowledgement note, select the acknowledged evaluation, and then choose the **view note** link.



Random sampling of contacts for evaluation in Connect Customer

Connect Customer provides managers with a random sample of their agents' contacts for evaluation, removing manager bias and streamlining the evaluation process. On Contact Search, managers can specify the number of contacts that they need to evaluate for each agent, as per union agreements, regulation or internal guidelines. They then receive the required number of contacts, randomly selected from the specified timeframe, for example, 3 contacts per agent from the last week. In addition, managers can apply additional filters within Contact Search to make sure that the provided contacts are suitable for evaluation. For example, contacts must be longer than 180 seconds, have an associated audio or screen recording, transcripts, and have not yet been evaluated. After the sample is generated, you can select an evaluation form and create draft evaluations in bulk for each of the contacts within the sample. Evaluations created in this way will denote that the contact was selected through random sampling, and provide auditability to make sure that the filter criteria did not introduce any bias in selection.

Random sampling of contacts for evaluation

1. Login to Amazon Connect with a user, who has the following set of permissions on their security profile:

    1. Contact Search - View
    2. Sample contacts
    3. Evaluation forms – perform evaluations

2. Select the timeframe of contacts for evaluation, such as trailing week. You can sample contacts from a maximum period of 5 weeks.

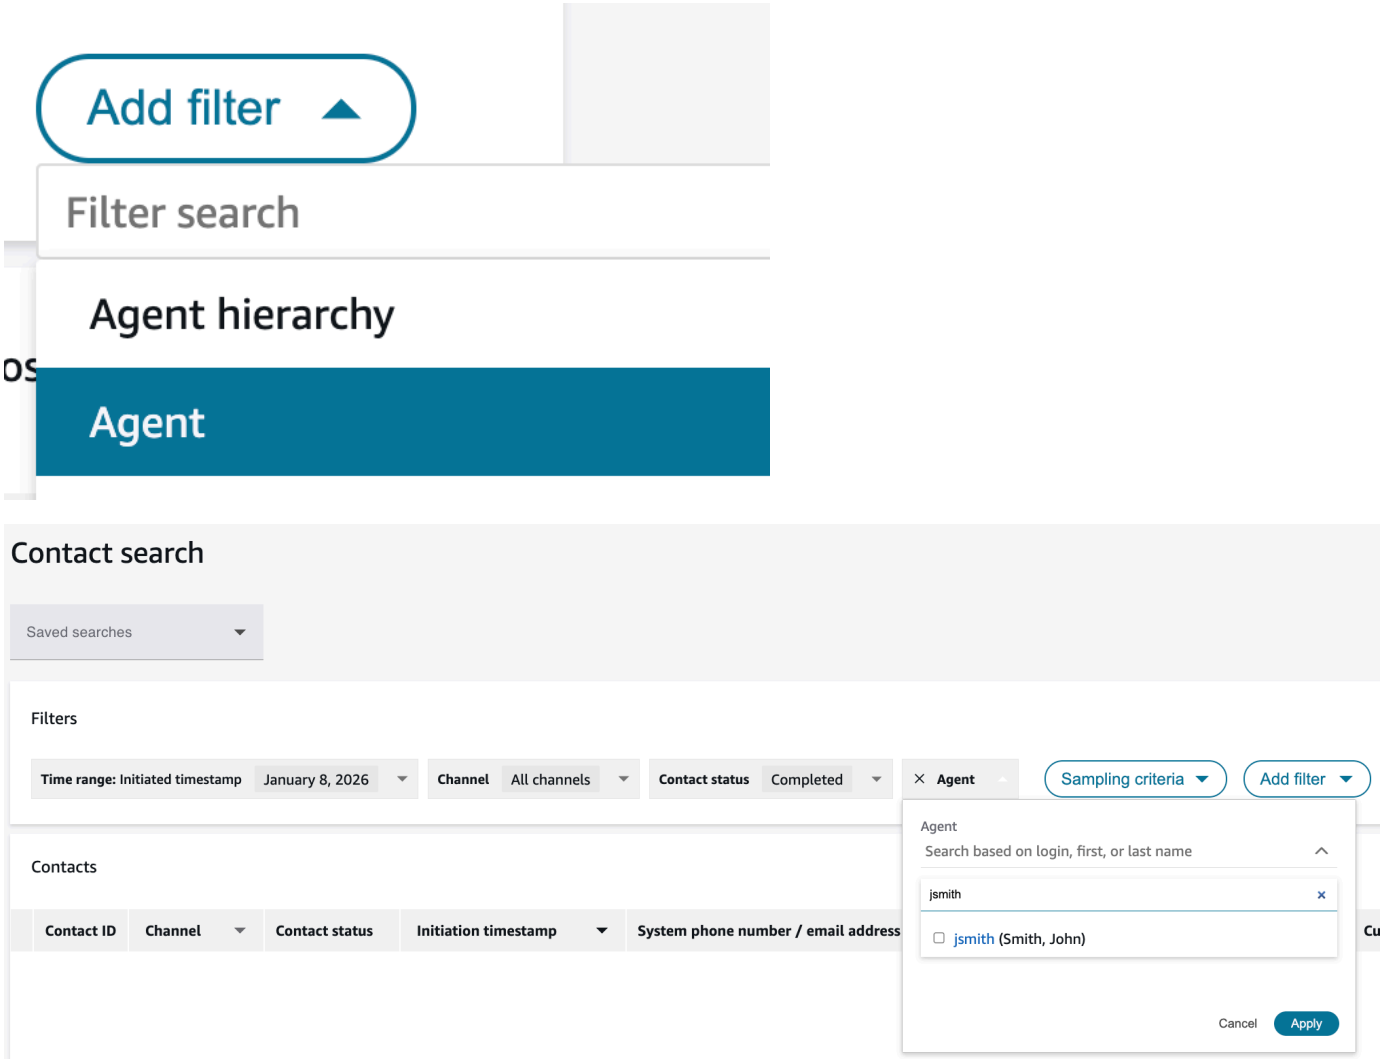
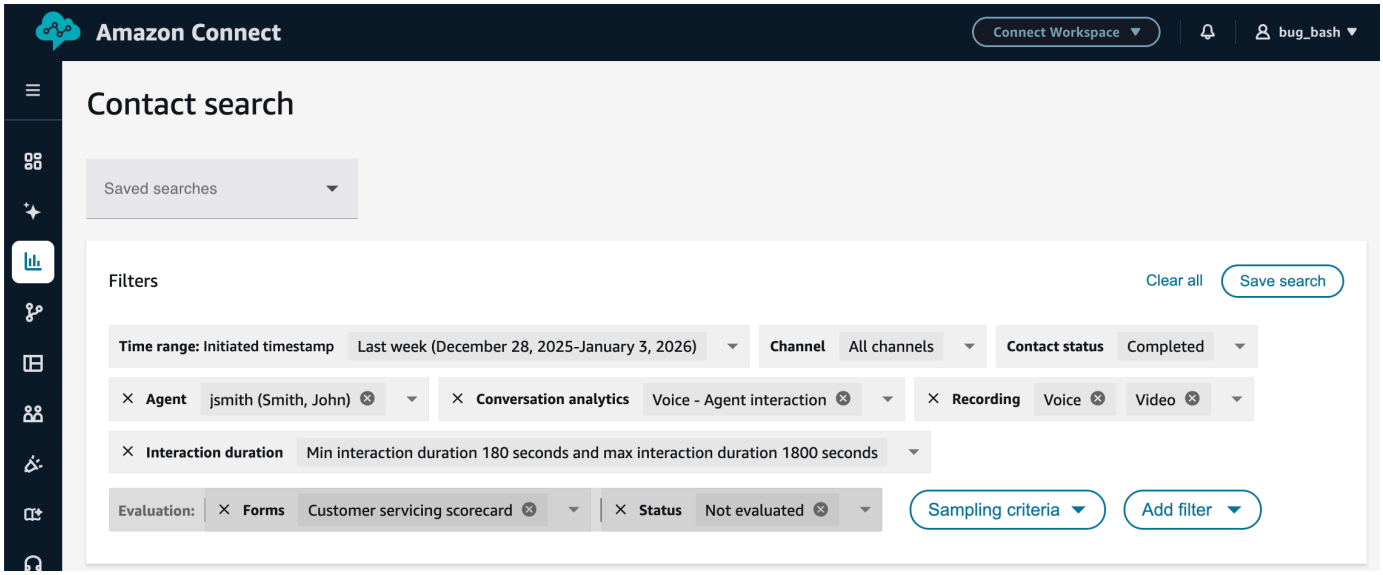
Apply

3. Select the agent or agent hierarchy that you need to evaluate.

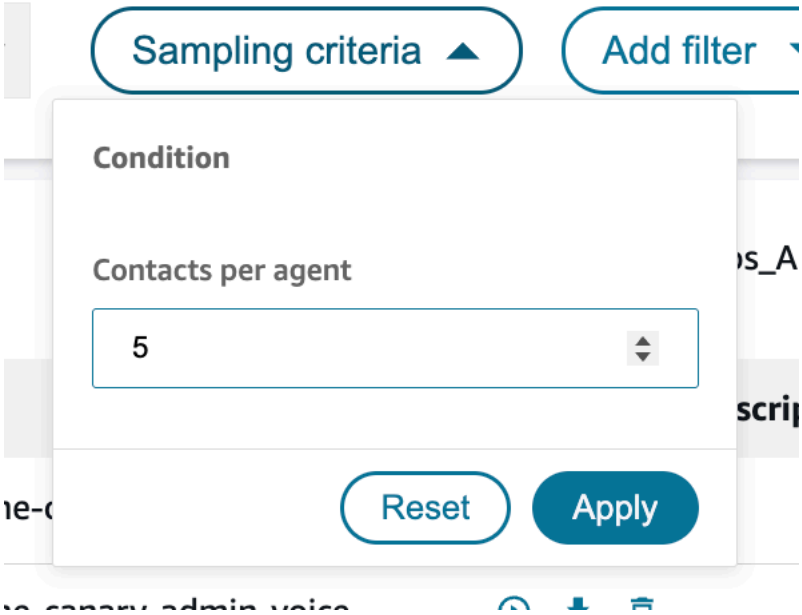


4. Apply any additional filters to select only those contacts that are suitable for evaluation.

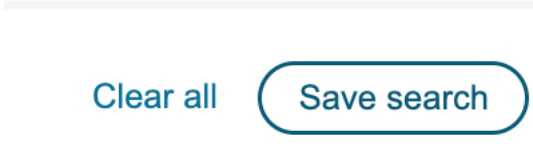
   - **Conversational analytics**: Ensures that the contact is analyzed by conversational analytics and has a transcript
   - **Recording**: Filter contacts with audio recording (voice) or screen recording (video)
   - **Interaction Duration**: You can choose contacts with a minimum and maximum agent-customer interaction
   - **Evaluation Status**: Only select contacts that have not yet been evaluated



5. Specify the sampling criteria, such as 5 contacts per agent and choose **apply** to generate a sample.

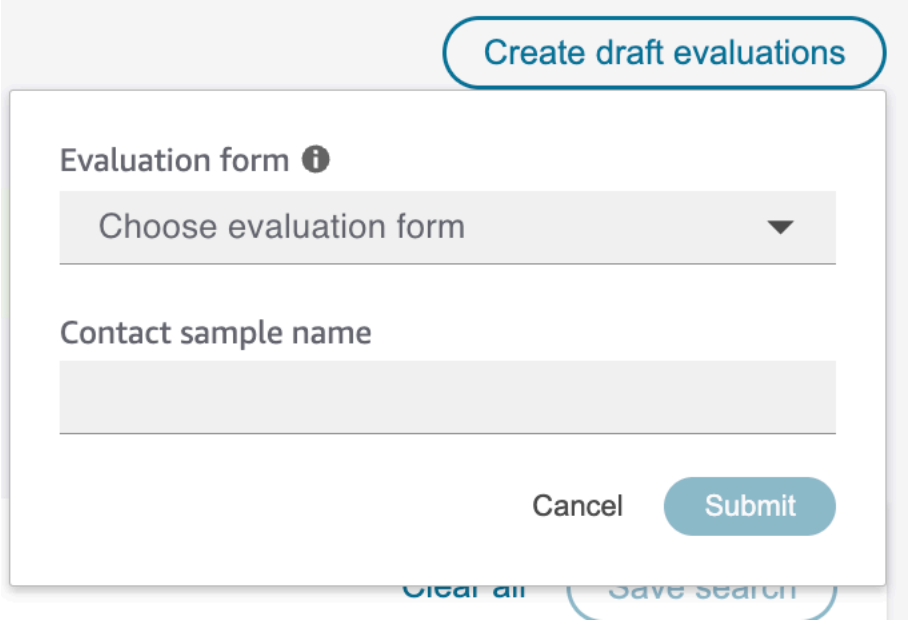


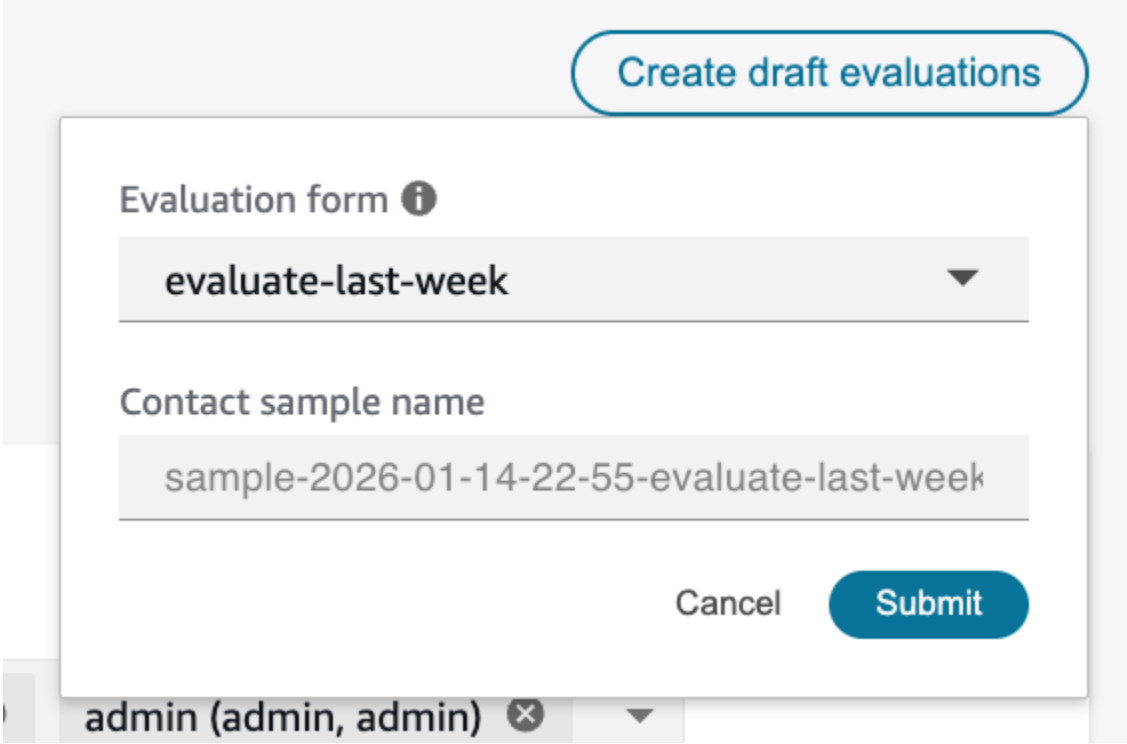
6. You can save the set of filters and sampling criteria within saved search.



7. After the sample is generated, you can create draft evaluations in bulk across all the contacts.

- Select **Create Draft Evaluations**
- Select the **Evaluation Form**

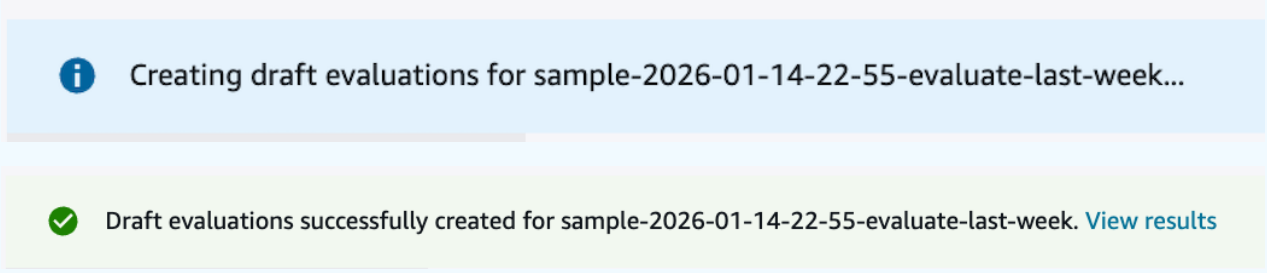




This associates the draft evaluations with the sample name.

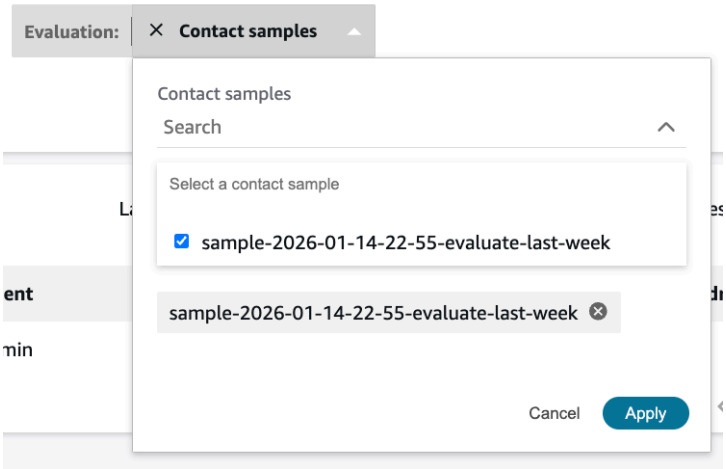
Note

This step is required if you need to retrieve the contact sample in the future.



Retrieving and viewing sampled contacts for evaluation

To retrieve the contact sample in the future, navigate to Contact search and apply the filter Evaluation – contact samples. Contact samples are specific to the user that generated the sample.



Auditing sampling criteria

If you open an evaluation, it will indicate if contact sampling was used to create the evaluation. You can choose **Yes** to audit the filter criteria used to generate the contact sample, making sure that filters did not introduce any bias (for example, negative customer sentiment) during the contact selection process.

Request reviews of (appeal) performance evaluations in Connect Customer

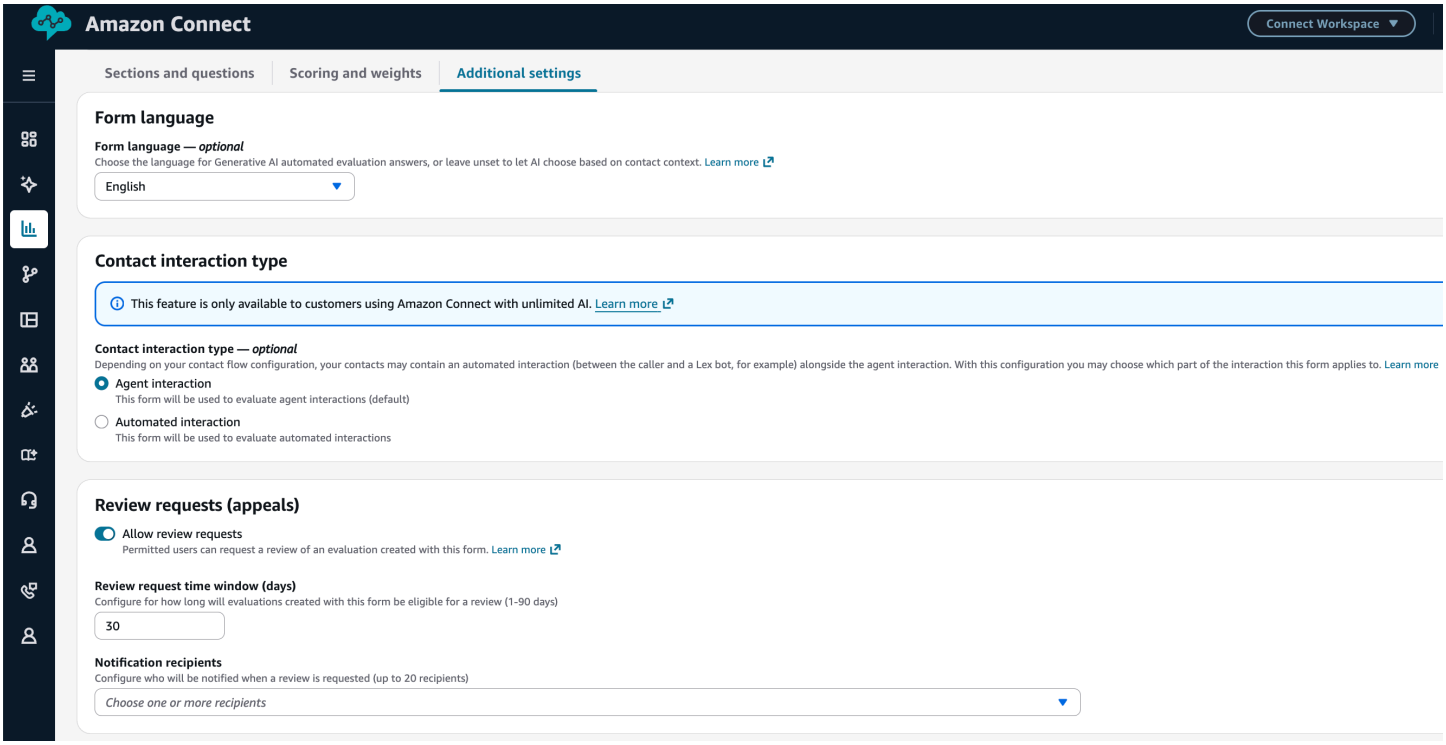
When an agent performance evaluation is submitted, you can automatically notify the agent to review their evaluation. For example, you can set up a rule to send an email to the agent when an evaluation is available. After they have reviewed an evaluation, they can acknowledge the evaluation. If they disagree with the feedback within an evaluation, they can request a review of (appeal) performance evaluations. When a review is requested, designated managers are automatically notified through email. They can then revise the evaluation or add additional notes

that justify the original evaluation, before completing the review. Upon completion, the user who had requested the review and the agent evaluated is notified through email.

How do I enable review requests (appeals)?

With Connect Customer, you can specify which evaluation forms support review requests. To enable review requests on an evaluation form:

1. Log in to Connect Customer with a user account that has the following security profile permission: **Analytics and Optimization** - **Evaluation forms - manage form definitions** - **Create**
2. Choose **Analytics and optimization**, then choose **Evaluation forms**.
3. Open an existing form by choosing on the hyperlink for the Last version or create a new evaluation form.
4. Choose the **Additional settings** tab
5. Choose **Allow review requests**
6. You can specify the time window till when a review can be requested on an evaluation. The time window is measured from the time of the original submission of an evaluation.
7. You can also choose one or more recipients who will be notified through email when a review is requested. The email has a link to the contact with the evaluation for which a review is requested. For the users to receive emails on a SAML authenticated instance, the secondary email needs to be provided within the user's profile in Connect.
8. After you **Activate** the form, subsequent evaluations performed using the form will support review requests.



Who can request reviews of an evaluation?

For users to request reviews of evaluations, they should have the permissions: **Evaluation forms - request evaluation reviews - Create and View**, in addition to access to the underlying contacts and evaluations. Permissions to request reviews can be granted to agents, or their supervisors, who can request evaluation reviews from the quality management team on the behalf of their agents. Supervisors granted the permission to **request evaluation reviews** can request review on any evaluation that they can access.

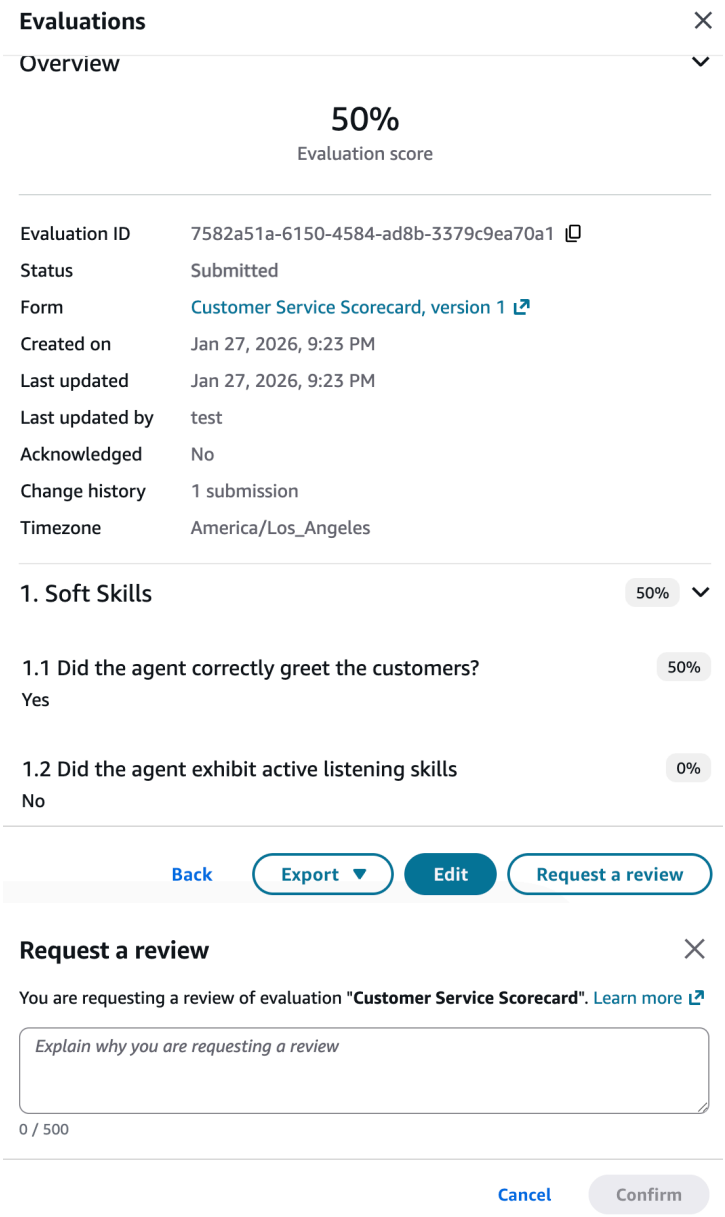
Users granted the permission **Evaluation forms - request evaluation reviews - Delete** permission can delete a request before the review has started.

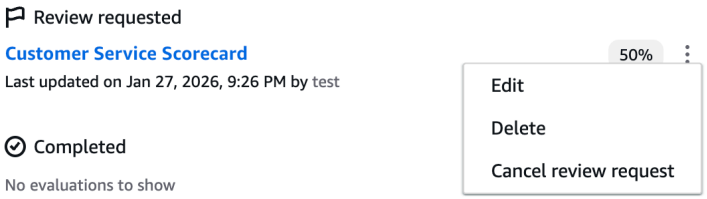
Who can review an evaluation?

Users with the permission **Evaluation forms - review evaluations - Create and View** permissions can perform reviews. If certain personas need to be consulted on reviews, but should not be granted permissions to perform reviews themselves, then you can grant them **Evaluation forms - review evaluations - View** permissions.

Requesting a review

1. On the **Contact details** page, open a completed evaluation for which you want to request a review
2. Select **request a review** at the bottom of the evaluation
3. Explain why you are requesting a review (you cannot leave this blank). Choose **confirm**
4. The evaluation will show under **Review requested** on the evaluations pane
5. You can cancel a request if the review is yet to be started

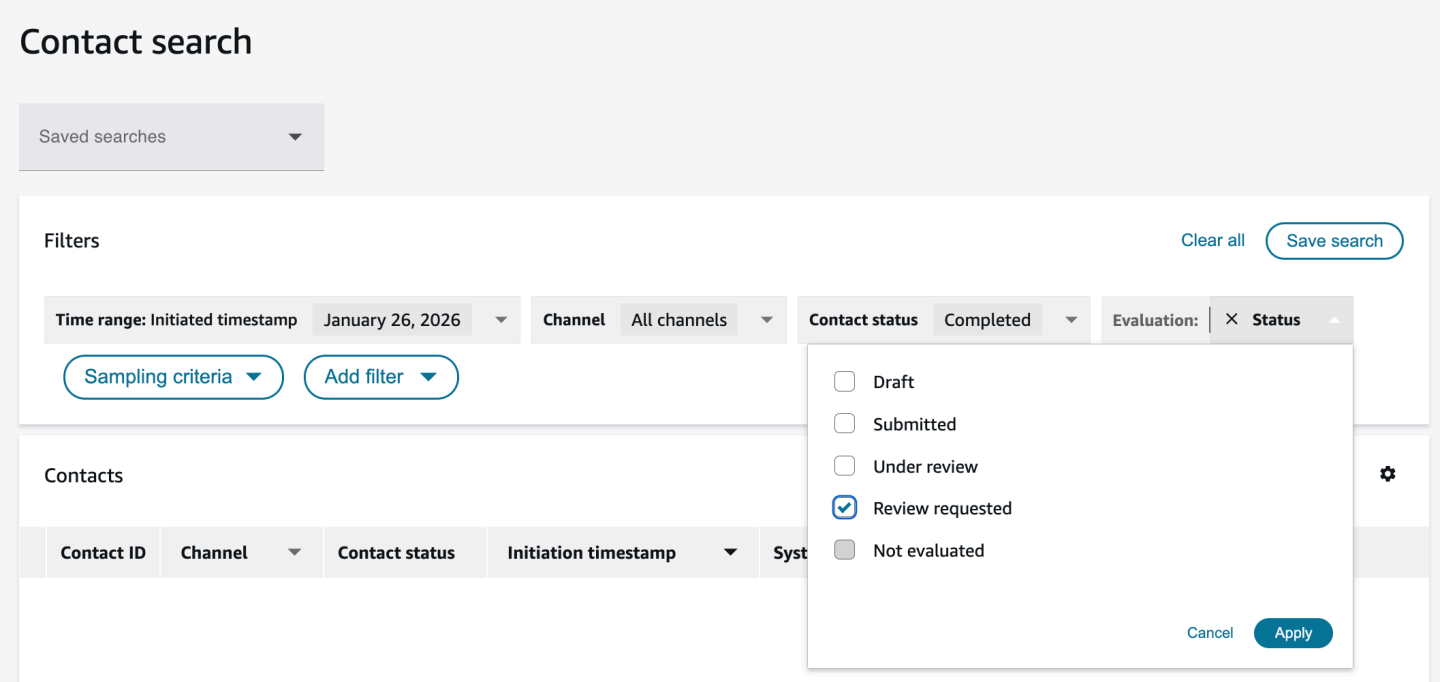




Searching for pending reviews

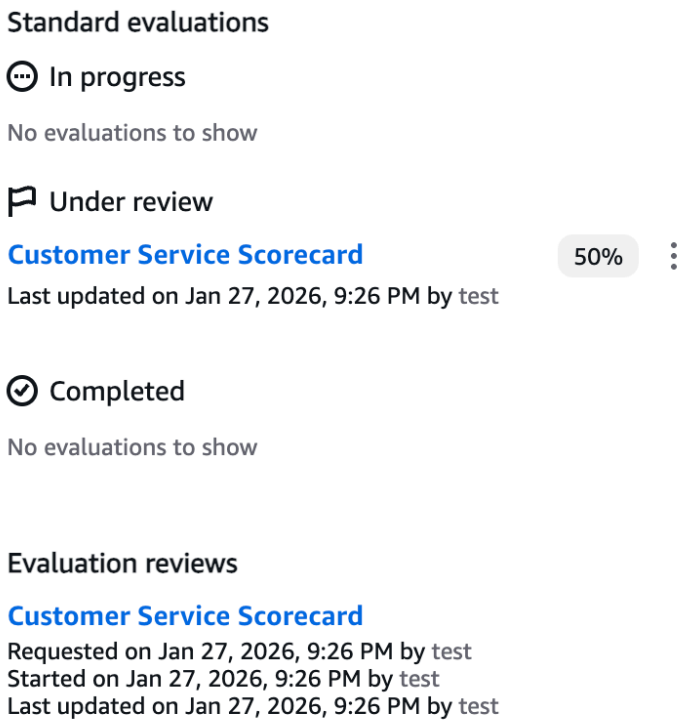
As described previously, you can configure in the evaluation form, who would be automatically notified through email if a review is requested. These notification emails contain links to contacts with evaluations for which a review is requested. Additionally, users with appropriate permissions can search for contacts with evaluations for which a review is requested or which are already under review:

1. Log in to Connect Customer with a user account that has permissions to access contact records and the **Evaluation forms - perform evaluations** permission.
2. On the navigation bar, choose **Analytics and optimization**, **Contact search**.
3. Use the time range filter to search for contacts from the relevant time window, for example, last month.
4. Use the evaluation status filter with the value **Review requested** to search for contacts with evaluations where a review has been requested, and is yet to be picked up for review
5. Use the evaluation status filter with the value **Under review** to search for contacts with evaluations that are picked up for review



Starting and completing reviews

1. Open the evaluations pane on the **Contact details** page.
2. Choose an evaluation listed under **Review requested**.
3. Choose **Start review**.
4. The original evaluation is listed under **Under review** and can be viewed by choosing on it.
5. The in-progress review is listed under **Evaluation reviews**. Users with the **Evaluation forms - review evaluations - Create** permissions can make edits to the evaluation such as changing answers, amending the notes. You can **Save** your review at anytime and choose **Resolve review** to finalize the review.
6. This will send an automated email notification to the user who had requested the review.

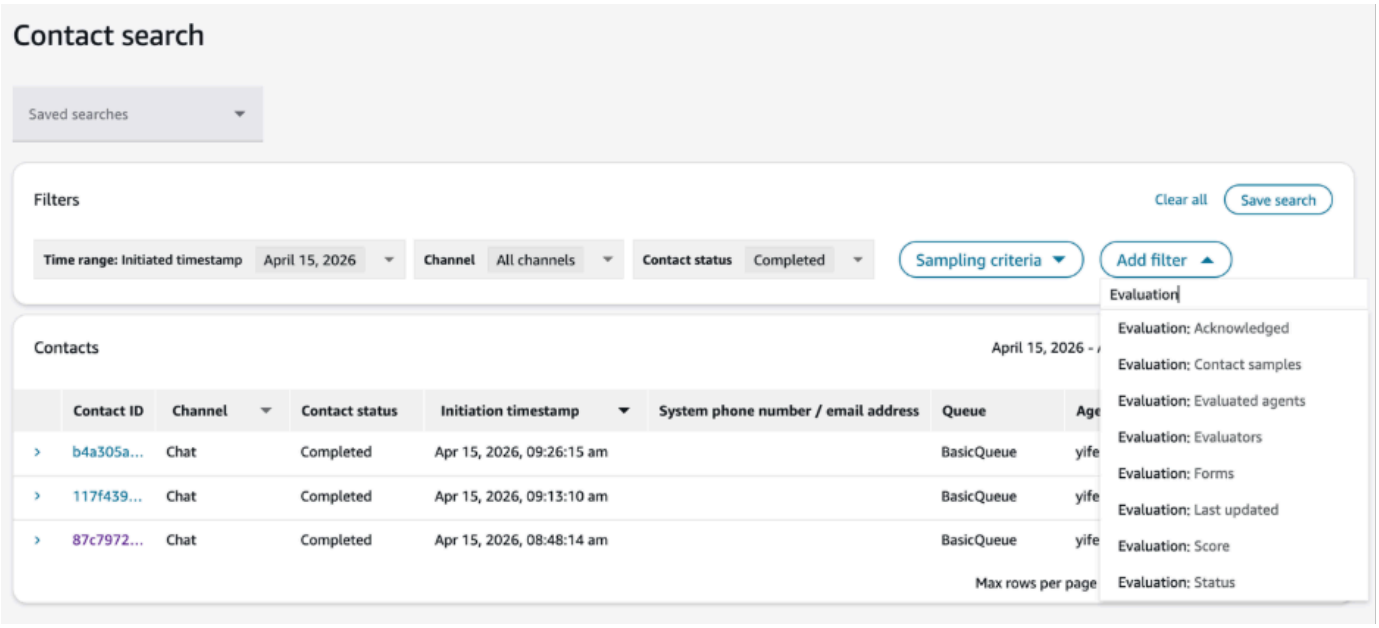


Search for and view evaluations in Connect Customer

Users can search for evaluated contacts and view evaluations side-by-side alongside audio or screen recordings, conversation transcripts, summaries and insights.

Searching for evaluated contacts

1. Log in to Connect Customer with a user account that has permissions to search for and view contacts and either the **Evaluation forms - perform evaluations** or **Evaluation forms – view my received evaluations** permission.
2. In Connect Customer choose **Analytics and optimization**, **Contact search**.
3. Use the filters on the page to narrow your search. For the date selection, you can search for up to 8 weeks of contacts at a time. You can review contacts and associated evaluations from up to 2 years ago.



4. Choose the contact ID in the search results to open a contact and review associated evaluations.

View evaluations on the contact details page

1. Choose **Evaluations** on the top right of the page.
2. If the contact has received an evaluation it will show under **Completed**.
3. Choose the evaluation to review the completed evaluation.

AI answer details in submitted evaluations

When you view a submitted evaluation that contains answers filled using native generative AI, you can also view the AI answer details. These details include the reasoning behind each AI answer and the relevant reference points from the transcript. AI answer details appear only when the submitted answer matches the answer that AI provided.

Use a reference ID to represent questions in a report about contact center agent performance

A *reference ID* is a token that appears in the JSON output file. It represents a specific question. When building reports, you can use it in place of the exact wording of a question.

For example, a question might be "Did agents stick to the script?" but the next day the question might be changed to "Was there good script adherence?" Regardless of how the question is worded, the reference ID always stays the same.

Evaluation metrics in Connect Customer

You can view the following metrics on the Agent performance evaluations dashboard. With these metrics, you can view aggregated agent performance, and get insights across agent cohorts and over time.

Average evaluation score

This metric provides the average evaluation score for all submitted evaluations. Evaluations for calibrations are excluded from this metric.

The average evaluation score corresponds to the grouping. For example, if the grouping contains evaluation questions, then the average evaluation score is provided for the questions. If the grouping does not contain evaluation form, section or question, then the average evaluation score is at an evaluation form level.

Metric type: Percent

Metric category: Contact evaluation driven metric

How to access using the Connect Customer API:

- GetMetricDataV2 API metric identifier: `AVG_EVALUATION_SCORE`

How to access using the Connect Customer admin website:

- Dashboard: Agent performance evaluations dashboard

Calculation logic:

- Get sum of of evaluation scores: forms + sections + questions.
- Get total number of evaluations where scoring has been completed and recorded.
- Calculate average score: (sum of scores) / (total evaluations).

Notes:

- Excludes calibration evaluations.
- Score granularity depends on grouping level.
- Returns percentage value.
- Requires at least one filter from: queues, routing profiles, agents, or user hierarchy groups.
- Based on contact initiation date.
- Data for this metric is available starting from January 10, 2025 0:00:00 GMT.

Average evaluation score (Submit time)

This metric provides the average evaluation score across all submission events by the evaluator, including resubmissions. Each submission event, including every resubmission of the same evaluation, is included in the average. Evaluations for calibrations are excluded from this metric.

The average evaluation score is provided at an evaluation form level.

Metric type: Percent

Metric category: Contact evaluation driven metric

How to access using the Connect Customer API:

- GetMetricDataV2 API metric identifier: `AVG_EVALUATION_SCORE_BY_SUBMIT_TIME`

How to access using the Connect Customer admin website:

- Dashboard: Agent performance evaluations dashboard

Calculation logic:

- Get sum of of evaluation scores across forms.
- Get total number of submission events where scoring has been completed and recorded, including resubmissions.
- Calculate average score: (sum of scores) / (total submission events).

Notes:

- Includes all resubmissions.
- Excludes calibration evaluations.
- Provided at an evaluation form level.
- Returns percentage value.
- Requires at least one filter from: queues, routing profiles, agents, or user hierarchy groups.
- Based on evaluation submission timestamp.

Average weighted evaluation score

This metric provides the average weighted evaluation score for all submitted evaluations. Evaluations for calibrations are excluded from this metric.

The weights are per the evaluation form version that was used to perform the evaluation.

The average evaluation score corresponds to the grouping. For example, if the grouping contains evaluation questions, then the average evaluation score is provided for the questions. If the grouping does not contain evaluation form, section or question, then the average evaluation score is at an evaluation form level.

Metric type: Percent

Metric category: Contact evaluation driven metric

How to access using the Connect Customer API:

- GetMetricDataV2 API metric identifier: `AVG_WEIGHTED_EVALUATION_SCORE`

How to access using the Connect Customer admin website:

- Dashboard: Agent performance evaluations dashboard

Calculation logic:

- Get sum of weighted scores using form version weights.
- Get total number of evaluations where scoring has been completed and recorded.
- Calculate weighted average: (sum of weighted scores) / (total evaluations).

Notes:

- Uses evaluation form version-specific weights.
- Excludes calibration evaluations.
- Score granularity depends on grouping level.
- Returns percentage value.
- Requires at least one filter from: queues, routing profiles, agents, or user hierarchy groups.
- Based on contact initiation date.
- Data for this metric is available starting from January 10, 2025 0:00:00 GMT.

Automatic fails percent

This metric provides the percentage of performance evaluations with automatic fails. Evaluations for calibrations are excluded from this metric.

If a question is marked as an automatic fail, then the parent section and the form is also marked as an automatic fail.

Metric type: Percent

Metric category: Contact evaluation driven metric

How to access using the Connect Customer admin website:

- Dashboard: Agent performance evaluations dashboard

Calculation logic:

- Get total automatic fails count.
- Get total evaluations performed.
- Calculate percentage: (automatic fails / total evaluations) * 100.

Notes:

- Automatic fail cascades up (question → section → form).
- Excludes calibration evaluations.
- Returns percentage value.
- Requires at least one filter from: queues, routing profiles, agents, or user hierarchy groups.
- Based on contact initiation date.
- Data for this metric is available starting from January 10, 2025 0:00:00 GMT.

Evaluations performed

This metric provides the number of evaluations performed with evaluation status as "Submitted." Evaluations for calibrations are excluded from this metric.

Metric type: Integer

Metric category: Contact evaluation driven metric

How to access using the Connect Customer API:

- GetMetricDataV2 API metric identifier: `EVALUATIONS_PERFORMED`

How to access using the Connect Customer admin website:

- Dashboard: Agent performance evaluations dashboard

Calculation logic:

- Check evaluationId present?
- Verify itemType is form.

- Count submitted evaluations (excluding calibrations).

Notes:

- Counts only submitted evaluations.
- Excludes calibration evaluations.
- Returns integer count.
- Requires at least one filter from: queues, routing profiles, agents, or user hierarchy groups.
- Based on contact initiation date.
- Data for this metric is available starting from January 10, 2025 0:00:00 GMT.

Evaluations performed (Submit time)

This metric provides the number of evaluations submitted by the evaluator, including resubmissions. Each submission event, including every resubmission of the same evaluation, is also counted here. Evaluations for calibrations are excluded from this metric.

Metric type: Integer

Metric category: Contact evaluation driven metric

How to access using the Connect Customer API:

- GetMetricDataV2 API metric identifier: `EVALUATIONS_PERFORMED_BY_SUBMIT_TIME`

How to access using the Connect Customer admin website:

- Dashboard: Agent performance evaluations dashboard

Calculation logic:

- Check evaluationId present?
- Verify itemType is form.
- Count every submission event (excluding calibrations), including resubmissions.

Notes:

- Counts every submission event, including resubmissions.
- Excludes calibration evaluations.
- Returns integer count.
- Requires at least one filter from: queues, routing profiles, agents, or user hierarchy groups.
- Based on evaluation submission timestamp.

Agent evaluation form output in Connect Customer

This section shows the export output path for evaluations, provides an example of evaluation form scores, and describes the evaluation form metadata.

Topics

- Verify your S3 bucket
- Example output locations
- Known issue: Two output files for the same evaluation
- Example scores
- Evaluation form metadata definitions
- Sample exported evaluation

Verify your S3 bucket

When you enable **Contact evaluations** in the Connect Customer console, you are prompted to create or choose an S3 bucket to store the evaluations. To verify the name of the bucket, navigate to your instance alias, choose **Data storage**, **Contact evaluations**, then **Edit**.

Example output locations

Following is the output file path for evaluation forms:

- *contact_evaluations_S3_bucket*/Evaluations/*YYYY/MM/DD/hh:mm:ss.sTZD*-*evaluation_id*.json

For example:

```
amazon-connect-s3/
Evaluations/2022/04/14/05:04:20.869Z-11111111-2222-3333-4444-555555555555.json
```

Known issue: Two output files for the same evaluation

Conversational analytics generates two output files for the same evaluation form.

- One file is written to the new default S3 path. You can configure the path in the AWS console.
- Another file, which will be deprecated, is written to a different, previous S3 path. You can disregard this file.

  The previous S3 path looks like the following:

  - *s3_bucket*/Evaluations/contact_*contactId*/evaluation_*evaluationId*/YYYY-MM-DDThh:mm:ss.sTZD.json

Example scores

The following example shows a typical score.

```

Evaluation form metadata definitions

The following list describes the fields in the evaluation form.

evaluationId

A unique identifier for the contact evaluation

Type – String

Length constraints – Minimum length of 1. Maximum length of 500

metadata

contactId

The identifier of the contact in this instance of Amazon Connect.

Type – String

Length constraints – Minimum length of 1, maximum length of 256

accountId

The identifier of AWS account running the instance of Connect Customer.

Type – String

Length constraints – Constraints: 12 digits

Pattern – `^\d{12}$`

instanceId

The identifier of the Amazon Connect instance. You can find the instance ID in the Amazon Resource Name (ARN) of the instance.

Length constraints – Minimum length of 1, maximum length of 100

agentId

The identifier of the agent who performed the contact.

Type – String

Length constraints – Minimum length of 1, maximum length of 500

evaluationDefinitionTitle

The title of the evaluation form.

Type – String

Length constraints – Minimum length of 1, maximum length of 128

evaluator

Name of the user who last updated the evaluation.

Type – String

evaluationDefinitionId

The unique identifier for the evaluation form.

Type – String

Length constraints – Minimum length of 1, maximum length of 500

evaluationDefinitionVersion

The version of the evaluation form.

Type – Integer

Valid range – Minimum value of 1

evaluationStartTimestamp

The evaluation's creation timestamp.

Type – Timestamp

Example – 2025-11-14T17:57:08.649Z

evaluationSubmitTimestamp

The evaluation's submission timestamp.

Type – Timestamp

Example – 2025-11-14T17:59:29.052Z

score

The evaluation's score.

creator

The entity that created the evaluation the very first time (as opposed to "evaluator" which represents the entity that last submitted the evaluation). When the call is made from the

Connect Customer admin website it contains the username. When the call comes from the API it contains the ARN of the caller.

Type – String

autoEvaluated

Indicates whether the evaluation was submitted using fully automated evaluations.

Type – Boolean

resubmitted

Indicates whether the evaluation has been re-submitted (edited and submitted again).

Type – Boolean

evaluationSource

The type of evaluation answer source.

Type – String

Valid values:

- `ASSISTED_BY_AUTOMATION` - indicates that question automation was used to answer some of the questions.
- `MANUAL` - indicates that the evaluation was performed manually.
- `AUTOMATED` - indicates that the evaluation was submitted using fully automated evaluations (see "autoEvaluated" field).

evaluationType

The type of evaluation.

Type – String

Valid values:

- `CONTACT_EVALUATION` - evaluation of a contact.

calibrationSessionId

The identifier of the calibration session associated with this evaluation.

Type – String

Length constraints – Minimum length of 1, maximum length of 500

evaluatedParticipantId

The identifier of the participant being evaluated.

Type – String

Length constraints – Minimum length of 1, maximum length of 256

evaluatedParticipantRole

The role of the participant being evaluated.

Type – String

Valid values:

- `AGENT` - the agent participant.
- `CUSTOMER` - the customer participant.
- `SYSTEM` - the system participant.

acknowledgerComment

Comment left by the user who acknowledged the evaluation.

Type – String

Length constraints – Minimum length of 0, maximum length of 3072

evaluationAcknowledgedByUserId

The identifier of the person who acknowledged the evaluation.

Type – String

Length constraints – Minimum length of 1, maximum length of 500

evaluationAcknowledgedByUserName

The name of the person who acknowledged the evaluation.

Type – String

evaluationAcknowledgedTimestamp

The evaluation's acknowledgment timestamp.

Type – Timestamp

Example – 2025-12-24T15:45:56.662Z

sections

Array of the sections of the evaluation.

sectionRefId

The identifier of the section. An identifier must be unique within the evaluation form.

Type – String

Length constraints – Minimum length of 1, maximum length of 40

parentSectionRefId

The identifier of the parent section.

Type – String

Length constraints – Minimum length of 1, maximum length of 40

sectionTitle

The title of the section.

Type – String

Length constraints – Constraints: Minimum length of 0, maximum length of 128

notes

The notes left for the section.

Type – String

Length constraints – Minimum length of 0, maximum length of 3072

> **Note**
>
> Notes have the following limits:
>
> - Individual notes have a limit of 3072 characters.

- The combined notes in an evaluation have a limit of *N* x 1024 characters, where *N* is the number of questions in the evaluation.

score

The score for the section.

percentage

The score percentage for an item in a contact evaluation.

Type – Double

Valid range – Minimum value of 0, maximum value of 100

automaticFail

The flag that marks the item as automatic fail. If the item or a child item gets an automatic fail answer, this flag will be true.

Type – Boolean

notApplicable

The flag that marks the item as automatic fail. If the item or a child item gets an automatic fail answer, this flag will be true.

Type – Boolean

questions

Array of the questions of the evaluation.

questionRefId

The identifier of the question. An identifier must be unique within the evaluation form.

Type – String

Length constraints – Minimum length of 1, maximum length of 40.

sectionRefId

The identifier of the parent section.

Type – String

Length constraints – Minimum length of 1, maximum length of 40

questionType

The type of the question.

Type – String

Valid values – `TEXT | SINGLESELECT | NUMERIC`

questionText

The title of the question.

Type – String

Length constraints – Minimum length of 0, maximum length of 350

answer

The answer for the question.

value

The string/numeric value for an answer in a contact evaluation.

Type – String/Double

Length constraints – String: Minimum length of 0, maximum length of 128

notes

The notes left for the section.

Type – String

Length constraints – Minimum length of 0. Maximum length of 3072

> **Note**
>
> Notes have two character limits. Individual notes have a limit of 3072 characters. The combined notes in an evaluation have a limit of N x 1024 characters, where N is the number of questions in the evaluation.

metadata

notApplicable

Flag that marks the question as not applicable.

Type – Boolean

assistedSuggestion

Answer suggested by the generative AI.

Type – String

automation

status

The status of the automation answer.

Type – String

Valid values – `UNAVAILABLE | SYSTEM_ANSWER | OVERRIDDEN_ANSWER`

systemSuggestedValue

The string or numeric value for an automation answer in a contact evaluation.

Type – String or Double

Length constraints – String: Minimum length of 0, maximum length of 128

score

The score for the question.

- automaticFail - The flag that marks the item as critical for the form and the full form will fail (marked with zero score) when the item fails. If the item or a child item gets an automatic fail answer, this flag will be true and the full form will also fail.

  Type – Boolean

- notApplicable - The flag that marks the item as not applicable for scoring, it will be excluded from scoring calculations.

  Type – Boolean

Sample exported evaluation

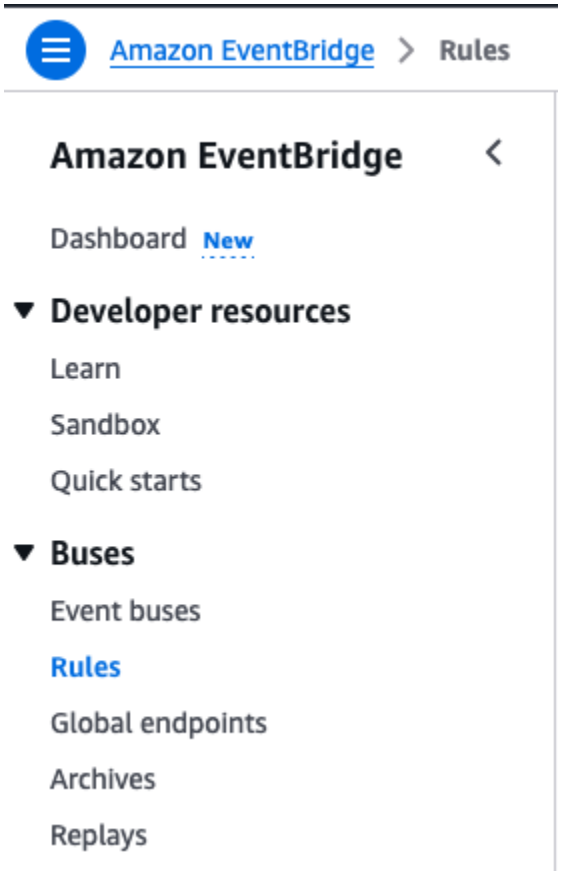
Monitor performance evaluation failure events

You can monitor failures of automated evaluations as well as S3 exports of contact evaluations using EventBridge and CloudWatch. You can use these events to investigate and fix failures. The following guide is a walk through of the process of creating custom EventBridge rules to monitor performance evaluation failure events.

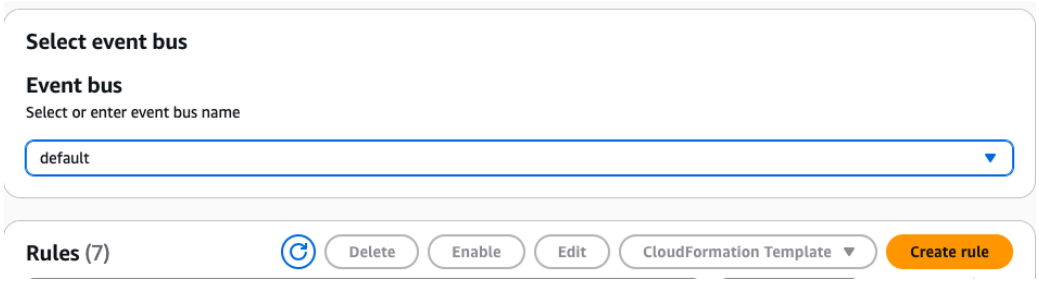
Step-by-step guide

This is a guide on how to create an EventBridge rule to log Connect Customer failed auto-evaluation submission events and failed S3 exports of contact evaluations in your AWS console.

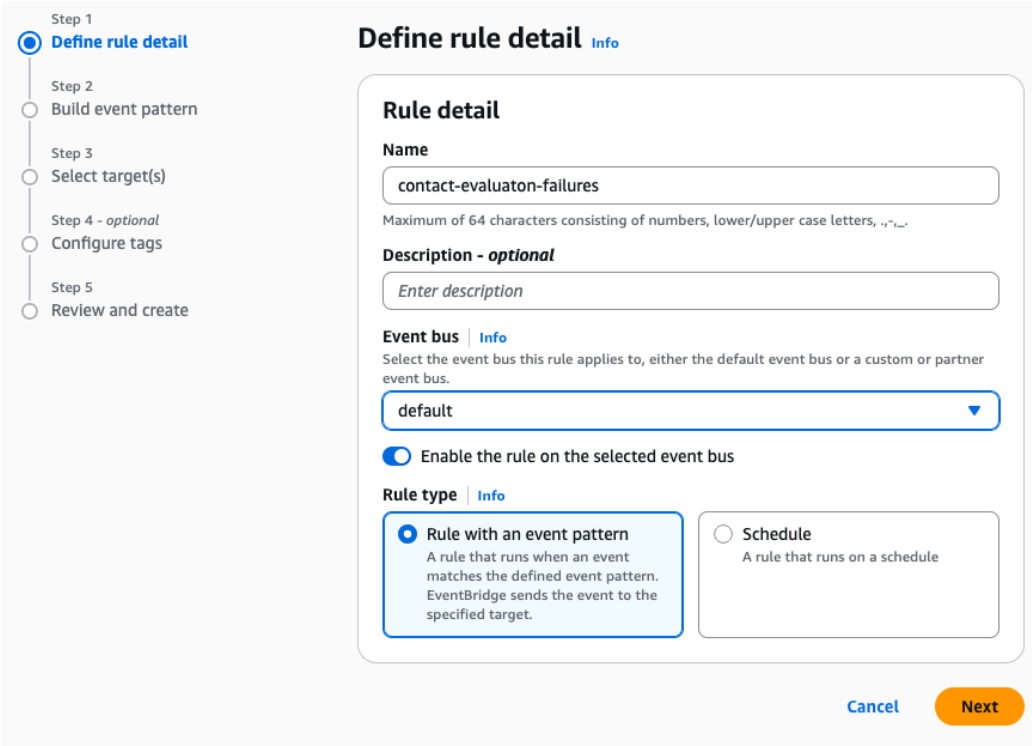
1. Log into your AWS account and navigate to the EventBridge console. Choose **Rules** under the **Buses** section.



2. Choose **Create rule** with the default Event bus selected.



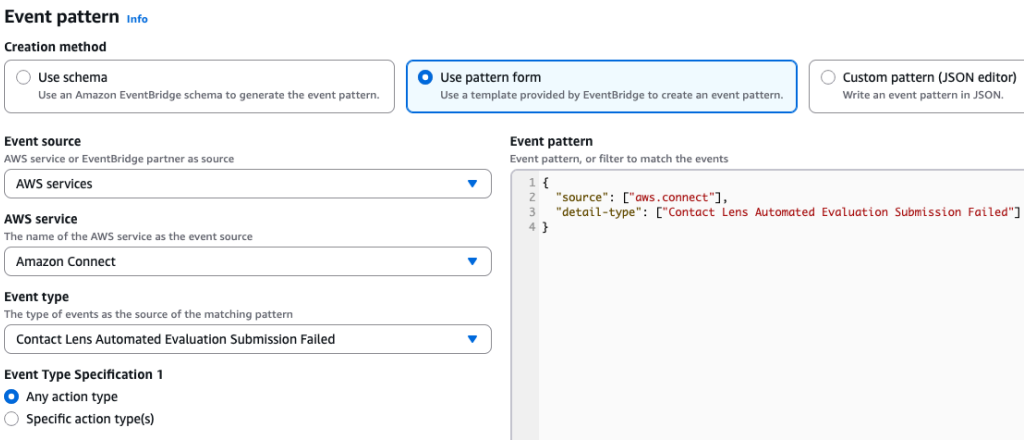
3. Give the rule a name and select **Rule with an event pattern** for the Rule type. Choose **Next**.



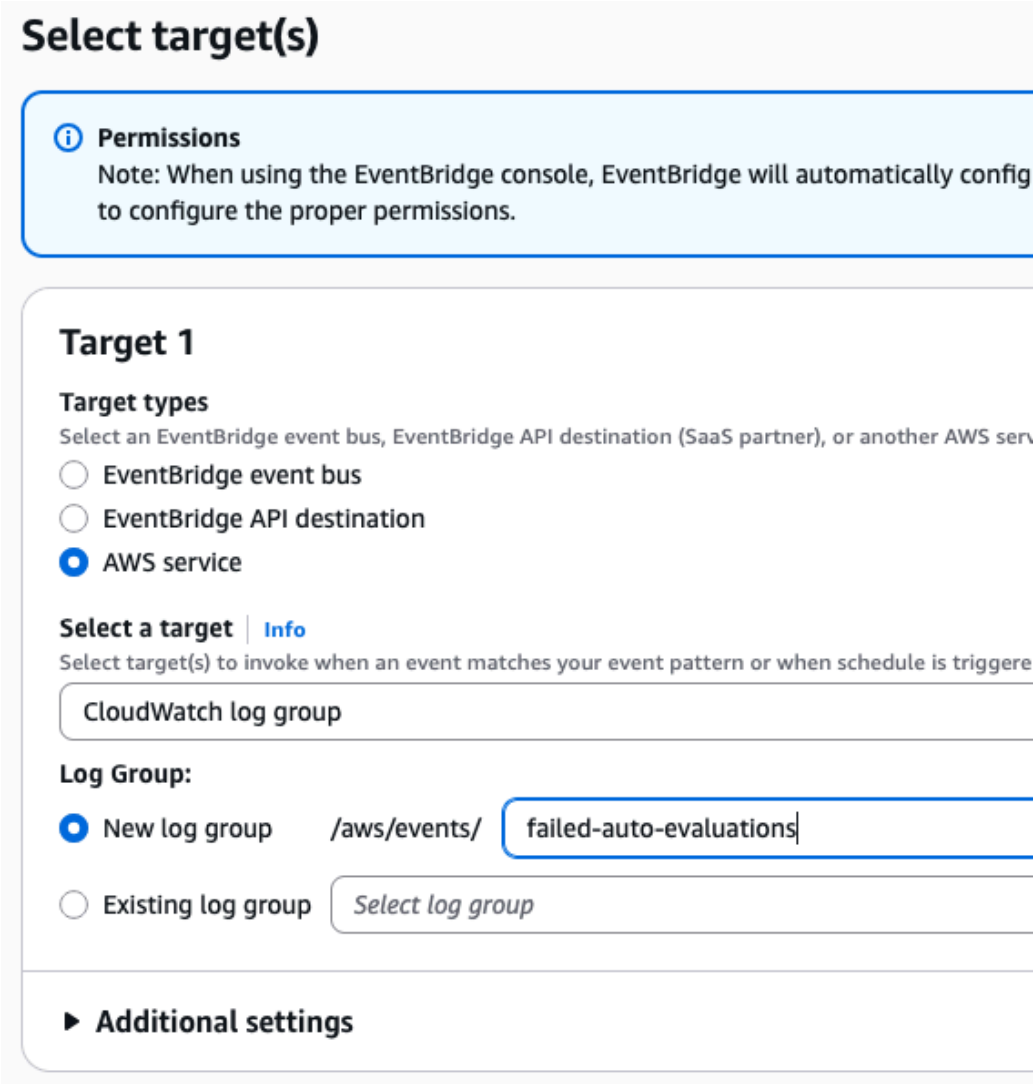
4. With **AWS events or EventBridge partner events** selected under **Events**, select the **Use pattern form** option under **Event pattern**. This is where you will define the pattern to match for triggering the rule.
5. Type and select **Amazon Connect** under the **AWS service** dropdown to narrow down the event types. Select the desired event type in the dropdown below. Choose **Next** after the pattern is set up.

   To subscribe to EventBridge event types, create a custom EventBridge rule that matches the following:

   - `"source" = "aws.connect"`
   - `"detail-type"` can be one of the following:
     - `"Contact Lens Automated Evaluation Submission Failed"`
     - `"Contact Lens Evaluation Export Failed"`



6. In the next step, you can configure the target(s) to process/receive the matched events. For simplicity, select the **CloudWatch log group** option under **Select a target** and choose a log group.
7. Choose **Next** and advance to the final **Review and create** step. Choose **Create rule** once more to complete the rule creation process.
8. Now, if the rule is in the **Enabled** state and a matching event occurs, corresponding logs should show up in the configured CloudWatch log group with the relevant IDs under the metadata section and the failure reason under the data section.



Select target(s)
Permissions
Note: When using the EventBridge console, EventBridge will automatically config
to configure the proper permissions.

    "version": "1.0.0",
```

```
    "metadata": {
      "contactId": "4266f8e9-8420-4ee7-96cd-515d2edae1f2",
      "instanceId": "d9b0b09d-7dab-47e5-9f82-d6787fbc068c",
      "formId": "8b1365bd-1415-41a9-a491-af226e1bda4e"
    },
    "data": {
      "reasonCode": "ANALYSIS_FILE_ERROR",
      "message": "Automated contact evaluation submission failed due to an error when
 searching/retrieving/parsing the analysis file."
    }
  }
}
```

Common errors

The following errors might occur when the system eventually fails to process evaluations after multiple retry attempts.

Automated evaluation submission errors

Error	Error message
AUTOMATED_SUBMISSION_FAILED	Automated contact evaluation submission failed because some of the questions could not be answered. Please verify the evaluation form or the Connect Customer rule configurations.
ANALYSIS_FILE_ERROR	Automated contact evaluation submission failed due to an error when searching/retrieving/parsing the analysis file.
INTERNAL_SERVER_ERROR	Automated contact evaluation submission failed due to an internal server error. Please expect delayed processing.
QUOTA_EXCEEDED_ERROR	Automated contact evaluation submission failed because the remaining quota for using generative AI to automatically answer evaluation questions for the contact is insufficient.

Evaluation S3 export errors

Error	Error message
S3_BUCKET_ACCESS_DENIED	Contact evaluation JSON export failed due to insufficient permissions.
S3_STORAGE_NOT_CONFIGURED	The export S3 bucket is not configured for your instance.
INTERNAL_SERVER_ERROR	Contact evaluation JSON export failed due to an internal server error. Please expect delayed delivery of the export file.

Calibration sessions for performance evaluations

With Connect Customer conversational analytics, you can conduct calibration sessions to drive consistency and accuracy in how managers evaluate agent performance, so that agents receive feedback that is consistent. During a calibration, multiple managers can evaluate the same contact using the same evaluation form. You can then review differences in evaluations filled by different managers to align managers on evaluation best practices and identify opportunities to improve the evaluation form, for example, rephrasing an evaluation question to be more specific, so that it is consistently answered by managers. You can also compare manager's answers with a designated expert, to measure and improve manager accuracy on evaluating agent performance. The expert is usually the quality manager who is conducting the calibration session.

Permissions needed for calibrations

You need the following permissions for calibrations:

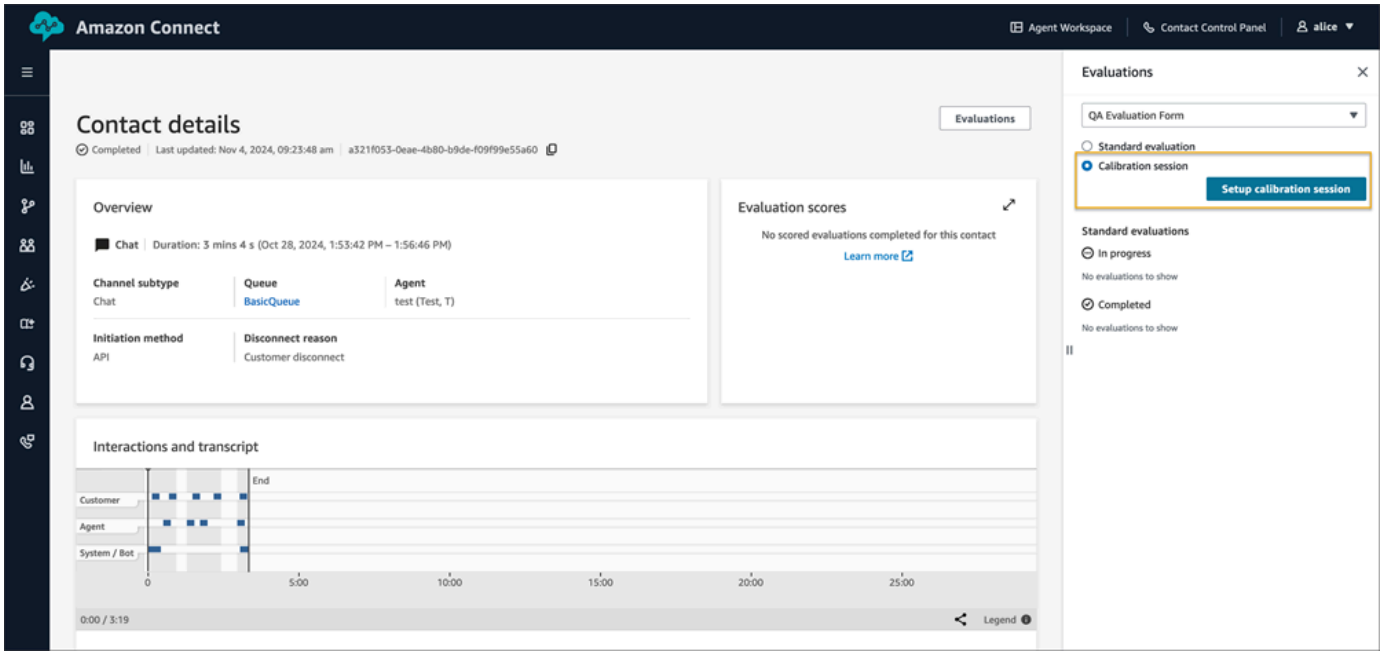
- **Creating calibration sessions:** Add the permission **Evaluation forms - manage calibration sessions** to the security profiles of the set of users that should be permitted to conduct calibration sessions for performance evaluations.
- **Participating in a calibration session:** Any user who has the permission to perform evaluations, namely **Evaluation forms - perform evaluations**, can participate in a calibration session if they are added as one of the participants.

In addition, for both sets of users, you also need permissions to search and view contacts. For more information, see Manage who can search for contacts and access detailed information.

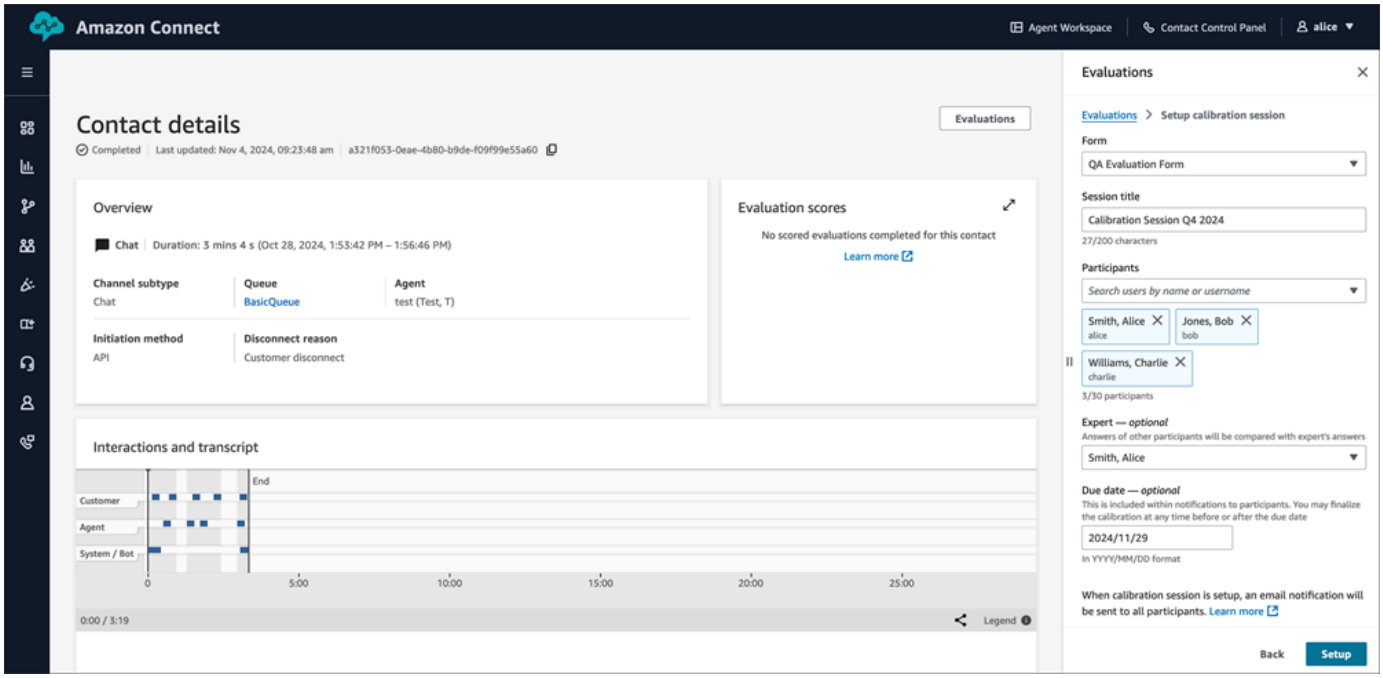
Create a calibration session

To create a calibration session

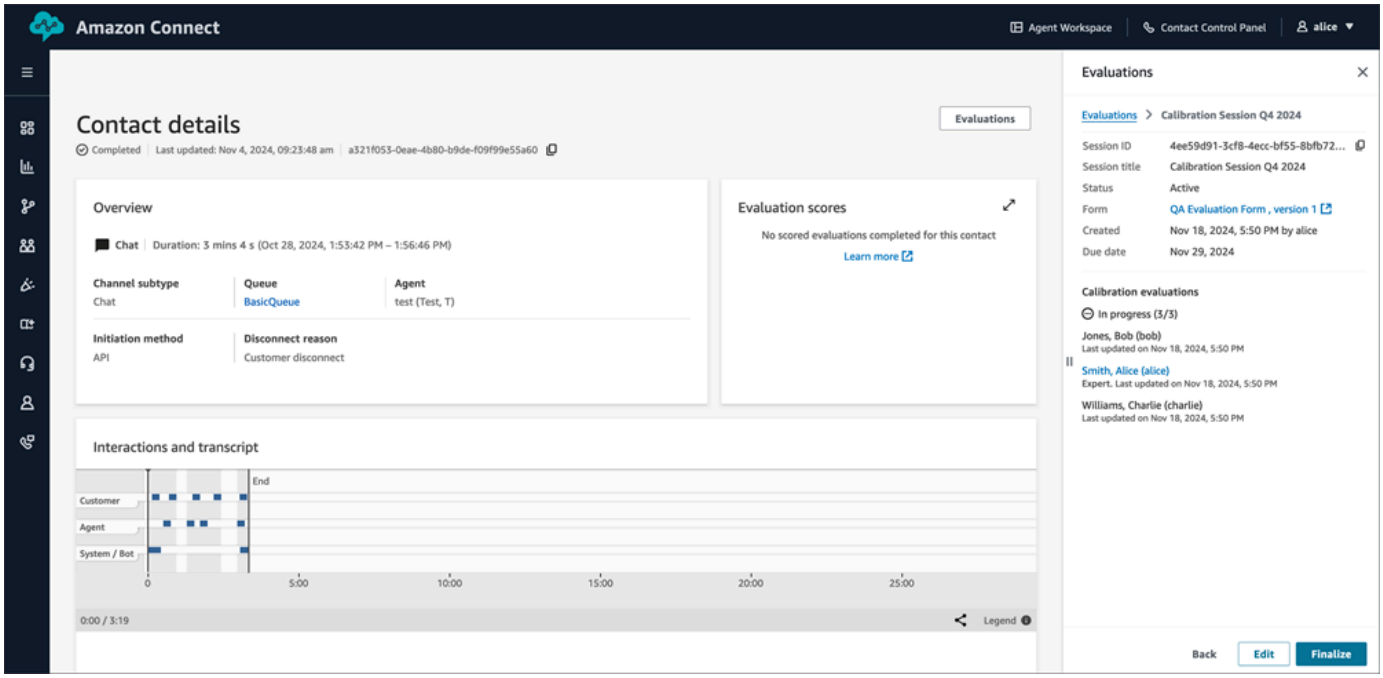
1. Login to Amazon Connect Customer with a user account that has the necessary permissions within their security profile.
2. On the left navigation menu, choose **Analytics and optimization, Contact search**.
3. Search for a contact that you want to perform calibrations on, for example, minimum interaction duration, specific queue.
4. On the **Contact details** page of a contact, choose **Evaluations** on the top right to open the **Evaluations** side panel.
5. In the side panel, select the **Calibration session** radio button, choose the desired form for the calibration using the dropdown menu, and then choose the **Setup calibration session** button.



6. Enter a title for the calibration session, select the participants, and optionally designate an expert participant and set a due date.



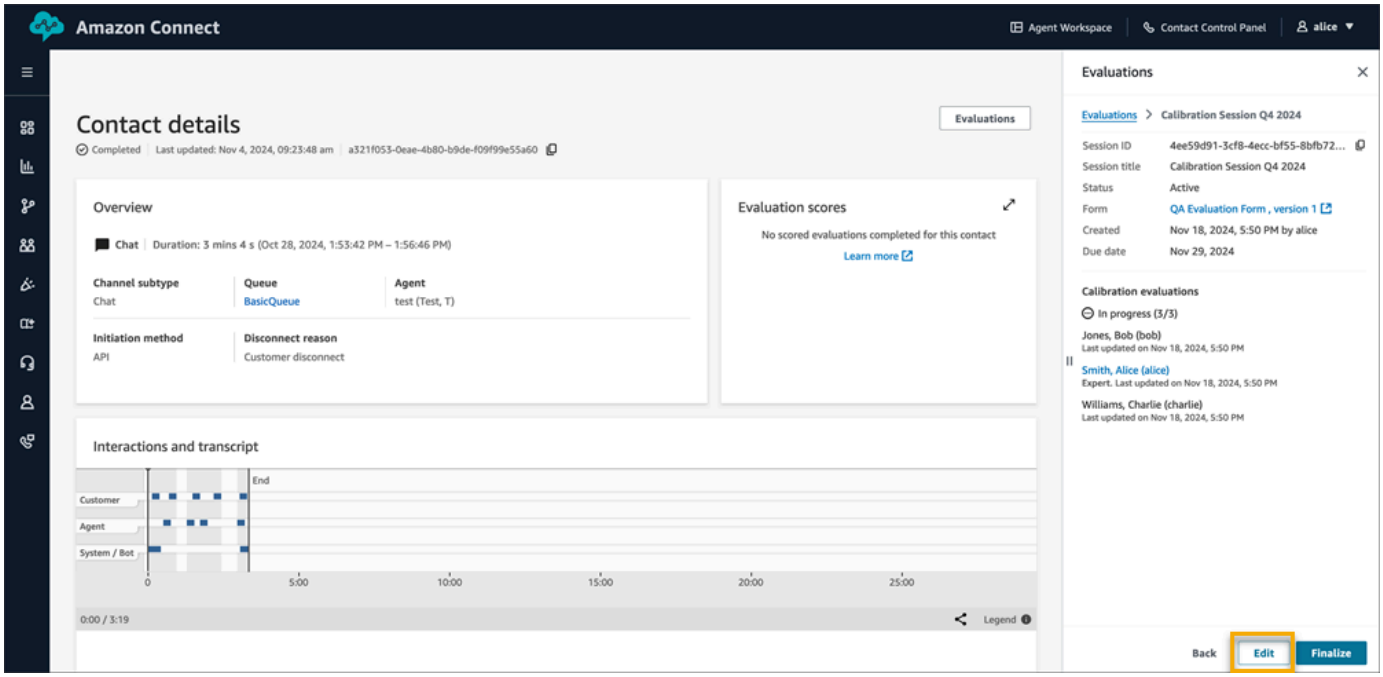
7. After creation, the calibration session will appear in the side panel. An evaluation will be automatically generated for each participant.



Edit a calibration session

To edit a calibration session

1. On the side panel locate the calibration sessions and choose **Edit**.



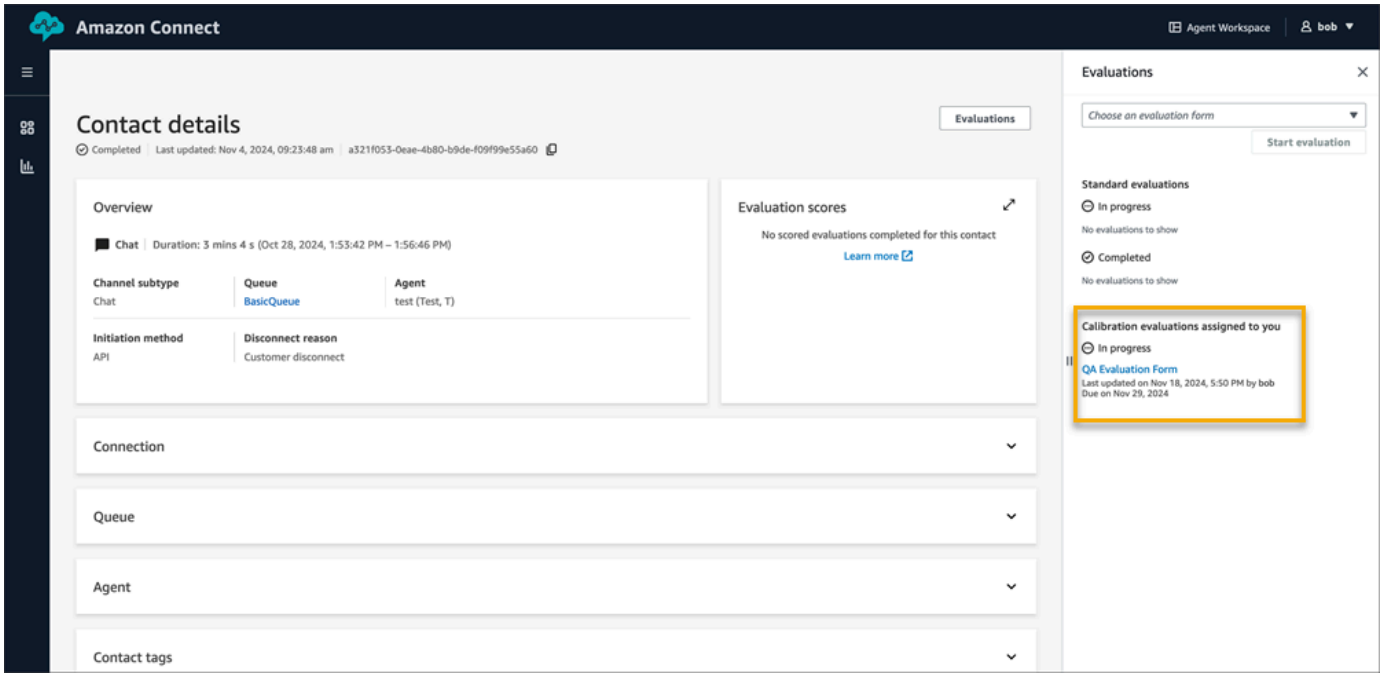
2. In the form that opens in the side panel you can modify the calibration session title, add or remove participants, optionally designate an expert participant, and set or adjust the due date.
3. Choose **Save** to update the calibration session. The changes will be reflected in the side panel. New participants will automatically receive an evaluation, while removed participants will have their evaluations deleted.

Perform evaluations as a part of a calibration session

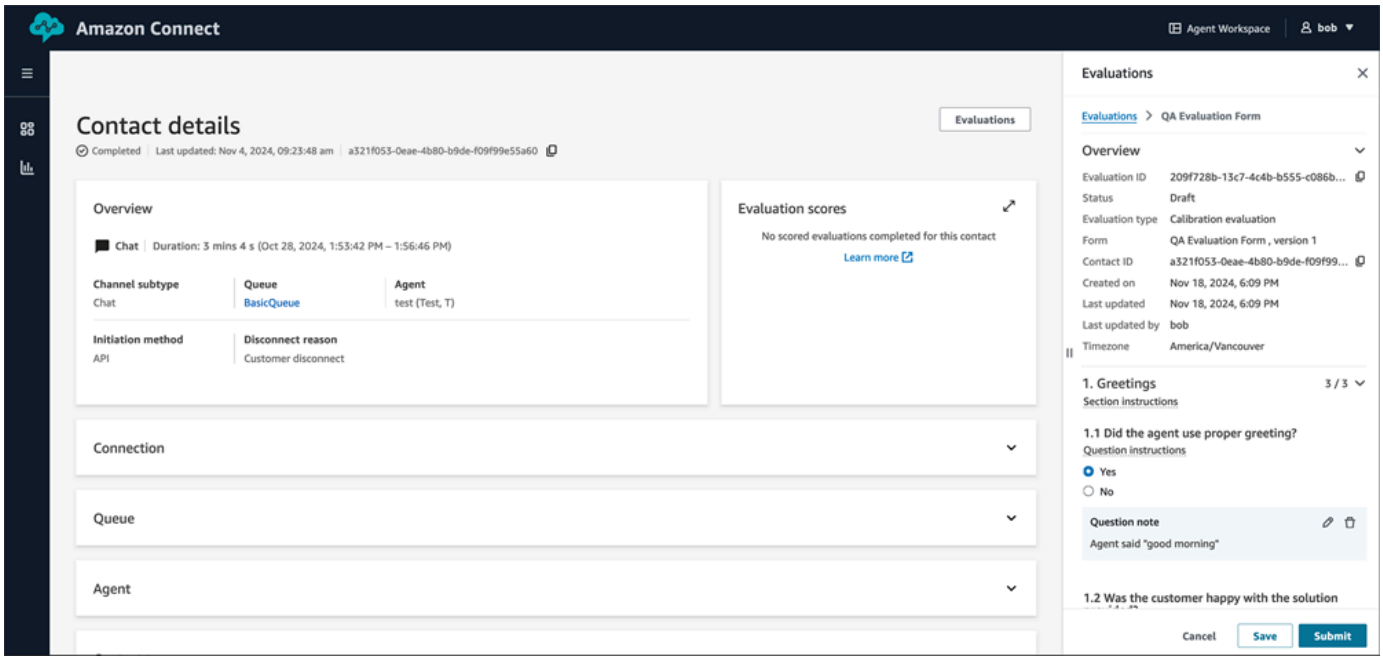
Use the following procedure to perform evaluations as a part of a calibration session:

To perform evaluations

1. On the side panel locate the **Calibration evaluations assigned to you** section to view your calibration evaluations.



2. Choose an evaluation to open it. You can respond to these evaluations in the same manner as standard evaluations, with options to save your progress or submit the completed evaluation. Automation is disabled on calibration sessions.

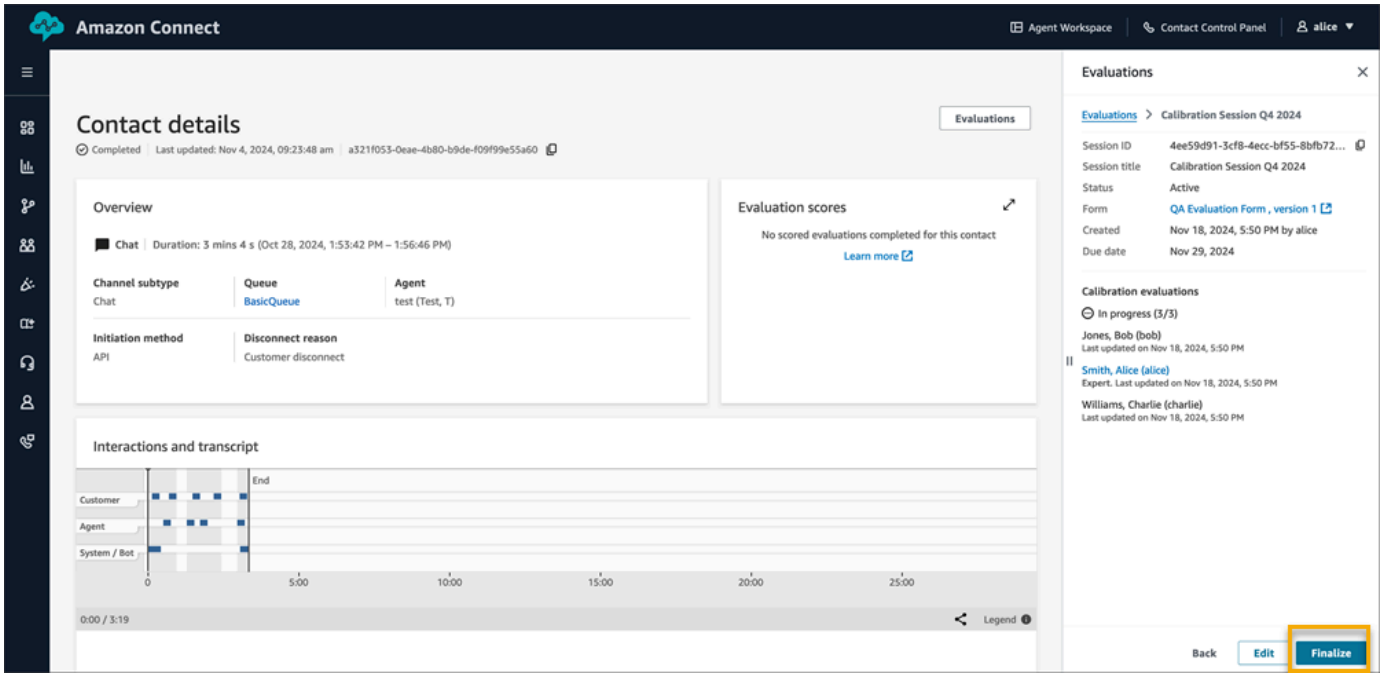


3. Calibration managers can access a list of all evaluations associated with a specific calibration session by viewing the calibration session details in the side panel. Calibration managers will also be able to view evaluations submitted by participants.

Finalize a calibration

To finalize a calibration

1. Access the calibration session details view and choose **Finalize**.



2. Confirm the finalization when prompted. After a session is finalized, neither the session nor its evaluations can be edited.
3. Within a few seconds, a calibration report will be available for download in .csv format. This report contains the answers of participants that have submitted evaluations, along with the weighted scores for each question, section and the overall form, evaluator notes and comparison of the evaluator's scores with the expert evaluator.

   Use the field **absolute deviation from expert** (lower is better) for each participant to determine if an evaluator is significantly deviating from the expert while answering evaluation questions. You can also see **average absolute deviation from expert** (lower is better) to see if there are certain questions that get inconsistent answers from participants and need improvement (For example, better phrasing, more specific questions)

Finding calibration sessions

Amazon Connect Customer notifies users participating in calibration sessions through email (for example, if a user is added as a participant, if there is a change to the due date). If a user managing

a calibration session has added themselves as the **expert** participant, then they would also receive emails. The email contains a link to the contact which is being used for calibration. For users to receive email notifications, you need to assign emails to the users on Connect Customer. For more information, see Add users to Connect Customer.

As a manager setting up a calibration, you can copy the contact ID to search for the contact on which the calibration session was set up. If you have not added yourself as an expert or if user emails are not set up within Connect Customer, you will not receive an email containing a link to the contact on which the calibration session was set up.

Ingest agent activities from third-party applications to evaluate agent performance

You can import agent activities completed in third-party applications into Connect Customer. These activities are imported as Connect Customer tasks, which you can evaluate alongside work completed in Connect Customer. This provides managers with a unified application for quality management.

To import activities completed in third-party applications (such as application processing or social media interactions) as completed tasks, use the CreateContact API. When you import these activities, you can capture details relevant for performance evaluation as task attributes. Unlike tasks created in the Connect Customer admin website, these imported tasks are already marked as completed and don't need to be accepted by the agent who completed the activity in the external application.

Managers can then evaluate these external activities alongside native Connect Customer interactions and back-office tasks. This gives managers a unified view of agent performance in the Agent performance evaluations dashboard.

Example: score agents on back-office work

The following example shows how you turn work completed outside of Connect Customer into evaluation results. Suppose your agents process insurance claims in a separate back-office application, and you want to score the quality of that work.

1. Each time an agent finishes a claim, your back-office application calls the CreateContact API. Each call records the completed activity as a Connect Customer task, along with the agent who did the work and attributes such as the claim type.

2. A quality manager searches Contact search for these completed tasks. The manager filters on the attributes that you captured, such as `ExternalContactType`, to find a specific type of activity.
3. The manager opens a task and scores it with an evaluation form, the same way that they score a call or a chat.
4. These scores appear next to the scores for native Connect Customer contacts in the Agent performance evaluations dashboard. As a result, you get one view of agent performance across both Connect Customer interactions and external back-office work.

The rest of this topic describes each step in detail.

How to ingest activities from third-party applications

The following steps are typically performed by an IT admin.

- Make sure that agents or back-office workers who you want to evaluate are users on Connect Customer. To add new users, see Add users to Connect Customer.
- Use the CreateContact API to ingest all external activities completed by these agents into Connect Customer as completed Connect Customer tasks.

  You can ingest:

  - All activities completed in third-party applications (for example, triggered by the completion of these activities). This provides you with a comprehensive view of agent activities in a single application.
  - A percentage of agents' external activities as a sample that you use for performance evaluation.

  Following is a sample API request for ingesting a claims authorization activity that was completed in another system.

```
awscurl \
--service connect \
-X PUT \
'https://connect.us-east-1.amazonaws.com/Prod/contact/create-contact' \
--region us-east-1 \
-d \
'{
  "Channel":"TASK",
```

```
  "InstanceId":"8f3b9ab3-df68-4124-8573-2626b5c939ac",
  "InitiationMethod":"API",
  "InitiateAs":"COMPLETED",
  "UserInfo": {"UserId": "arn:aws:connect:us-west-2:295154396770:instance/8f3b9ab3-
df68-4124-8573-2626b5c939ac/agent/1c99b776-8e56-4aaa-a1bf-b950ffbe61e4"},
  "Name": "Processing Authorization #12345",
  "Description": "Customer Name: John Doe; Customer Condition: Asthma; Medication:
 Levocetrizin",
  "Attributes": {
    "Authorization": "12345",
    "ExternalContactType": "Authorization"
  },
  "References": {
    "ThirdPartySystemURL": {
      "Type": "URL",
      "Value": "https://example.com/customer/12345"
    }
  }
}'
```

- You can add additional activity information within attributes. This information might be useful for quality managers who are searching and evaluating contacts. For example, the previous API call includes a custom attribute called `ExternalContactType`. It enables managers to distinguish between different types of external activities within Contact search.

  You can also add links to the third-party system within contact references. These links enable managers to reference additional information that's not included with the task.

- To enable managers to search for activities using these attributes, you need to enable search on these attributes. For more information, see Search for contacts in Connect Customer by using custom contact attributes or contact segment attributes.

> **Note**
>
> Only tasks that are created after this setting is configured are searchable using these attributes.

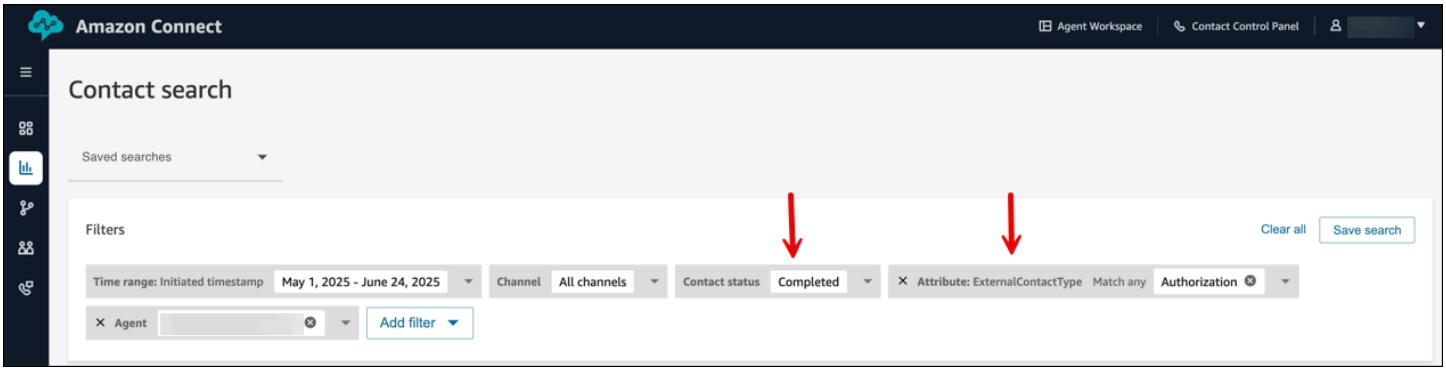
How to evaluate external activities

The following steps are typically performed by managers.

Managers can evaluate ingested activities in Connect Customer the same way that they evaluate native Connect Customer contacts. For more information, see Evaluate performance.

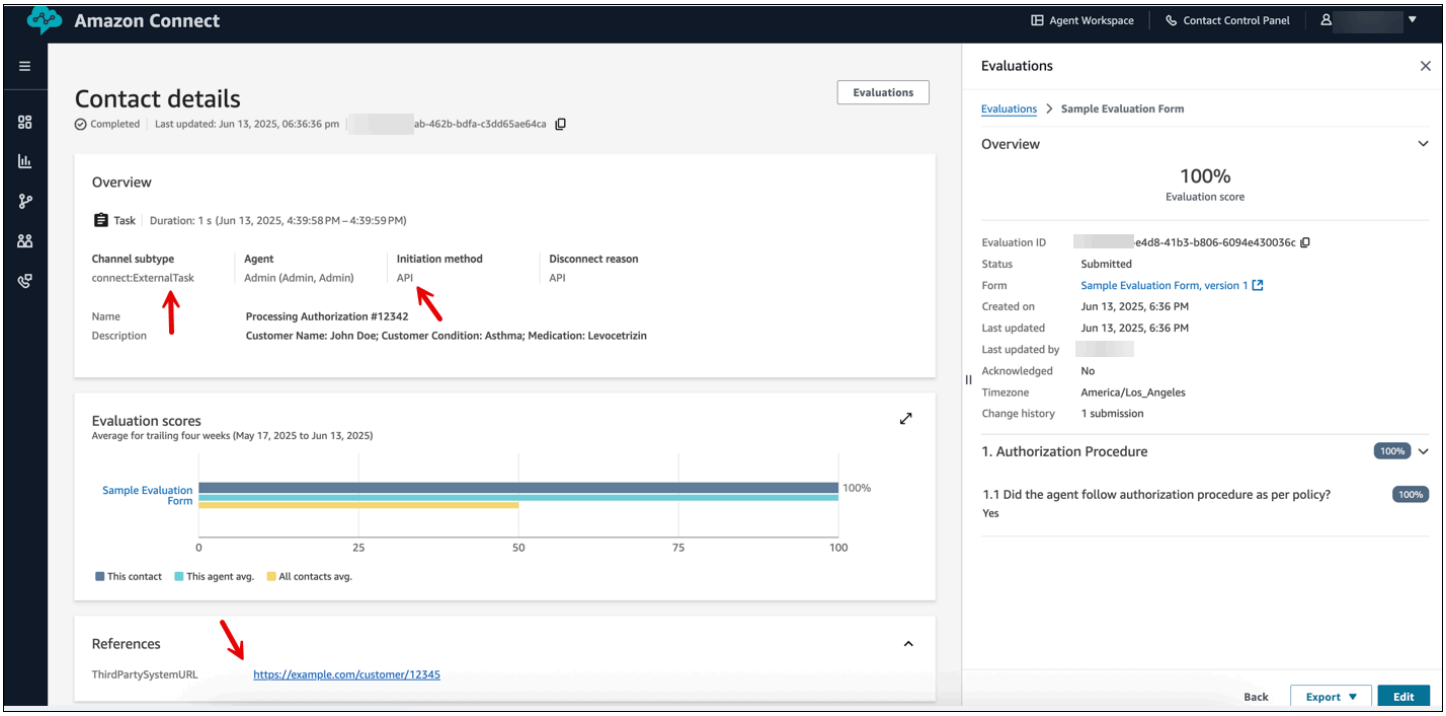
If your admin has configured search on custom contact attributes, you can search for external activities with identifiers, such as the type of activity and ID.

The following image shows a search for `Completed` contacts, with `Attribute` = `ExternalContactType`.



The following image shows an example of what contact details look like for a completed external contact. In this image:

- Channel subtype = connect:ExternalTask
- Initiation method = API
- References includes the URL to the third-party system

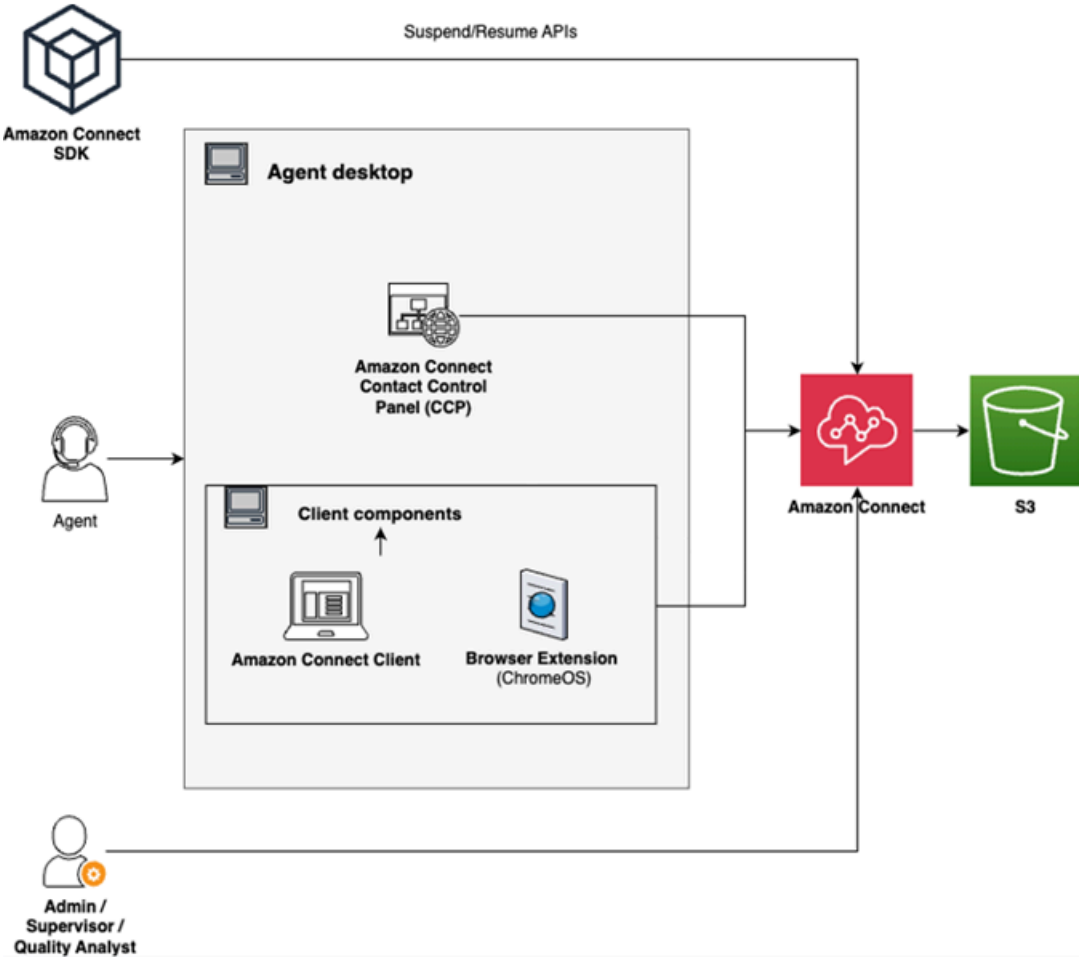


Set up and review agent screen recordings in Connect Customer

To help coach your agents to provide great customer service, you can use the screen recording feature to gain quality management insights. It records the agent's desktop, which helps you identify opportunities to improve performance. This information is also useful for ensuring compliance.

For example, let's assume it takes most agents two minutes to process a refund, but Jane Doe takes four minutes. You can watch a recording of her desktop when she's doing a refund and discover why she is taking longer.

The following diagram shows the high-level components of screen recording. For a sequence diagram that shows the network calls between different components, see Network requirements.



Topics

- Connect Customer Client Application
- System and network requirements for screen recording in Connect Customer
- Enable screen recording for your Connect Customer instance
- Review agent screen recordings in the Connect Customer Client Application
- Rule-based redaction for agent screen recordings in Connect Customer
- Download the Connect Customer Client Application log files for troubleshooting
- Use Amazon EventBridge events to track screen recording status
- Screen recording with Connect Customer Global Resiliency
- Frequently asked questions about Connect Customer screen recording capabilities

Connect Customer Client Application

Connect Customer screen recording is supported in Windows and Chrome OS. This page provides the download and installation instructions for the screen recording application in each operating system, and the minimum system requirements for the agent devices.

> **Important**
>
> To use Rule-based redaction for screen recordings, you must install Connect Customer Client Application version 3.0.2 or later. Rule-based redaction also requires the Connect Customer browser extension on every browser that agents use during recorded contacts. For deployment instructions, see Deploy the browser extension.

Topics

- Windows
- Chrome OS
- Release notes

Windows

Version information

- Version: v3.0.6 (latest)
- Release date: November 6, 2026
- Download link: AmazonConnectClientWin-v3.0.6
- Release note: For more information, see Release notes.

The above link downloads the **AmazonConnectClientWin-[version].zip** file. The zip file contains the **Amazon.Connect.Client.Service.Setup.[version].msi** file. For installation instructions, see the section called “Client installation instructions”.

To be notified when there is an update to the Connect Customer Client Application, we recommend subscribing to the RSS feed of this administrator guide. Choose the **RSS** link that appears under the title of this page (it's next to the PDF link).

Client installation instructions

In this step you install the **Amazon.Connect.Client.Service** file onto the agent's desktop, or into the virtual environment that the agent uses. This is the Connect Customer Client Application.

> **Note**
>
> - In case of Windows multi-session OS, run the installer only once on the machine. Screen recording on Windows multi-session OS is supported only by version 2.0.0 or later.
> - If your Connect Customer instance is in AWS GovCloud (US-West), you must install version 2.0.3 or later.
> - You need to configure an allowlist of Connect Customer domains that are allowed to communicate with the client application. Screen recordings are captured only from Connect Customer domains specified in your allowlist.

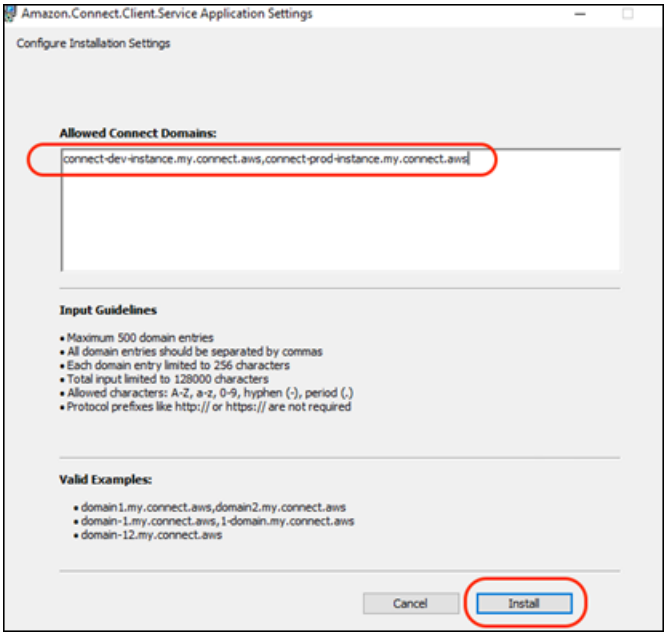
Programmatic installation by using software distribution tools

- Download the latest version of the **Amazon.Connect.Client.Service.Setup.msi** file.
- Use your organization's software distribution mechanism, such as Software Center, to install the **Amazon.Connect.Client.Service** client app on agent desktops.
- Deploy using your organization's enterprise software distribution system such as Microsoft System Center Configuration Manager, SCCM, or other automated deployment tools.
- Include the `ALLOWED_CONNECT_DOMAINS` parameter by using the following syntax:

```
msiexec /i Amazon.Connect.Client.Service.Setup.msi ALLOWED_CONNECT_DOMAINS="connect-dev-instance.my.connect.aws,connect-prod-instance.my.connect.aws"
```

Manual installation

- Download the latest version of the **Amazon.Connect.Client.Service.Setup.msi** file.
- Choose the installer file.
- Enter the Connect Customer domains allowlist when prompted. The following image shows an example of how to specify a domain in the allowlist on the **Configure Installation Settings** dialog box. For more examples, see *Guidelines for specifying your Amazon Connect domains allowlist* below.



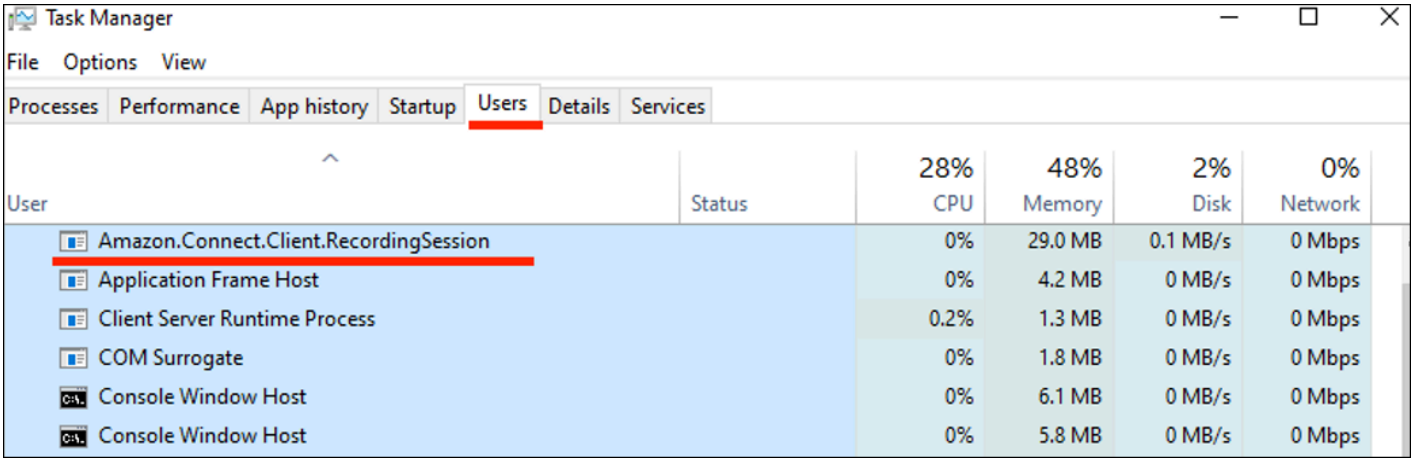
- Choose **Install** to complete the installation.

Verify the Connect Customer Client Application is running and functioning correctly

To verify that the application is running:

- In Windows Task Manager, check for a background process named **Amazon.Connect.Client.Service**. This is the Connect Customer Client Application.
- In Windows Task Manager, under **Users processes**, check for another process named **Amazon.Connect.Client.RecordingSession** after the user accepts the very first contact where screen recording is enabled.

  The following image shows **Amazon.Connect.Client.RecordingSession** in Task Manager.



To verify that the application is functioning correctly and creating log files:

1. Navigate to the following directory: `C:\ProgramData\Amazon\Amazon.Connect.Client.Service\logs`
2. Open log files that are present in the directory.
3. In a successful installation the log files contain the following line: `Checking that services are still running, result : true`
4. Navigate to the following directory: `%USERPROFILE%\AppData\Local\Amazon\Amazon.Connect.Client.RecordingSession\Logs`
5. Open log files that are present in the directory.
6. In a successful installation the log files contain the following line: `Session initiation completed with result: True`

Guidelines for specifying your Connect Customer domains allowlist

Be sure to adhere to the following guidelines when you enter domains in the **Allowed Connect Domains** box. Otherwise your installation will fail.

- Format: Comma-separated Connect Customer domains
- Valid characters for Connect Customer domains: Use only A-Z, a-z, 0-9, hyphen (-), period (.)
- Protocol prefixes such as https:// or http:// are not required.
- Limitations:
  - Maximum 500 domain entries
  - Maximum 256 characters per domain entry
  - Maximum 128,000 characters total input length

If your instance uses Connect Customer Global Resiliency, include the Region-specific sub-domains for both Regions of your instance pair, for example `us-east-1.`*`your-instance-alias`*`.my.connect.aws,us-west-2.`*`your-instance-alias`*`.my.connect.aws`. For more information, see Screen recording with Global Resiliency.

Following are examples of how to specify your domain.

Correct

- domain1.my.connect.aws,domain2.my.connect.aws

- ddomain-1.my.connect.aws, 1-domain.my.connect.aws
- domain-12.my.connect.aws
- us-east-1.domain.my.connect.aws,us-west-2.domain.my.connect.aws (Region-specific sub-domains for a Connect Customer Global Resiliency instance pair)

Incorrect

- _123domain.foo
- domain:2.foo
- *domain.my.connect.aws
- https://domain1.my.connect.aws
- *.my.connect.aws

Chrome OS

Connect Customer screen recording feature on ChromeOS requires two components:

- Isolated Web App
- Google Chrome Browser Extension

The installation of these components on Agent Chrome devices can be performed through Google Enterprise Admin Console. The following URLs configure the installation of the Isolated Web App and Chrome browser extension, and you can set them to automatic update through web manifest configuration JSON.

Download location and Install instructions

Complete the following steps on the Google Enterprise Admin Console. Apply the policy for all the agent devices where screen recording feature needs to be enabled.

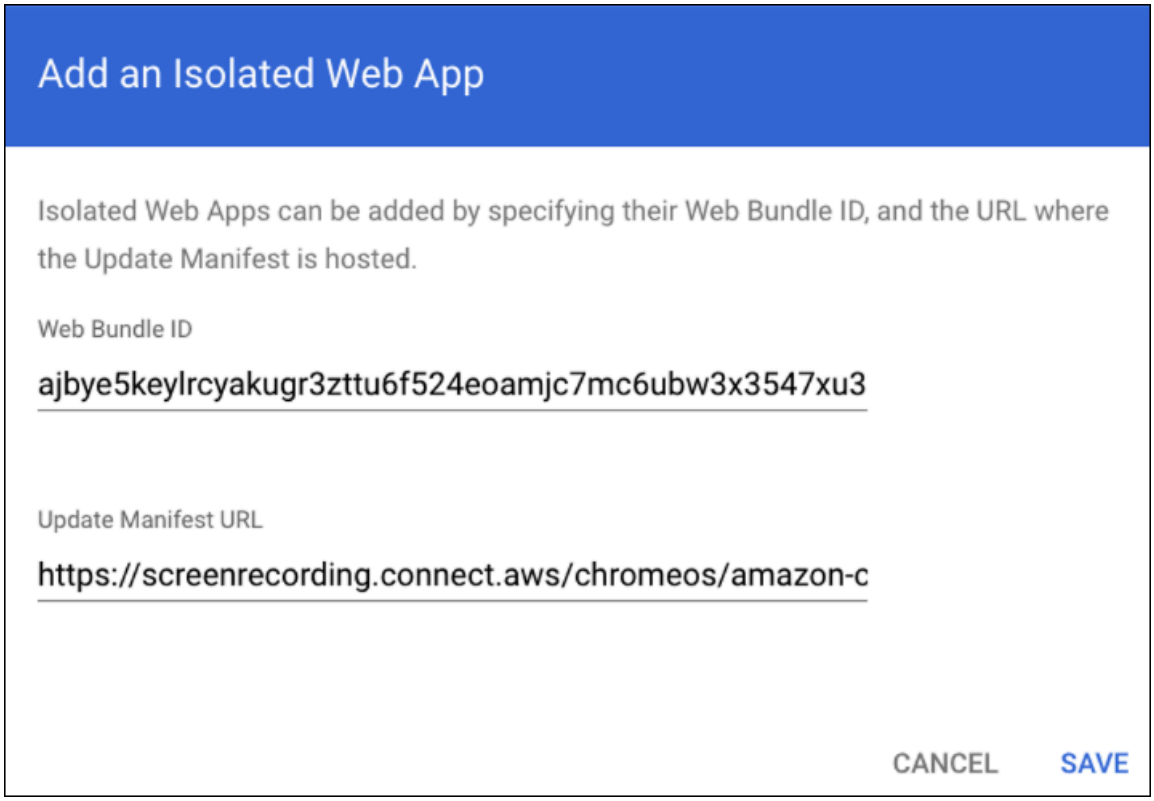
Install Isolated Web App

- Web Bundle ID: `ajbye5keylrcyakugr3zttu6f524eoamjc7mc6ubw3x3547xu3hxqaacai`
- Update Manifest URL: `https://screenrecording.connect.aws/chromeos/amazon-connect-client-iwa/releases/update_manifest.json`

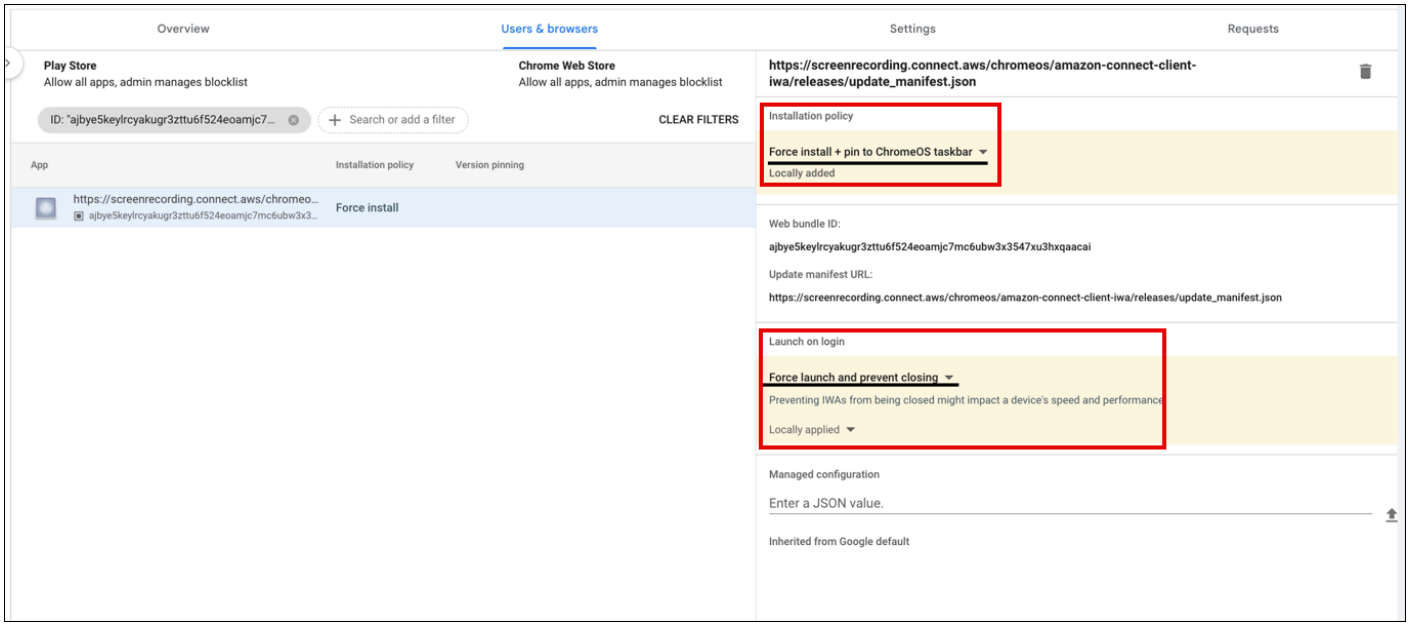
To install Isolated Web App

1. Navigate to the Google Admin Portal (https://admin.google.com) and login with your Google enterprise admin credentials.
2. Select **Add an Isolated Web App**.
3. Copy and paste the following details, and then choose **Save**:
   - Web Bundle ID: `ajbye5keylrcyakugr3zttu6f524eoamjc7mc6ubw3x3547xu3hxqaacai`
   - Update Manifest URL: https://screenrecording.connect.aws/chromeos/amazon-connect-client-iwa/releases/update_manifest.json

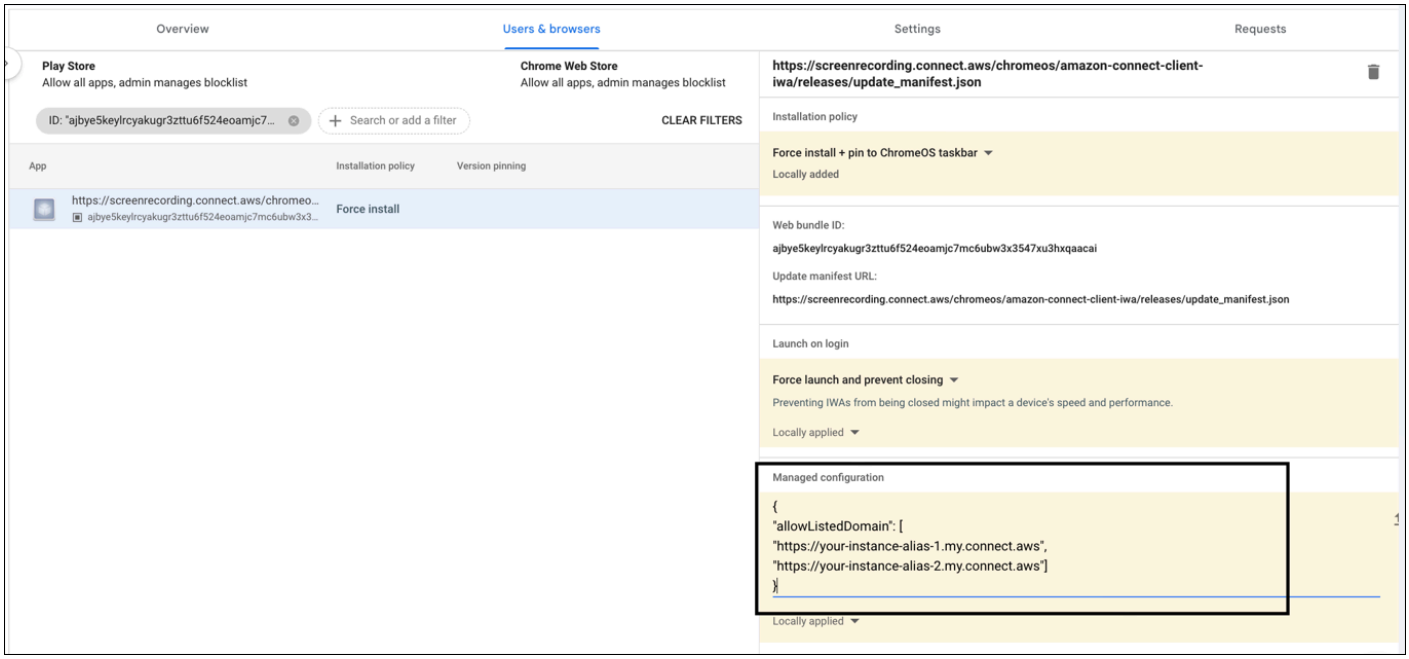
   The following image shows an example **Add an Isolated Web App** dialog box that has been completed.



4. Configure **Installation Policy** to `Force Install + Pin to ChromeOS Taskbar` and change **Launch on Login** to `Force Launch and Prevent Closing` to make sure Isolated Web App starts automatically when a computer is logged into and restarts.



5. Configure **Managed configuration** to allowlist your Connect Customer domains that are allowed to initiate screen recording on agent machines. An example of **Managed configuration** is shown in the following image.



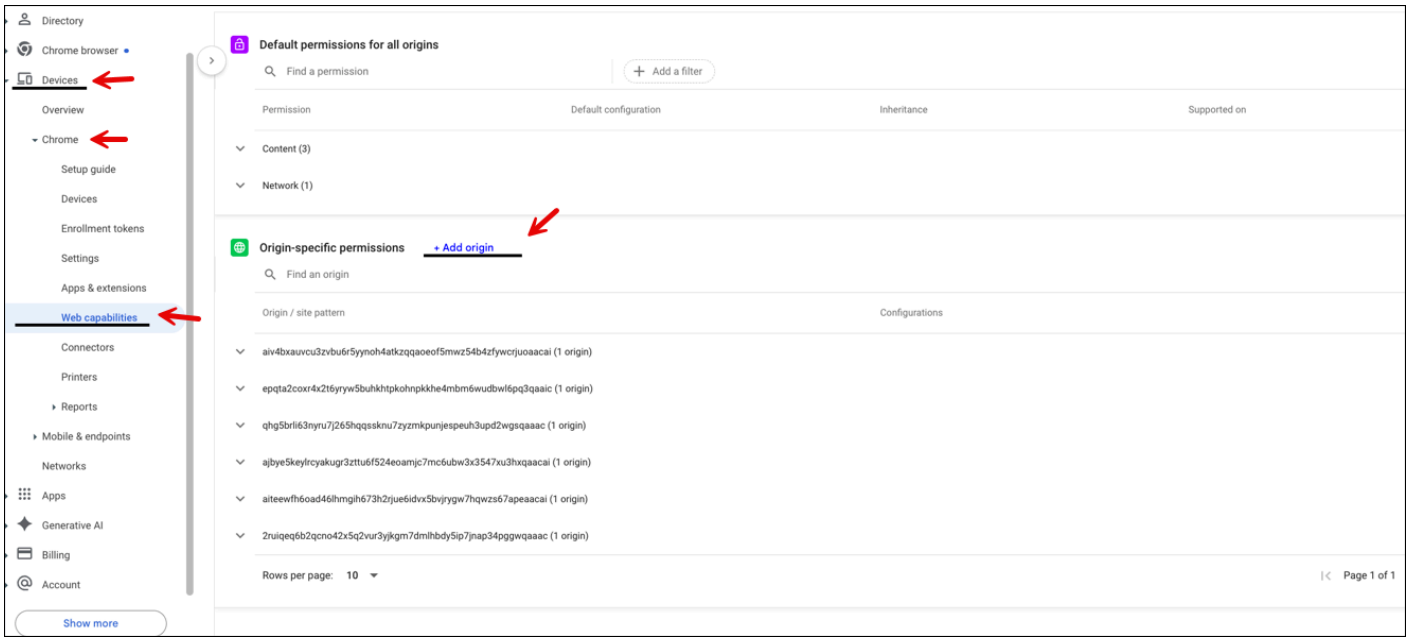
- The key name MUST be `allowListedDomain`. Domain names should not include any paths, query strings, or trailing slashes (/).
- Replace `your-instance-alias-*` with your actual Connect Customer instance alias.

```
{
"allowListedDomain": [
```

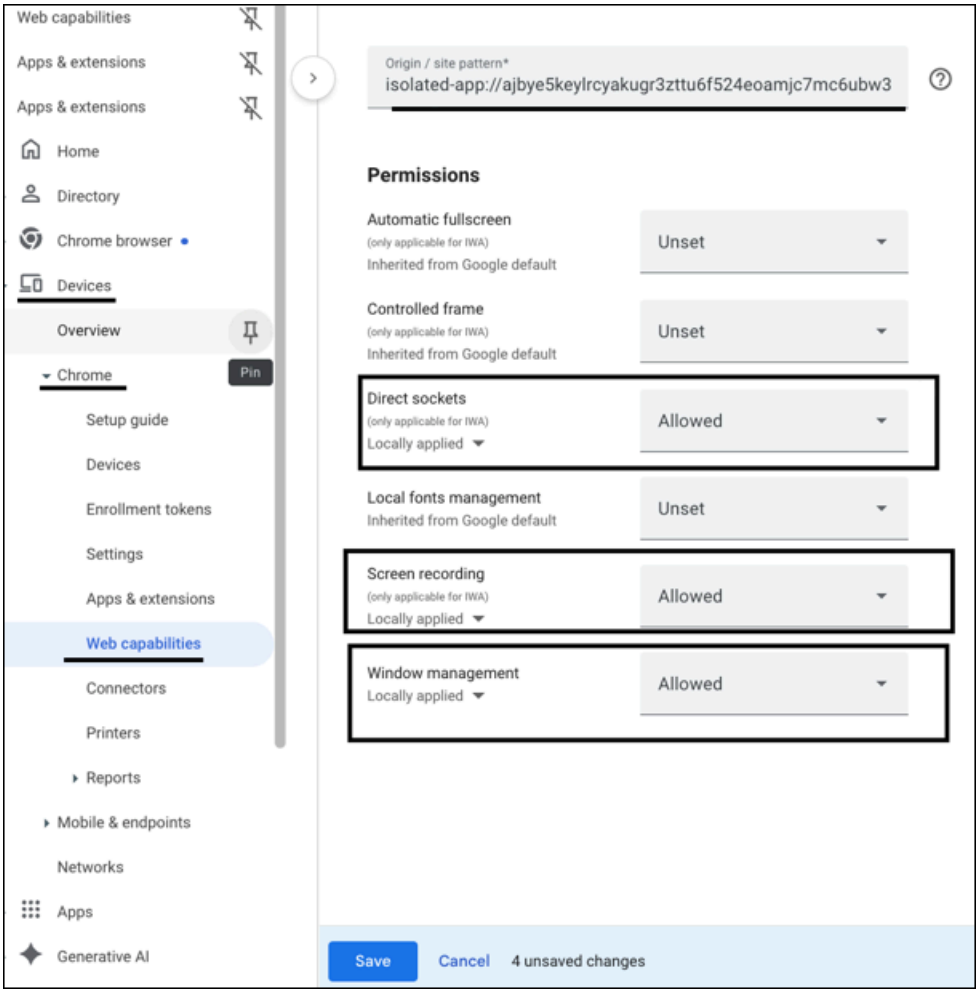
```
"https://your-instance-alias-1.my.connect.aws",
"https://your-instance-alias-2.my.connect.aws"]
}
```

6. Complete the following steps to configure the Isolated Web App to allow Direct sockets, Screen recording, and Window management permissions:
   - Navigate to **Devices**, **Chrome**, **Web capabilities**, **Add Origin**.
   - input `ajbye5keylrcyakugr3zttu6f524eoamjc7mc6ubw3x3547xu3hxqaacai`, and then choose **Save**.

   The following image shows where Devices, Chrome, and Web capabilities are located in the left navigation menu in Chrome.



The following image shows the location of **Direct sockets**, **Screen recording**, and **Window management** on the Web capabilities page.

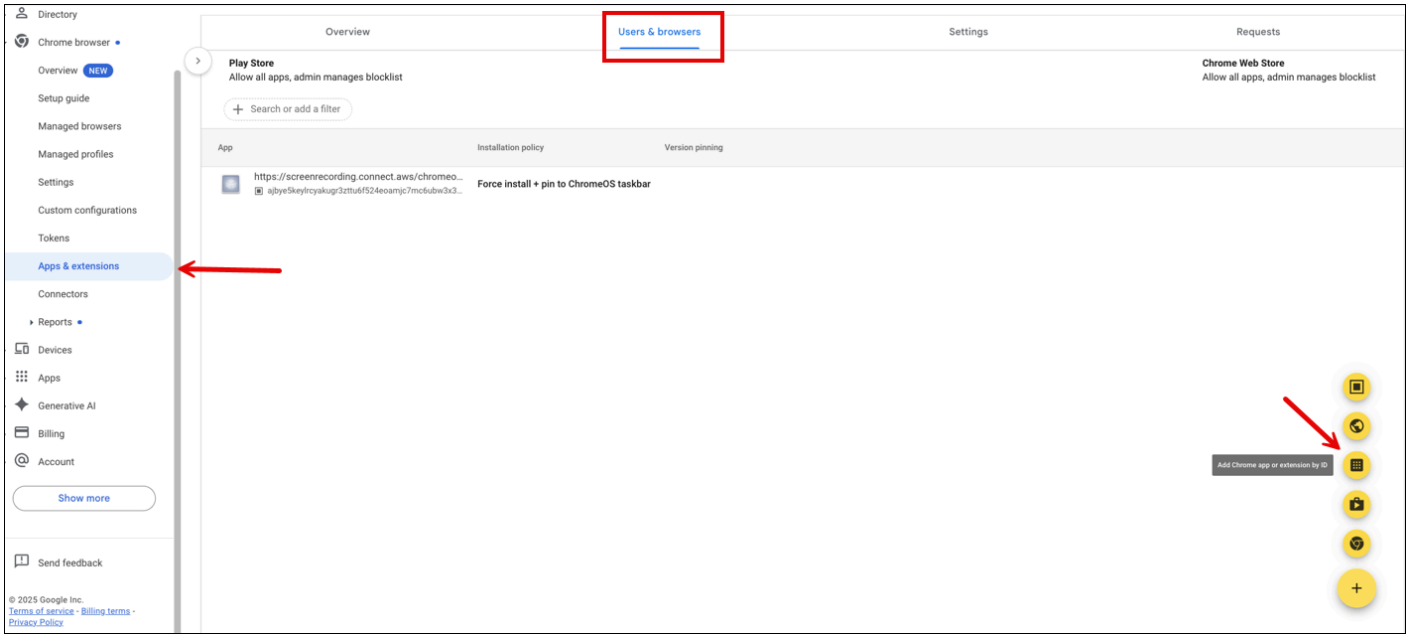


Install Google Chrome Browser Extension

- Extension ID: cjmichfmnimgeoadokmeaiclklkdccod
- Custom URL: `https://screenrecording.connect.aws/chromeos/amazon-connect-extension/releases/updates.xml`

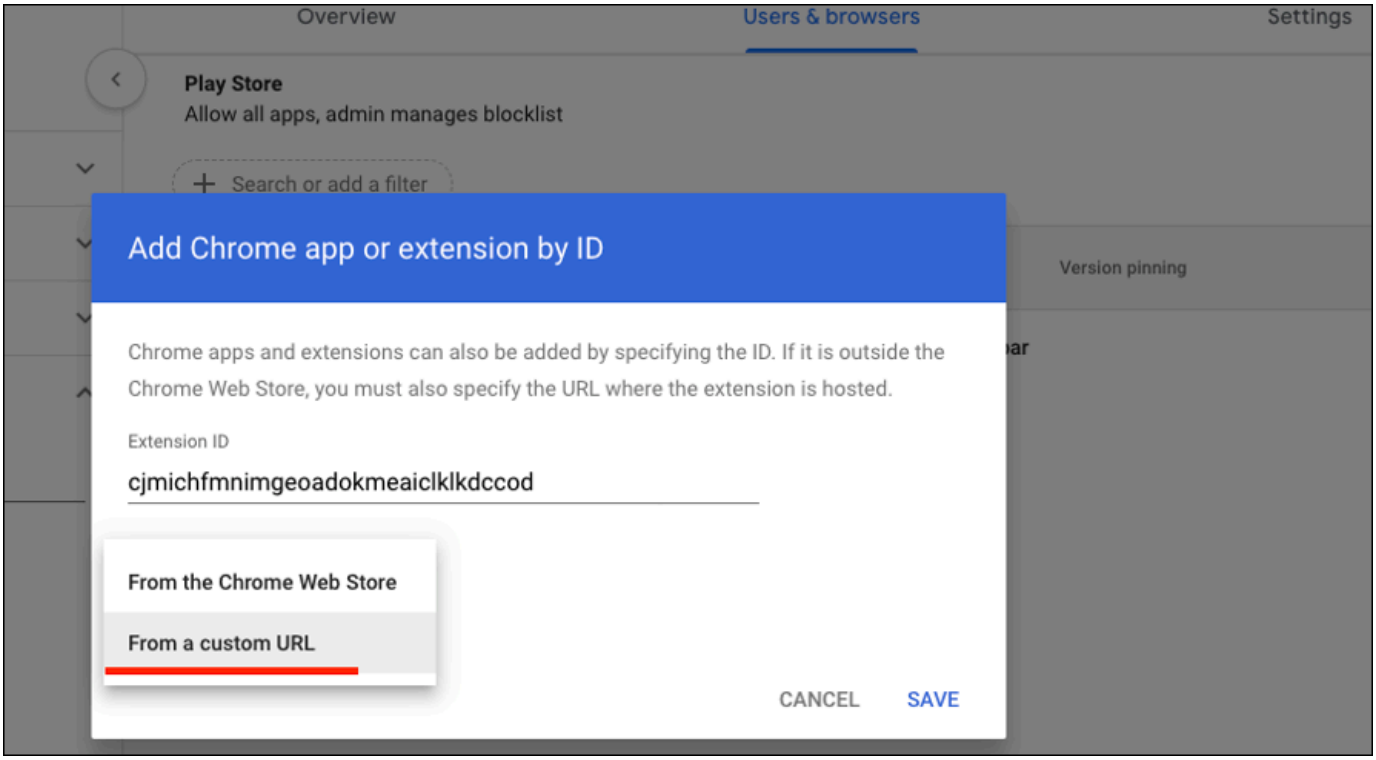
To install Google Chrome Browser Extension

1. Navigate to **Add Chrome app or extension by ID**, as shown in the following image.

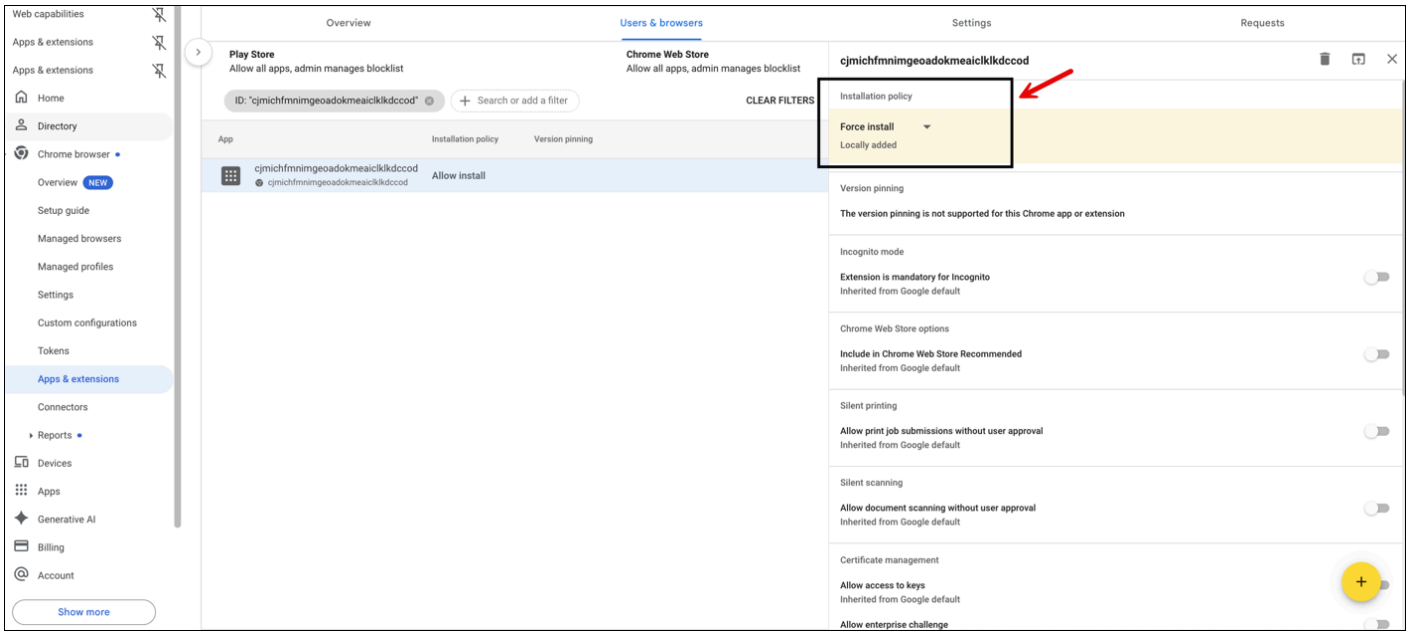


2. In the **Add Chrome app or extension by ID**, choose **From a custom URL** and enter the following information:

   - Extension ID: `cjmichfmnimgeoadokmeaiclklkdccod`
   - Custom URL: `https://screenrecording.connect.aws/chromeos/amazon-connect-extension/releases/updates.xml`



3. Configure **Installation Policy** to **Force Install**, and then choose **Save**, as shown in the following image.



Release notes

Version summary

The following table summarizes the differences between Connect Customer Client Application versions. Version 3.0.6 is cumulative: it includes the capabilities introduced in 3.0.2 and the corrections delivered in 3.0.3, 3.0.4, 3.0.5, and 3.0.6.

Version	Release date	Download	Summary
3.0.6	November 6, 2026	Download v3.0.6	Improves rule-based redaction accuracy for browser windows during page loads and navigation.
3.0.5	October 21, 2026	-	Improves rule-based redaction accuracy, screen recording reliability, and installer upgrades.
3.0.4	August 13, 2026	-	Fixes an `Amazon.Connect.Client.Messaging.NativeHost.exe` crash during full browser shutdown and the resulting Windows Event Viewer errors.

Version	Release date	Download	Summary
3.0.3	July 30, 2026	-	Improves redaction completion at contact end, window-monitoring cleanup, and support for international characters in window titles.
3.0.2	June 1, 2026	-	Adds optional rule-based screen recording redaction and supporting browser and Windows monitoring components.
2.0.3	June 13, 2025	Download v2.0.3	Provides standard agent screen recording. It does not include rule-based redaction for screen recordings.

Release notes for v3.0.6

Features

No new features in this release. Version 3.0.6 is a fix release that improves rule-based screen recording redaction.

New components

No new components in this release.

Fixes in 3.0.6

- Reduced brief over-redaction of browser windows during page loads and navigation when rule-based screen recording redaction is enabled.

System prerequisites

No additional prerequisites need to be installed on the agent's workstation for this release.

Release notes for v3.0.5

Features

No new features in this release. Version 3.0.5 is a fix release that improves rule-based screen recording redaction, screen recording reliability, and the installer.

New components

No new components in this release.

Fixes in 3.0.5

- Improved the accuracy and responsiveness of rule-based screen recording redaction, especially for browser windows.
- Improved the reliability of starting new screen recordings.
- Improved installer upgrades and error reporting.

System prerequisites

No additional prerequisites need to be installed on the agent's workstation for this release.

Release notes for v3.0.4

Features

Compared with version 2.0.3, version 3.0.x adds optional rule-based screen recording redaction. Configured in contact flows, it creates a separate redacted recording using URL or window title rules in denylist or allowlist mode, with no agent action required.

New components

- Browser helper (`Amazon.Connect.Client.Messaging.NativeHost.exe`, a new executable) – Relays browser context from the extension to the Connect Customer Client Application.
- Window-monitoring library (`Amazon.Connect.Client.WindowMonitor.dll`, a new library) – Tracks application-window changes and positions.

Fixes in 3.0.4

- Fixed a `NativeHost.exe` crash that could occur after complete browser shutdown, and eliminated associated Windows Event Viewer error logs. Closing only the CCP tab or another browser tab did not trigger the defect. Screen recordings and other Connect Customer features were unaffected in earlier versions as `NativeHost.exe` automatically restarts whenever the agent reopens the browser and CCP.

System prerequisites

No additional prerequisites need to be installed on the agent's workstation for this release.

System and network requirements for screen recording in Connect Customer

This topic provides the system requirements for using screen recording, and describes the detailed dataflow it uses in each platform.

System requirements

Here are the minimum system requirements for agent devices to perform screen recording. You'll need to scope additional memory, bandwidth, and CPU for the operating system and anything else running on the device to avoid resource contention.

- CPU: 2.0 GHz (4 cores or 4 vCPU recommended)
- Memory: 4 GB
- Network: 600 Kbps

Supported operating systems

- 64-bit Windows 10 and 11 based on the x86-64 architecture
- Chrome OS version 140 or higher enrolled in a Google Enterprise Domain

> **Note**
>
> When Windows multi-session configuration is enabled allowing multiple agents to use a single Windows host, make sure that the agent's workstation has the recommended resource availability for each concurrent session.

Network requirements

URLs to add to your firewall allow list

To ensure smooth screen recording functionality, add the following URL patterns to your allow list.

Client App authentication

`https://your-connect-instance-alias.my.connect.aws/taps/client/auth`

Screen recording upload (from CCP)

We recommend the wildcard `connect-recording-staging-*.s3.dualstack.your-region-name.amazonaws.com`

If you prefer not to use wildcards, the full list of endpoints is available at https://screenrecording.connect.aws/config/connect-recording-endpoint-allowlist.json

This list might be updated in the future. Refer to the `createDate` field at the top of the file to check for updates.

Browser extension updates (required for rule-based redaction)

If you use rule-based redaction, the agent's browser must be able to download and update the Connect Customer browser extension. Allow outbound HTTPS to the following.

We recommend the wildcard `https://screenrecording.connect.aws/*`, which covers all current and future extension paths for both browsers.

If you prefer not to use wildcards, allow these specific URLs:

Browser	URL
Google Chrome and Microsoft Edge	`https://screenrecording.connect.aws/chromeos/amazon-connect-extension/releases/updates.xml`
Google Chrome and Microsoft Edge	`https://screenrecording.connect.aws/chromeos/amazon-connect-extension/releases/amazon-connect-extension.crx`
Mozilla Firefox	`https://screenrecording.connect.aws/firefox/amazon-connect-extension/releases/updates.json`

Browser	URL
Mozilla Firefox	`https://screenrecording.connect.aws/firefox/amazon-connect-extension/releases/amazon-connect-extension.xpi`

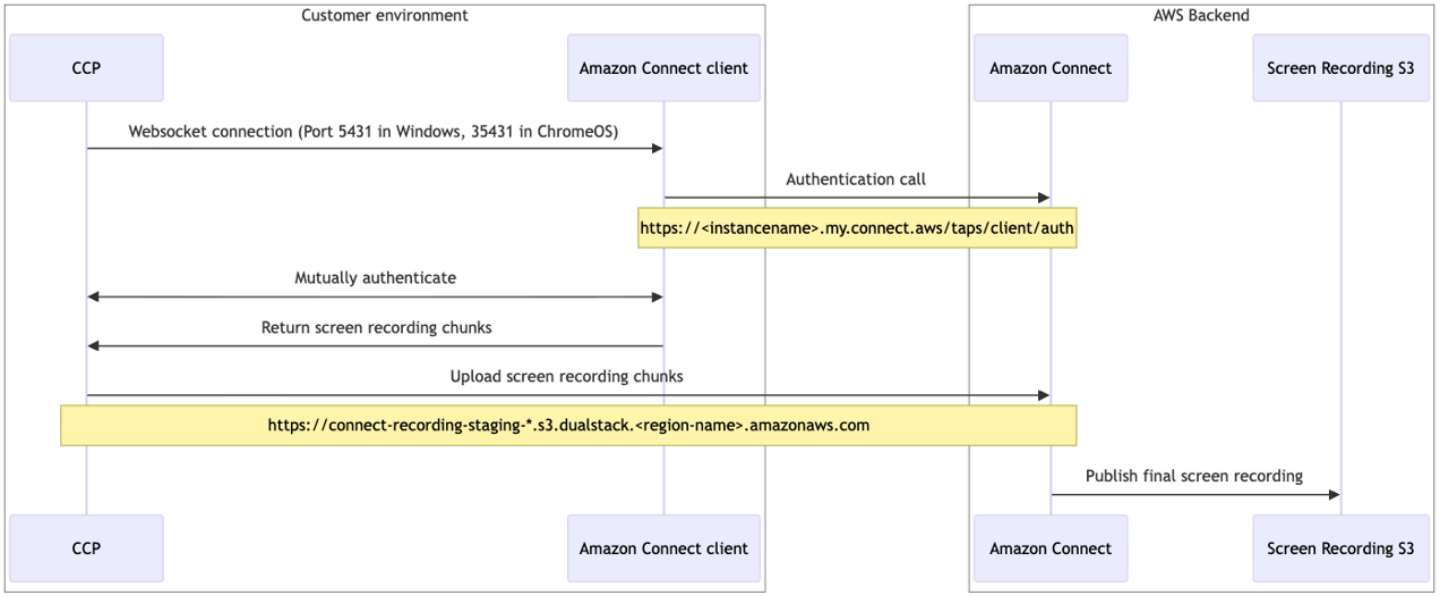
For extension identifiers and deployment instructions, see Deploy the browser extension.

Port used for screen recording

The Connect Customer Client Application communicates with the CCP through a local websocket on port 5431 (on Windows) and 35431 (on Chrome OS).

Sequence diagram

The following sequence diagram shows the network calls between different components involved in screen recording.



- In Windows, the Connect Customer Client is the combination of the Amazon.Connect.Client.Service background process and Amazon.Connect.Client.RecordingSession.
- In ChromeOS, the Connect Customer Client is the combination of Isolated Web App and Browser extension.

Browser enterprise policy for local network access

Modern browsers enforce Local Network Access (LNA) restrictions on WebSocket connections. These restrictions block the local WebSocket connection between the Contact Control Panel and the Connect Customer Client Application, causing screen recordings to fail.

For screen recording to work, you must deploy the appropriate browser enterprise policy to your agents' workstations for each browser they use. The policy pre-grants the minimal network access for the Contact Control Panel, so agents are neither blocked nor prompted. Configure the policy to allow the Contact Control Panel to reach the Connect Customer Client Application over the local connection; the policy name, the value to configure, and the configuration examples differ by browser – see the following sections.

Google Chrome and Microsoft Edge

Starting with Google Chrome version 147 and Microsoft Edge version 147, Chromium-based browsers enforce LNA restrictions on WebSocket connections.

Deploy the **LoopbackNetworkAllowedForUrls** enterprise policy. Example policy value: `[*.]my.connect.aws`

- For Google Chrome, see LoopbackNetworkAllowedForUrls in the Chrome enterprise policy documentation.
- For Microsoft Edge, see LoopbackNetworkAllowedForUrls in the Edge enterprise policy documentation.

The following example commands set the registry policy for the domain `[*.]my.connect.aws` on Windows:

```
reg add "HKLM\SOFTWARE\Policies\Google\Chrome\LoopbackNetworkAllowedForUrls" /v 1 /t
 REG_SZ /d "[*.]my.connect.aws"
reg add "HKLM\SOFTWARE\Policies\Microsoft\Edge\LoopbackNetworkAllowedForUrls" /v 1 /t
 REG_SZ /d "[*.]my.connect.aws"
```

For more details on this browser change, see New permission prompt for Local Network Access in the Chrome developer documentation.

Mozilla Firefox

Starting with Mozilla Firefox version 154, Firefox enforces LNA restrictions on WebSocket connections.

Deploy the **LocalNetworkAccess** enterprise policy and add the loopback address `127.0.0.1` to the **SkipDomains** list. On Firefox, list the loopback address that the Connect Customer Client Application listens on, rather than your Contact Control Panel domain.

> **Note**
>
> This policy permits local network access to the loopback address from any site, not only from your Contact Control Panel. It is currently the most restrictive policy that allows screen recording to work on Firefox. A more narrowly scoped policy that limits the exemption to your Contact Control Panel is pending a future Firefox update.

Example `policies.json` configuration:

```
{
  "policies": {
    "LocalNetworkAccess": {
      "Enabled": true,
      "SkipDomains": ["127.0.0.1"],
      "Locked": true
    }
  }
}
```

The following example command sets the equivalent policy through the Windows registry (GPO):

```
reg add "HKLM\SOFTWARE\Policies\Mozilla\Firefox\LocalNetworkAccess\SkipDomains" /v 1 /t
 REG_SZ /d "127.0.0.1"
```

For details, see LocalNetworkAccess in the Firefox enterprise policy documentation.

Requirements for rule-based redaction

If you use Rule-based redaction for screen recordings, agent workstations must meet the following additional requirements.

- **Browser** – One of the following:
  - Google Chrome 120 or later
  - Microsoft Edge 120 or later
  - Mozilla Firefox 120 or later

  Browsers other than Chrome, Edge, and Firefox do not report URLs to the Connect Customer Client Application, so URL rules cannot match pages in those browsers. You can still match windows in those browsers by using window title rules based on the browser's window title.
- **Connect Customer Client Application** – Version 3.0.2 or later. See Connect Customer Client Application.
- **Connect Customer browser extension** – Version 2.1.0 or later. The extension must be installed and enabled on every browser that agents use during recorded contacts. See Deploy the browser extension.
- **Local network access policy** – If agents use Chrome version 147 or later, Edge version 147 or later, or Firefox version 154 or later, deploy the browser enterprise policy to allow local network access from the Connect Customer CCP origin to 127.0.0.1:5431. For details, see the section called “Browser enterprise policy for local network access”.

Display scaling from 100% through 200% is supported on single-monitor and multi-monitor workstations.

Enable screen recording for your Connect Customer instance

This topic provides steps to enable screen recording for your Connect Customer instance, download and install the Connect Customer Client Application, and perform key configuration steps.

Topics

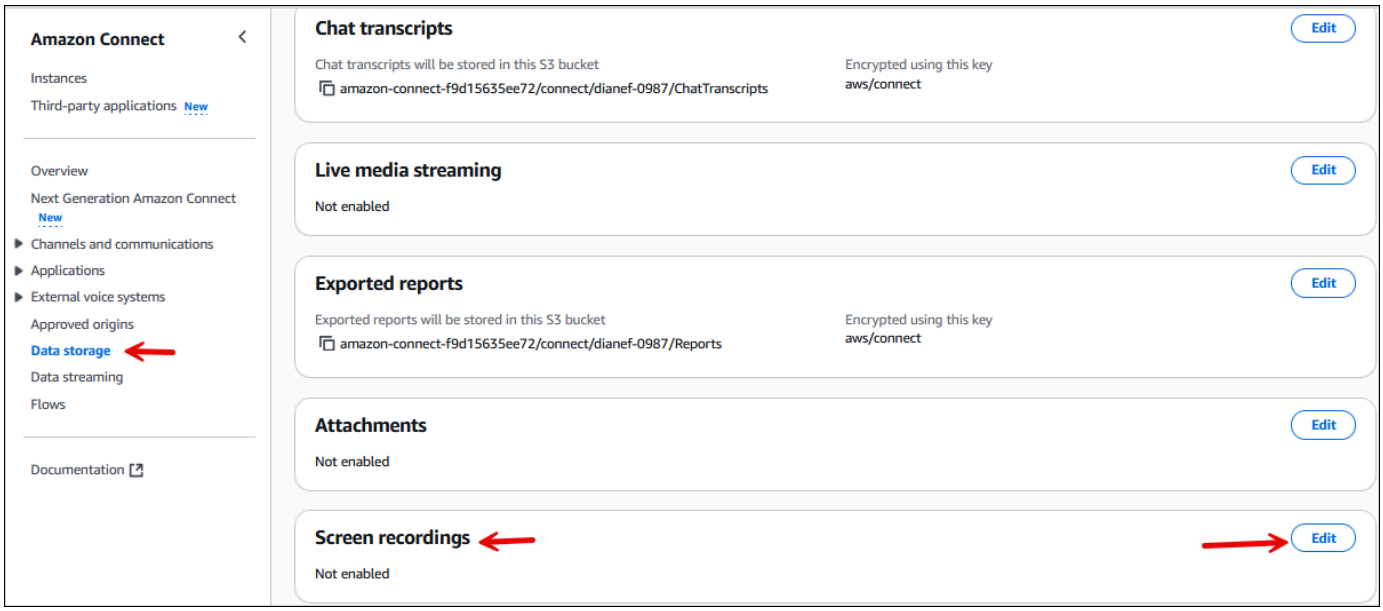
- Step 1: Enable screen recording for your instance
- Step 2: Download and install the Connect Customer Client Application
- Step 3: Configure the Set recording and analytics behavior block
- Configuration tips
- Next steps

Step 1: Enable screen recording for your instance

> **Important**
>
> If your Connect Customer instance was created before October, 2018, and you don't have service-linked roles set up, follow the steps in Use service-linked roles to migrate to the Connect Customer service-linked role.

The steps in this section explain how to update your instance settings to enable screen recording, and how to encrypt recording artifacts.

1. Open the Connect Customer console at https://console.aws.amazon.com/connect/.
2. Choose your instance alias.
3. In the navigation pane, choose **Data storage**, scroll down to **Screen recordings** and choose **Edit**, as shown in the following image.



4. Choose **Enable screen recording**, and then choose **Create a new S3 bucket (recommended)** or **Select an existing S3 bucket**.
5. If you chose **Create a new Amazon S3 bucket (recommended)**, enter a name in the **Name** box. If you chose to use an existing bucket, select it from the **Name** list.
6. (Optional) To encrypt the recording artifacts in your Amazon S3 bucket, select **Enable encryption**, then choose a KMS key.

> **Note**
>
> When you enable encryption, Connect Customer uses the KMS key to encrypt any intermediate recording data while the service processes it.

7. When finished, choose **Save**.

For more information about instance settings, see Update settings for your Connect Customer instance.

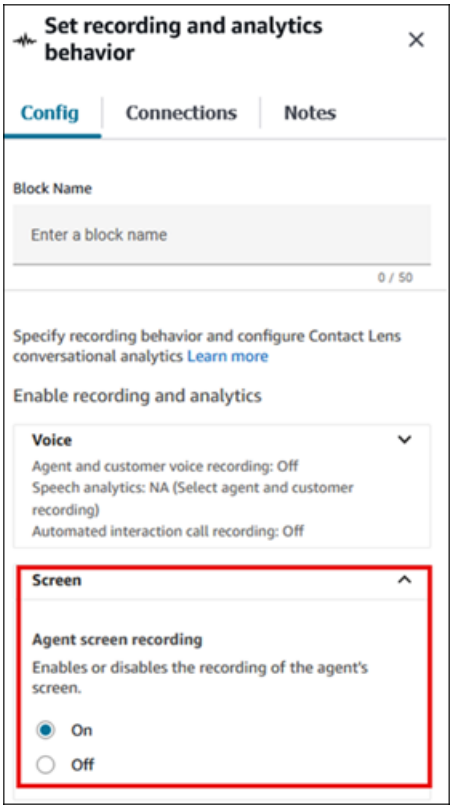
> **Note**
>
> If your instance uses Connect Customer Global Resiliency, enable screen recording on both the source and replica instances — the data storage configuration is not copied to the replica Region. For more information, see Screen recording with Global Resiliency.

Step 2: Download and install the Connect Customer Client Application

Follow the instructions in Connect Customer Client Application to download and install the Connect Customer Client Application for your operating system.

Step 3: Configure the Set recording and analytics behavior block

- Add a Set recording and analytics behavior block immediately after the point of entry to the flow. Add the block to every flow that you want to enable for screen recording.
- The following image shows the properties page of the Set recording and analytics behavior block. In the **Screen Recording** section, choose **On**.



Configuration tips

- To enable supervisors to search for contacts that have screen recordings, add a Set contact attributes block before **Set recording and analytics behavior**. Add a custom attribute called something like **screen recording = true**. Supervisors can search on this custom attribute to find those that have screen recordings.
- You might want to add a Distribute by percentage block before **Set recording and analytics behavior**. This enables you to use screen recording for some but not all contacts.
- You might want to use the SuspendContactRecording and ResumeContactRecording APIs to prevent sensitive information from being captured in the screen recording.

Next steps

To hide sensitive content such as payment entry pages or unapproved applications from agent screen recordings based on URL patterns, add rule-based redaction to your contact flows. See Rule-based redaction for screen recordings.

Review agent screen recordings in the Connect Customer Client Application

Use screen recordings to identify areas for agent coaching (for example, long contact handle duration or non-compliance with business processes) by watching an agent's actions while they handle a call, chat, or task contact.

The screen recording is synchronized with the voice recording and contact transcript. You can hear or read what is being said at the same time.

> **Note**
>
> Screen recordings are only available for Completed contacts.

Topics

- Step 1: Assign permissions to review screen recordings in the Connect Customer Client Application
- Step 2: Review screen recordings
- Watch in Picture-in-picture mode
- View a redacted screen recording

Step 1: Assign permissions to review screen recordings in the Connect Customer Client Application

To allow users to review screen recordings, assign the following **Recordings and Transcripts** security profile permission:

- **Screen recording - Access**: Allows a user, such as a supervisor or Quality Assurance team member, to access and review screen recordings.

> **Important**
>
> If rule-based redaction is not enabled, screen recording merges the screen recording video with the unredacted call recording file. If users have permission to view screen recordings, they can listen to the unredacted audio.

To overcome this, you can enable rule-based redaction which merges the screen recording video with the redacted call recording (if enabled). You will have to update the permissions to choose which users get access to redacted and unredacted screen recording.

- **Screen recording - Enable download button**: Allows a user, such as a supervisor or Quality Assurance team member, to view a download button on the **Contact details** page to download screen recording videos.
- **Screen recording (redacted) - Access**: Allows a user, such as a supervisor or Quality Assurance team member, to open the **Contact details** page media player and view redacted screen recordings produced by rule-based redaction.
- **Screen recording (redacted) - Enable download button**: Allows a user to view a download button on the **Contact details** page to download redacted screen recordings. Requires the **Screen recording (redacted) - Access** permission.

For information about how to add more permissions to an existing security profile, see Update security profiles in Connect Customer.

Step 2: Review screen recordings

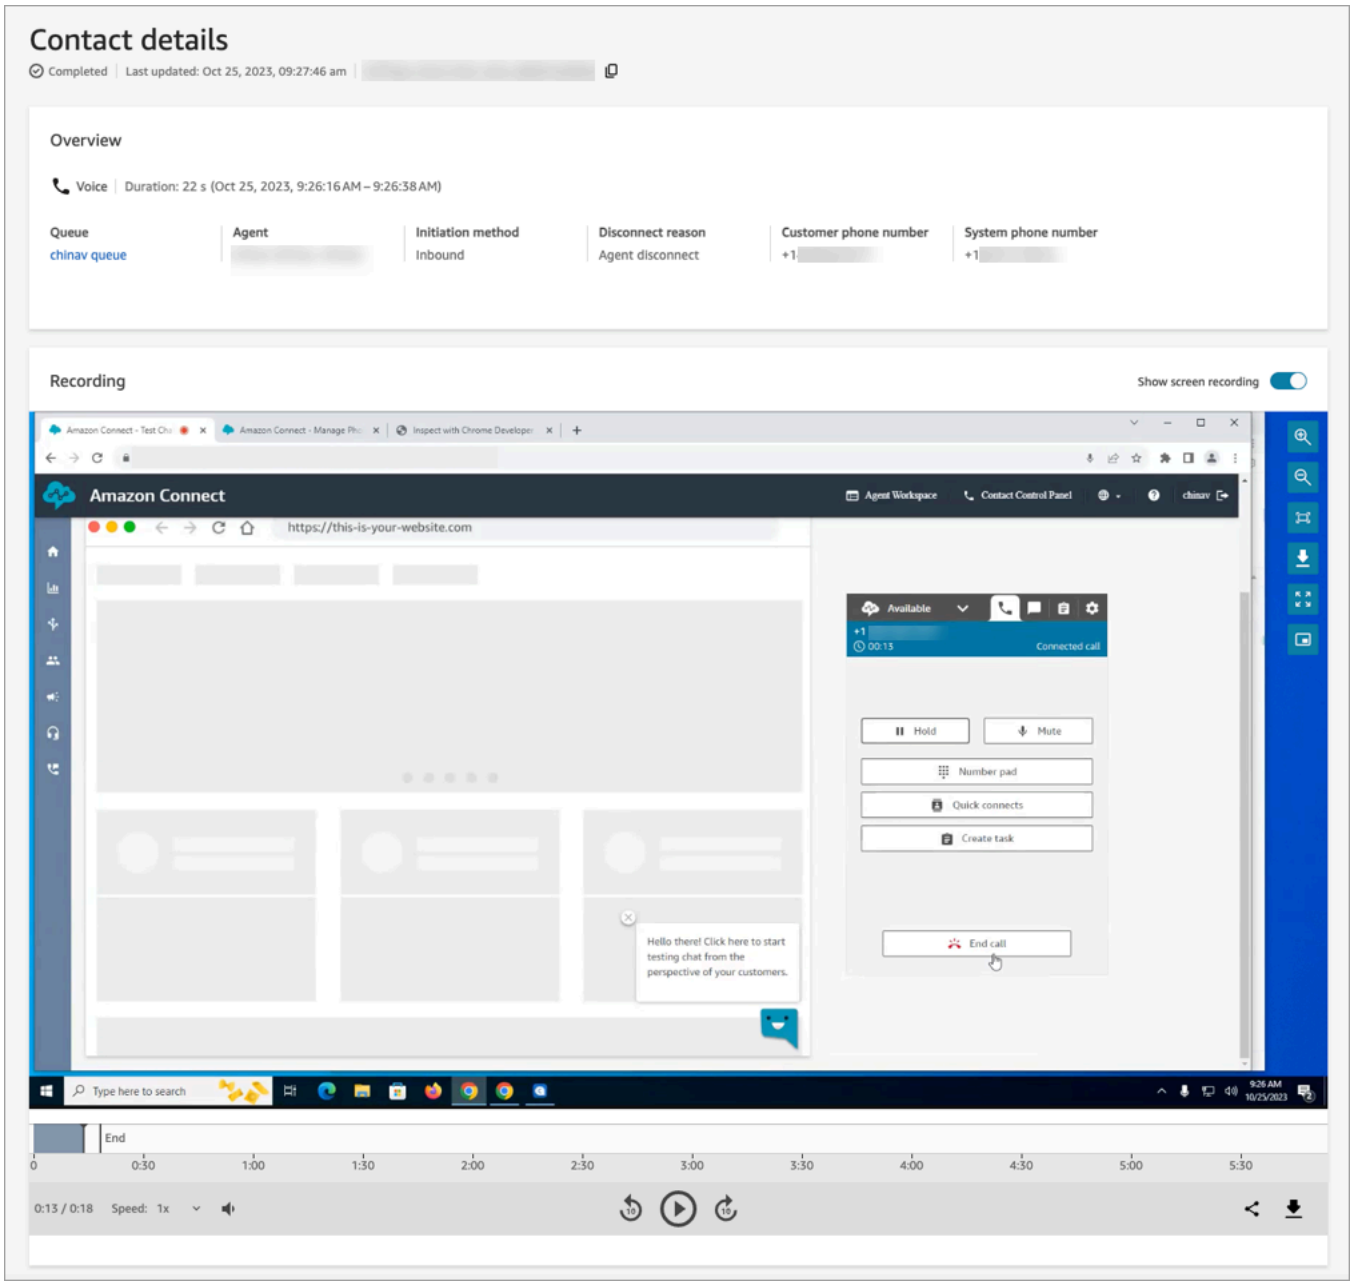
1. Log in to Connect Customer with a user account that has the **Analytics and optimization** - **Screen recording - Access** permission in its security profile.

   If you also have **Screen recording - Enable download button** permission, you can view a button on the **Contact details** page that you can use to download a screen recording and view it offline.
2. On the navigation menu, choose **Analytics and optimization**, **Contact search**.
3. Search for the contact you want to review.

   Tip

   If you've added a custom attribute to your flows to indicate when screen recording is enabled, you can search by the custom attribute to locate contact records with screen recordings. For more information, see Configuration tips.
4. Choose or tap the contact ID to view the **Contact details** page.

5. The **Recording** section contains a video player that displays the screen recording, as shown in the following image.

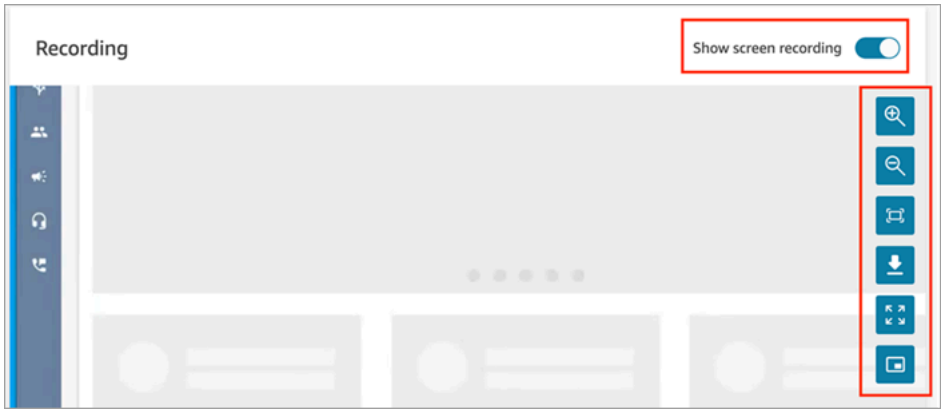


Important

Screen recording playback in the **Contact details** page is not supported in the legacy `https://your-instance-alias/awsapps.com` domain. We recommend using the `https://your-instance-alias.my.connect.aws/` domain to play screen

recordings. For more information, see Update your Connect Customer domain in this guide.

6. Use the right-side controls to zoom in and out, fit the video to the window, download video, expand to full-screen, and play picture-in-picture.



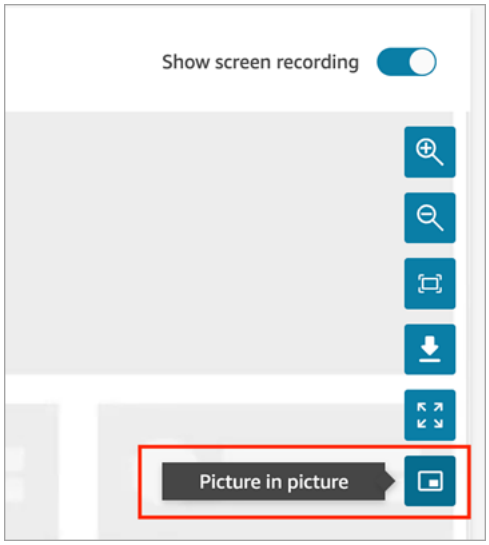
7. If you don't see a video recording, check that the **Show screen recording** toggle is on.

   If no video appears, then the screen recording might not yet be ready (that is, uploaded into the Amazon S3 bucket). If the problem persists, contact AWS Support Center.

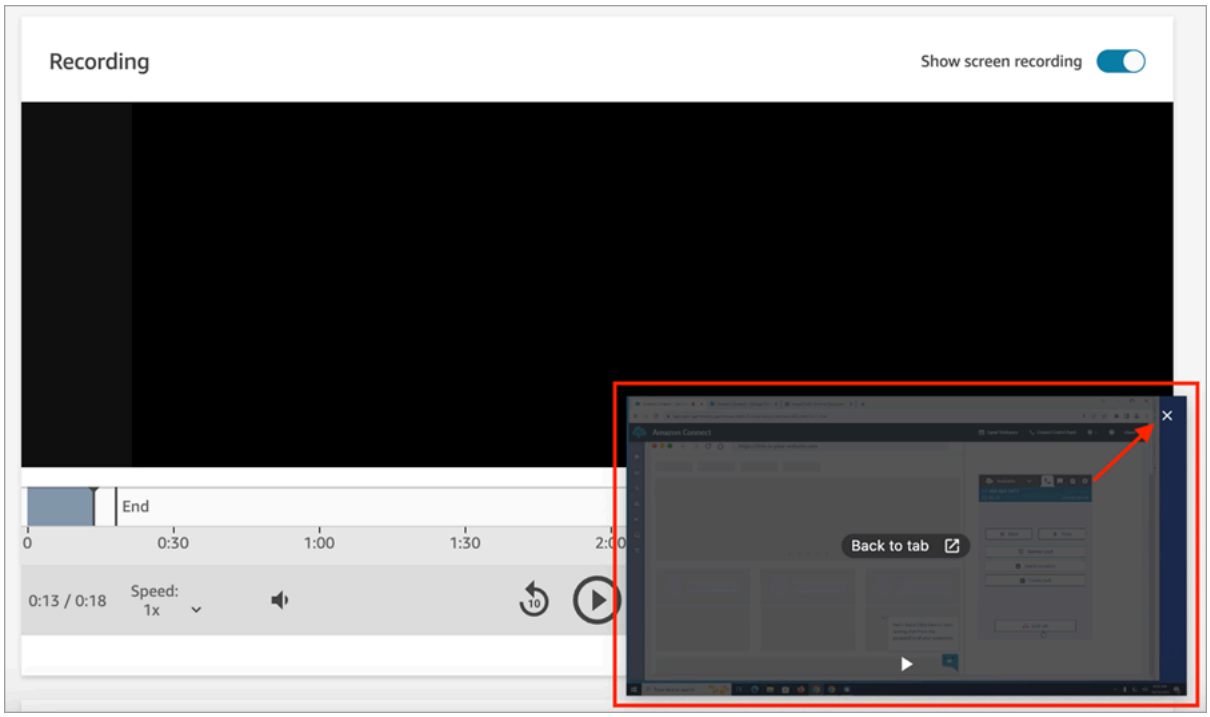
Watch in Picture-in-picture mode

You might want to move the video elsewhere on your monitor while you watch it. For example, you can reposition the video so you can read the transcript. Use **Watch in Picture-in-picture** mode to achieve this.

1. Choose the picture-in-picture button on the right side controls, as shown in the following image.



2. Choose the **X** in the top right corner to pop the window back. The following image shows the video in Picture-in-picture mode, and the location of the **X** to pop the window back.



View a redacted screen recording

If a contact was recorded with Rule-based redaction for screen recordings enabled, a separate redacted version of the recording is available. In a redacted recording, browser windows and application windows that match a redaction rule are masked, while the rest of the agent's screen is unchanged.

The **Contact details** page automatically determines which version to display based on your security profile permissions and whether redaction was enabled for the contact. There is no manual toggle. If you have both the redacted and unredacted access permissions and redaction was enabled for the contact, the page plays the redacted version.

To view a redacted recording:

1. Open the Connect Customer admin website. On the navigation menu, choose **Analytics and optimization**, then **Contact search**.
2. Search for the contact whose recording you want to review.
3. Open the contact detail page.
4. In the **Recordings** section, choose **Screen recording**.

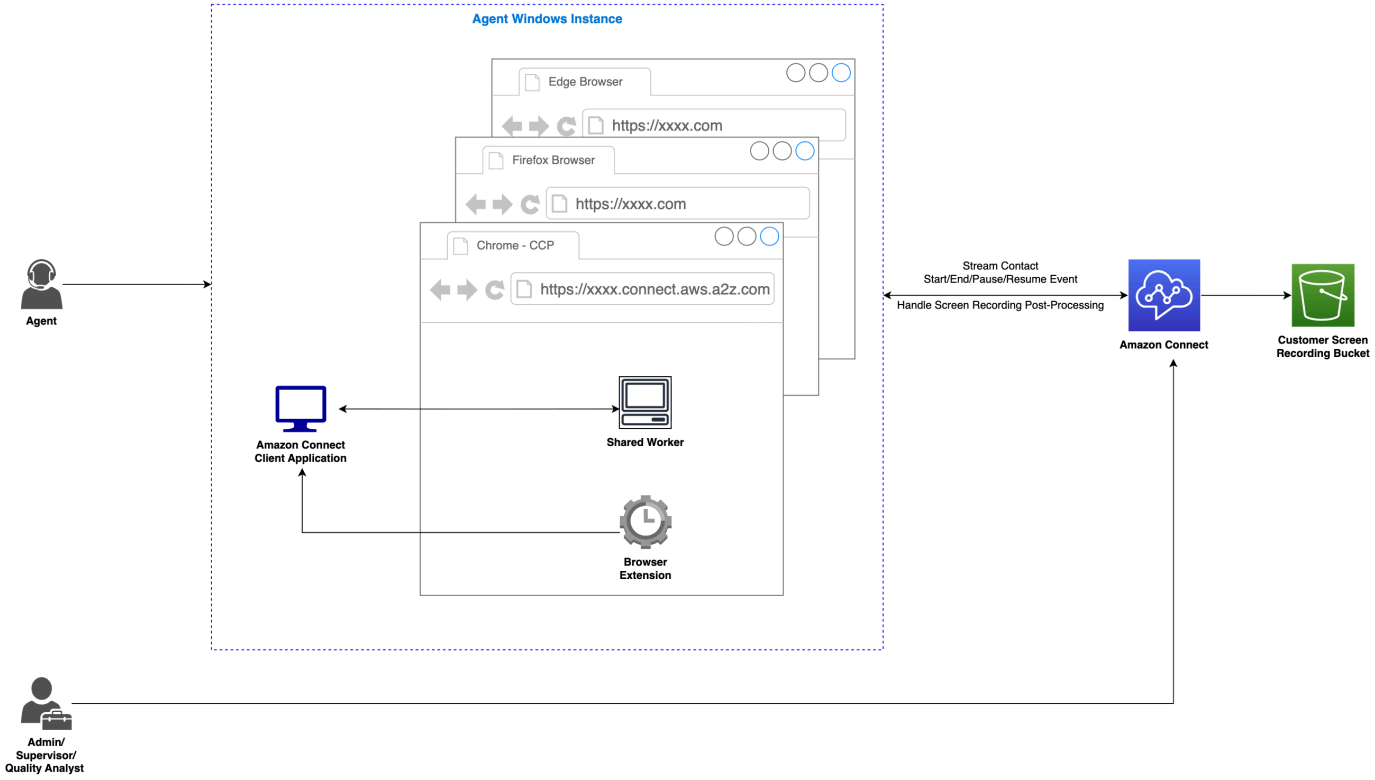
For information about the permissions that control access to redacted and unredacted recordings, see Permissions for redacted recordings.

The audio in a redacted recording depends on whether conversational analytics call recording redaction is also enabled for the contact. If it is, the redacted video is stitched with the redacted call recording. If not, the redacted video has no audio. To redact audio from call recordings, see Use sensitive data redaction with conversational analytics.

Rule-based redaction for agent screen recordings in Connect Customer

Rule-based redaction for agent screen recordings automatically hides sensitive content from recorded agent desktops based on the browser pages and application windows that agents view during a contact. When an agent navigates to a URL or opens an application window that matches one of your redaction rules, the matching window is masked in the final recording. Redaction is applied when the recording is assembled. The original unredacted video is not exposed to users who only have access to redacted recordings.

Use rule-based redaction to enforce internal privacy policies that prohibit capturing specific applications or pages that contain customer data.



Topics

- How rule-based redaction works
- Permissions for redacted recordings
- Limitations
- Where redacted recordings are stored
- AWS Region availability
- Next steps
- Configure rule-based redaction in a contact flow
- Deploy the Connect Customer browser extension

How rule-based redaction works

Rule-based redaction evaluates each browser page and application window the agent views during a recorded contact against the redaction rules you configure, and produces a redacted version of the recording in which matching windows are masked. The rest of the agent's screen is unchanged.

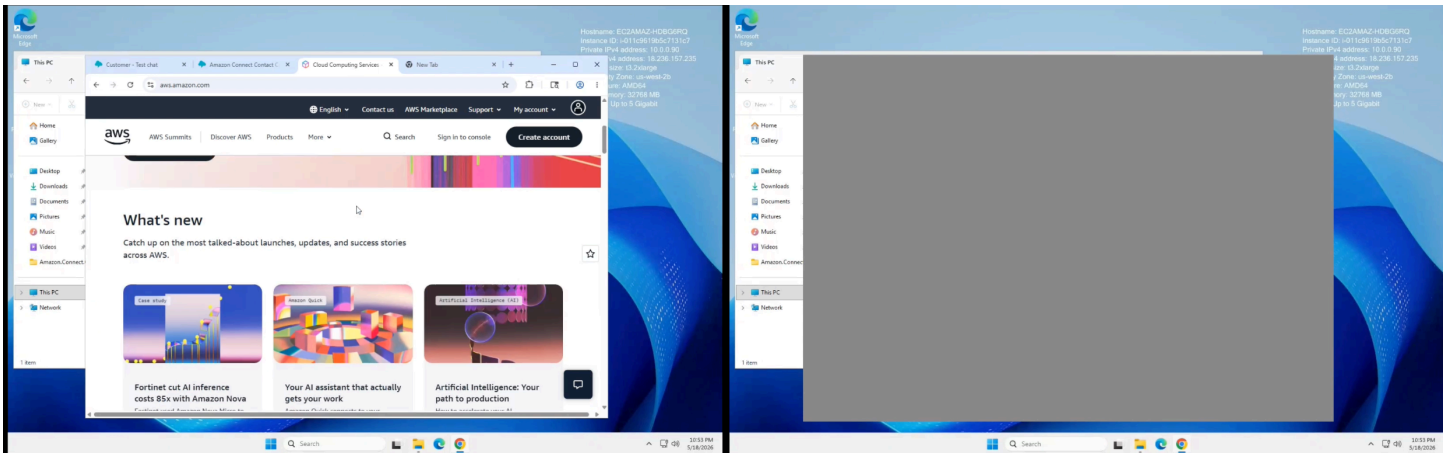
The redacted recording is produced in addition to the unredacted original. Both versions are stored in your Amazon S3 bucket under separate prefixes, so you can grant access to each version independently through security profile permissions.

Rule-based redaction runs in three stages.

- **Configure** – In a contact flow, add a **Set recording, analytics, and processing behavior** block, enable screen recording, and enable redaction. In the same block, specify URL rules that match browser pages, window title rules that match native application windows, or both, and choose a mode that either hides or shows the matched content. Redaction applies to every contact that runs through the flow. For instructions, see Configure rule-based redaction.
- **Record** – When an agent handles a contact that runs through the flow, their screen is recorded as usual. For rules to match, the Connect Customer browser extension must be installed on every browser the agent uses. For deployment instructions, see Deploy the browser extension.
- **Review** – After the contact ends, a redacted version of the recording is available on the contact detail page, subject to the user's security profile. For details, see Review agent screen recordings and Permissions for redacted recordings.

What a redacted recording looks like

The redacted recording is identical to the unredacted recording except that browser windows and application windows that match a rule are masked. The following image shows the same agent screen recorded with rule-based redaction off (left) and on (right) with a rule that redacts `aws.amazon.com`.



Redaction modes

Rule-based redaction uses one of two modes.

- **Denylist - hide matching content** – Only content that matches a rule is masked in the final recording; all other content remains visible. Use this mode when agents work across a wide range of applications and you only need to hide specific pages or applications that contain sensitive data.
- **Allowlist - show matching content** – Only content that matches a rule remains visible in the final recording; all other browser windows and native application windows are masked. Use this mode when agents are expected to work in a small set of approved applications and you want to exclude everything else.

What rule-based redaction does not do

- It does not redact voice or chat content. For call recording redaction, see Use sensitive data redaction with conversational analytics. When rule-based redaction is enabled for a contact, Connect Customer stitches the redacted video with the redacted call recording if conversational analytics call recording redaction is also enabled, and with no audio otherwise.
- It does not hide content at the field level. Entire matching windows are masked; individual fields, DOM elements, or regions within a window cannot be selectively hidden.
- It does not apply redaction in real time. Redaction is applied only when the recording is assembled after the contact ends.
- It does not push configuration changes to contacts that are already in progress. Updates to a configuration take effect for the next new contact.

Permissions for redacted recordings

Rule-based redaction introduces two new security profile permissions that control who can view and download redacted screen recordings. Together with the existing screen recording permissions, they let you grant broad access to redacted recordings while restricting the unredacted originals to a smaller group.

Both new permissions are in the **Recordings and Transcripts** category of the security profile. For general information about security profiles, see Security profiles.

Permission	Grants the ability to
Screen recording (redacted) - Access	Open the contact detail page media player and view redacted screen recordings.

Permission	Grants the ability to
Screen recording (redacted) - Enable download button	Download redacted screen recordings. Requires **Screen recording (redacted) - Access**.

You assign permissions in the Connect Customer admin website. On the navigation menu, choose **Users**, then **Security profiles**.

If a user has both the unredacted and redacted access permissions, and redaction was enabled for the contact, the contact detail page displays the redacted recording.

Limitations

- URL-based rules match browser pages on Google Chrome, Microsoft Edge, and Mozilla Firefox. Browsers other than Chrome, Edge, and Firefox do not report URLs to the Connect Customer Client Application, so URL rules cannot match pages in those browsers. You can still match windows in other browsers by using window title rules based on the browser's window title.
- The redacted recording is produced in addition to the unredacted original. Both files are stored in your Amazon S3 bucket. Use Amazon S3 lifecycle policies if you need to expire the unredacted originals on a different shorter schedule than the redacted versions.
- Each flow block supports up to 100 URL and window title rules. Each pattern string is 1 to 128 characters.
- Windows is the only supported agent workstation operating system.

Where redacted recordings are stored

Redacted recordings are stored in the same Amazon S3 bucket as the unredacted recordings, as a sibling of the unredacted file. The redacted key is rooted at the parent of your configured prefix, under a fixed `Analysis/ScreenRecordings/Redacted/` path.

```
s3://your-bucket/your-prefix-parent/Analysis/ScreenRecordings/
Redacted/year/month/day/contact-id_screen_recording_redacted_UTC-timestamp.mp4
```

In this path, *`your-prefix-parent`* is your configured screen recordings prefix with its last segment removed. For example, with the console default prefix `connect/`*`your-instance-alias`*`/ScreenRecordings`, redacted recordings are stored under `connect/`*`your-instance-alias`*`/Analysis/ScreenRecordings/Redacted/`.

Users with the appropriate permission can view and download redacted recordings from the contact detail page in the Connect Customer admin website. For instructions, see Review agent screen recordings.

AWS Region availability

Rule-based redaction is available in the same AWS Regions that support Connect Customer agent screen recording. For the current list of supported Regions, see Connect Customer endpoints and quotas.

Next steps

To start using rule-based redaction, complete the following steps.

- Confirm that your Connect Customer instance, agent workstations, and browsers meet the requirements. See System and network requirements.
- Update the Connect Customer Client Application to version 3.0.2 or later on every agent workstation. See Connect Customer Client Application.
- Deploy the Connect Customer browser extension to every browser that agents use during recorded contacts. See Deploy the browser extension.
- In a contact flow, add or update a **Set recording, analytics, and processing behavior** block to enable screen recording, enable redaction, and configure your rules and mode. See Configure rule-based redaction.
- Grant the appropriate security profile permissions to the users who need to view redacted or unredacted recordings.

For information about reviewing recordings after they are redacted, see Review agent screen recordings. For troubleshooting, see Download log files for the screen recording app. For frequently asked questions, see Frequently asked questions about Connect Customer screen recording capabilities.

Configure rule-based redaction in a contact flow

You configure rule-based redaction directly in the **Set recording, analytics, and processing behavior** flow block. The block contains the redaction mode (allowlist or denylist), the URL rules, and the window title rules that apply to contacts routed through the flow. Because the configuration lives in the flow, you can apply different redaction behavior to different contacts based on queue, contact attributes, or any other flow logic.

For an overview of how rule-based redaction works, see Rule-based redaction for screen recordings.

Topics

- Prerequisites
- Configure rule-based redaction in a flow block
- Rule syntax
- Example configurations
- Reuse a configuration across multiple flows
- Update or remove rule-based redaction

Prerequisites

Before you configure rule-based redaction, complete the following.

- Enable agent screen recording on your Connect Customer instance. See Enable screen recording.
- Confirm that agent workstations meet the requirements for rule-based redaction. See System and network requirements.
- Install or update the Connect Customer Client Application to version 3.0.2 or later. See Connect Customer Client Application.
- Deploy the Connect Customer browser extension to every browser that agents use during recorded contacts. See Deploy the browser extension.

Configure rule-based redaction in a flow block

1. Open the Connect Customer admin website. On the navigation menu, choose **Routing**, then **Flows**.
2. Open the contact flow in which you want to apply redaction. The flow must run before the contact is routed to an agent.
3. Add a **Set recording, analytics, and processing behavior** block to the flow. For general information about this block, see Set recording and analytics behavior.
4. Open the block. On the **Config** tab:
   - For **Select action**, choose **Set recording and analytics behavior**.
   - For **Select channel**, choose **Screen recording**.

5. Under **Agent screen recording**, select **Enable screen recording**.
6. Expand **Redaction configuration** and select **Enable redaction**.
7. For **Mode**, choose one of the following.

   - **Allowlist - show matching content** – Only content that matches a rule remains visible in the final recording; all other browser and application windows are masked.
   - **Denylist - hide matching content** – Only content that matches a rule is masked in the final recording; all other content remains visible.

8. (Optional) Under **URL rules**, add rules to match browser pages. For each rule:

   - For **Comparison type**, choose a comparison type.
   - For **URL rule**, enter the pattern to match against.
   - To add another URL rule, choose **Add URL rule**.

9. (Optional) Under **Window title rules**, add rules to match native application windows. For each rule:

   - For **Comparison type**, choose a comparison type.
   - For **Window title rule**, enter the pattern to match against.
   - To add another window title rule, choose **Add window title rule**.

10. Save and publish the flow.

Window title rules
Add window title rule

Important

Rule-based redaction supports configurations with no URL or window title rules.

- An empty **Denylist** masks no browser or application windows.
- An empty **Allowlist** masks all browser and application windows.

To preserve screen content and use redacted call audio, select **Denylist** and leave both rule lists empty. Enable conversational analytics call recording redaction for the contact. The resulting redacted screen recording preserves screen content and uses redacted audio. Without conversational analytics call recording redaction, the redacted screen recording has no audio.

You can add rules of either type, or both types, in the same block. The configuration applies to every contact that is routed through the flow until you change it.

Rule syntax

A flow block supports two types of rules.

Rule type	Matches against
URL rule	The URL displayed in the address bar of a browser window. Requires the Connect Customer browser extension. Supported on Google Chrome, Microsoft Edge, and Mozilla Firefox.
Window title rule	The window title of a native application on the agent's workstati on, such as a desktop application or a browser that is not otherwise supported for URL matching.

Each rule has a comparison type and a pattern value.

Condition	Matches when
Begins with	The URL or window title starts with the pattern.

Condition	Matches when
Contains	The URL or window title contains the pattern at any position.
Exact	The URL or window title is identical to the pattern.

A flow block supports up to 100 URL and window title rules. Each pattern is 1 to 128 characters.

Note

URL rules match on the scheme, host, and path of the address. Query parameters (the part after ?) and fragments (the part after #) are ignored during matching, so define rules using only the domain and path. This keeps redaction tied to the page itself, since those values can vary while the page stays the same.
For example, both of the following addresses resolve to the same page:

- Recommended: `https://aws.amazon.com/events/reinvent/`
- Avoid: `https://aws.amazon.com/events/reinvent/?nc2=h_dsc_ex_s1&trk=dc9b9d60-cc82-4cd5-8a61-0b33d6a79fab&sc_channel=ps`

Use the shorter form, since any query parameters or fragments in a rule are ignored when it is evaluated.

Example configurations

Example 1: Redact a payment page and a legacy desktop application

To redact the payment entry page on an internal CRM and the window of a legacy billing application:

- Mode: **Denylist - hide matching content**
- URL rules:
  - Comparison type: **Begins with**, URL rule: `https://crm.example.com/contacts/`
  - Comparison type: **Contains**, URL rule: `/payment`
- Window title rules:

- Comparison type: **Contains**, Window title rule: `Legacy Billing App`

Example 2: Allow only approved work applications

To hide everything except a small set of approved applications and websites:

- Mode: **Allowlist - show matching content**
- URL rules:
  - Comparison type: **Begins with**, URL rule: `https://connect.example.com/`
  - Comparison type: **Begins with**, URL rule: `https://crm.example.com/`
  - Comparison type: **Begins with**, URL rule: `https://knowledge.example.com/`
- Window title rules:
  - Comparison type: **Contains**, Window title rule: `Amazon Connect Client`
  - Comparison type: **Contains**, Window title rule: `Company CRM`

Example 3: Apply different redaction behavior based on queue

To apply different rule sets to contacts based on the queue they are routed to, branch your flow before each **Set recording, analytics, and processing behavior** block. Each branch can configure the block with a different mode and rule set. For information about branching in flows, see Connect Customer flows.

Reuse a configuration across multiple flows

If you want the same redaction rules to apply across several flows, put the configured **Set recording, analytics, and processing behavior** block inside a flow module and invoke the module from each parent flow. Flow modules let you share a reusable piece of flow logic, including block configurations, across multiple flows without manually copying the rules into each one. When you update the rules in the flow module, every parent flow that invokes it picks up the change.

For information about creating and invoking flow modules, see Create reusable flow modules.

Update or remove rule-based redaction

To change the redaction rules, mode, or behavior for a flow, edit the **Set recording, analytics, and processing behavior** block in the flow and save the flow. To stop applying redaction in the flow, clear **Enable redaction** in the **Redaction configuration** panel.

Changes take effect for contacts that start running through the flow after you save it. Contacts that are already in progress continue to use the configuration that was in effect when they started.

Deploy the Connect Customer browser extension

The Connect Customer browser extension reports the URL of each browser window to the Connect Customer Client Application so that URL rules configured in your flow block can be evaluated. Without the extension, URLs are not reported and URL rules cannot match, so browser pages that should be redacted by URL might appear in the recording. Window title rules do not depend on the extension; they match on native window titles and work without the extension installed.

If any of your flow blocks use URL rules, install the extension on every browser that agents use during recorded contacts. The extension is distributed by AWS and installed on agent workstations through your browser's enterprise extension policy. It is not published to the Chrome Web Store or Firefox Add-ons.

For an overview of rule-based redaction, see Rule-based redaction for screen recordings.

Topics

- Supported browsers
- Prerequisites
- Extension identifiers and update URLs
- Deploy the extension through enterprise policy
- Example: Deploying extensions to a list of users by using GPO
- Verify the extension is installed
- Remove the extension
- What happens if the extension is disabled during a contact

Supported browsers

Rule-based redaction supports the following browsers. Use any combination of these browsers on agent workstations.

Browser	Minimum version
Google Chrome	120

Browser	Minimum version
Microsoft Edge (Chromium-based)	120
Mozilla Firefox	120

Browsers other than Chrome, Edge, and Firefox do not report URLs to the Connect Customer Client Application, so URL rules cannot match pages in those browsers. You can still cover windows in those browsers by adding window title rules to your flow block.

Prerequisites

- Supported browser and version from the preceding table.
- Connect Customer Client Application version 3.0.2 or later. See Connect Customer Client Application.
- (Optional) An enterprise deployment tool that can push browser extension policies to specific users, such as Microsoft Group Policy Preferences (User Configuration), Microsoft Intune, Jamf Pro, or Google Chrome Browser Cloud Management. The extension is deployed at user scope.
- Outbound HTTPS access from each agent workstation to the extension update URL listed in the next section.

Extension identifiers and update URLs

Use the following values when you configure your enterprise browser extension policy.

> **Note**
>
> As a prerequisite, add the appropriate extension hosting URLs to your firewall allow list, depending on which browsers your agents use. For the firewall allow list, see Network requirements.

Browser	Extension ID	Update URL
Google Chrome and	`cjmichfmnimgeoadokmeaiclklkdccod`	`https://screenrecording.connect.aws/chromeos/amazon-co`

Browser	Extension ID	Update URL
Microsoft Edge		`nnect-extension/releases/updates.xml`
Mozilla Firefox	`amazon_connect_extension@amazon.com`	`https://screenrecording.connect.aws/firefox/amazon-connect-extension/releases/amazon-connect-extension.xpi`

Deploy the extension through enterprise policy

The Connect Customer browser extension is deployed at user scope. With user-scope deployment, you can target the extension to the specific users or groups who handle recorded contacts, without modifying per-machine settings on agent workstations.

Use any enterprise policy tool that can push per-user browser extension settings. Common options include:

- Microsoft Group Policy Preferences, scoped to **User Configuration** and filtered to a security group of agent users.
- Microsoft Intune, targeted to an Entra ID group of agent users through a user-assigned configuration profile.
- Jamf Pro or another MDM that supports per-user configuration profiles.
- Google Chrome Browser Cloud Management, scoped to an organizational unit of agent users.

For general information about browser policies, see:

- Chrome Enterprise policy list
- Microsoft Edge enterprise policy documentation
- Enterprise policies for Firefox

Policy payload

Configure the **ExtensionSettings** policy for each browser with the following properties.

Google Chrome and Microsoft Edge

```
{
  "cjmichfmnimgeoadokmeaiclklkdccod": {
    "installation_mode": "force_installed",
    "update_url": "https://screenrecording.connect.aws/chromeos/amazon-connect-
extension/releases/updates.xml"
  }
}
```

Mozilla Firefox

```
{
  "amazon_connect_extension@amazon.com": {
    "installation_mode": "force_installed",
    "install_url": "https://screenrecording.connect.aws/firefox/amazon-connect-
extension/releases/amazon-connect-extension.xpi"
  }
}
```

Windows user-scope registry example

If you deploy policies through the Windows registry under **User Configuration**, create string values under the per-user policy path for each browser. The same pattern applies to Chrome, Edge, and Firefox.

Browser	Registry path (under HKEY_CURRENT_USER)
Google Chrome	`HKCU\SOFTWARE\Policies\Google\Chrome\ExtensionSettings\cjmichfmnimgeoadokmeaiclklkdccod`
Microsoft Edge	`HKCU\SOFTWARE\Policies\Microsoft\Edge\ExtensionSettings\cjmichfmnimgeoadokmeaiclklkdccod`
Mozilla Firefox	`HKCU\SOFTWARE\Policies\Mozilla\Firefox\ExtensionSettings\amazon_connect_extension@amazon.com`

Create the following string values under each key.

Browser	Value name	Value data
Chrome or Edge	`installation_mode`	`force_installed`
Chrome or Edge	`update_url`	`https://screenrecording.connect.aws/chromeos/amazon-connect-extension/releases/updates.xml`
Firefox	`installation_mode`	`force_installed`
Firefox	`install_url`	`https://screenrecording.connect.aws/firefox/amazon-connect-extension/releases/amazon-connect-extension.xpi`

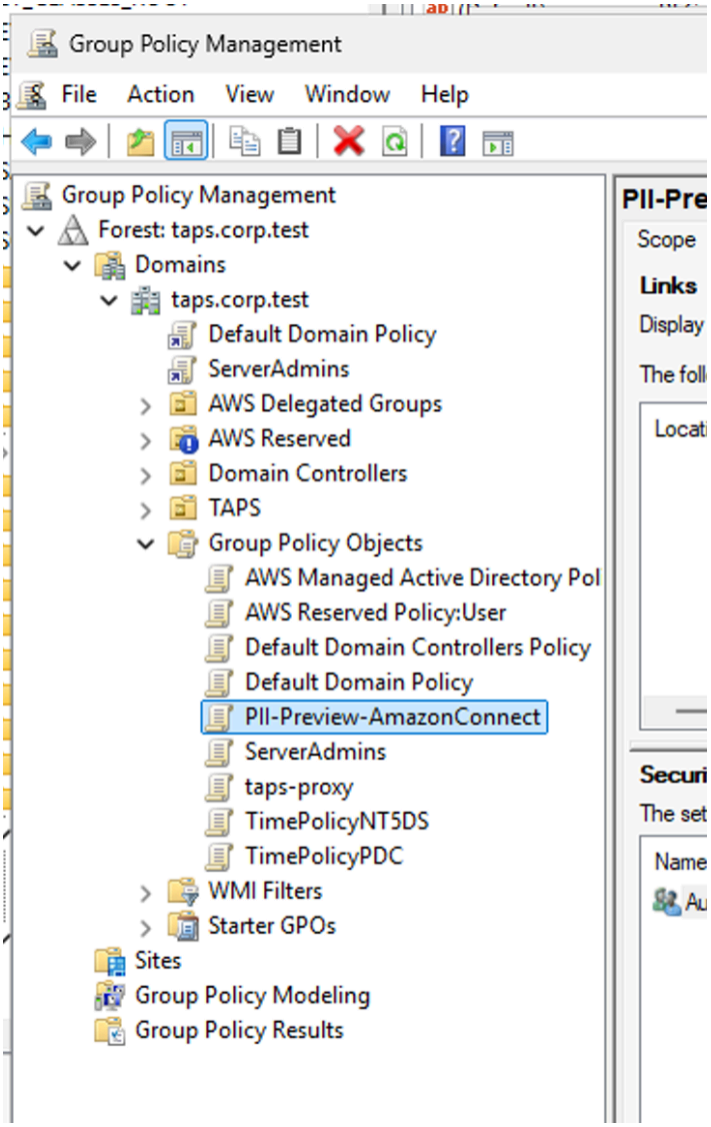
All values use the `REG_SZ` type.

Example: Deploying extensions to a list of users by using GPO

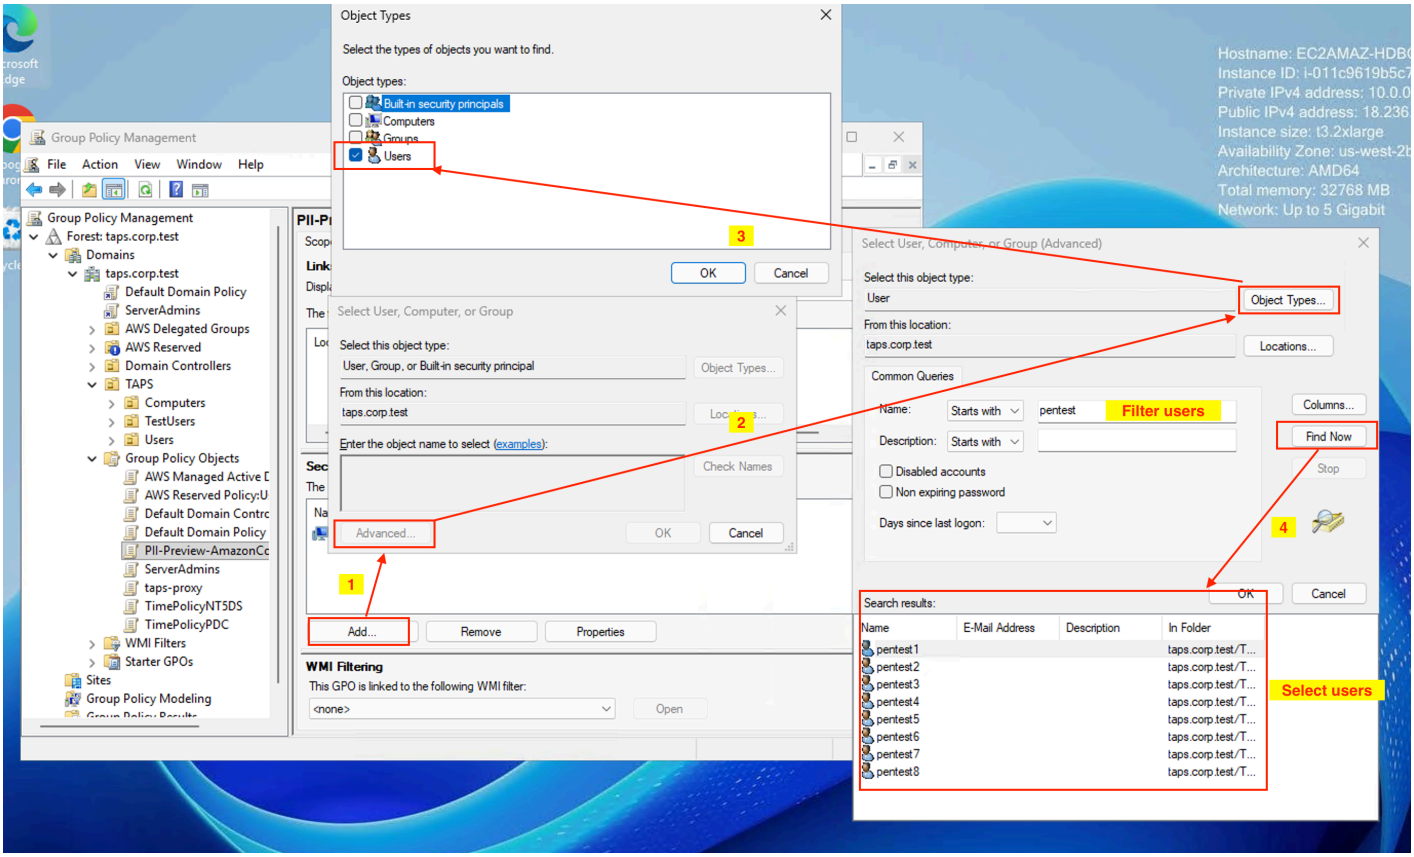
Step 1: Create the dedicated policy

> **Note**
>
> We recommend that you create a new, separate GPO rather than editing your primary domain policy. With a separate GPO, you can link or unlink the Connect Customer extension safely.

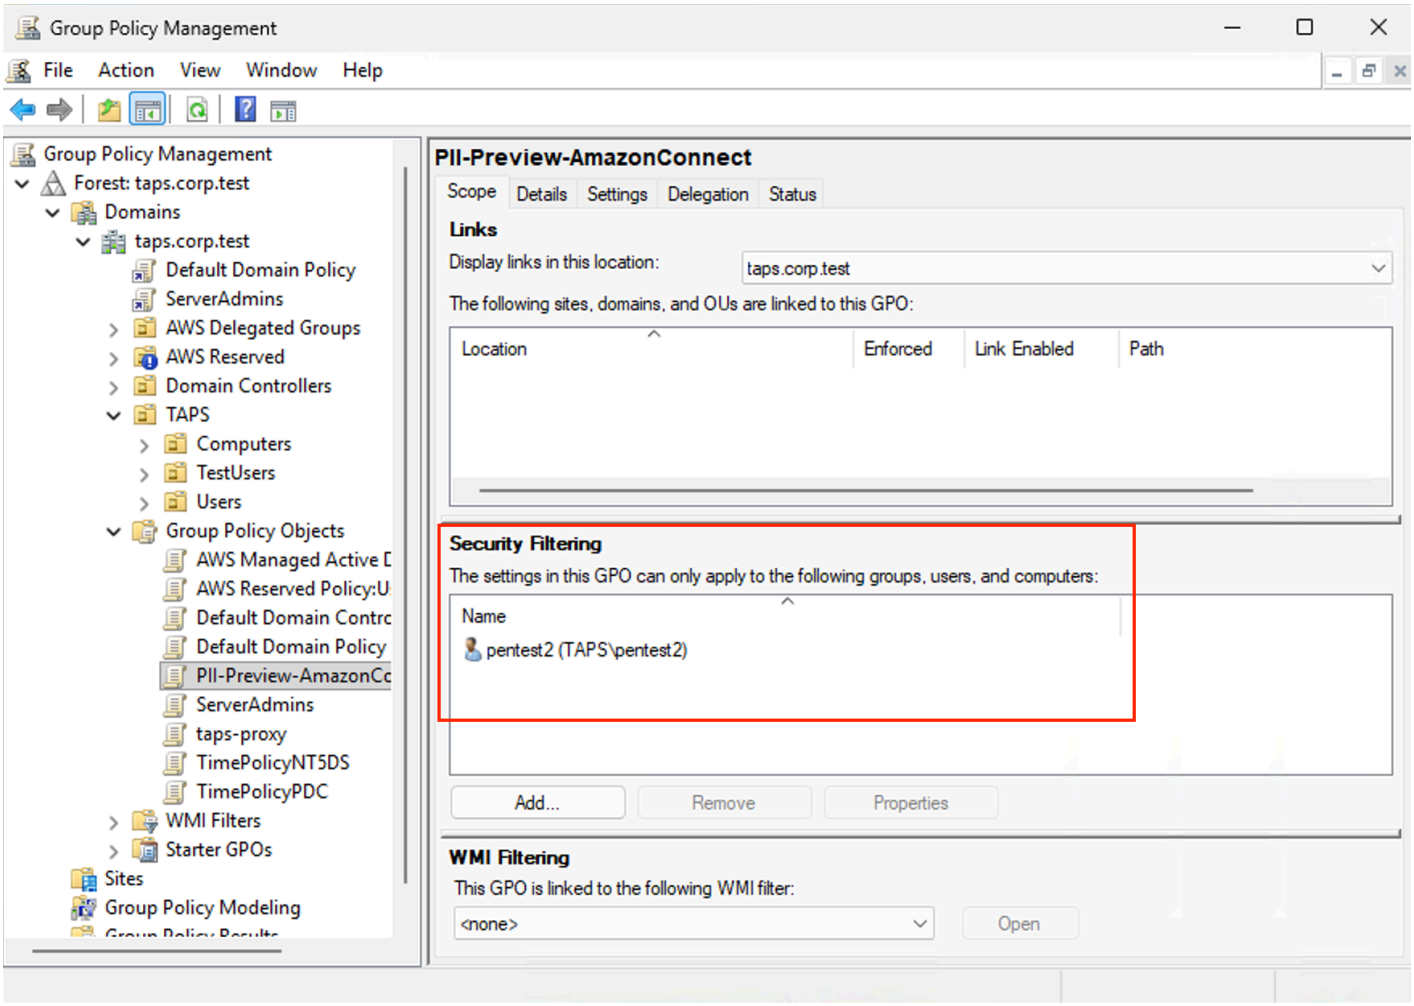
- Open **Group Policy Management** (`gpmc.msc`).
- Right-click **Group Policy Objects** and select **New**. For the name, enter `PII-AmazonConnect` (or similar).



- Set the targeting (scope):
  - Select the new GPO.
  - In the **Scope** tab, under **Security Filtering**, remove **Authenticated Users**.
  - Choose **Add** and select the security group containing your target agent computers.



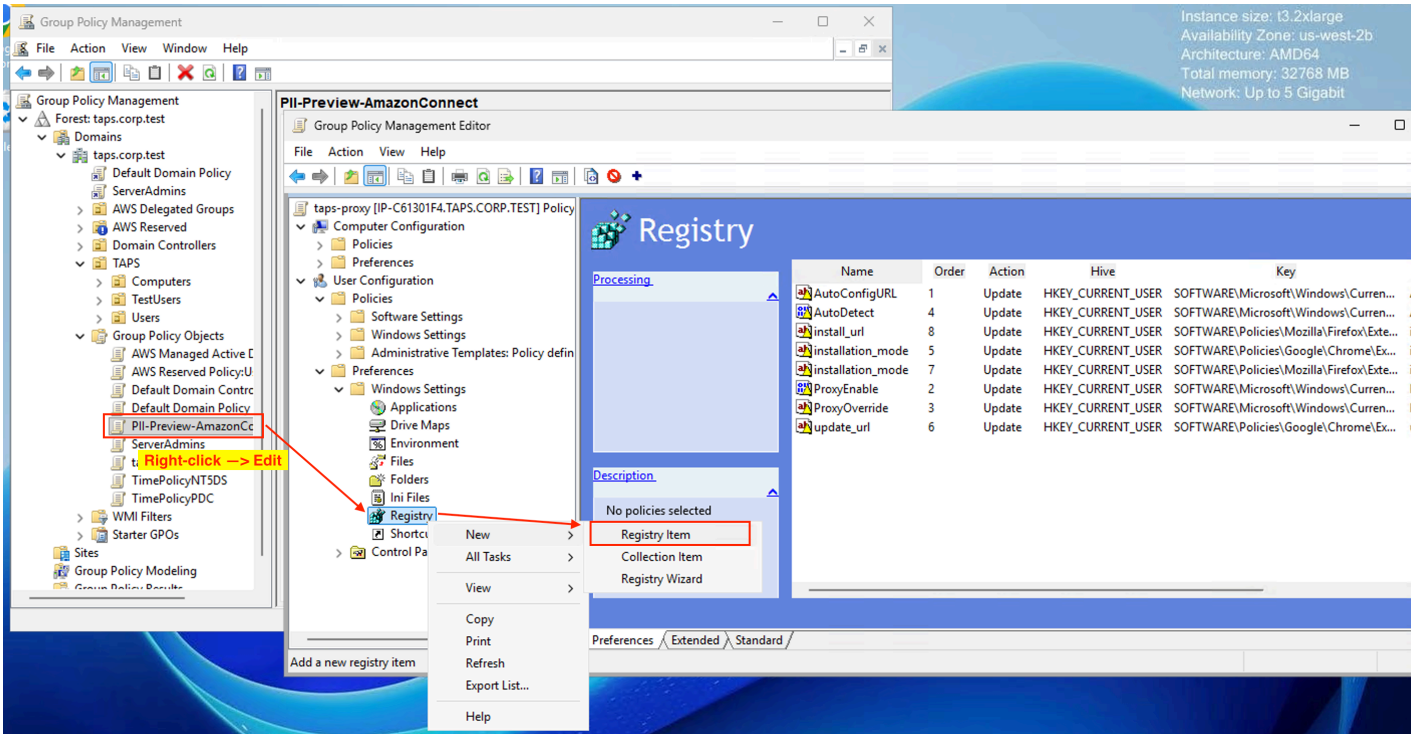
- Verify that the security filtering only contains machines that you intend to install extensions on.



Step 2: Configure the registry injection

This step creates the specific registry key that the browser reads to install the extension.

- Right-click your new GPO and select **Edit**.
- Navigate to the following path: **User Configuration**, **Preferences**, **Windows Settings**, **Registry**.
- Right-click in the empty space on the right and select **New**, **Registry Item**.



- Configure the properties as shown in the following tables.

The following values are common to all three browsers.

Property	Value
Action	Update
Hive	HKEY_CURRENT_USER
Value type	REG_SZ

For each browser, use the following key path and the two values it needs.

Google Chrome – key path `SOFTWARE\Policies\Google\Chrome\ExtensionSettings\cjmichfmnimgeoadokmeaiclklkdccod`

Value name	Value data
`installation_mode`	`force_installed`

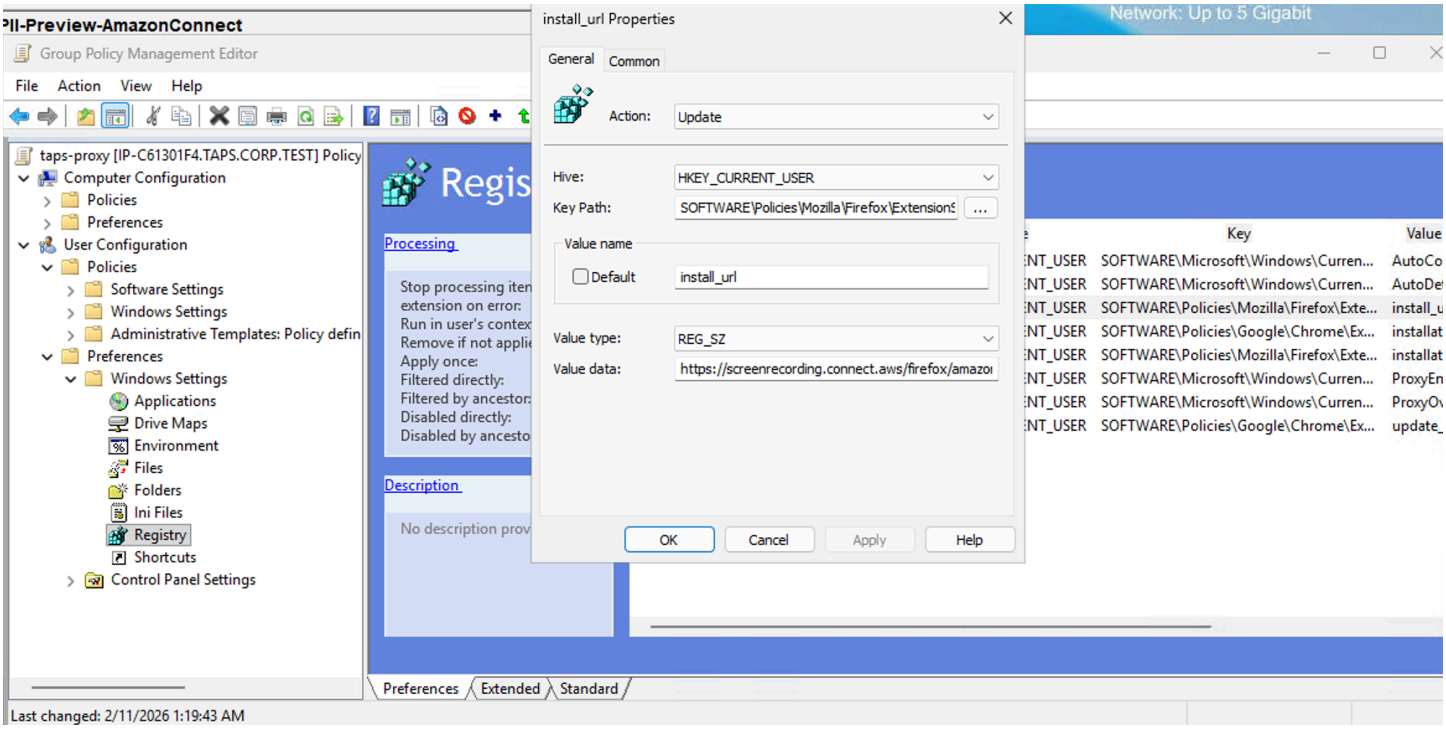
Value name	Value data
update_url	https://screenrecording.connect.aws/chromeos/amazon-connect-extension/releases/updates.xml

Microsoft Edge – key path SOFTWARE\Policies\Microsoft\Edge\ExtensionSettings\cjmichfmnimgeoadokmeaiclklkdccod

Value name	Value data
installation_mode	force_installed
update_url	https://screenrecording.connect.aws/chromeos/amazon-connect-extension/releases/updates.xml

Mozilla Firefox – key path SOFTWARE\Policies\Mozilla\Firefox\ExtensionSettings\amazon_connect_extension@amazon.com

Value name	Value data
installation_mode	force_installed
install_url	https://screenrecording.connect.aws/firefox/amazon-connect-extension/releases/amazon-connect-extension.xpi



Verify the extension is installed

After you deploy the extension, verify on a test workstation that the extension is installed, enabled, and running the expected version before you roll it out broadly.

Chrome or Microsoft Edge

- Open `chrome://extensions` (Chrome) or `edge://extensions` (Edge).
- Confirm that **Amazon Connect Client** appears in the list and is enabled.
- Confirm that the version is 2.1.0 or later.
- Open `chrome://policy` or `edge://policy`, choose **Reload policies**, and confirm that `ExtensionSettings` contains the Connect Customer extension ID with status **OK**.

Firefox

- Open `about:addons`. Confirm that **Amazon Connect Client** appears under **Extensions** and is enabled.
- Confirm that the version is 2.1.0 or later.
- Open `about:policies`. On the **Active** tab, confirm that `ExtensionSettings` contains the Connect Customer extension ID.

If any of these checks fail, see Download log files for the screen recording app.

Remove the extension

To stop using the Connect Customer browser extension on agent workstations, for example at the end of a pilot or when users change roles, remove the extension by reversing the deployment policy. You have two options.

Option 1: Remove users from the target group

Remove agent users from the security group or Entra ID group that your extension policy targets. When the next policy refresh runs, the extension is uninstalled from those users' browsers. Users who remain in the group continue to receive the extension.

This is the recommended approach for routine lifecycle changes such as role reassignments.

Option 2: Block the extension

To actively prevent the extension from being installed or used, change the policy payload's `installation_mode` from `force_installed` to `blocked`. The browser uninstalls the extension at the next policy refresh and prevents future installations.

Google Chrome and Microsoft Edge

```
{
  "cjmichfmnimgeoadokmeaiclklkdccod": {
    "installation_mode": "blocked"
  }
}
```

Mozilla Firefox

```
{
  "amazon_connect_extension@amazon.com": {
    "installation_mode": "blocked"
  }
}
```

If you deploy through the Windows registry, change the `installation_mode` value from `force_installed` to `blocked` under the user-scope registry paths listed in the section called "Windows user-scope registry example". You can leave the other values in place; `blocked` takes precedence.

Effect on recordings after removal

After the extension is removed or blocked, contacts handled by those agents are recorded without redaction applied. The contact records flag these recordings as unredacted. If rule-based redaction is required for compliance, route contacts only to agents whose security profile and browser still have the extension deployed.

What happens if the extension is disabled during a contact

If the extension is uninstalled or disabled while a recorded contact is active, browser URLs stop being reported to the Connect Customer Client Application for the remainder of the contact. URL rules can no longer match, and browser pages that should be redacted by URL might appear in the recording. Window title rules continue to match as normal.

To restore redaction for new contacts, reinstall or re-enable the extension before the next contact begins.

Download the Connect Customer Client Application log files for troubleshooting

When you open an AWS Support ticket for issues with screen recordings, include the log files for Connect Customer Client Application and shared worker from the agent desktop.

Connect Customer Client Application log files (Windows)

On the agent's desktop, navigate to:

- `C:\ProgramData\Amazon\Amazon.Connect.Client.Service\logs`

  This file contains the logs including the Websocket connection between browser and Client Application, and another Websocket connection between **Amazon.Connect.Client** and **Amazon.Connect.RecordingSession**.
- `%USERPROFILE%\AppData\Local\Amazon\Amazon.Connect.Client.RecordingSession\Logs`

  This file contains logs for screen recording activities. (Not applicable for version 1.x.)
- `%USERPROFILE%\AppData\Local\Amazon\Amazon.Connect.Client.Messaging.NativeHost\Logs`

  This file contains logs for extension IPC messages. (Not applicable for version < 3.x.)

Shared Worker logs (Windows and ChromeOS)

Open your CCP. It must be open so you can view the **ClientAppInterface** shared worker.

Chrome

1. Open a Chrome browser. For the URL type `chrome://inspect/#workers`.
2. In the **Shared workers** section, locate the shared worker named **ClientAppInterface**.
3. Choose **inspect** to open a DevTools instance.
4. Choose the **Console** tab, open the context menu for the log dump, and then select **Save as...** to store the log dump to a local file.

Firefox

1. Open a Firefox browser. For the URL type `about:debugging#workers`.
2. In the **Shared workers** section, choose **Inspect** for **/connect/ccp-naws/static/client-app-interface.js**.
3. Open the context menu for the **Console** tab and select **Save all Messages to File** to store the log dump to a local file.

Edge (Chromium)

1. Open a Chrome browser. For the URL type `edge://inspect/#workers`.
2. In the **Shared workers** section, locate the shared worker named **ClientAppInterface**.
3. Choose **inspect** to open a DevTools instance.
4. Choose the **Console** tab, open the context menu for the log dump, and then select **Save as...** to store the log dump to a local file.

Troubleshoot rule-based redaction

If you use Rule-based redaction for screen recordings, the following sections describe common issues and how to resolve them.

The redacted recording is missing

The redacted recording is produced after the contact ends and after the unredacted recording is finalized. It can take longer than the unredacted version to appear, especially when conversational

analytics call recording redaction is also enabled, because the redacted audio must be available before the redacted video is stitched. Allow extra time before treating it as missing.

If the redacted recording still has not appeared after a reasonable wait, check the following.

- Confirm that screen recording was enabled for the contact by checking the contact record.
- Confirm that the contact flow invoked the **Set recording, analytics, and processing behavior** block with rule-based redaction enabled before the contact was routed to the agent. For instructions, see Configure rule-based redaction.
- Confirm that the Connect Customer browser extension was installed and enabled on the agent's browser during the contact. See Deploy the browser extension.
- Confirm that the Connect Customer Client Application on the agent workstation is version 3.0.2 or later.

The redacted recording has no audio

When rule-based redaction is enabled for a contact, Connect Customer stitches the redacted video with the redacted call recording only if conversational analytics call recording redaction is also enabled for the contact. If conversational analytics call recording redaction is not enabled, the redacted recording is produced with no audio. This prevents the original audio from being exposed alongside a redacted video and is by design.

- To produce a redacted recording that includes redacted audio, enable conversational analytics call recording redaction for the contact in addition to rule-based screen redaction. See Use sensitive data redaction with conversational analytics.
- If a user needs to review the original audio, remove the **Screen recording (redacted) - Access** permission and grant them the **Screen recording - Access** permission so they can play the unredacted recording, which preserves the original audio.

The redaction overlay appears in the wrong position

- Confirm that the agent's Connect Customer Client Application is version 3.0.2 or later. Earlier versions have known issues with multi-monitor DPI scaling.
- Confirm that the Connect Customer browser extension is version 2.1.0 or later.
- If the issue persists on a specific workstation, collect diagnostic logs using the Connect Customer Client Application log collection tool, then open an AWS Support case.

The Connect Customer browser extension is missing on an agent's workstation

The extension is deployed at user scope through your enterprise browser policy, so this typically indicates that the agent is not in the targeted user group, or that the policy has not yet been applied on the workstation.

- Confirm that the agent is included in the security group or Entra ID group that your enterprise extension policy targets. For details, see Deploy the browser extension.
- On the agent's workstation, open `chrome://extensions`, `edge://extensions`, or `about:addons` to confirm whether the extension is present and enabled.
- If the policy was applied recently, ask the agent to restart the browser so the policy refresh picks up the new extension.
- For Chrome and Edge, you can also open `chrome://policy` or `edge://policy` and confirm that **ExtensionSettings** contains the Connect Customer extension ID with status **OK**.

An authorized user cannot view a redacted recording

- Confirm that the user's security profile includes the **Screen recording (redacted) - Access** permission. If the user also needs to download the redacted recording, confirm that the profile includes **Screen recording (redacted) - Enable download button**. For details, see Permissions for redacted recordings.
- Confirm that the contact flow for the contact enabled rule-based redaction. A contact that was recorded without a redaction rule does not produce a redacted file.

A redacted recording shows unredacted content

- Confirm that the Connect Customer browser extension is installed and was enabled during the contact. If the extension is uninstalled or disabled, the Connect Customer Client Application records without redaction.
- Confirm that the Connect Customer Client Application on the agent workstation is version 3.0.2 or later.

Related information

For general agent screen recording troubleshooting, including browser Local Network Access (LNA) restrictions, see Troubleshoot screen recording.

Use Amazon EventBridge events to track screen recording status

With Amazon EventBridge, you can view the status of agent screen recordings in near real-time. The event for each agent screen recording includes success/failure status, failure codes with descriptions, recording location, recording size, installed client version, and screen recording start and end times.

Note

Screen recording status tracking with Amazon EventBridge is available in every AWS Region that supports Connect Customer agent screen recording, except AWS GovCloud (US-West).

Note

If your instance uses Connect Customer Global Resiliency, set up your Amazon EventBridge rules and targets in both Regions of your instance pair. When an agent handles a contact that originated in the other Region, the contact's status events are split between the two Regions, and some events are delivered in both Regions. For more information, see Screen recording with Global Resiliency.

You can integrate with other AWS services to get analytical or monitoring insights of agent screen recordings:

- Query with Amazon CloudWatch Log Insights
- Get near real-time alerts in an AWS Quick dashboard
- Create aggregated reports outside of Connect Customer
- Connect your other customized data pipeline solutions with Amazon EventBridge

Topics

- Create a rule to match Amazon EventBridge events
- Configure the target of the created Amazon EventBridge rule

Amazon EventBridge event payload formats

Event with screen recording status - INITIATED

This event is emitted when a contact is accepted by the agent, which might be before recording starts, for every contact with agent screen recording enabled.

```

```
  "region": "us-west-2",
  "resources": [
    "arn:aws:connect:us-west-2:your_aws_account_id:instance/your_instance_id/contact/
ccccccccc-cccc-cccc-cccc-ccccccccccccc",
    "arn:aws:connect:us-west-2:your_aws_account_id:instance/your_instance_id"
  ],
  "detail": {
    "version": "1.0",
    "recordingStatus": "FAILED",
    "eventDeduplicationId": "aaaaaaaa-bbbb-cccc-dddd-eeeeeeee",
    "instanceArn": "arn:aws:connect:us-west-2:your_aws_account_id:instance/
your_instance_id",
    "contactArn": "arn:aws:connect:us-west-2:your_aws_account_id:instance/
your_instance_id/contact/ccccccccc-cccc-cccc-cccc-ccccccccccccc",
    "agentArn": "arn:aws:connect:us-west-2:your_aws_account_id:instance/
your_instance_id/agent/your_agent_id",
    "clientInfo": {
      "appVersion": "3.0.2.0",
    },
    "failureInfo": {
      "code": "UNKNOWN",
      "message": "Unknown failure",
      "source": "UNKNOWN"
    },
    "recordingInfo": {
      "startTime": "2026-01-01T00:00:00.000Z"
    }
  }
}
```

The following table lists the possible values in the `failureInfo` object.

code	message	source
`CLIENT_LOCAL_NETWORK_ACCESS_BLOCKED`	The browser's local network access policy blocked the connection to the Amazon Connect Client Application	`CLIENT`
`CLIENT_APP_NOT_RUNNING`	The Amazon Connect Client Application is not running on the agent's desktop	`CLIENT`
`CLIENT_UNSUPPORTED_OS`	The agent's operating system is not supported for screen recording	`CLIENT`

code	message	source
CLIENT_AUTH_ERROR	The Amazon Connect Client Application failed to authenticate	CLIENT
CLIENT_CONNECTION_ERROR	Amazon Connect Client Application is not connected	CLIENT
MULTIPLE_CCP_INTERACTION	Detected multiple browser interactions with CCP	CLIENT
USER_ERROR	Request encountered a user configuration error	CLIENT
SERVICE_ISSUE	Request encountered a service exception	SERVICE
UNKNOWN	Unknown failure	UNKNOWN

Create a rule to match Amazon EventBridge events

To subscribe to Amazon EventBridge events for screen recording status, you need to create an Amazon EventBridge rule that matches the defined event source and event detail-type. This can be achieved through either the AWS Console or AWS CDK libraries.

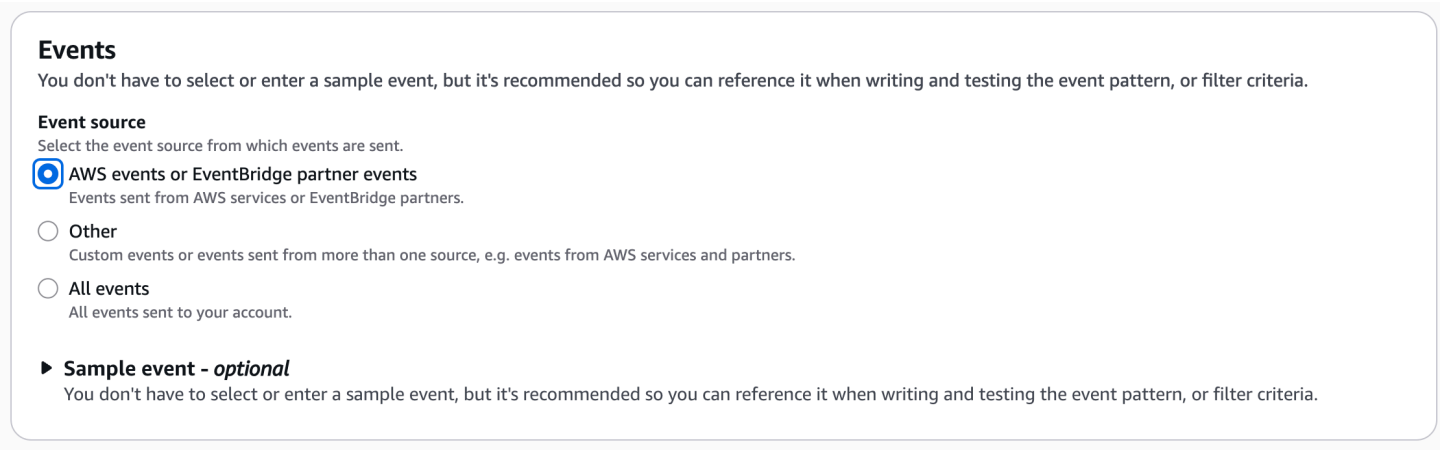
Create a rule using the AWS Console

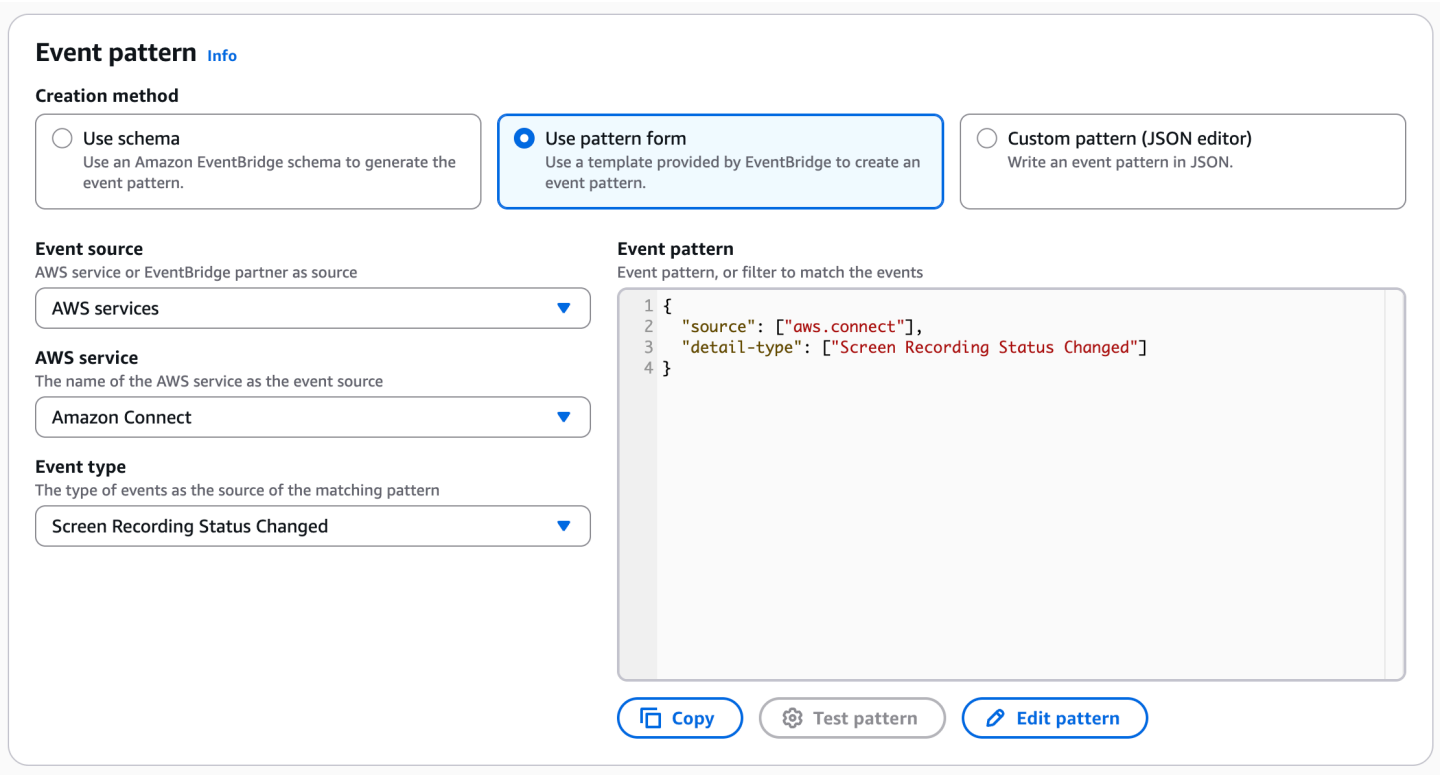
In the AWS Console, create a new rule in Amazon EventBridge → Buses → Rules.

Use the default event bus

Use a template event pattern

Select the defined event pattern from the dropdown lists.





If the event type is not showing up in the dropdown list, you can alternatively create the same pattern using **Custom pattern (JSON editor)** with:

```
{
  "source": [ "aws.connect" ],
  "detailType": [ "Screen Recording Status Changed" ]
}
```

Create a rule using AWS CDK

Alternatively, if you manage AWS resources with AWS CDK, here is a sample TypeScript code snippet to construct an Amazon EventBridge rule:

```
import { Rule } from 'aws-cdk-lib/aws-events';

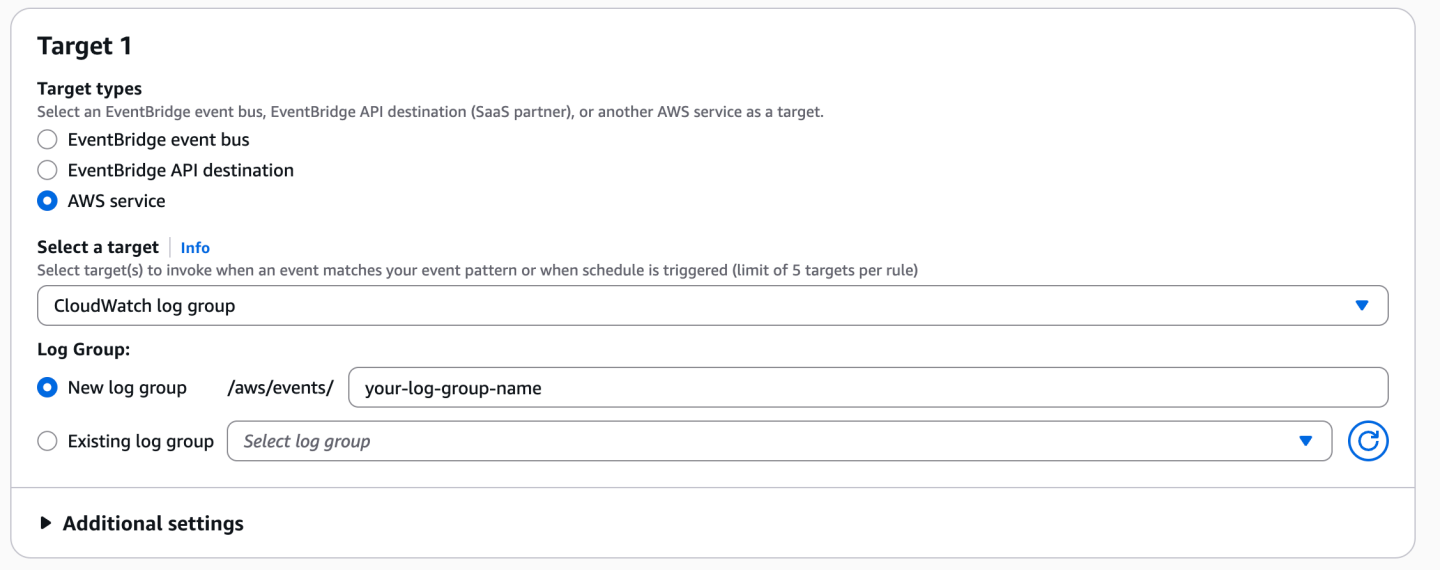
const eventBridgeRule = new Rule(this, 'YourEventBridgeRuleLogicalName', {
    ruleName: 'your-event-bridge-rule-name',
    description: 'your rule description',
    eventPattern: {
        source: [ "aws.connect" ],
        detailType: [ "Screen Recording Status Changed" ]
    }
});
```

Configure the target of the created Amazon EventBridge rule

Amazon EventBridge supports a number of AWS services as targets. Depending on your needs, it's flexible to build your own event processing pipeline with other AWS services. You can define up to five targets for each rule. For more information, see Amazon EventBridge targets in the *Amazon EventBridge User Guide*.

Amazon CloudWatch log group as an example target

The following example uses an Amazon CloudWatch log group as a target.



In AWS CDK code, create the resource and add it to the Amazon EventBridge rule:

```
import { LogGroup, RetentionDays } from "aws-cdk-lib/aws-logs";
import { CloudWatchLogGroup } from 'aws-cdk-lib/aws-events-targets';

const logGroup = new LogGroup(this, 'YourLogGroupLogicalName', {
    logGroupName: '"/aws/events/your-log-group-name',
    retention: RetentionDays.ONE_YEAR
});

eventBridgeRule.addTarget(new CloudWatchLogGroup((logGroup)));
```

Example Amazon CloudWatch Log Insights queries

Using Amazon CloudWatch Insights query language, here are some example queries:

- **Sample query on success ratio**

```
fields @timestamp, @message, detail
| stats sum(detail.recordingStatus= "PUBLISHED") as Count_Success,
  sum(detail.recordingStatus= "INITIATED") as Count_Total,
  Count_Success / Count_Total as Success_Ratio
```

- **Sample query to get counts of each recording status**

```
fields @timestamp, @message, detail
| stats count(*) as Count group by detail.recordingStatus as recordingStatus
```

- **Sample query on failed contacts with most common failure codes**

```
fields @timestamp, @message, detail
| filter detail.recordingStatus = "FAILED"
| stats count(*) as Count group by detail.failureInfo.code as FailureCode
| sort by Count desc
```

- **Sample query on agents with most failed contacts**

```
fields @timestamp, @message, detail
| filter detail.recordingStatus = "FAILED"
| stats count(*) as Count group by detail.agentArn as AgentArn
| sort by Count desc
```

Screen recording with Connect Customer Global Resiliency

Agent screen recording is supported on instances that have Set up Connect Customer Global Resiliency. With Global Resiliency, your Connect Customer instance is paired with a replica instance in another AWS Region, and agents can handle contacts in either Region. Screen recording works in both Regions of the pair, including after you shift agents from one Region to the other. However, replicating an instance does not copy every screen recording setting to the replica Region — complete the steps in this topic so that recording works in both Regions.

Topics

- Set up screen recording for a Global Resiliency instance pair
- How screen recordings work across Regions

Set up screen recording for a Global Resiliency instance pair

1. **Enable screen recording in both Regions.** The ReplicateInstance API does not copy data storage configuration to the replica instance, so the replica has no screen recording storage until you configure it. Follow the steps in Step 1: Enable screen recording for your instance on your source instance, and then repeat them on the replica instance in the replica Region. Each Region delivers its recordings to the Amazon S3 bucket configured in that Region. If the replica Region has no screen recording storage configured, contacts originating from that Region are not recorded.
2. **Update the Connect Customer Client Application domains allowlist.** With Global Resiliency, agents access the CCP through Region-specific sub-domains in the format *`region`*`.`*`your-instance-alias`*`.my.connect.aws`. Add the sub-domains for both Regions of your instance pair to the allowlist, for example `us-east-1.`*`your-instance-alias`*`.my.connect.aws,us-west-2.`*`your-instance-alias`*`.my.connect.aws`. For Windows, see the section called "Guidelines for specifying your Connect Customer domains allowlist". For Chrome OS, add the same sub-domains to the `allowListedDomain` managed configuration. If the allowlist contains only your original single-Region domain, screen recording fails after agents sign in through Global Resiliency domains.
3. **Update your firewall allow list for both Regions.** The screen recording upload endpoints described in Network requirements are Regional. Allow the upload endpoints for both Regions of your instance pair.
4. **Confirm your flows.** Flows, including the **Set recording and analytics behavior** block, are mirrored to the replica instance by ReplicateInstance, and changes you make to flows after

replication are continuously synchronized between the two instances in both directions. You do not need to configure screen recording separately in your replica Region flows. For more information, see What resources are mirrored in the replica instance.

5. **If you use Amazon EventBridge to track screen recording status**, set up your Amazon EventBridge rules and targets in both Regions of your instance pair. When the Region an agent is signed in to differs from the Region a contact originated from, the status events for that contact are split between the two Regions: events reported from the agent's workstation, including client-side failure events, are delivered in the agent's Region, while the `PUBLISHED` event is delivered in the contact's originating Region. Some events, such as `INITIATED` and `COMPLETED`, can be delivered in both Regions with different `eventDeduplicationId` values. To receive every event for every contact, create rules in both Regions, and use the contact ARN in the event detail to correlate events for the same contact across Regions. For more information, see Use Amazon EventBridge events to track screen recording status.

How screen recordings work across Regions

- A contact's screen recording is delivered to the Amazon S3 bucket configured in the Region from which the contact originated, regardless of which Region the agent is signed in to.
- Shifting agents to the other Region does not change where recordings are delivered. If contacts continue to originate from the first Region, their screen recordings continue to be delivered to that Region's Amazon S3 bucket, even while the agents handling them are active in the other Region.
- Cross-Region contact search can surface a contact from either Region of your instance pair. For more information about contact search across Regions, see Contact search and contact details.
- The Connect Customer Client Application on the agent workstation works in both Regions; no reinstallation is required when agents change Regions, provided both Regions' domains are in the allowlist.

Frequently asked questions about Connect Customer screen recording capabilities

This topic provides frequently asked questions about using Connect Customer screen recording capabilities.

Topics

- Screen recording FAQ
- Rule-based redaction FAQ

Screen recording FAQ

General specifications

- **What is the file format of screen recordings?**

  The screen recording files are saved in MP4 format.
- **Which Connect Customer channels are supported?**

  You can generate screen recordings for voice, chat, and task contacts. Screen recording is not supported for email contacts.
- **Does screen recording support concurrent user sessions on Windows using Virtual Desktop Infrastructure (VDI) environments?**

  Yes, screen recording supports concurrent user sessions on Windows when using Connect Customer Client Application version 2.0.0 or later.
- **Where are the screen recording files stored in my AWS account?**

  The screen recordings are delivered to your Amazon S3 bucket and encrypted using the KMS key you specify. This is similar to how call recordings are stored and encrypted.
- **How can I be notified when there is a latest version of the client application?**
  - For Windows, to be notified when there is an update to the Connect Customer Client Application, we recommend subscribing to the RSS feed of this administrator guide. Choose the **RSS** link that appears under the title of this page (it's next to the PDF link).
  - For ChromeOS, Isolated Web App and Chrome Extension are hosted and managed by Amazon Connect. They are automatically updated as newer versions are published.
- **Can I opt only for screen recording and not for call recording?**

  Yes, you can enable screen recording without call recording for a voice call.
- **How do I find the Amazon S3 location of the screen recording?**

  You can find the screen recording location in the RecordingsInfo section of the contact record. See the **Location** field.
- **How do I enable screen recording for a percentage of my contacts?**

You can use the Distribute by percentage block in the flow to enable a percentage of contacts for screen recording.

- **Is screen recording PCI compliant?**

  Connect Customer, including the screen recording capability, is compliant with the Payment Card Industry Data Security Standard (PCI DSS). However, you are responsible for determining whether your specific implementation meets your compliance requirements.

  > **Important**
  >
  > During a video call or screen sharing session, agents are able to see the customer's video or screen share even when the customer is on hold. It is the customer's responsibility to handle PII accordingly. If you want to change this behavior, you can build a custom CCP and communication widget. For more information, see Integrate in-app, web, video calling, and screen sharing natively into your application.

- **Does screen recording work with custom CCP and custom agent applications?**

  Screen recording is designed to work with custom CCP and agent workspace built with the Connect Customer Streams JS library. We recommend testing your custom solution before deploying screen recording in production.

- **Does screen recording work with Connect Customer Global Resiliency?**

  Yes. Screen recording is supported on Connect Customer Global Resiliency instance pairs, including after you shift agents between Regions. Additional setup is required: you must enable screen recording storage in both Regions and add both Regions' domains to the Connect Customer Client Application allowlist. For details, see Screen recording with Global Resiliency.

- **Can I use screen recording anywhere in the world?**

  Screen recording is available in AWS GovCloud (US) and all AWS commercial Regions where Connect Customer is available. However, your use of screen recording might be subject to compliance with privacy and other laws. Please consult your compliance team before enabling this capability for your agents.

  To use screen recording in AWS GovCloud (US-West) requires client version 2.0.3 or later.

- **Are agents alerted when screen recording is enabled for a contact?**

By default Connect Customer doesn't provide a notification feature. However, you can use the Connect Customer Streams JS library to create a notice or other visual indicator on an agent's desktop to signal that screen recording is in use.

- **What happens if an agent closes the browser during a contact, or immediately after a contact ends?**

  If the browser is closed at the beginning of contact before any screen capture data can be uploaded to Connect Customer, the final screen recording might not be published. If the browser is closed immediately after a contact ends but before the final screen capture data can be uploaded, the screen recording is published when the agent next logs in to CCP.

- **Does screen recording STOP when an agent places a customer on hold?**

  No, the screen recording continues recording when an agent places a customer on hold.

- **Is screen recording supported when Agents are logged into multiple CCP instances?**

  No, screen recording is not supported when Agents are logged into multiple CCP instances simultaneously either in the same or different browsers. You might see inconsistent behavior with screen recordings in these cases.

Configuration

- **Can I opt only for screen recording and not for call recording?**

  Yes, you can enable screen recording without call recording for a voice call. To do so, disable voice recording in the Set recording and analytics behavior block while keeping the screen recording enabled.

- **How do I find the Amazon S3 location of the screen recording?**

  You can find the screen recording location in the RecordingsInfo section of the contact record. See the **Location** field.

- **How do I enable screen recording for a percentage of my contacts?**

  You can use the Distribute by percentage block in the flow to enable a percentage of contacts for screen recording.

- **What is the average size of a screen recording file per minute in S3?**

The average size of screen recording is 1.5MB/minute. This size can vary depending on factors like video encoding.

- **What is the frame rate for screen recording and is this configurable?**

  The screen is recorded at 5 frames per second and this is not configurable.

- **What codec is used for screen recording?**

  Screen recording uses OpenH264 codec.

- **Is there a way to choose which audio (redacted or unredacted) gets used for screen recording?**

  By default, the screen recording uses unredacted audio.

  To preserve screen content and use redacted call audio, enable screen recording and rule-based redaction in the contact flow. Select **Denylist** and leave the URL and window title rule lists empty. Enable conversational analytics call recording redaction for the contact.

  The resulting redacted screen recording preserves screen content and contains redacted audio. Without conversational analytics call recording redaction, the redacted screen recording has no audio.

  Grant the **Screen recording (redacted) - Access** permission to anyone who needs access to the redacted recording. Remove the **Screen recording - Access** permission from anyone who must not access the original recording.

- **Is there a service limit for screen recording?**

  No, there is no service limit or quota for screen recording service.

- **Is there a maximum duration for screen recording?**

  No, the screen recording solution imposes no maximum duration for a recording.

- **How many agent monitors can be recorded?**

  Screen recording can record up to 3 screens/monitors.

- **Can I configure my call/screen recording storage S3 bucket to enable bucket level encryption with a KMS key that is different from the KMS key used as part of instance data storage configuration?**

No, the same key should be used at bucket level and also as part of instance data storage configuration.

- **Where are screen recordings stored?**

  Screen recordings are delivered to your Amazon S3 bucket under your configured prefix:

  ```
  s3://your-bucket/your-prefix/year/month/day/contact-id_UTC-timestamp.mp4
  ```

  Here, *your-prefix* is the Amazon S3 prefix configured for your instance. The console default is `connect/`*your-instance-alias*`/ScreenRecordings`, and the prefix is configurable.

Performance

- **What are the bandwidth requirements for screen recording?**

  We recommend 500 Kbps bandwidth for screen recording, regardless of the number of concurrent contacts. The system requirements specify 600 Kbps total network bandwidth to account for additional agent workstation traffic.

- **Why do I see higher CPU usage after installing screen recording client application on my windows machine?**

  Screen recording in general is a CPU intensive application and hence CPU use increase is expected. We recommend making sure you provide sufficient resources as documented in System requirements to avoid any resource contention issues.

Rule-based redaction FAQ

General specifications

- **Do I need to replace my existing screen recording setup to use rule-based redaction?**

  No. Rule-based redaction for screen recordings is an extension of Connect Customer agent screen recording. You enable it on a per-contact basis through a contact flow.

- **Is there an additional charge for rule-based redaction?**

  Rule-based redaction is included with Connect Customer agent screen recording at no additional charge. Standard recording and storage rates apply.

- **Does rule-based redaction affect storage costs?**

  Connect Customer stores both the unredacted and redacted recordings in your Amazon S3 bucket. You pay standard Amazon S3 storage rates for both files. If you do not need to retain the unredacted originals, you can use an Amazon S3 lifecycle policy to expire them on a shorter schedule than the redacted versions.

- **Does rule-based redaction apply to call recordings?**

  Rule-based redaction applies only to agent screen recordings. It does not redact audio. When rule-based redaction is enabled for a contact, Connect Customer stitches the redacted video with the redacted call recording if conversational analytics call recording redaction is also enabled for the contact, and with no audio otherwise. To redact audio from call recordings, see Use sensitive data redaction with conversational analytics.

- **Does rule-based redaction use artificial intelligence or machine learning?**

  No. Rule-based redaction is purely pattern matching. It evaluates each browser page URL and application window title against the rules you configure, and does not use artificial intelligence, machine learning, or generative AI.

- **Can I redact only part of a page, such as a single form field?**

  No. Rule-based redaction masks entire browser or application windows that match a rule. Field-level redaction is not supported.

- **Does rule-based redaction work in Citrix or other virtual desktop environments?**

  Yes, provided that the Connect Customer Client Application and the Connect Customer browser extension are installed in the virtual desktop session. Performance depends on the virtual desktop configuration.

- **What happens if an agent opens a matching URL in a private browsing window or an unsupported browser?**

  Private browsing windows are reported by the Connect Customer browser extension the same as regular windows and are redacted according to your URL rules. Browsers other than Google Chrome, Microsoft Edge, and Mozilla Firefox do not report URLs to the Connect Customer Client Application, so URL rules cannot match pages in those browsers. To cover those cases, add window title rules that match on the browser's window title, or use group policy to restrict agents to Chrome, Edge, or Firefox during recorded contacts.

- **How does redaction behave with multiple browser windows or tabs, or when a matching page is left open in the background?**

  Redaction follows what is visible on screen, not which window the agent is actively using:

  - Each browser window is evaluated independently. A matching window is masked; non-matching windows remain visible.
  - For multiple tabs in the same window, redaction follows the visible tab. If the visible tab matches a rule, the whole window is masked. If a matching page is open but is not the visible tab, that window is not masked.
  - A matching window stays masked whenever it is visible, even if the agent is working in another window beside it. Only the visible portion is masked — if the matching window is covered, minimized, or on an inactive tab, there is nothing on screen to mask.
  - On the first contact after an agent begins their session, if a matching page was opened before the extension observed it, that window might briefly not be masked at the start of the recording. Redaction applies as soon as the agent selects any tab in the window, and subsequent contacts are unaffected.
- **Does rule-based redaction pause or stop the recording when a matching window is detected?**

  No. The agent's screen is captured continuously throughout the contact. Matching windows are masked only in the final redacted recording that is produced after the contact ends; the capture itself is never paused.
- **Can I preview a redacted recording before the contact ends?**

  No. Redaction is applied when the recording is assembled after the contact ends.
- **Are agents notified when they visit a page that matches a redaction rule?**

  No. Agents are not notified when a page or window matches a redaction rule. Connect Customer does not provide a built-in notification for rule matches.
- **What browser information can the Connect Customer browser extension access?**

  The extension only reads the URL of each browser page and the title of the visible tab. It cannot access other browser data such as cookies, page content, or browsing history. These URLs and window titles are the only information used to match your redaction rules.
- **What APIs does rule-based redaction consume, and how are they authenticated?**

  Rule-based redaction introduces no new public APIs, and the browser extension consumes none. The extension communicates locally with the Connect Customer Client Application on the

agent's workstation using the browser's native messaging channel; the extension is signed and scoped to the Connect Customer native messaging host. Redaction reuses the existing screen recording upload path, so it inherits that path's authentication and authorization — no additional credentials or permissions are required.

- **What happens if the Connect Customer browser extension fails or is not running?**

  Because redaction is applied after the contact ends, the extension does no real-time video processing during the contact — it only reports page URLs and window titles — so it is unlikely to affect the responsiveness of the agent's desktop. The possible failure cases are:

  - If the extension is not installed or not running, URLs are not reported, so URL rules cannot match and browser pages that should be redacted by URL might appear in the recording. Window title rules do not depend on the extension and continue to work.
  - The extension does not connect to Connect Customer directly; it communicates with the Connect Customer Client Application on the agent's workstation. If the Connect Customer Client Application is not running, screen recording does not function at all — not only redaction.
  - If the extension fails to report a matching URL during a contact, that page is not masked in the final output, and the unredacted recording still contains the full capture.

  For troubleshooting, see Download log files for the screen recording app.

Configuration

- **Does rule-based redaction require conversational analytics?**

  No. The URL and window-title matching that drives rule-based redaction is independent of conversational analytics and works without it enabled. However, audio in the *redacted* recording does depend on it: when rule-based redaction is enabled for a contact, the redacted screen recording is stitched with the redacted call recording only if conversational analytics call recording redaction is also enabled for that contact — otherwise the redacted recording has no audio. The unredacted screen recording always uses the unredacted audio.

- **Can I change the redaction rule during an active contact?**

  No. The redaction configuration is fixed for the duration of a contact.

- **Where are redacted recordings stored?**

Redacted recordings are stored in the same Amazon S3 bucket as the unredacted recordings, as a sibling of the unredacted file. The redacted key is rooted at the parent of your configured prefix, under a fixed `Analysis/ScreenRecordings/Redacted/` path.

```
s3://your-bucket/your-prefix-parent/Analysis/ScreenRecordings/
Redacted/year/month/day/contact-id_screen_recording_redacted_UTC-timestamp.mp4
```

In this path, *`your-prefix-parent`* is your configured screen recordings prefix with its last segment removed. For example, with the console default prefix `connect/`*`your-instance-alias`*`/ScreenRecordings`, redacted recordings are stored under `connect/`*`your-instance-alias`*`/Analysis/ScreenRecordings/Redacted/`.

- **How can I audit whether a specific contact was recorded with redaction enabled?**

  The flow that applied the redaction configuration is captured in the contact record. For information about accessing contact records, see Contact records data model.

- **Can I use rule-based redaction with the SuspendContactRecording and ResumeContactRecording APIs?**

  Yes. You can use the SuspendContactRecording and ResumeContactRecording APIs for screen recording in conjunction with rule-based redaction.

Performance

- **Does enabling rule-based redaction delay when a recording is available?**

  Your unredacted screen recording is unaffected — it is captured, delivered, and available on the same timeline as before. Redaction runs as a separate post-processing step, so the redacted recording becomes available after both the redacted screen recording and the redacted call recording have finished processing.

- **How much CPU and memory does the browser extension add?**

  The browser extension is lightweight — it only reports page URLs and window titles to the Connect Customer Client Application — and adds roughly 1% additional CPU and memory usage on top of the existing screen recording baseline. The most resource-intensive component remains the screen capture process in the Connect Customer Client Application. Follow the minimum system requirements in System requirements.

Search for completed and in-progress contacts in Connect Customer

> **Note**
>
> End of support notice: On May 20, 2026, AWS will end support for Amazon Connect Customer Voice ID. After May 20, 2026, you will no longer be able to access Voice ID on the Amazon Connect Customer console, access Voice ID features on the Connect Customer admin website or Contact Control Panel, or access Voice ID resources. For more information, visit Amazon Connect Customer Voice ID end of support.

This topic is for administrators and contact center managers who need to search for contacts using the Connect Customer admin website. For the APIs used to search for contacts programmatically, see APIs to search contacts.

Topics

- Important things to know
- Key search features
- Manage who can search for contacts and access detailed information
- How to search for a contact
- Additional fields: Add columns to your search results
- Download search results
- APIs to search contacts
- Search for in-progress contacts in Connect Customer
- Search for contacts in Connect Customer by using custom contact attributes or contact segment attributes

Important things to know

- You can search for contacts as far back as two years ago.
- You can search for both completed and in-progress contacts. For contacts handled by agents, a contact is only marked as completed after the agent has completed After Contact Work (ACW).

- The ability to search for in-progress contacts varies by channel (see Contact events data model for reference):
  - **Voice**
    - You can search for in-progress queued callbacks after they are queued, connected to an agent or disconnected.
    - For other voice contacts, you can search them only after they are connected to an agent, or have been disconnected. Queued in-progress voice contacts (with the exception of callbacks) are not shown on the **Contact search** page.
  - **Chat**: You can search for contacts after they are connected to system, queued, connected to an agent or disconnected.
  - **Tasks** and **Email**: You can search for all in-progress contacts after they are initiated.
- The search results for a given query are limited to the first 10K results returned.
- You cannot search for multiple contact IDs at the same time.

Key search features

- Search by custom contact attributes (user-defined attributes).
- Search for contacts that are in progress or completed using the **Contact status** filter.
- Search a time range up to 8 weeks. Within the time range filter, you can specify the **Timestamp type**. With this timestamp type, you can specify the time range. You can choose from initiated, connected to agent, disconnected, and scheduled timestamps.

  Important
  - Time range filter on Contact search has Timestamp type set to "Initiated" by default. Before the Timestamp type selection was introduced, the Timestamp type used by the Time Range filter was "Disconnected".
  - Saved searches on Contact search created before the launch of the ability to search for in-progress contacts (launched September 2023) have been updated with the filters Contact status = "Completed" and Timestamp type = "Disconnected". These selections were implied before the launch of in-progress contacts.
- Multi-select filters for agent names, contact queues and the name of the initial flow for the contact.

- Filter for agent hierarchy. You can progressively apply filters to drill-down into agent hierarchy levels.

  > **Note**
  >
  > When you select multiple values at any hierarchy level, you cannot filter on the next hierarchy level(s).

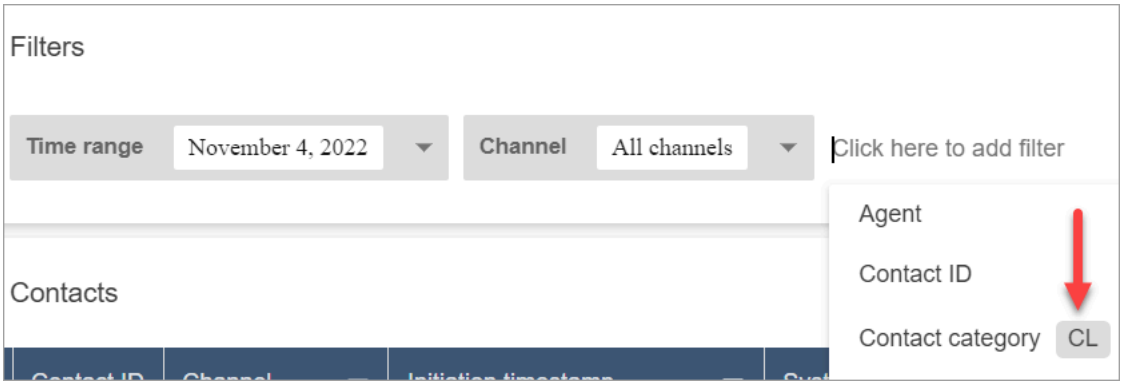
- Filter contacts by channel and channel subtype, such as SMS.
- Filter contacts by tags. You can include up to 10 tags in the filter. To control which tag combinations appear in the results, choose **Match any**, **Match all**, or **Match none**.
- Filter contacts by task template.

  > **Important**
  >
  > Filtering contacts by task template does not reflect updated templates for in-progress contacts. Contact search will only show the original template until the contact terminates.

- Filter to search for email contacts using email address (To, From and CC) and email subject. Searching on an email subject is not case sensitive. Also, searching for a subset of words within an email subject provides search results. For example, if you enter **inquiry**, Connect Customer returns emails with the subject **Customer Inquiry**.
- Filters for conversation analytics. You can search for contacts that have conversational analytics enabled. For example, **Conversational analytics: Voice - Agent interaction** returns contacts where the agent interaction has been analyzed by conversational analytics. You can search for Contact categories by specifying the full category name. Choose to search using **Match any** or **Match all** or **Match none**. For example, you can search contacts with both "category A" and "category B", or with either one of the two categories.

  For the complete list of conversational analytics filters, see Search conversations analyzed by conversational analytics. You can apply these filters only if your organization has enabled conversational analytics.

  In the **Add filter** drop-down box, the conversational analytics filters have **CL** next to them. You can apply these filters only if your organization has enabled conversational analytics.



If you want to remove the conversational analytics filters from a user's drop-down list, remove the following permissions from their security profile:

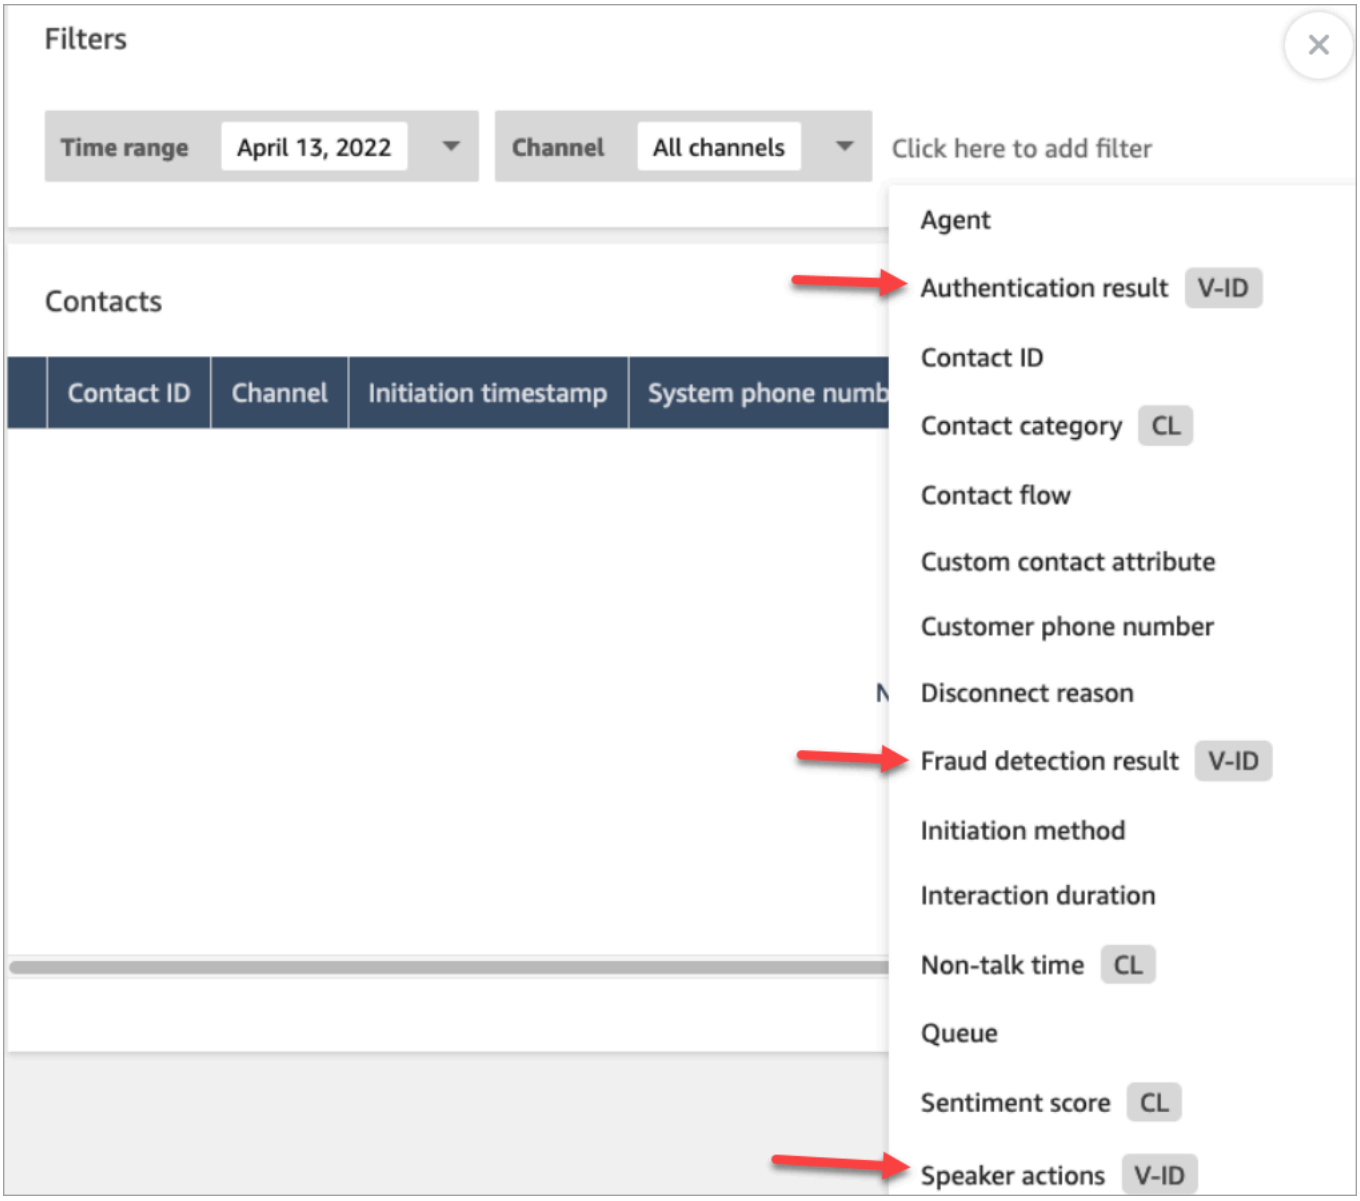
- **Search contacts by conversation**: This controls access to the sentiment scores, non-talk time, and category searches.
- **Search contacts by keywords**: This controls access to the keywords search.
- **Conversational analytics**: On the **Contact details** page, this displays graphs that summarize conversational analytics.

- Filters for recordings. Using the **recording** filter, you can filter for contacts with a screen recording (video) or audio recording (voice).
- Filter for Active Region. Search for contacts by the AWS Region where they were handled. This filter is available for Connect Customer instances using global resiliency, where contacts might be handled in a different AWS Region than the region you are logged into.

> **Important**
>
> Some Connect Customer features might be unavailable when accessing cross-region contact data. For complete details, refer to the Set up Connect Customer Global Resiliency.

- Filters for Voice ID. You can search for the Voice ID authentication and fraud detection status of contacts, if your organization has enabled Voice ID. To access this functionality, on your security profile, you need **Analytics and Optimization**, **Voice ID - attributes and search** - **View** permission.

  The following image shows the filters available to search Voice ID: **Authentication result**, **Fraud detection result**, **Speaker actions**.



Manage who can search for contacts and access detailed information

Before users can search for contacts in Connect Customer, or access detailed contact information, they need to be assigned to the **CallCenterManager** security profile, or have the following **Analytics and Optimization** permissions:

- At least one of the following permissions is required to view contacts on **Contact search** and **Contact details** pages:
  - **Contact search - View**: Allows a user to access all contacts on **Contact search** and **Contact details** pages.

- **View my contacts - View**: On the **Contact search** and **Contact details** pages, allows agents to view only those contacts that they handled.

- **Restrict contact access** (Optional): Manage a user's access to results on the **Contact search** page based on their agent hierarchy group. For example:
  - Agents who are assigned to AgentGroup-1 can only view contact records for contacts handled by agents in that hierarchy group, and any groups below them. (If they have permissions for **Recorded conversations**, they can also listen to call recordings and view transcripts.)
  - Agents assigned to AgentGroup-2 can only access contact records for contacts handled by their group, and any groups below them.
  - Managers and others who are in higher level groups can view contact records for contacts handled by all the groups below them, such as AgentGroup-1 and 2.

  For this permission, **All** = **View** since **View** is the only action granted.

  For more information about hierarchy groups, see Organize agents into teams and groups for reporting and access by creating hierarchies.

> **Important**
>
> - Deleting a hierarchy level severs the link to existing contacts. This action can not be reversed.
> - When you change a user's hierarchy group, it might take a couple of minutes for their contact search results to reflect their new permissions.

The following table lists the typical permissions and what contacts can be viewed on **Contact search** and **Contact details** pages.

Contact search permission	View My Contacts permission	Restrict Contact Access permission	Which contacts can be viewed
Enabled	Disabled	Disabled	All

Contact search permissio n	View My Contacts permissio n	Restrict Contact Access permissio n	Which contacts can be viewed
Enabled	Disabled	Enabled	All contacts within your agent hierarchy , handled by an agent at your hierarchy level or below.
Disabled	Enabled	Disabled	Only contacts handled by the user (agent) to whom the permission is granted.
Disabled	Disabled	Disabled	No contacts

> **Important**
>
> We do not recommend assigning permissions in any other combination than what is shown in the preceding table.

- **Conversational analytics**: On the **Contact details** page for a contact, you can view graphs that summarize conversational analytics: customer sentiment trend, sentiment, and non-talk time.
- **Call recordings (redacted) - Access**: If your organization uses conversational analytics, you can assign this permission so agents access only those agent call recordings in which sensitive data has been redacted.
- **Contact transcripts (redacted) - Access**: If your organization uses conversational analytics, you can assign this permission so agents access only those contact transcripts in which sensitive data has been redacted.
- **Call recordings (unredacted) - Access**: Use this permission to manage who can access recordings on the **Contact search** and **Contact details** pages. If desired, you can use **Restrict contact access** to make sure they only have access to detailed information for those contacts handled by their hierarchy group.
- **Contact transcripts (unredacted) - Access**: Use this permission to manage who can view unredacted chat and email conversations, and unredacted voice transcripts produced by conversational analytics on the **Contact search** and **Contact details** pages. If desired, you can

use **Restrict contact access** to make sure they only have access to detailed information for those contacts handled by their hierarchy group.

- **Evaluation forms - perform evaluations**: Allows users to search for evaluations by evaluation form, score, last updated date/range, evaluator, and status.
- **Voice ID - attributes and search**: If your organization uses Voice ID, users with this permission can search for and view Voice ID results in the **Contact detail** page.
- **Users - View** permission: You must have this permission to use the **Agent** filter on the **Contact search** page.

By default, the Connect Customer **Admin** and **CallCenterManager** security profiles have these permissions.

For information about how to add more permissions to an existing security profile, see Update security profiles in Connect Customer.

How to search for a contact

1. Log in to Connect Customer with a user account that has permissions to access contact records.
2. In Connect Customer choose **Analytics and optimization**, **Contact search**.
3. Use the filters on the page to narrow your search. For date, you can search up to 8 weeks at a time.

> **Tip**
>
> To see if a conversation was recorded, you need to be assigned to a profile that has **Manager monitor** permissions. If a conversation was recorded, by default the search result will indicate so with an icon in the **Recording** column. You won't see this icon if you don't have permission to review the recordings.

Additional fields: Add columns to your search results

Use the options under **Additional fields** to add columns in your search results. These options are not used to filter your search.

For example, if you want to include columns for **Agent Name** and **Routing profile** in your search output, choose those columns here.

To display the tags applied to each contact, add the **Tags** column.

> **Tip**
>
> The **Is transferred out** option indicates whether the contact was transferred out to another agent, queue, or an external number. This option only indicates cold transfers, where the agent disconnected before the contact was transferred. For the date and time (in UTC time) when the transfer was connected, see `TransferCompletedTimestamp` in the ContactTraceRecord.

Download search results

You can download up to 3,000 search results at a time.

APIs to search contacts

Use the following APIs to search contacts programmatically:

- SearchContacts
- DescribeContact
- DescribeContactEvaluation

Search for in-progress contacts in Connect Customer

For a contact that is handled by an agent, a contact is considered **In Progress** until the agent completes After Contact Work. For a contact that is never handled by an agent, a contact is considered **In Progress** until the contact is disconnected.

Topics

- Permissions needed to search for in-progress contacts
- Contact states supported by Contact search
- How to search for in-progress contacts
- Filter contacts by using timestamp types

- View in progress contacts
- Review real-time transcripts

Permissions needed to search for in-progress contacts

The permissions needed to search for in-progress contacts are the same as those for searching for completed contacts. For more information, see Manage who can search for contacts and access detailed information.

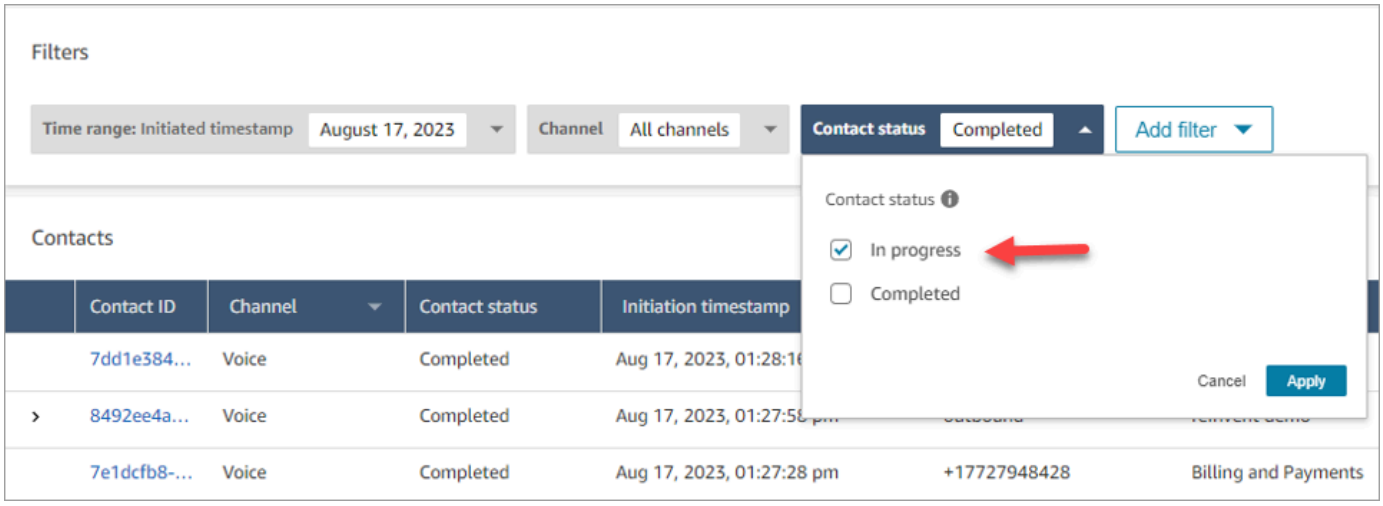
Contact states supported by Contact search

The ability to search for in-progress contacts varies by channel (see Contact events data model for reference):

- **Voice**
  - You can search for in-progress queued callbacks after they are queued, connected to an agent or disconnected.
  - For other voice contacts, you can search them only after they are connected to an agent, or have been disconnected. Queued in-progress voice contacts (with the exception of callbacks) are not shown on the **Contact search** page.
- **Chat**: You can search for contacts after they are connected to system, queued, connected to an agent or disconnected.
- **Tasks** and **Email**: You can search for all in-progress contacts after they are initiated.

How to search for in-progress contacts

1. Log in to Connect Customer with a user account that has permissions to access contact records.
2. In Connect Customer choose **Analytics and optimization**, **Contact search**.
3. Select the **Contact status** filter and change the selected value to **In progress**. The default Contact status is **Completed**.



Filter contacts by using timestamp types

You can search for contacts in a particular contact state using **Timestamp type** within the **Time range** filter. For example, you can search for task contacts that are scheduled for the next day by selecting **Contact status = In progress**, **Timestamp type = Scheduled** and the appropriate date within **Time range**.

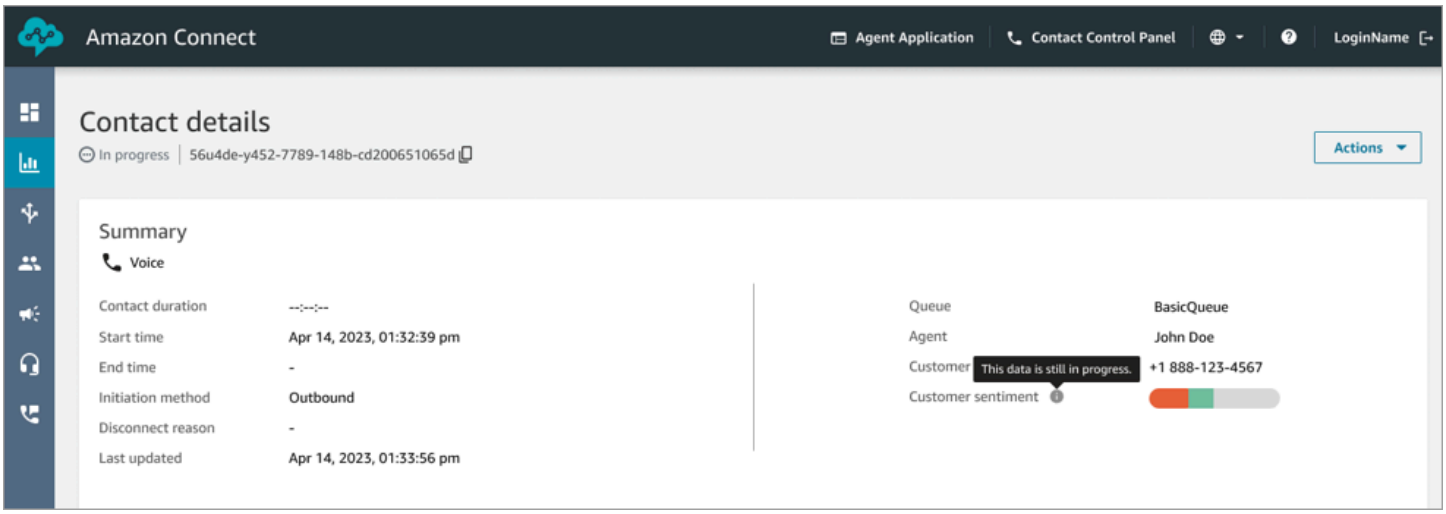
The following timestamp types are supported: initiated, connected (to agent), disconnected and scheduled. When you search for contacts using a certain **Timestamp type**, the search results do not contain contacts that do not have that timestamp populated, for example, if you search for a contact with **Timestamp type = Disconnected** and **Contact status = In progress**, then you will only view contacts that are in After Contact Work state.

Important

- The **Time range** filter on the **Contact search** page has **Timestamp type** set to **Initiated** by default. Before the Timestamp type selection was introduced, the Timestamp type used by the **Time range** filter was **Disconnected**.
- Saved searches on **Contact search** created before the launch of the ability to search for in-progress contacts (launched September 2023) have been updated with the filters **Contact status = Completed** and **Timestamp type = Disconnected**. These selections were implied before the launch of in-progress contacts.

View in progress contacts

You can choose a Contact ID within the **Contact search** results to view details of an in-progress contact.



Important things to know

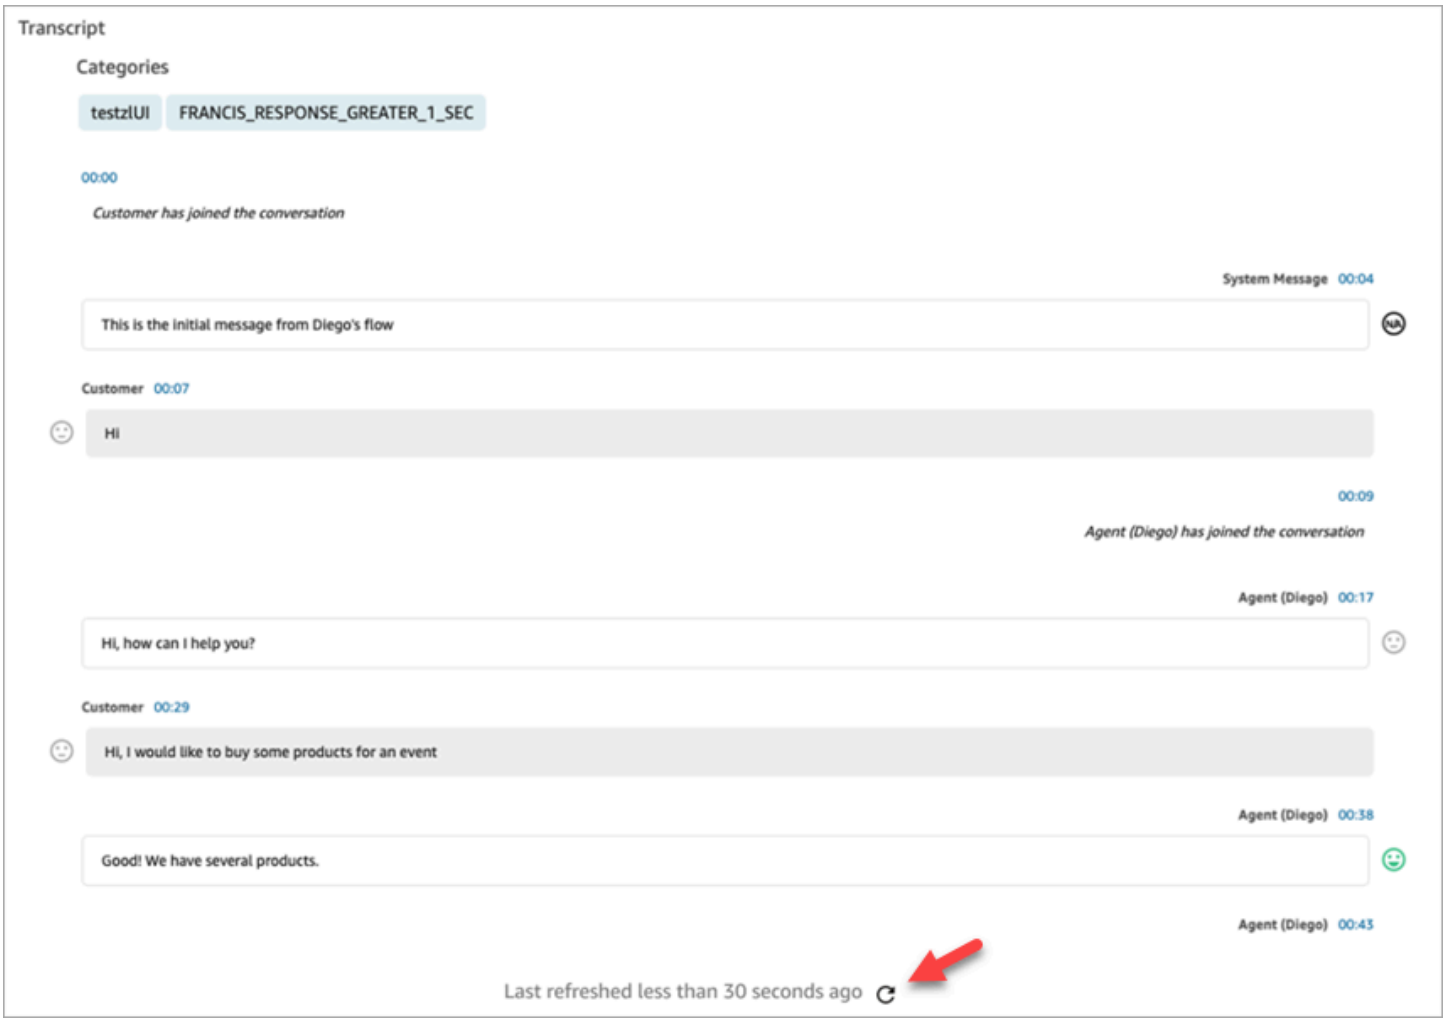
- The **Contact details** page for an in-progress contact shows data available at the time **Contact details** page was opened. It does not automatically refresh as the contact progresses. You need to refresh the page manually using your browser.
- Certain fields on **Contact search** and might have missing or inconsistent information while the contact is in progress. After a contact is completed, information is eventually made consistent with the underlying contact record, after the page is manually refreshed.
- There might be a delay between the contact being **Completed** and the contact being marked as **Completed** on the contact record.

Review real-time transcripts

For voice contacts, with real-time call analytics enabled, you can view transcripts of a contact in real-time on a **Contact details** page if you have the security profile permission **Contact transcripts (unredacted) - Access**.

> **Note**
>
> Redaction is not supported for in-progress voice contacts. Users with **Contact transcripts (unredacted) - Access** can not view in-progress voice contacts.

Choose the refresh icon on the bottom of the transcript to pull the latest available turns of the conversation. The following image shows the location of the refresh icon on the page.



Search for contacts in Connect Customer by using custom contact attributes or contact segment attributes

You can create search filters based on custom contact attributes (also called user-defined contact attributes) or contact segment attributes.

For example, if you add `AgentLocation` and `InsurancePlanType` to your contact records as custom attributes, you can search for contacts with specific values in these attributes, such as calls handled by agents located in Seattle, or calls made by customers who purchased homeowners insurance.

Topics

- Required permissions to configure searchable contact attributes

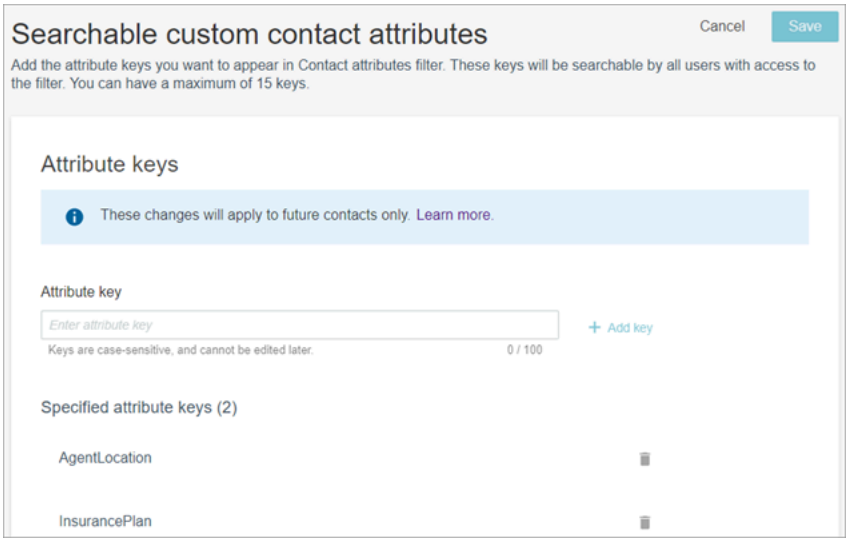
- Configure searchable custom contact attributes
- Edit, add, or remove contact attributes
- Filter contact search results on contact attributes
- Filter contact search results on contact segment attributes

Required permissions to configure searchable contact attributes

By default, a custom attribute isn't indexed until someone with appropriate permissions, such as an admin or manager, specifies it should be searchable. You grant permissions to select users so they can configure which custom contact attributes can be added as a search filter.

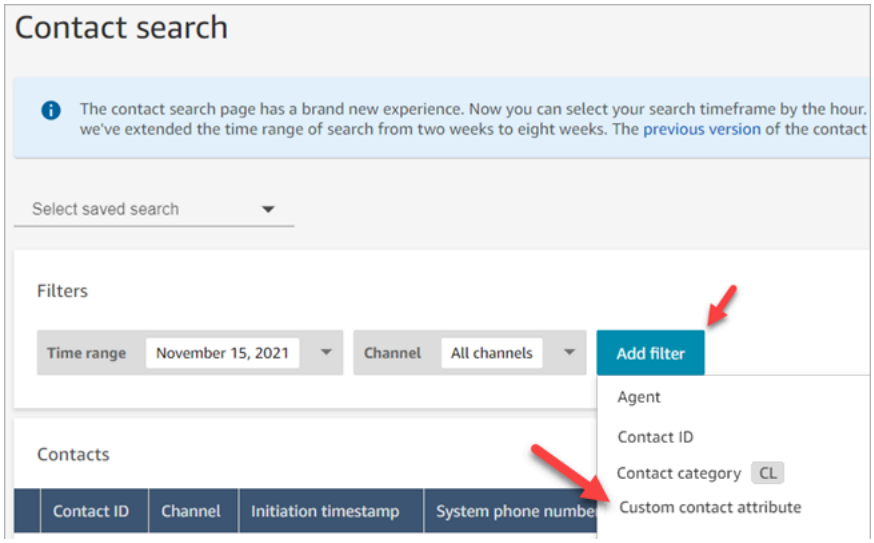
Assign the following permissions to their security profile:

- Enable one of the following permissions to access the **Contact Search** page:
  - **Contact search**. You can search for all contacts.
  - **View my contacts**: Allows agents to view only those contacts that they handled.
- **Contact attributes**: Allows users to view contact attributes. Also controls access to the search filters based on contact attributes.
- **Configure searchable contact attributes** - **All**: People who have this permission determine what custom data will be searchable (by people who have the **Contact attributes** permission). It allows them to access the following configuration page:

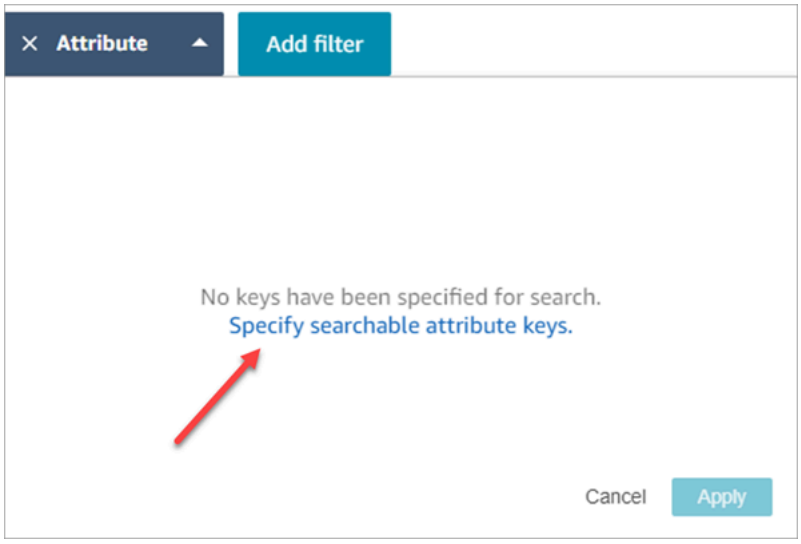


Configure searchable custom contact attributes

1. On the **Contact search** page, choose **Add filter**, **Custom contact attribute**. Only people with **Configure searchable contact attributes** permissions in their security profile see this option.



2. The first time you choose **Custom contact attribute**, the following box appears, indicating no attributes have been configured for this Connect Customer instance. Choose **Specify searchable attribute keys**.



3. In the **Attribute key** box, type the name of your custom attribute, and then choose **Add key**.

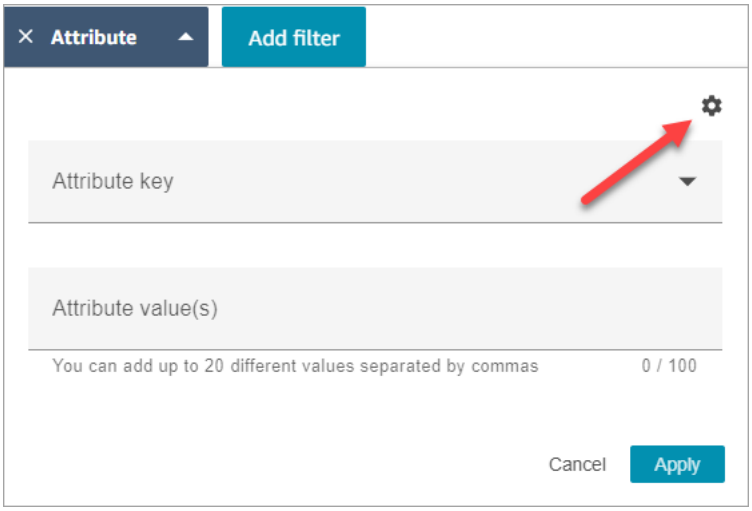
> **Important**
>
> You must type the exact key name. It is case sensitive.

4. When finished, choose **Save**.

Your users will be able to search on these keys for any future contacts.

Edit, add, or remove contact attributes

To edit, add, or remove keys, choose **Attribute**, **Settings**. If you don't see the **Settings** option, you don't have the required permissions.



Filter contact search results on contact attributes

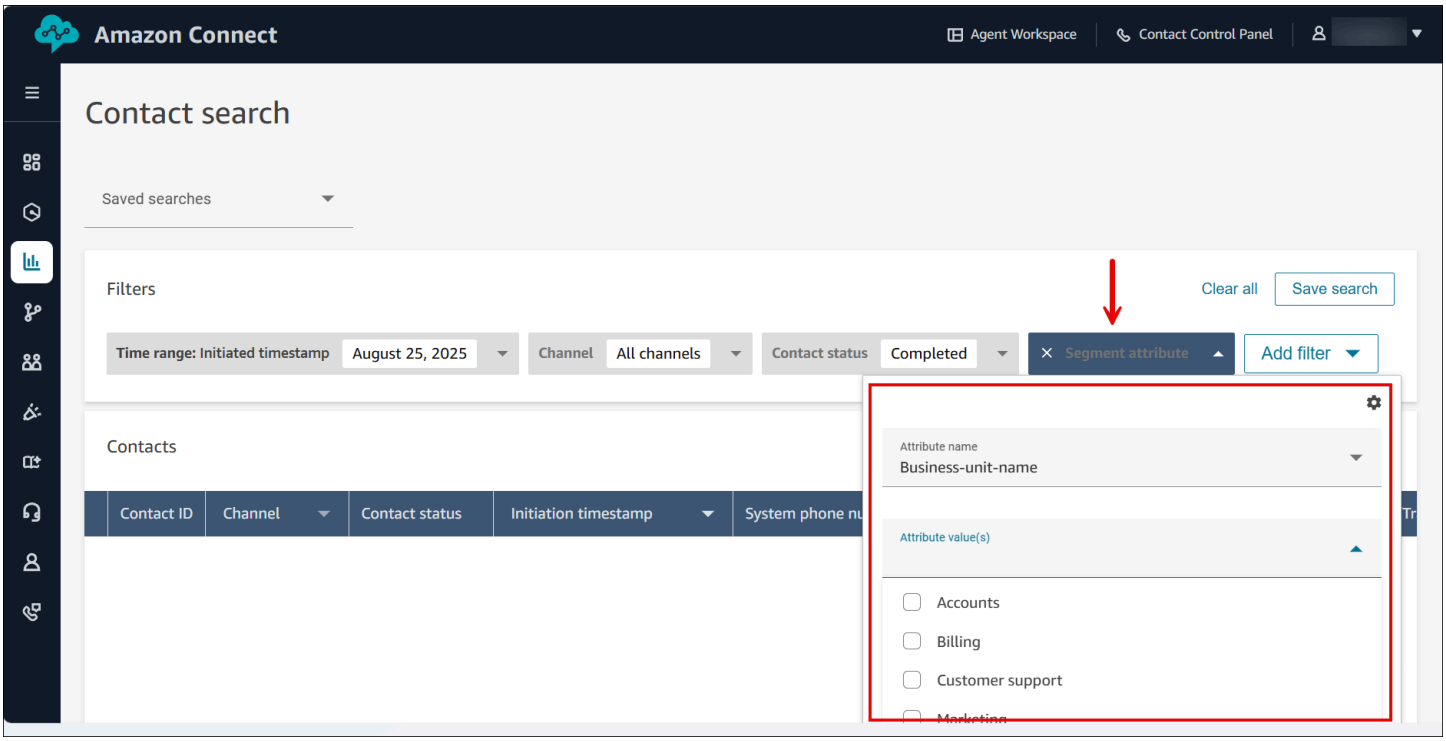
Users who have the **Contact attributes** permission in their security profile can find contacts by using the contact attribute filters.

1. On the **Contact search** page, choose **Add filter**, **Custom contact attribute**, and then choose **Specify searchable attribute keys**.
2. On the **Searchable customer contact attributes** page, in the **Attribute key** box, enter the attribute key, and choose **+Add key** and then choose **Save**.
3. Return to the **Contact search** page. Use **Add filter** to choose from the dropdown menu the attribute you just added. In the **Attribute value box**, enter the value you want to find.

Filter contact search results on contact segment attributes

After you create predefined attributes and attached them to a contact segment (explained in Use contact segment attributes), you can filter contact search results based on the segment attribute values.

The following image shows the **Contact search** page, and the option to filter contact search results based on custom segment attribute values.



1. On the **Contact search** page, under the **Add filter** drop-down, select **Custom contact segment attributes**.
2. Select the predefined attribute you want to apply to filtering criteria. For example, the previous images shows Business-unit-name as the **Attribute name**.
3. If the selected predefined attribute has established values, they are listed under **Attribute value(s)** as a multi-selection choice. For example, the previous image shows Accounts, Billing, Customer Support, and Marketing as options.
4. Choose **Apply**.

Monitor live and recorded conversations using Connect Customer conversational analytics

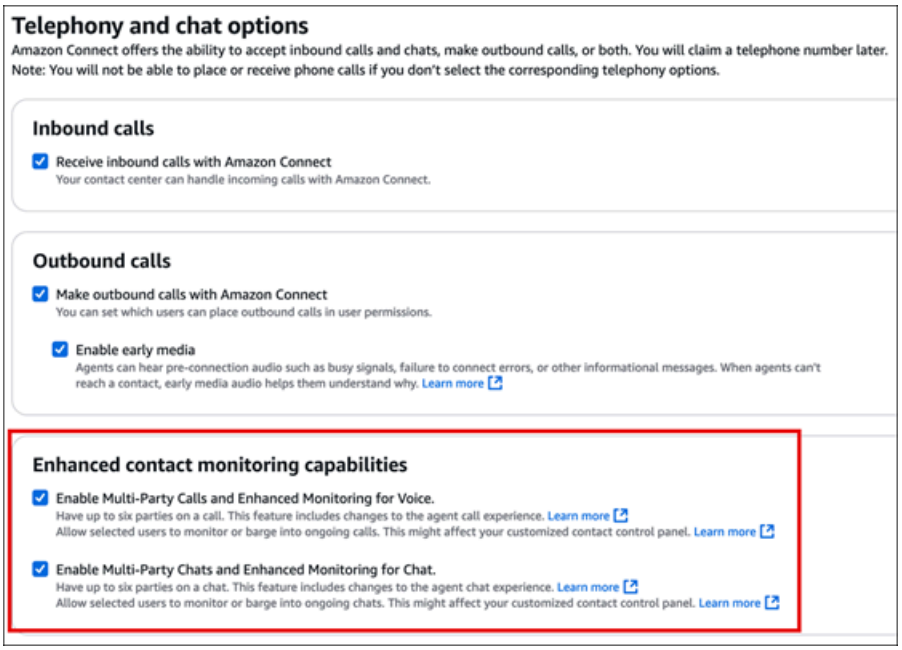
Managers can monitor or listen-in to live conversations between agents and contacts. They can also review and download recordings of past interactions for both automated interactions (IVR) and agent interactions.

Connect Customer provides two options to set up contact monitoring:

- **Multi-party contacts**: Monitor live conversations that have up to six participants. There's no additional charge for this option.

  With this option, you can barge into live conversations (voice and chats), and record chat transcripts.

  You enable this capability on the Connect Customer console by choosing **Enable Multi-Party Calls and Enhanced Monitoring for Voice** and **Enable Multi-Party Chats and Enhanced Monitoring for Chat**, as shown in the following image.



- **Three-party voice contacts**: Monitor conversations that have up to three participants. This is the default behavior. There's no additional charge for this option.

  You cannot barge into calls or chats.

  You enable this capability by adding a Set recording and analytics behavior block to your flow.

How agents manage the conferencing experience is very different between these two options. Enhanced monitoring provides more functionality for the agents. See Comparison of enhanced contact monitoring (multi-party) and three-party functionality in Connect Customer.

> **Important**
>
> New events are added to the agent event stream when you choose **Enhanced contact monitoring capabilities**.

If you choose to start with the default three-party capability enabled by the Set recording and analytics behavior block, and then later switch to **Enhanced contact monitoring capabilities**, know that new events will be added to the agent event stream. This will cause problems if you have customized your contact center based on the previous agent event stream.

When, what, and where for contact recordings in Connect Customer

This topic explains when conversations are recorded, where recordings are stored, and how to access them. It also provides best practices for managing recordings and transcripts.

Topics

- When is a conversation recorded?
- Where are recordings and transcripts stored?
- When are recordings available?
- Prevent agents from accessing recordings
- Headset requirements for listening to recordings

When is a conversation recorded?

- The call recording feature has options for choosing whether to record the customer and system audio during IVR interactions or any combination of customer, agent, or both during agent interactions.
- There are a total of two possible recordings per contact: one for automated interactions (that is, IVR) and one for agent interactions. Enabling or disabling recording for automated interactions takes effect immediately. Conversely, modifying recording for agent interactions only takes effect after the agent joins the call.
- Agent audio is NOT transmitted to Connect Customer when the agent is not on a call. On November 9, 2023, Connect Customer deployed an optimization to improve agent productivity that pre-configures the microphone media stream of the agent's browser before the contact arrives. This reduces setup time for both incoming and outgoing calls. As a result, the microphone icon in the agent's browser appears to be on, even when the agent is not on a call.
- When a customer is on hold during agent interaction, the agent is still recorded.
- The transfer conversation between agents is recorded.
- When a call is transferred during a flow or IVR interaction (for example, by using the Transfer to phone number block) the recording continues to capture what the customer says and hears even after they are tranferred to an external voice system.
- Any transfers to external numbers during the agent interaction are not recorded after the agent leaves the call.
- If a participant mutes their own microphone, for example, to consult with a someone sitting next to them, their side-bar conversation is not recorded.

Where are recordings and transcripts stored?

Agents and contacts are stored on separate, stereo audio channels.

- For automated (IVR) interactions, the stereo file contains customer audio in the right channel and system prompts in the left channel.
- For agent interactions, the agent audio is stored in the right channel and customer (as well as conferenced third parties) audio in the left channel.

Recordings are stored in the Amazon S3 bucket that are created for your instance. Any user or application with the appropriate permissions can access the recordings in the Amazon S3 bucket.

Encryption is enabled by default for all call recordings using Amazon S3 server-side encryption with KMS. The encryption is at the object level. The reports and recording objects are encrypted; there's no encryption at the bucket level.

You shouldn't disable encryption.

Important

- For voice conversations to be stored in an Amazon S3 bucket, you need to enable recording in the flow block using the Set recording and analytics behavior block.
- For chat conversations, if there's an S3 bucket for storing chat transcripts, then all chats are recorded and stored there. If no bucket exists, then no chats are recorded. However, if you want to monitor chat conversations, you still need to add the Set recording and analytics behavior block to the flow.
- If a recording is moved from one S3 bucket to another for any reason, such as the retention period has expired, then the recording will no longer be accessible by Connect Customer.

Tip

We recommend using the contact ID to search for recordings.
Even though many call recordings for specific contact IDs might be named with the contact ID prefix itself (for example, 123456-aaaa-bbbb-3223-2323234.wav), there is no guarantee that the contact IDs and name of the contact recording file *always* match. By using **Contact ID** for your search on the Contact search page, you can find the correct recording by referring to the audio file on the contact record.

When are recordings available?

When the recording for an agent interaction is enabled, the recording is placed in your S3 bucket shortly after the contact is disconnected. When IVR recording is enabled, the recording is placed in your S3 bucket shortly after the contact is disconnected or after the call is answered by an agent. You can review the recording for both agent interactions and automated interactions (IVR).

Important

You can also access the recording from the customer's contact record. The recording is available in the contact record, however, only after the contact has left the After Contact Work (ACW) state. The IVR recording becomes available shortly after the call gets connected to the agent or contact is disconnected.

Tip

Connect Customer uses the Amazon S3 PutObject and MultipartUpload APIs to upload the call recording to your S3 bucket. If you are using S3 Event Notifications when call recordings are uploaded successfully to your bucket, make sure you enable the notification for **All object create events**, or for both *s3:ObjectCreated:Put* and *s3:ObjectCreated:CompleteMultipartUpload* event types.

Prevent agents from accessing recordings

To prevent agents from accessing recordings outside of their agent hierarchy, assign them the **Restrict contact access** security profile permission. For more information, see Assign permissions to review past contact center conversations in Connect Customer.

Headset requirements for listening to recordings

You need to use an output device (headset or other device) that supports stereo output so you can hear both the agent and customer audio.

Agent and customer recordings are presented in two separate channels. With a full headset, each side will play one channel. But for a one-ear headset, there isn't a mechanism to mix two channels into one.

How to set up S3 Object Lock for immutable call recordings

You can use Amazon S3 Object Lock in combination with your recording bucket to help prevent call recordings and IVR recordings from being deleted or overwritten for a fixed amount of time, or indefinitely.

Object Lock adds another layer of protection against object changes and deletion. It can also help meet regulatory requirements for Write-Once-Read-Many (WORM) storage.

Important things to know

- You can enable Amazon S3 Object Lock on new and existing buckets.
- You must enable versioning on your call recording bucket.
- After you enable Amazon S3 Object Lock, you cannot remove it.
- We recommend using a dedicated call recording bucket because all objects will be locked after the default Object Lock retention policy is applied.
- Make sure that your retention policy is appropriate for your requirements. After the policy is configured, your call recordings will be protected from deletion for the duration specified.
- We strongly recommended you thoroughly test the policy in a non-production environment before implementing it in production.

Step 1: Create an S3 bucket with Object Lock enabled

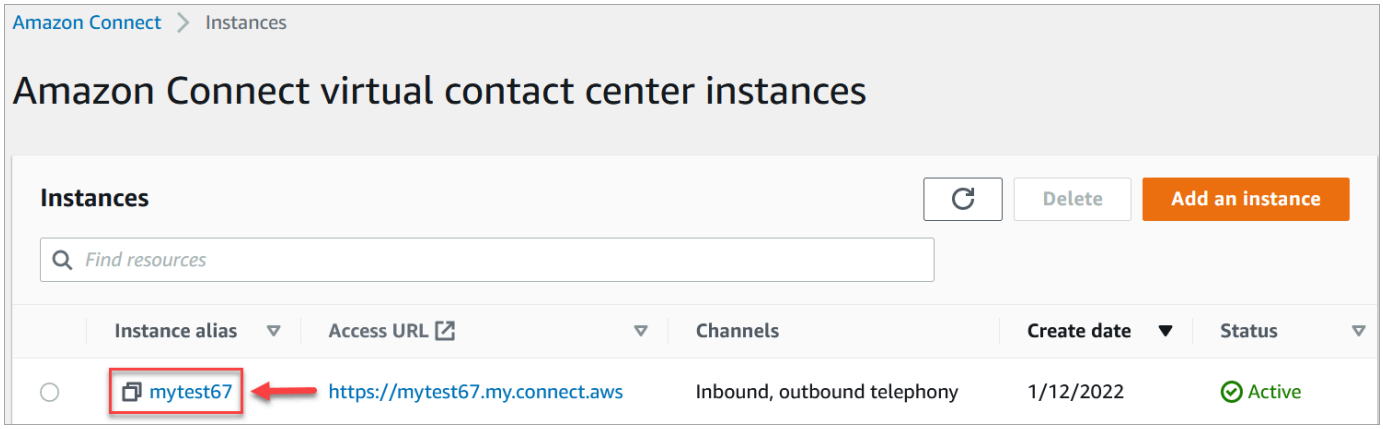
For a tutorial on creating a new S3 bucket with Object Lock enabled, see Protect Data on Amazon S3 Against Accidental Deletion or Application Bugs Using S3 Versioning, S3 Object Lock, and S3 Replication.

Step 1A: Enable Object Lock for an existing Amazon S3 bucket

For information about enabling Object Lock on an existing bucket, see Enable Object Lock on an existing Amazon S3 bucket, in the *Amazon S3 User Guide*.

Step 2: Configure Connect Customer to use the S3 bucket for call recordings

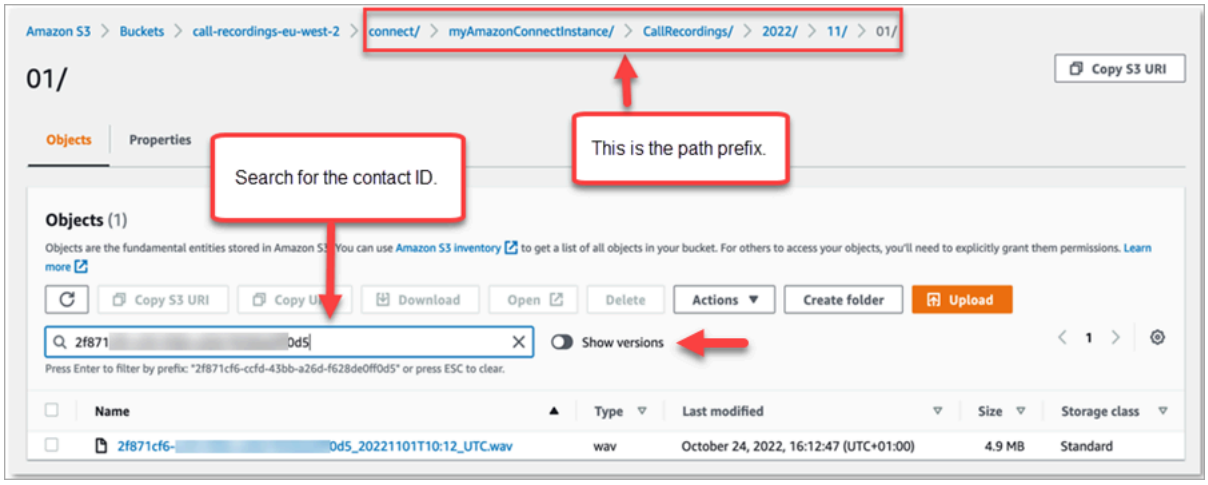
1. Open the Connect Customer console at https://console.aws.amazon.com/connect/.
2. On the instances page, choose the instance alias.



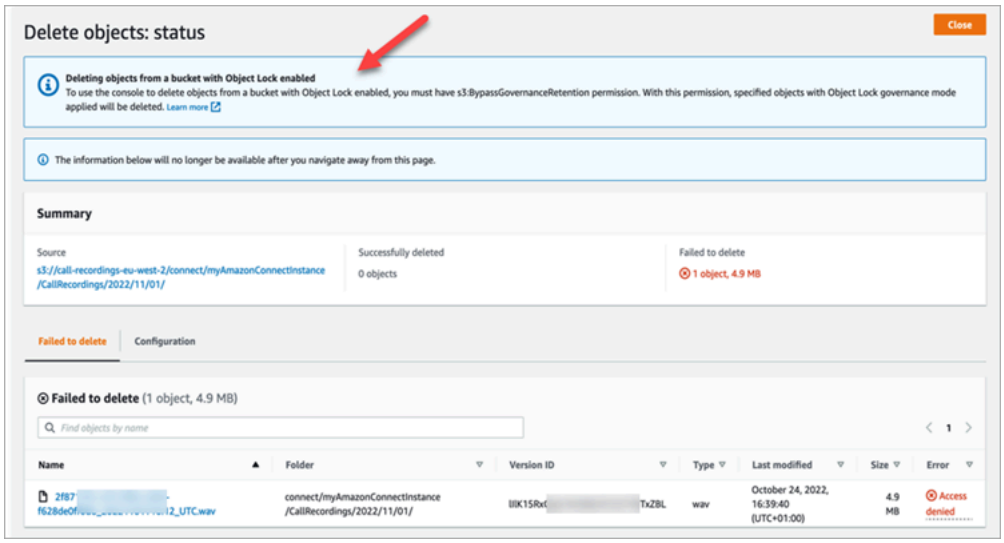
3. In the navigation pane, choose **Data storage**.
4. In the **Call recordings** section, choose **Edit**.
5. Choose **Select an existing S3 bucket**, and then in the **Name** dropdown box choose the bucket that you enable Object Lock for.
6. Choose **Save**.

Step 3: Test Object Lock is enabled

1. Make a test call to your contact center to generate a call recording.
2. Log in to Connect Customer at https://*your-instance*.my.connect.aws/home, with an Admin account, or an account that has permissions to search for contacts.
3. Choose **Analytics and optimization**, **Contact search**. Search for your call recording to find the contact ID. Copy the contact ID. You're going to use it in the next step to locate the call recording in your S3 bucket.
4. Open the Amazon S3 console, select the bucket you created in Step 1, and follow the path prefix. The path to the call recording includes the year, month, and day the recording was made. After you're in the correct path prefix, search for the contact ID of the call recording.



5. Select the **Show versions** toggle next to the **Search** box. With this option, you can attempt to delete the object instead of only applying a delete marker. Applying a delete marker is the standard behavior when you delete an object from an S3 bucket with versioning enabled.
6. Select the call recording (the box to the left of the recording name), and then choose **Delete**. In the confirmation box, enter **permanently delete** and select **Delete objects**.
7. Review the **Delete objects: status** notification to confirm that the delete operation has been blocked due to the Object Lock policy.



Comparison of enhanced contact monitoring (multi-party) and three-party functionality in Connect Customer

This topic describes how the agent's experience differs when enhanced contact monitoring (multi-party) is enabled instead of the default three-party capability.

For information about new functionality in the existing Connection and Contact API in Connect Customer Streams, see the Connect Customer Streams Readme.

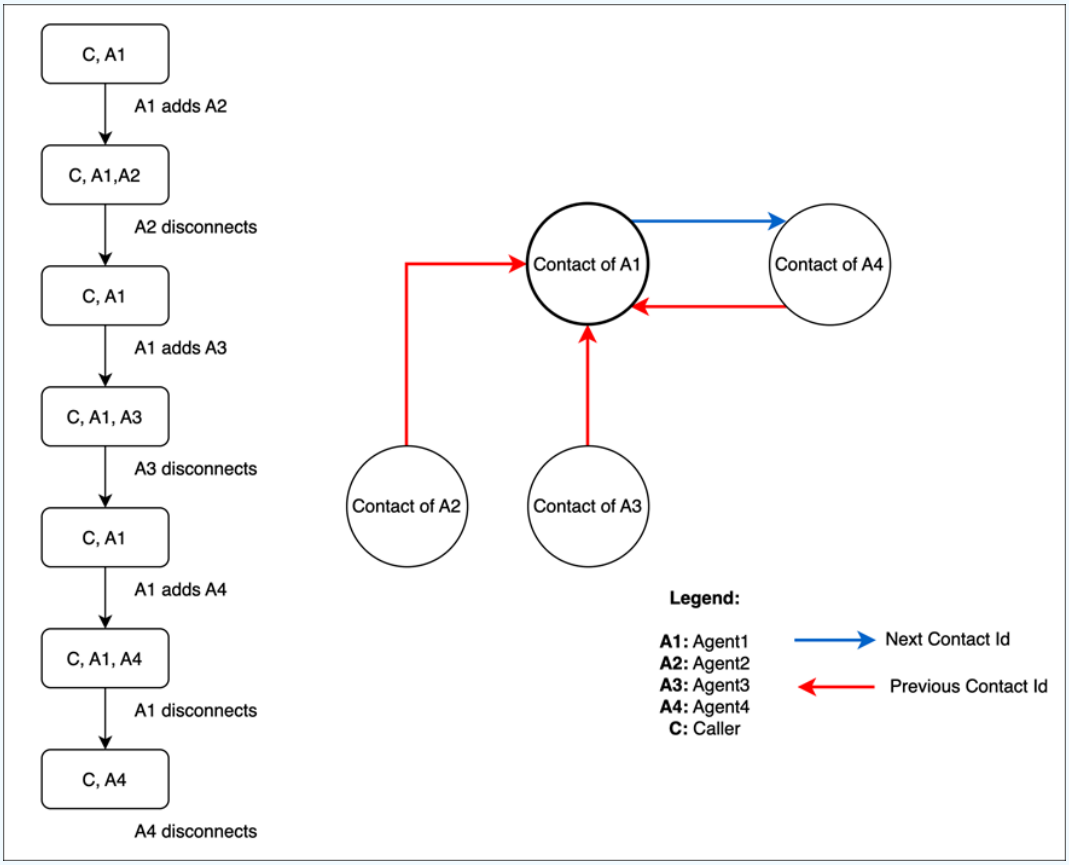
Following are key features for agents who use multi-party monitoring:

- All agents see all of the connections in a call.
- All agents have exactly the same capabilities as any other agent on the call. This takes effect the moment an agent accepts the invitation to join the call.
- Before a warm transfer is complete, an agent can start talking to the caller as well as disconnect any other agent on the call.

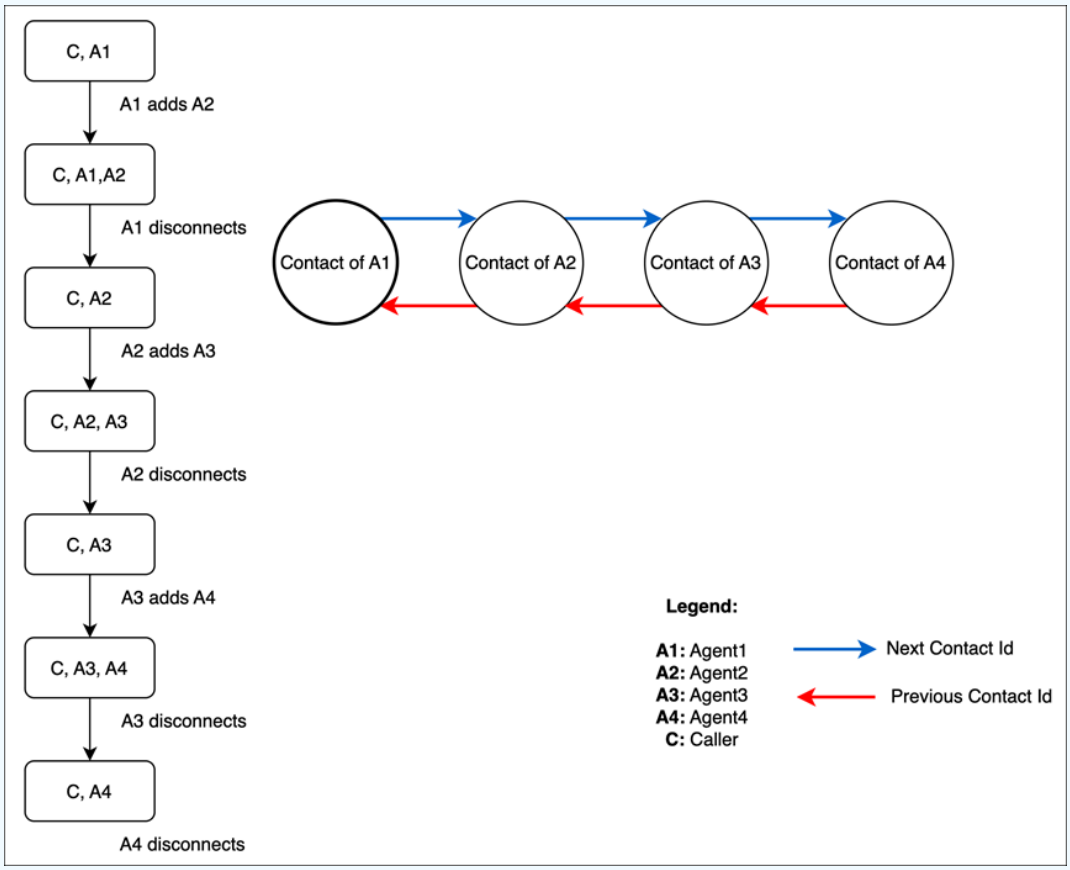
Note

When calls have three or more participants, agents can add participants to the call even after a caller drops.

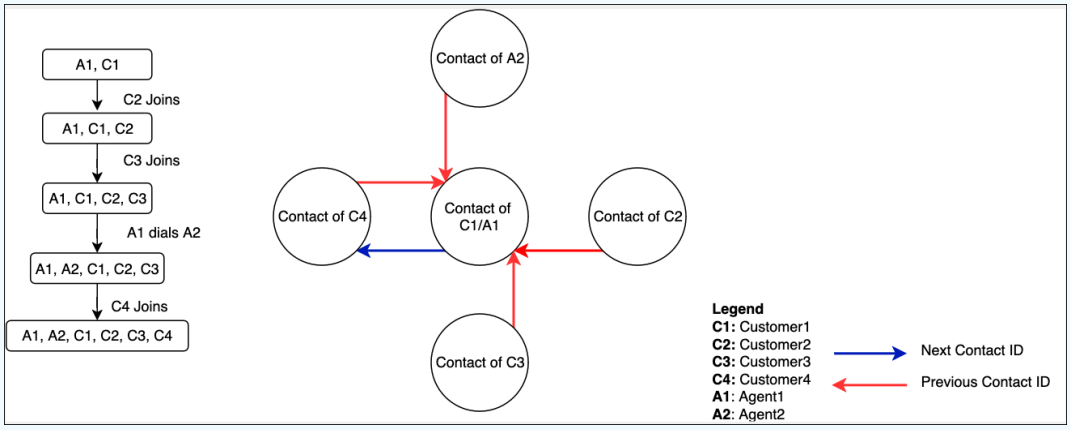
The following example illustrates how previous and next contact IDs are mapped when an agent performs a series of consults followed by a transfer.



The following example illustrates how previous and next contact IDs are mapped in a scenario where agents perform a series of transfers.



The following example illustrates how previous and next contact IDs are mapped in a scenario where additional web, in-app, and video calling users are added



The following table summarizes the differences between the agent's experience using the Contact Control Panel (CCP) for three-party calls and multi-party calls. For more information about the

agent's experience with multi-party conversations, see Host multi-party calls and Host multi-party chats.

- Primary agent: the first agent on the call.
- Secondary agent: any agent other than the first agent on the call.

Three-party calls	Multi-party calls
Agent can control hold, resume, and disconnect only the parties they add.	All agents have the same call control capabilities.
Agent can add one other participant to an existing call, for a total of three participants (the agent, the caller, and another participant).	Any agent on the call can add additional participants, as long as the total number of participants on the call, including themselves, does not exceed six. **Note** When calls have three or more participants, agents can add participants to the call even after a caller drops.
Agent can put only the party they added on hold.	Any agent on the call can put any party on hold.
When a primary agent places a secondary agent on hold, the secondary agent can't take themselves off hold.	Any agent on the call can take themselves off hold.
Secondary agent can talk to the primary agent during hold.	Secondary agents cannot talk to each other until they are taken off hold.
Primary agent can only mute themselves. Secondary agent can only mute themselves.	Any agent on the call can mute any other participant on the call.
An agent can only unmute themselves, not another agent.	An agent can only unmute themselves, not another agent.

Three-party calls	Multi-party calls
	Note However, an agent can unmute participants who are not agents.
When an agent disconnects (leaves or is disconnected), call control continues to be available to the remaining agent(s) on the call.	When an agent disconnects, control of the call is transferred to the remaining agents.
Only the primary agent can disconnect a party on the call. The secondary agent can disconnect the caller only if the primary agent has disconnected.	All agents have the capability to disconnect any other party.
The primary agent can see two connections (caller and another party), while a secondary agent sees only the transfer connection.	All agents can see all connections.
An agent only sees **internal transfer** for another agent on the call.	An agent sees the quick connect ID for other agents, instead of just **internal transfer**.
Not applicable.	When a party is being dialed, an agent on a multi-party call cannot add another party until the prior dial operation is completed (party added or call leg terminated).
Additional WebRTC users cannot be added.	Additional WebRTC users can be added.

Enable enhanced multi-party contact monitoring in Connect Customer

Enhanced contact monitoring applies to voice calls and all supported types of chats: chat/SMS, WhatsApp, and Apple Messages for Business.

Calls

Enhanced contact monitoring enables agents to host up to 6 participants on a call. Two supervisors can monitor the call. It also enables managers to barge into conversations.

For example, agents can have a group of six participants in the call at the same time. Two supervisors can monitor the call. The two supervisors can do two silent monitor sessions, or one silent monitor and one barge-in session.

The total number of participants on a call would look like this:

1. Customer - participant
2. Agent 1 - participant
3. Agent 2 - participant
4. Agent 3 - participant
5. Agent 4 - participant
6. Agent 5 - participant
7. Supervisor who can listen but not barge in the call
8. Supervisor who can listen or barge in the call

There is no limit to the number of conversations that can be monitored in an instance.

Chats

Enhanced contact monitoring enables agents to host four additional participants on an ongoing customer service chat, for a total of six participants: the agent, the customer, and four other people. Agents can use quick connects to add participants.

Regardless of whether the enhanced contact monitoring capability is enabled for an instance, you can have up to five people monitor a chat at the same time. Only one supervisor can be in barged in mode for a given chat.

The total number of participants on the chat would look like this:

1. Customer
2. Agent
3. Supervisor who can monitor the chat and barge in
4. Supervisor who can monitor the chat but not barge in

5. Supervisor who can monitor the chat but not barge in
6. Supervisor who can monitor the chat but not barge in
7. Supervisor who can monitor the chat but not barge in

Important things to know

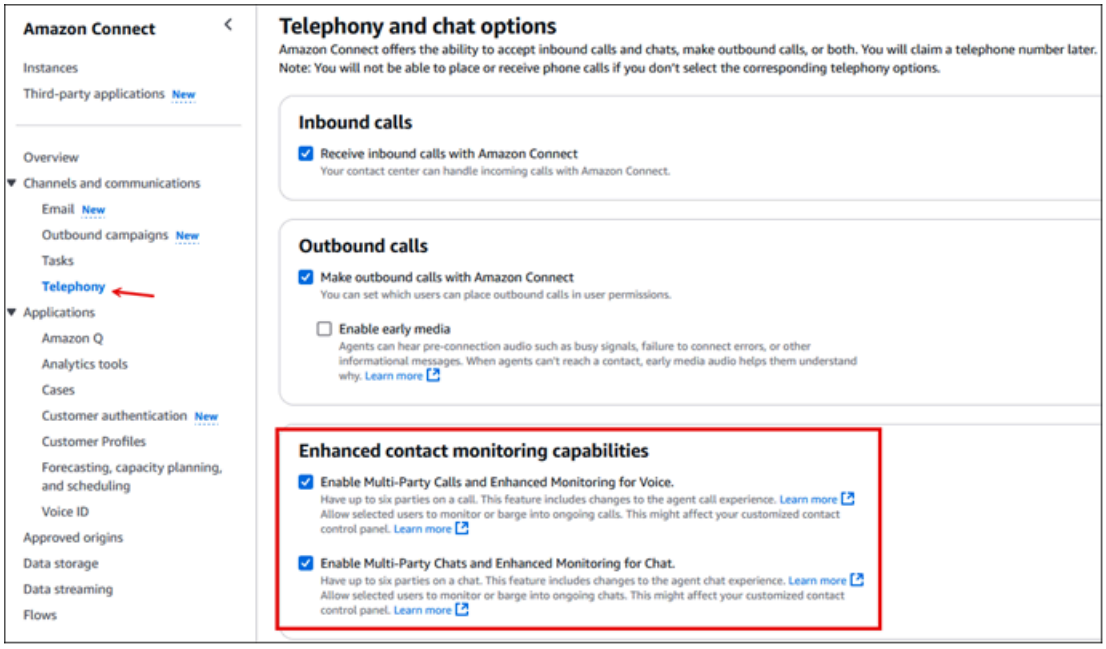
- New events are added to the agent event stream when you choose **Enhanced contact monitoring capabilities** on the Connect Customer console.

  However, if you instead choose to start with the default three-party capability enabled by the Set recording and analytics behavior block, and then later switch to **Enhanced contact monitoring capabilities**, know that new events will be added to the agent event stream. This will cause problems if you have customized your contact center based on the previous agent event stream.
- If you do not enable **Enhanced contact monitoring capabilities** at the instance level, you need to add and configure a Set recording and analytics behavior block to your flow in order to get the chat monitoring and barge features.
- By default, calls can have three participants, such as two agents and a caller, or an agent, a caller, and an external party. When you enable enhanced contact monitoring, the agent's experience changes. See Comparison of multi-party and three-party functionality.
- All agents have a ParticipantRole of 'AGENT' in the transcript. Supervisors have a ParticipantRole of 'SUPERVISOR' in the transcript.
- The initiation method for the contact where the agent is invited is TRANSFER. For information about how to distinguish in reporting how often a participant is being invited instead of being transferred to, see Identify conferences and transfers by using Connect Customer contact records.
- This feature is only available in CCPv2. That is, the URL to access the CCP is `https://instance name.my.connect.aws/ccp-v2/` and the URL to access the agent workspace is `https://instance-name.my.connect.aws/agent/`. It's also available in custom CCP using Connect Customer Streams.js.
- Before enabling the multi-party calls, if you are using conversational analytics or planning to do so in the future, see Multi-party calls and conversational analytics. conversational analytics supports calls with up to 2 participants. We recommend that you disable conversational analytics in the Set recording and analytics behavior block for contacts that are expected to have 3 and more participants.

- In custom CCPs, use the updated Connect Customer Streams API to enable multi-party calling, up to six parties. See the Connect Customer Streams documentation on GitHub.
- AWS GovCloud (US-West): You can't enable this feature using the console user interface. Instead, use the UpdateInstanceAttribute API or contact AWS Support.

How to enable enhanced multi-party contact monitoring

1. In the Connect Customer console, on the menu pane, choose **Telephony**.
2. On the **Telephony and chat options** page, scroll to the **Enhanced contact monitoring capabilities** section.



3. Choose the options you want to enable, and then choose **Save**.
4. Log in to the Connect Customer admin website. Assign security profile permissions to managers so they can monitor and barge live conversations, and review recordings.
5. Show managers how to monitor live conversations, barge live conversations and review past recordings in Connect Customer.

Enable three-party call monitoring in Connect Customer

Important

This topic applies only if you have **NOT** enabled **Enhanced contact monitoring capabilities** on the Connect Customer console as explained in Enable enhanced multi-party contact monitoring.
It only applies to voice calls that are limited to three parties or less.
For information about how the conferencing experience differs for agents when enhanced monitoring capabilities are enabled, see Comparison of multi-party and three-party functionality.
We recommend choosing three-party monitoring only if you have an external system that imposes a technical constraint that requires you to choose this option. Otherwise, enhanced monitoring is the way to go. There is no pricing difference.

You can add and configure a Set recording and analytics behavior block to your flows to enable 3 participants on a contact, and 5 supervisors monitoring the call. Managers cannot barge in to a call.

For example, you can have a group of 3 participants on the call at the same time. Up to 5 supervisors can monitor the call.

The total number of participants on a call would look like this:

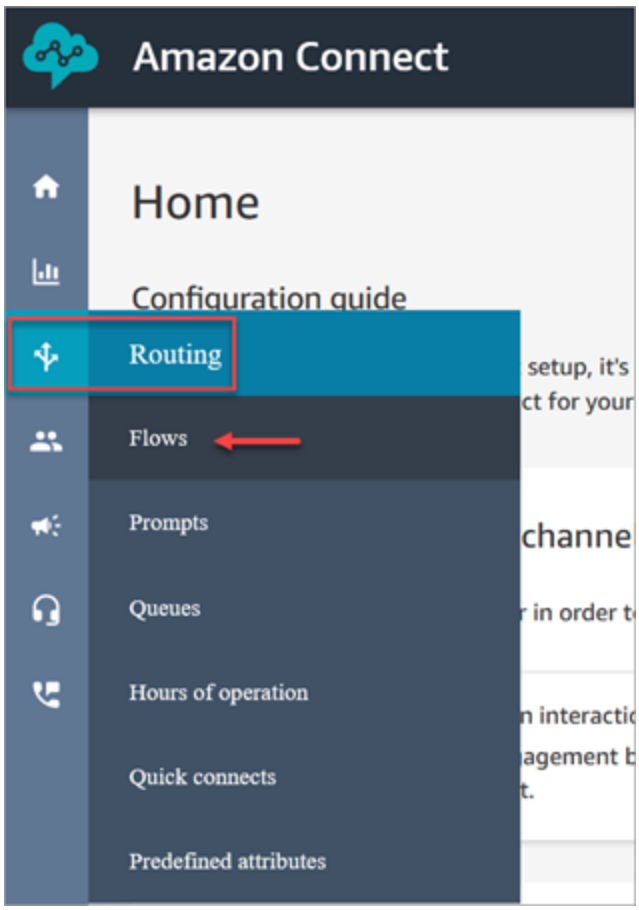
1. Customer - participant
2. Agent 1 - participant
3. Agent 2 - participant
4. Supervisor who can listen but not barge in the call
5. Supervisor who can listen but not barge in the call
6. Supervisor who can listen but not barge in the call
7. Supervisor who can listen but not barge in the call
8. Supervisor who can listen but not barge in the call

To view a sample flow with the **Set recording behavior** block configured, see Sample recording behavior in Connect Customer.

> **Note**
>
> We recommend using the **Set recording behavior** block in an inbound or outbound whisper flow for the most accurate behavior.
> Using this block in a queue flow does not always guarantee that calls are recorded. This is because the block might run after the contact is joined to the agent.

To set up monitoring for three-party contacts

1. Log in to your Connect Customer instance using an account that has permissions to edit flows.
2. On the navigation menu, choose **Routing**, **Flows**.



3. Open the flow that handles customer contacts you want to monitor.
4. In the flow, before the contact is connected to an agent, add a Set recording and analytics behavior block to the flow.

5. To configure the Set recording and analytics behavior block, under **Agent and customer voice recording**, choose **On** and then choose **Agent and Customer**. This only takes effect after the agent joins the call.
6. Choose **Save** and then **Publish** to publish the updated flow.
7. Assign security profile permissions to managers monitor conversations.
8. Show managers how to monitor conversations.

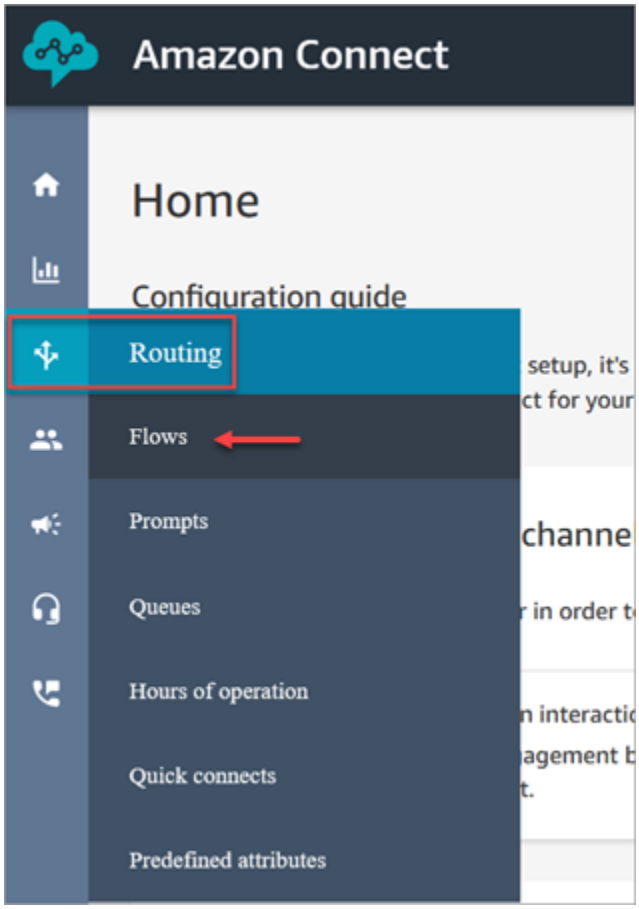
Enable contact recording

To enable the recording of voice conversations, you need to add a Set recording and analytics behavior block to your flow. You need to do this regardless of whether your Connect Customer instance is enabled for multi-party contacts (enhanced contact monitoring) or third-party contacts.

> **Important**
>
> **Chats**: You only need to perform these steps for chat conversations if enhanced contact monitoring for chat contacts is not enabled for your instance. Otherwise, chat transcripts are automatically recorded because an S3 bucket was created to store them when you set up your instance. To stop recording chat transcripts, remove the S3 bucket.

To set up recording of conversations

1. Log in to your Connect Customer instance using an account that has permissions to edit flows.
2. On the navigation menu, choose **Routing**, **Flows**.



3. Open the flow that handles customer contacts you want to record.
4. In the flow, before the contact is connected to an agent, add a Set recording and analytics behavior block to the flow.
5. To configure the Set recording and analytics behavior block, choose from the following:

   - Automated interaction call recording
     - **On** starts recording customer and IVR audio immediately.
     - **Off** pauses any ongoing IVR recording.
   - Agent and customer voice recording
     - When **On**, you can select from Agent and Customer, Agent only, or Customer only. This only takes effect after the agent joins the call.
     - When **Off**, no recording is captured when the agent joins the call.
   - To record chat conversations, choose **Agent and Customer**.

> **Important**
>
> You only need to perform these steps for chat conversations if enhanced contact monitoring for chat contacts is not enabled for your instance. Otherwise, chat transcripts are automatically recorded because an S3 bucket was created to store them when you set up your instance. To stop recording chat transcripts, remove the S3 bucket.

6. Choose **Save** and then **Publish** to publish the updated flow.
7. Assign security profile permissions to managers so they can review recordings.
8. Show managers how to access past recordings in Connect Customer. See Review recorded conversations.

To set up recording behavior for outbound calls

1. Create a flow, using the outbound whisper flow type.
2. Add a Set recording and analytics behavior block to that flow.
3. Set up a queue that will be used for making outbound calls. In the **Outbound whisper flow** box, choose the flow that has Set recording and analytics behavior in it.

To set up human readable logs that contain key interaction points with Amazon Lex V2

1. Log in to the Connect Customer console.
2. On the navigation menu, choose **Flows**.
3. Scroll down the page, choose **Enable Bot Analytics and Transcripts in Connect Customer**, and then choose **Save**.
4. In the Connect Customer admin website, assign security profile permissions to managers so they can view details of the interaction with DTMF menus and Lex bots and/ or additional information about flows.

Assign permissions to monitor live conversations in the Connect Customer Contact Control Panel (CCP)

For managers to monitor live conversations, you assign them the **CallCenterManager** and **Agent** security profiles. To allow agent trainees to monitor live conversations, you might want to create a security profile specific for this purpose.

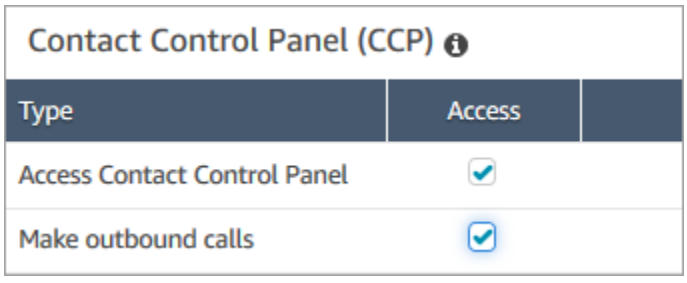
To assign a manager permissions to monitor a live conversation

1. Go to **Users**, **User management**, choose the manager, and then choose **Edit**.
2. In the Security Profiles box, assign the manager to the **CallCenterManager** security profile. This security profile also includes a setting that makes the icon to download recordings appear in the results of the **Contact search** page.
3. Assign the manager to the **Agent** security profile so they can access the Contact Control Panel (CCP), and use it to monitor the conversation.
4. Choose **Save**.

To create a new security profile for monitoring live conversations

1. Choose **Users**, **Security profiles**.
2. Choose **Add new security profile**.
3. Expand **Analytics and optimization**, then choose **Access metrics** and **Real-time contact monitoring**.

   Access metrics is needed so they can access the real-time metrics report, which is where they choose which conversations to monitor.
4. Expand **Contact Control Panel**, then choose **Access Contact Control Panel** and **Make outbound calls**.



These permissions are needed so they can monitor the conversation through the Contact Control Panel.

5. Choose **Save**.

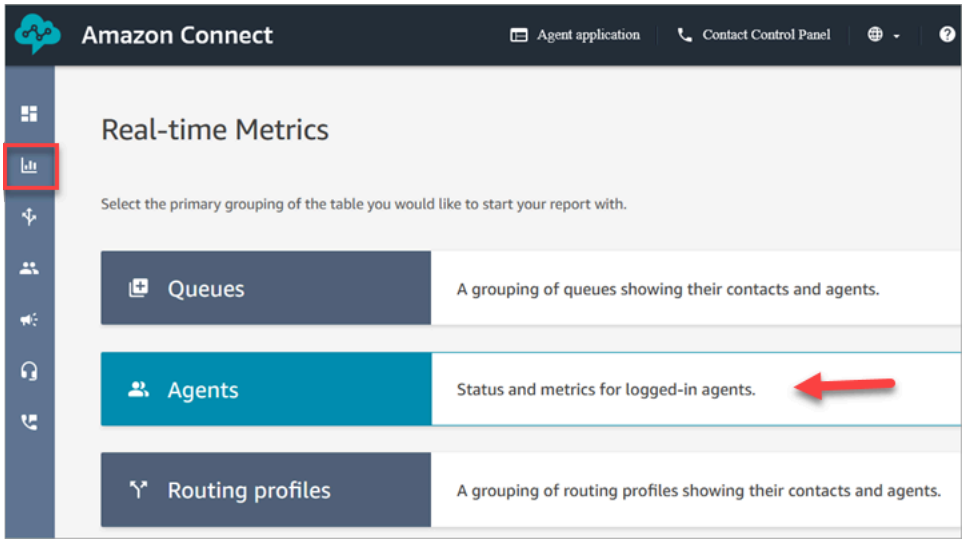
Next, show your managers how to monitor conversations. Continue to Listen to live conversations or read live chats in Connect Customer.

Listen to live conversations or read live chats in Connect Customer

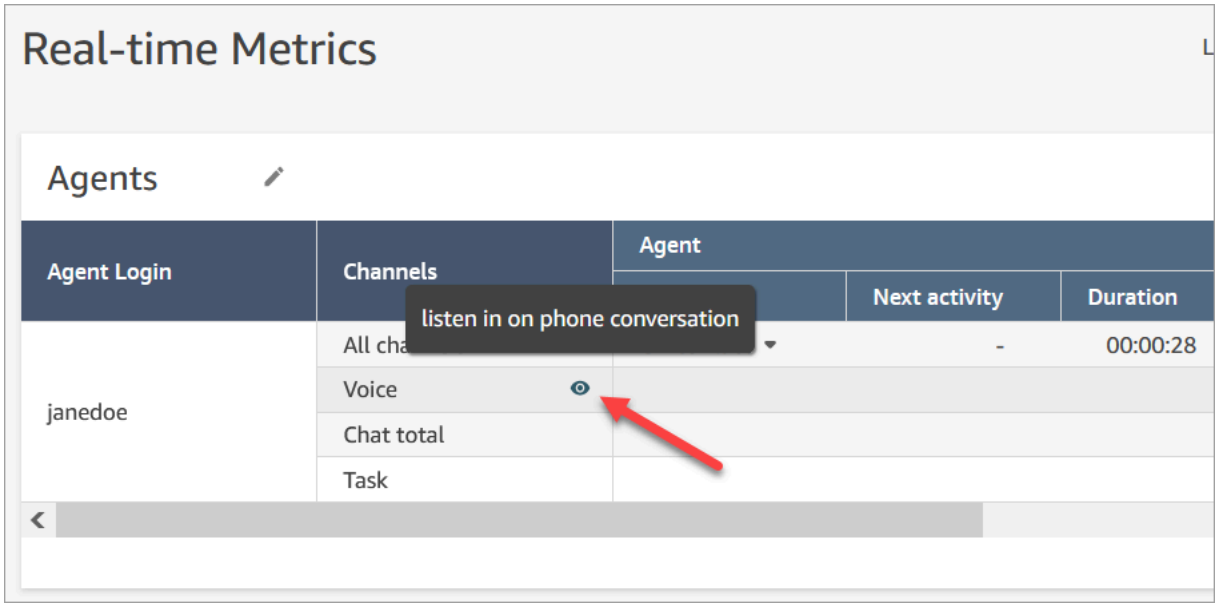
Before you can listen to live conversations or read live chats, the Connect Customer admin needs to enable the feature, assign you permissions, and make sure you are assigned to a routing profile that supports the channel being monitored. After that's done, you can do these steps.

For information about how many people can listen in to a conversation or follow a chat, see Connect Customer feature specifications.

1. Log in to Connect Customer with a user account that is assigned the **CallCenterManager** security profile, or that has the **Real-time contact monitoring** security profile permission.
2. Open the Contact Control Panel (CCP) by choosing the phone icon in the top-right corner of your screen. You'll need the CCP open to connect to the conversation.
3. To choose the agent conversation you want to monitor, in Connect Customer choose **Analytics and optimization**, **Real-time metrics**, **Agents**. The following image shows the **Real-time metrics** page, with an arrow pointing to the **Agents** option.



4. To monitor voice conversations: Next to the names of agents in a live voice conversation, there is an eye icon. Choose the icon to start monitoring the conversation. The following image shows the eye icon next to the **Voice** channel.



> **Note**
>
> **Firefox users**: When using the Firefox browser to monitor and barge, you need to switch to the CCP tab after starting to monitor. The CCP conforms to Firefox microphone usage guidance, and only has access to connect to your microphone when CCP tab is in focus.

When you're monitoring a conversation, the status in your CCP changes to **Monitoring**.

5. To monitor chat conversations: For each agent you'll see the number of live chat conversations they're in. Choose on the number. Then choose the conversation you want to start monitoring.

   When you're monitoring a conversation, the status in your CCP changes to **Monitoring**.

6. To stop monitoring the conversation, in the CCP choose **End call** or **End chat**.

   When the agent ends the conversation, monitoring stops automatically.

Barge into live voice and chat conversations between contact center agents and customers

New to monitoring?

New user? Check out the Connect Customer Supervisor Experience Workshop. This online course has a section on how to monitor contacts.

Supervisors and managers can barge into live voice and chat conversations between agents and customers. To set this up, you need to turn on the **Enhanced monitoring** capability in the Connect Customer console, provide managers with the appropriate permissions, and show them how to barge into conversations.

Looking for how many people can barge the same conversation at one time? See Connect Customer feature specifications.

There is no limit to the number of conversations that you can barge in an instance.

The barge feature is included in Connect Customer voice service fees. For pricing, see the Connect Customer Pricing page.

Tip

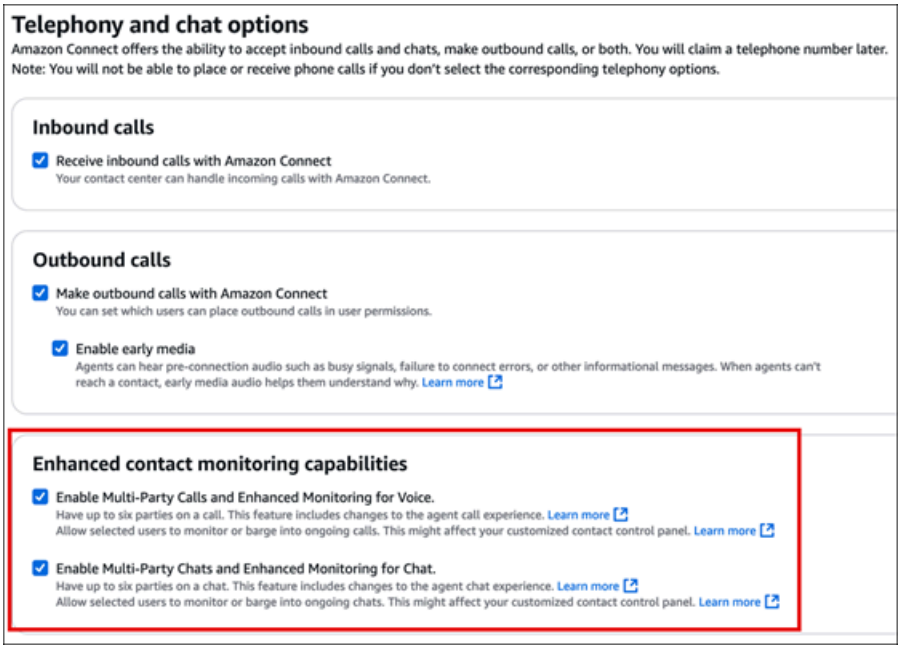
To monitor or barge live calls, you must be signed in to the Contact Control Panel (CCP) and set your status to something other than **Offline**.

Set up barge for voice and chat

In the Connect Customer console, select the following telephony options:

- **Enable Multi-Party Calls and Enhanced Monitoring for Voice**. This option enables access to multi-party calling, detailed contact records, silent monitoring, and barge capabilities.
- **Enable Multi-Party Chats and Enhanced Monitoring for Chat**. This option enables users with the appropriate security profile permissions to barge chats.

The following image shows these options on the **Telephony and chat options** page.



Note

- If multi-party calling is already enabled, to also enable enhanced monitoring you need to use the *UpdateInstanceAttribute* API with the `ENHANCED_CONTACT_MONITORING` attribute for the first time. Or, you can turn the feature OFF and then back ON to update your settings. For more information, see UpdateInstanceAttribute in the *Connect Customer API Reference Guide*.
- Any new instances will automatically have this feature enabled.
- Before enabling **Enhanced contact monitoring capabilities**, make sure that you are using the latest version of the Contact Control Panel (CCP) or Agent workspace. If you are using StreamsJS to customize or embed the CCP, upgrade to version 2.4.2 or later.
- For instances that do not have a service-linked role, you must create one to enable the feature. For more information on how to enable service-linked roles, see Use service-linked roles for Connect Customer.

Assign security profile permissions

For managers to barge live conversations, you assign them the **CallCenterManager** and **Agent** security profiles.

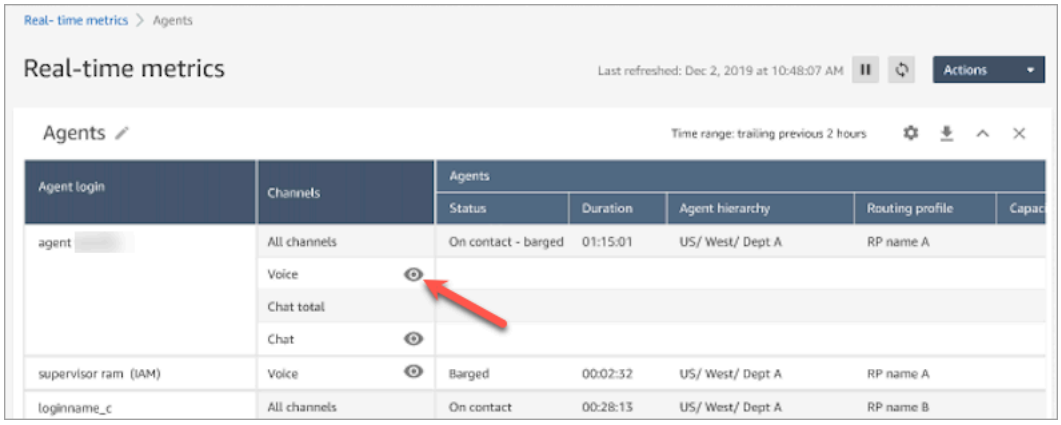
To allow specific supervisors to barge live conversations, we recommend that you create a security profile specific for this purpose. They need the following security profile permissions:

- **Access metrics**. You can access real-time metrics reports, which is where you choose which conversation you would like to monitor and barge.
- **Real-time contact monitoring**: You can monitor both voice and chat conversations.
- **Real-time contact barge-in**: You can barge both voice and chat conversations.
- **Access Contact Control Panel**

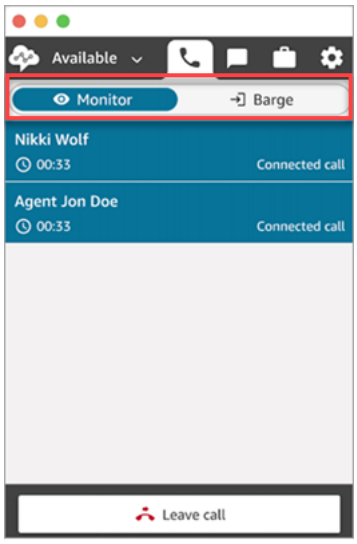
Barge live calls with contacts

> **Tip**
>
> For the number of supervisors who can monitor a call at the same time, see Connect Customer feature specifications.

1. Log in to the Connect Customer admin website at https://*instance name*.my.connect.aws/. Use an account that is assigned the **CallCenterManager** security profile or that has the required security profile permissions.
2. Open your CCP. It must be open before you can barge a call.
3. On the Connect Customer admin website navigation menu, choose **Analytics and optimization**, **Real-time metrics**, **Agents**.
4. Choose the eye icon that appears next to the **Voice** channel of the agent that you want to monitor, as shown in the following image. You can barge into a conversation that you had been monitoring already.

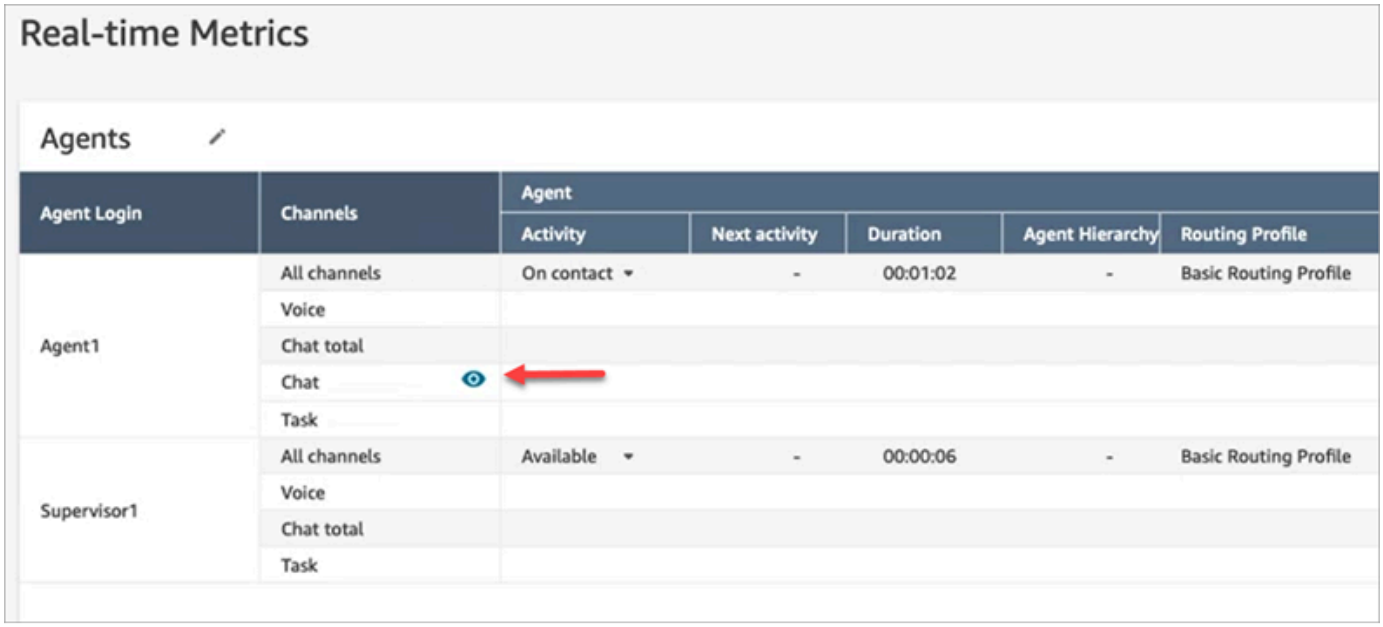


5. This takes you to the open CCP, as shown in the following image. You can monitor the call and toggle between the **Monitor** and **Barge** states. The following image shows the **Monitor** state.

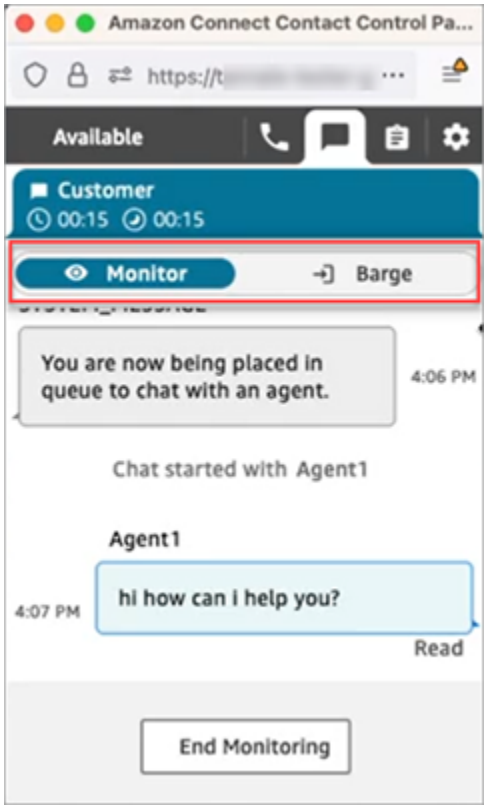


Barge live chats with contacts

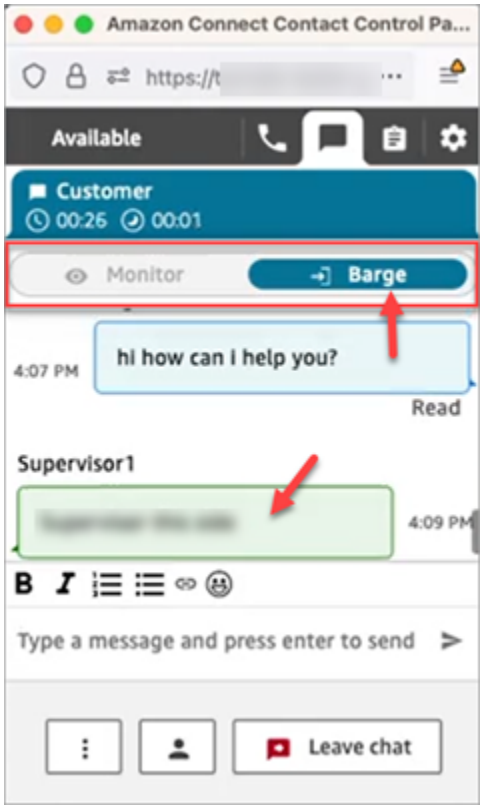
1. Log in to the Connect Customer admin website at https://*instance name*.my.connect.aws/. Use an account that is assigned the **CallCenterManager** security profile or that has the required security profile permissions.
2. Open your CCP. It must be open before you can barge a chat.
3. On the Connect Customer admin website navigation menu, choose **Analytics and optimization**, **Real-time metrics**, **Agents**.
4. Choose the eye icon that appears next to the **Chat** channel of the agent that you want to monitor, as shown in the following image. You can barge into a conversation that you had been monitoring already.



5. This takes you to the open CCP, as shown in the following image. You can monitor the chat conversation and toggle between the **Monitor** and **Barge** states. The following image shows the **Monitor** state.



Following is an example of what the CCP looks like when a supervisor barges into a chat.



Review recorded conversations between agents and customers using Connect Customer

Managers can review past conversations between agents and customers. To set this up, you need to set up recording behavior, assign managers the appropriate permissions, and then show them how to access the recorded conversations.

When is a conversation recorded? For detailed information about call recording behavior, see When, what, and where for contact recordings.

> **Tip**
>
> When call recording is enabled, the recording is placed in your S3 bucket shortly after the contact is disconnected. Then the recording is available for you to review it using the steps in this article.
>
> You can also access the recording from the customer's contact record. The recording is available in the contact record, however, only after the contact has left the After Contact Work (ACW) state.

How do I manage access to recordings? Use the **Call recordings (unredacted)** security profile permission to manage who can listen to recordings, and access the corresponding URLs that are generated in S3. For more information about this permission, see Assign permissions.

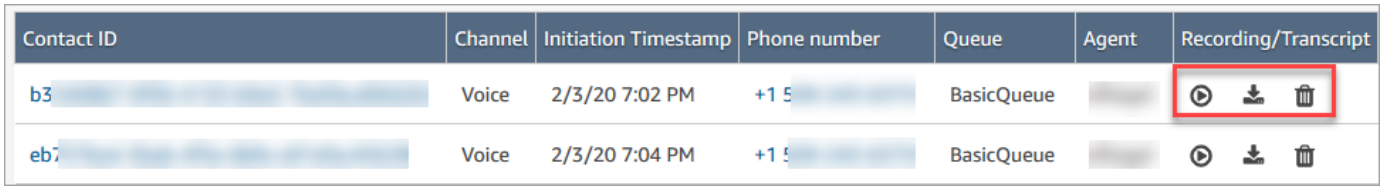
Review recordings and transcripts of past agent conversations

This section covers the steps that a manager takes to review past recordings and transcripts of past agent conversations. For chat contacts, the same transcript contains the agent interaction and the automated interaction (for example, with chat bots).

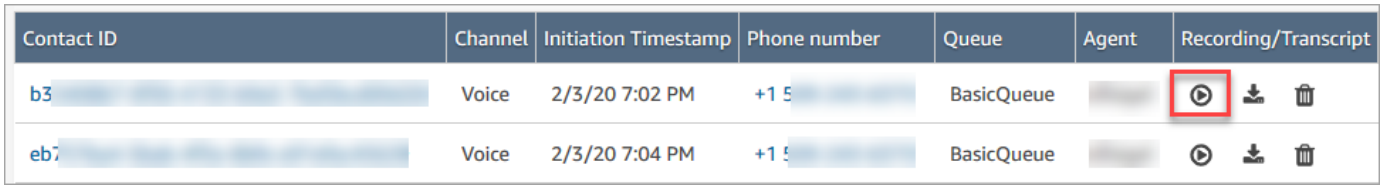
1. Log in to Connect Customer with a user account that has that has permissions to access the contact search page and to access recordings.
2. In Connect Customer choose **Analytics and optimization**, **Contact search**.
3. Filter the list of contacts by date, agent login, phone number, or other criteria. Choose **Search**.

> **Tip**
>
> We recommend using the **Contact ID** filter to search for recordings. This is the best way to make sure you get the right recording for the contact. Many recordings have the same name as the contact ID, but not all.

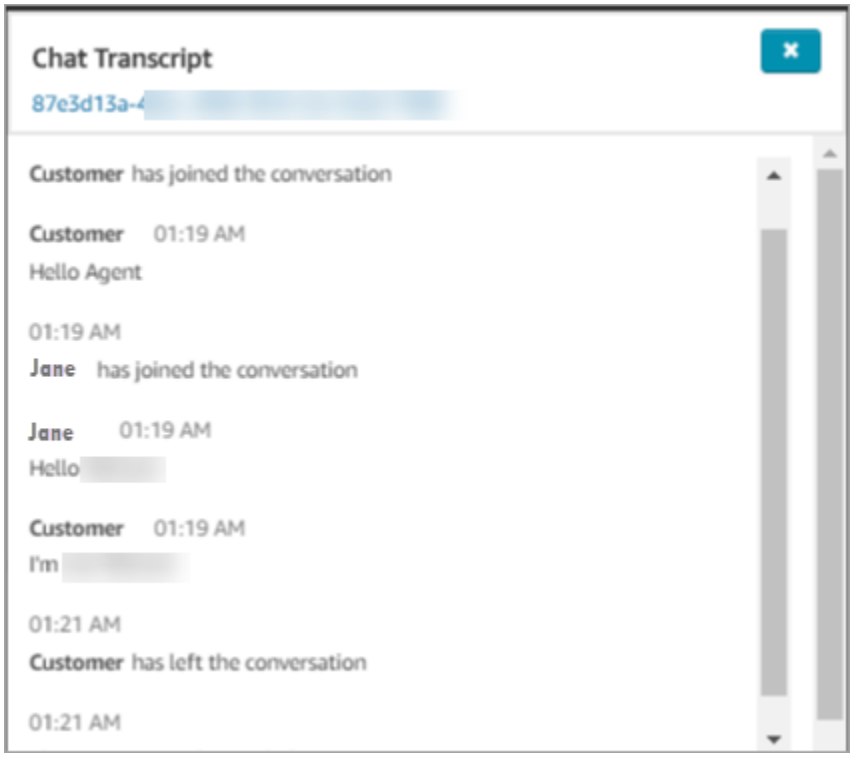
4. Conversations that were recorded have icons in the **Recording/Transcript** column, as shown in the following image. If you don't have the appropriate permissions, you won't see these icons.



5. To listen to a recording of a voice conversation, or read the transcript of a chat, choose the **Play** icon, as shown in the following image.



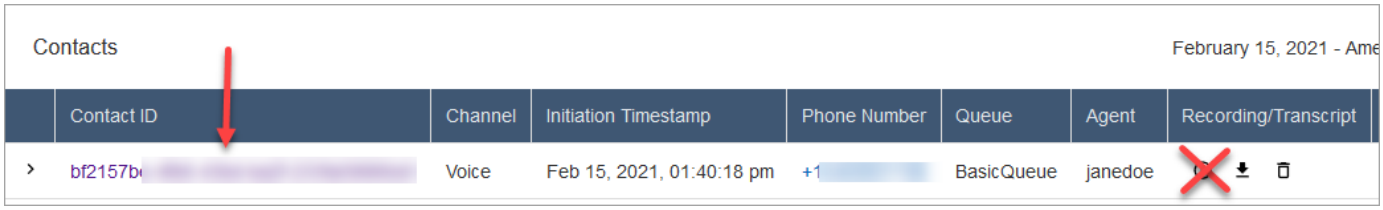
6. If you choose the play icon for a transcript, it appears, as shown in the following image.



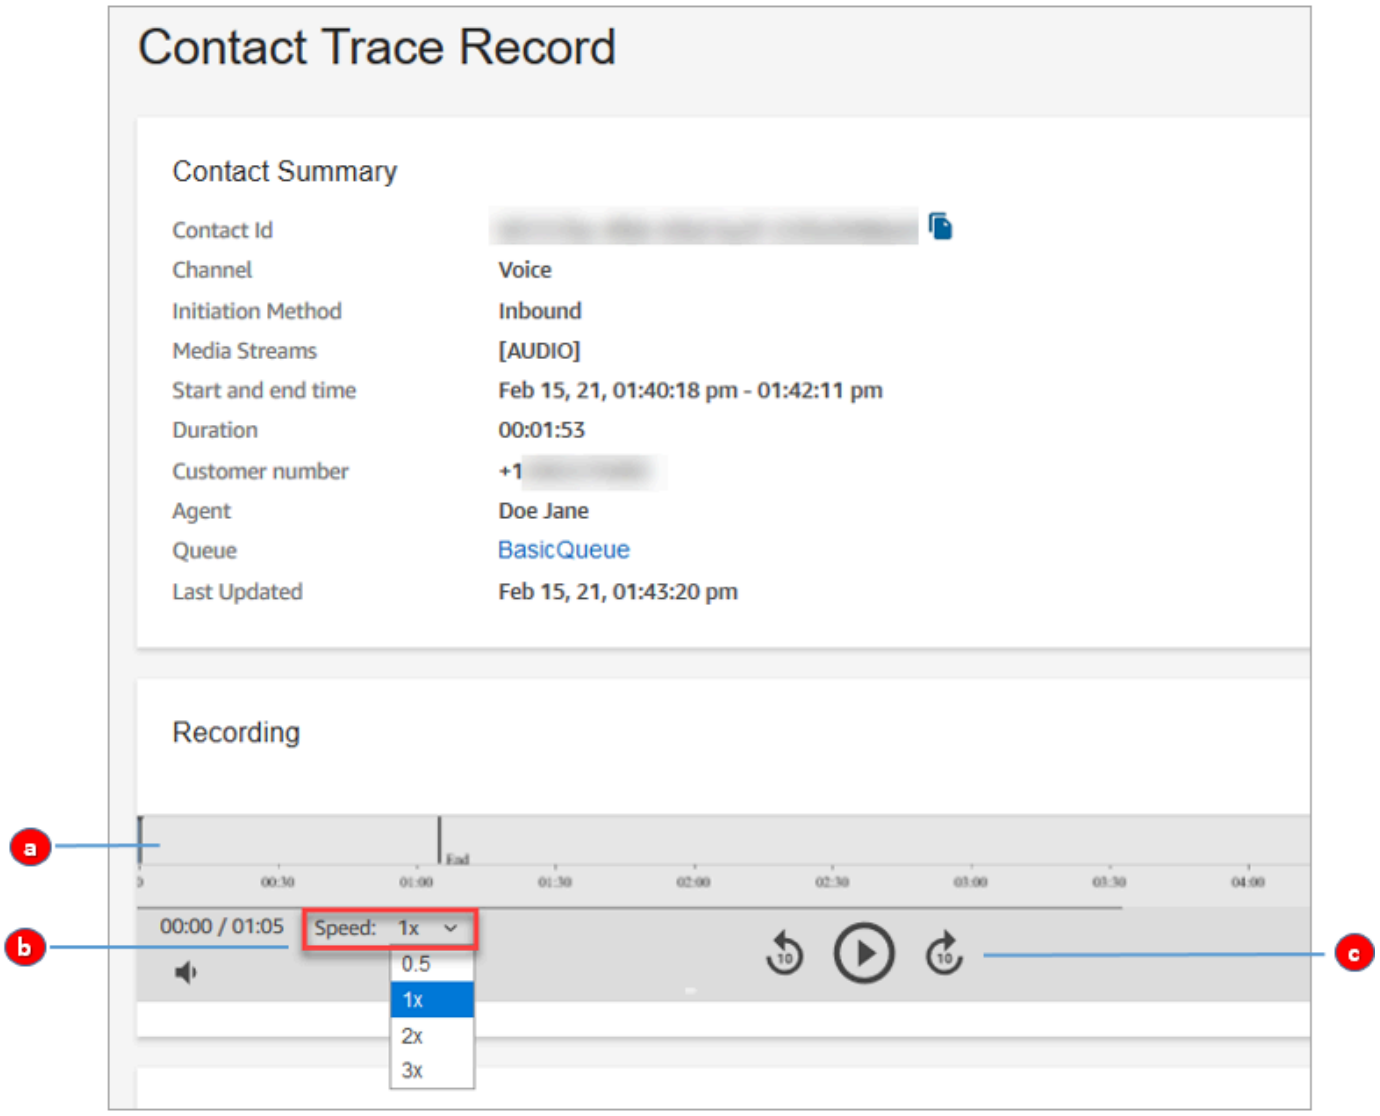
Pause, rewind, or fast-forward a recording

Use the following steps to pause, rewind, or fast-forward a voice recording.

1. On the **Contact search** results, instead of choosing the **Play** icon, choose the contact ID to open the contact record.



2. On the **Contact record** page, there are more controls to navigate the recording, as shown in the following image.



1. Choose or tap to the time you want to investigate.
2. Adjust the playing speed.
3. Play, pause, skip backwards or forwards in 10 second increments.

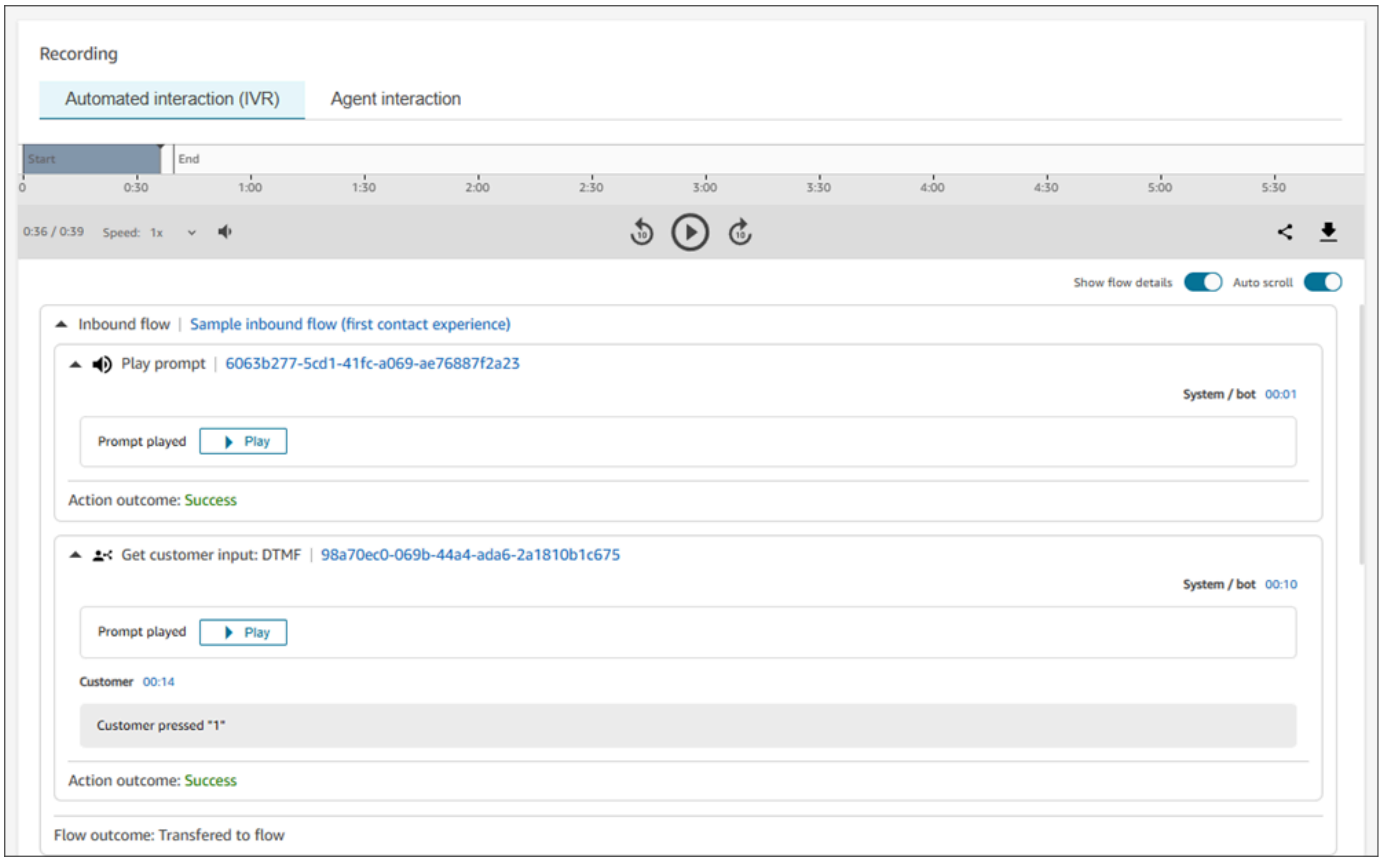
Troubleshoot problems pausing, rewinding, or fast-forwarding

If you are unable to pause, rewind or fast-forward recordings on the **Contact search** page, one possible reason could be that your network is blocking HTTP range requests. See HTTP range requests on the MDN Web Docs site. Work with your network administrator to unblock HTTP range requests.

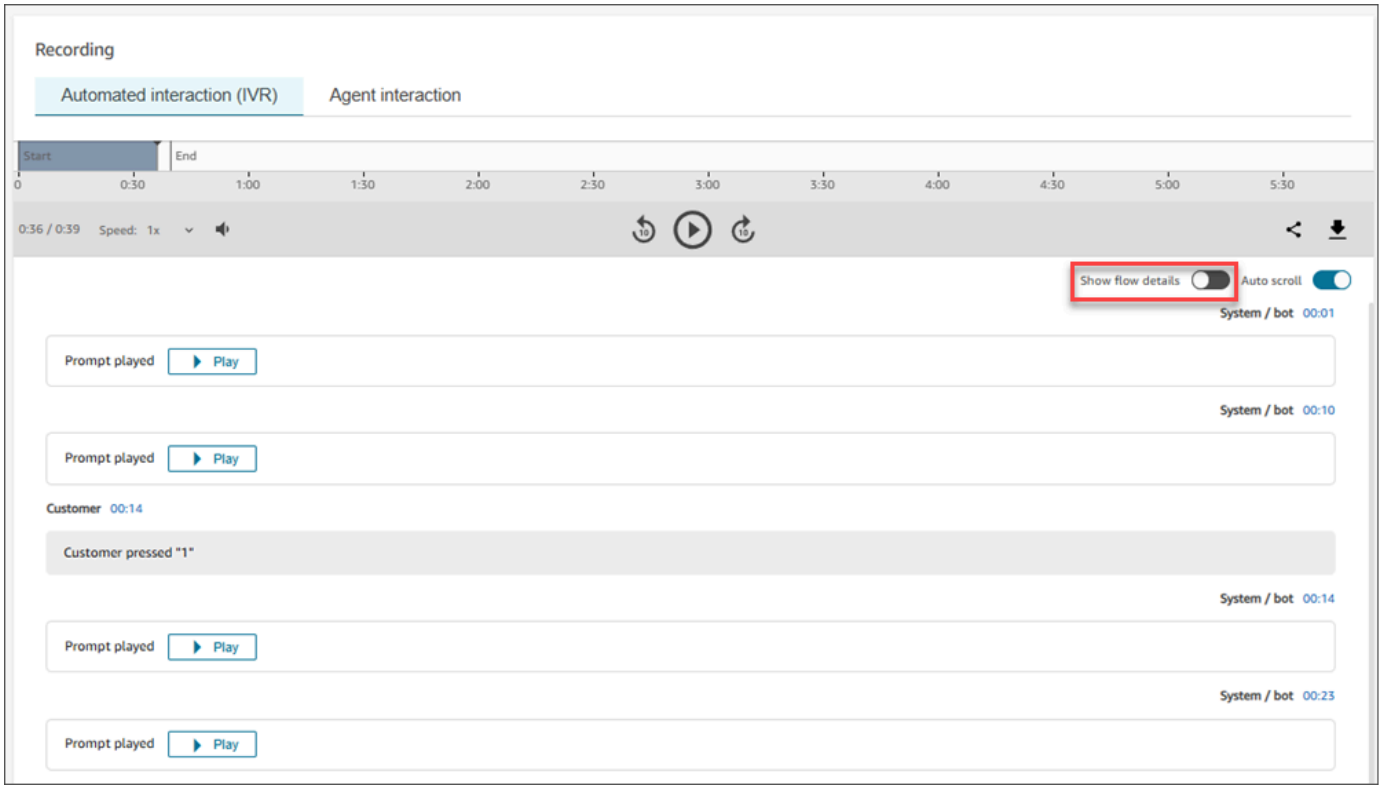
Review recordings and transcripts of automated voice interactions (with IVR and bots)

With IVR recordings and logs, you can monitor and improve your automated experiences to better resolve the needs of the end-customer and maintain audio and system execution records of the interaction for compliance purposes. To review automated interaction (IVR) recordings and logs:

1. Log in to Connect Customer with a user account that has permissions to access the contact search page and to access recordings. Note that to view information on flow execution, you would need permissions to view **Flows** and **Flow modules**.
2. On the navigation menu, choose **Analytics and optimization, Contact search**.
3. Search for the contact you want to review, for example, use can search by contact queues, the name of the initial flow for the contact, or user-defined custom contact attributes.
4. Choose the contact ID to view the **Contact details** page.
5. Under **Recording and Transcript** section, select **Automated Interaction (IVR)** that will contain an audio player that you can use to play the IVR recording, as shown in the following image. In this section you can also see the IVR prompts that were played, customers response to those prompts, as well as transcripts of Amazon Lex interactions.



6. If you only wish to view the details on the customer interaction (without seeing additional details on which flow was executed), you can turn off the **Show flow details** toggle. See image below:



Flow blocks available within the automated interaction logs and transcripts

You can view the following flow blocks within the Connect Customer UI on the contact details page;

- Get customer input
- Store customer input
- Play prompt
- Loop prompts
- Lamda functions

Assign permissions to review past contact center conversations in Connect Customer

To access recordings and transcripts on the Connect Customer admin website, you need security profile permissions to search for and view contacts on the **Contact search** page. You also need permissions to access:

- Recordings and transcripts of agent interactions
- Automated interactions (IVR) recordings
- Automated interactions (IVR) transcripts

This topic explains the required security profile permissions.

Topics

- Permissions to search and view contacts
- Permissions to access recordings and transcripts of agent interactions
- Permissions to view automated interaction (IVR) recordings and transcripts

Permissions to search and view contacts

Contacts and underlying recordings and transcripts are accessible through the **Contact search** and **Contact details** pages. At least one of the following permissions is required to view contacts on **Contact search** and **Contact details** pages:

- **Contact search - View**: Allows a user to access all contacts on **Contact search** and **Contact details** pages.
- **View my contacts - View**: On the **Contact search** and **Contact details** pages, allows agents to view only those contacts that they handled.

You can also enable the **Restrict contact access** permission to restrict access to contacts based on the user's hierarchy. For example:

- Agents who are assigned to AgentGroup-1 can only view contact records for contacts handled by agents in that hierarchy group and any groups below them.
- Agents assigned to AgentGroup-2 can only access contact records for contacts handled by their group, and any groups below them.

- Managers and others who are in higher level groups can view contact records for contacts handled by all the groups below them, such as AgentGroup-1 and 2.

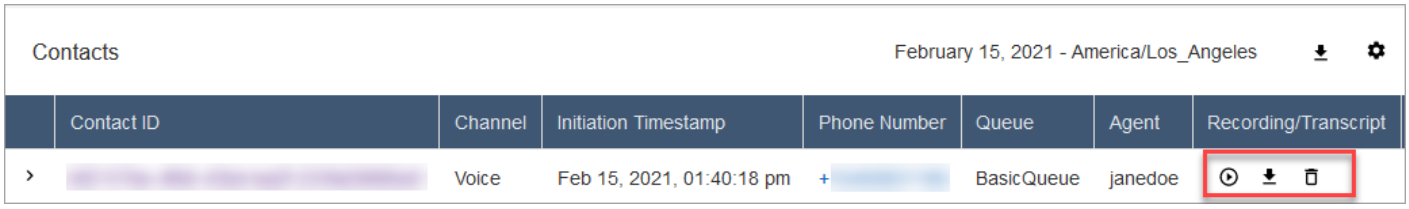
For more information, see Manage who can search for contacts and access detailed information.

Permissions to access recordings and transcripts of agent interactions

Complete the following steps to assign permissions to access agent interactions for voice, chat and email channels.

> **Note**
>
> For chat interactions, the same transcript contains the agent interaction and the automated interaction (for example, with chat bots).

1. Assign the **CallCenterManager** security profile so a user can listen to call recordings or review chat transcripts. This security profile also includes a setting that makes the icon to download recordings appear in the results of the **Contact search** page. The following image shows the recording play, download, and delete icons that are displayed to a user who has these permissions.



– OR –

1. Assign the following individual permissions:
   - **Call recordings (redacted) - Access**: If your organization uses Connect Customer conversational analytics, you can assign this permission so agents access only those agent call recordings in which sensitive data has been redacted.
   - **Contact transcripts (redacted) - Access**: If your organization uses Connect Customer conversational analytics, you can assign this permission so agents access only those contact transcripts in which sensitive data has been redacted.

The redaction feature is provided as part of conversational analytics. For more information, see Use sensitive data redaction to protect customer privacy using conversational analytics.

- **Manager monitor**: This permission allows users to monitor live conversations and listen to recordings.

  > **Tip**
  >
  > Be sure to assign managers to the **Agent** security profile so they can access the Contact Control Panel (CCP). This enables them can monitor the conversation through the CCP.

- **Call recordings (unredacted) - Access**: Use this permission to manage who can access recordings on the **Contact search** and **Contact details** pages, through corresponding URLs that are generated in S3. From there, these users can delete recordings.

  Note the following:

  - If users do not have **Call recordings (unredacted) - Access** permission—or they're not logged in to Connect Customer—they cannot listen to the call recording or access the URL in S3, even if they know how the URL is formed.
  - The **Call recordings (unredacted) - Enable download button** permission controls only whether the download button appears in the user interface. It does not control access to the recording.

- **Contact transcripts (unredacted) - Access**: Use this permission to manage who can view unredacted chat and email conversations, and unredacted voice transcripts produced by conversational analytics on the **Contact search** and **Contact details** pages.

  Note the following:

  - If users do not have **Call recordings (unredacted) - Access** permission—or they're not logged in to Connect Customer.
  - The **Call recordings (unredacted) - Enable download button** permission controls only whether the download button appears in the user interface. It does not control access to the recording.

- **Delete recorded conversations**: To enable a user to delete recordings on the **Contact search** and **Contact details** pages, choose the **Delete** permission.

- **Automated interaction voice (IVR) recordings (unredacted)**: Use this permission to grant access to manage and view IVR recordings on the **Contact details** page.
- **Automated interaction voice (IVR) transcripts (unredacted)**: Use this permission to grant access to transcripts for the above Automated Interaction Voice (IVR) Recordings.

Permissions to view automated interaction (IVR) recordings and transcripts

Assign the following permissions:

- **Automated interaction voice (IVR) recordings (unredacted) - Access**: Enables user's access to the recording of a contact during automated interactions (with IVR, Amazon Lex, or other bots).
- **Automated interaction voice (IVR) recordings (unredacted) - Enable Download Button**: Controls whether the download button appears next to the IVR recording on the **Contact details** page within Connect Customer.

Access automated interaction (IVR) logs and transcripts

Assign the following permissions:

- **Automated interaction voice (IVR) transcripts (unredacted) - Access**: Enables a user's access to the interaction between the customer, IVR and any bots. They can see the customer's keypad inputs in response to IVR prompts and see the transcript for the interaction with Amazon Lex.

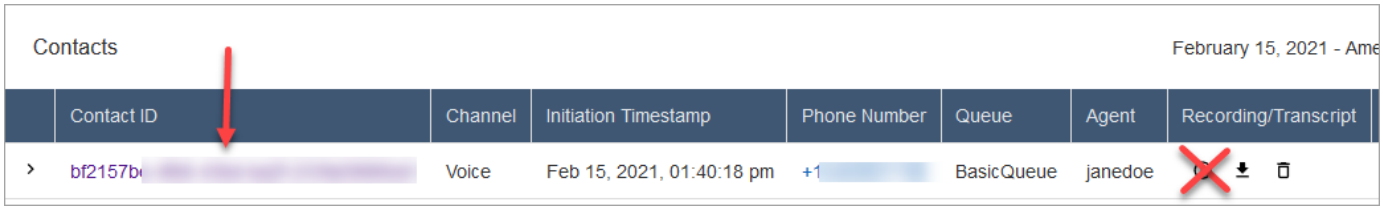
  The transcript obfuscates customer inputs entered for the Store customer input flow block. The transcript also obfuscates any slots that are configured to be obfuscated in the *Amazon Lex developer guide* within Amazon Lex. Users with access to the IVR recording can still listen to the voice customer inputs during Amazon Lex interactions.
- **Flow - View** and **Flow modules - View**: Grant users with both of these permissions so they can view flow execution details for voice contacts on the **Contact details** page. For example, which flow was executed and what was the outcome.

> **Note**
>
> These permissions also grant users with access to the Flows and Flow modules pages on the Connect Customer admin website.

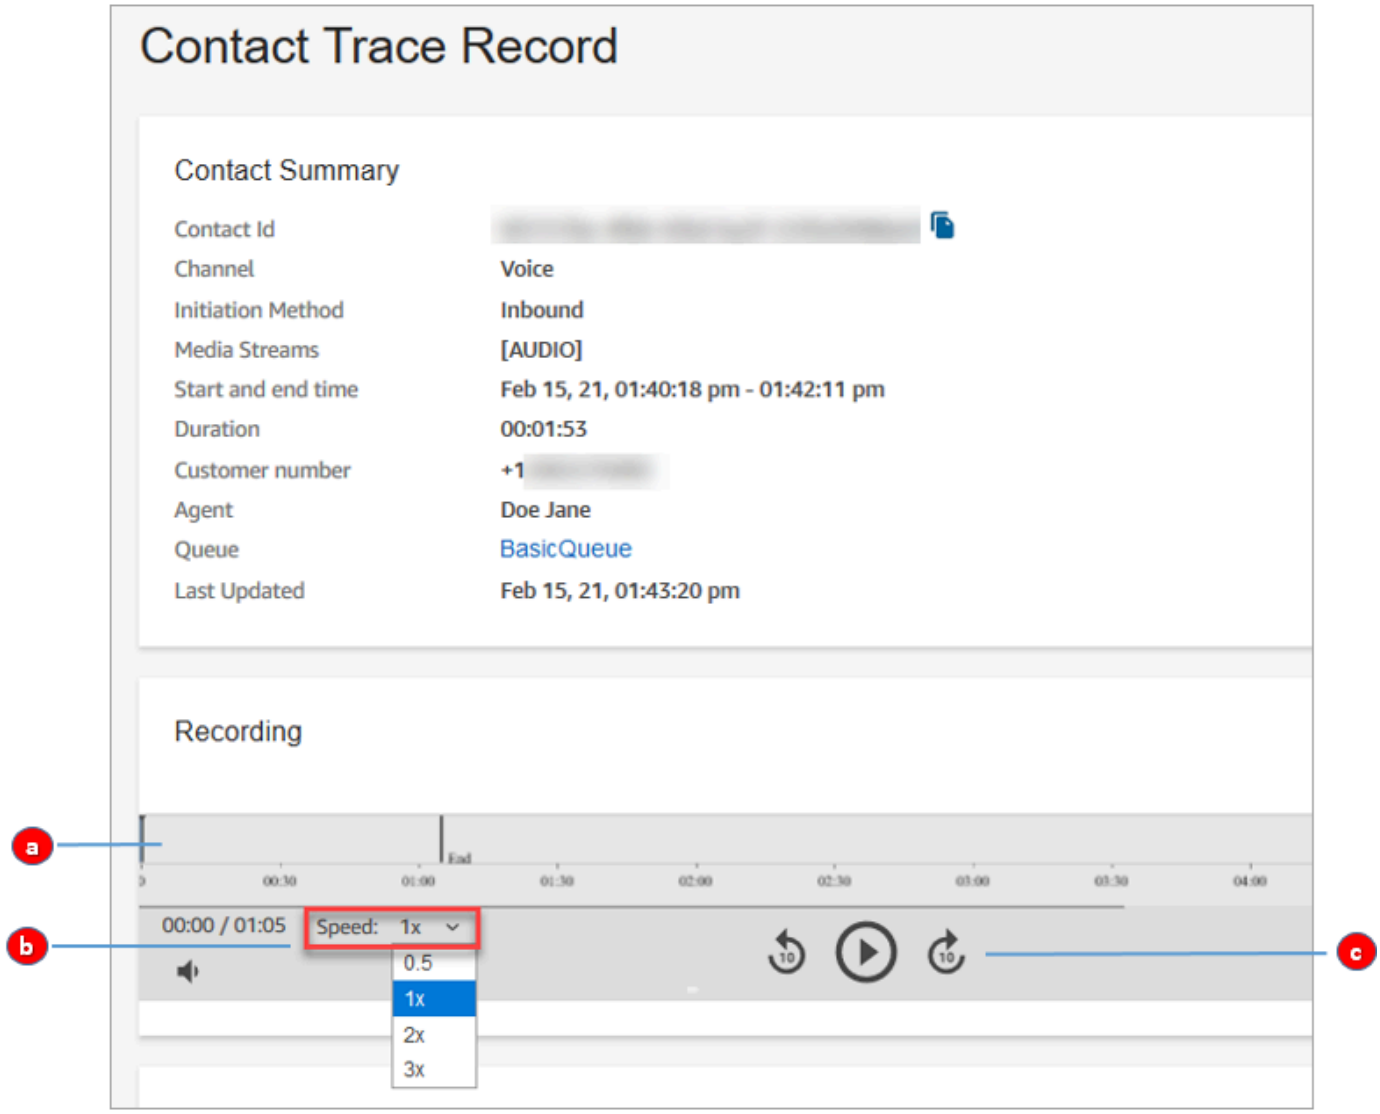
Pause, rewind, or fast-forward a recording

Use the following steps to pause, rewind, or fast-forward a voice recording.

1. On the **Contact search** results, instead of choosing the **Play** icon, choose the contact ID to open the contact record.



2. On the **Contact record** page, there are more controls to navigate the recording, as shown in the following image.



1. Choose or tap to the time you want to investigate.
2. Adjust the playing speed.
3. Play, pause, skip backwards or forwards in 10 second increments.

Troubleshoot problems pausing, rewinding, or fast-forwarding

If you are unable to pause, rewind or fast-forward recordings on the **Contact search** page, one possible reason could be that your network is blocking HTTP range requests. See HTTP range requests on the MDN Web Docs site. Work with your network administrator to unblock HTTP range requests.

Download recordings and transcripts of past conversations in Connect Customer

These are the steps that a manager does to download past recordings or transcripts of conversations.

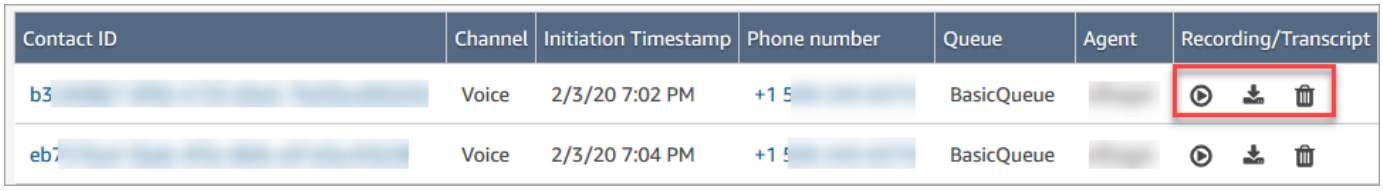
- If the contact reached you by phone call (the Voice channel), you can download a .wav file.
- If the contact reached you by chat (the Chat channel), you can download a .json file.

> **Tip**
>
> To have Connect Customer create transcripts of phone calls, see the conversational analytics feature.

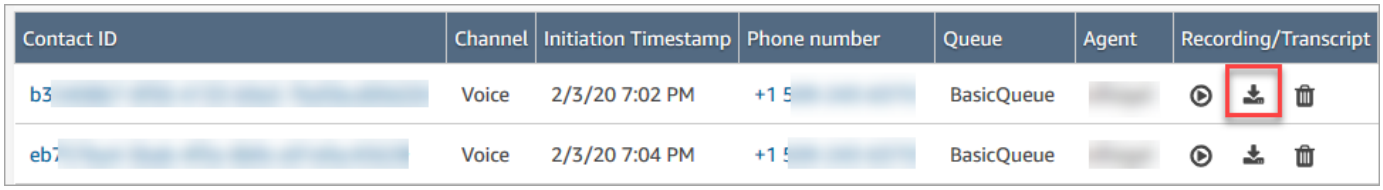
Download a voice recording as a .wav file

1. Log in to the Connect Customer admin website with a user account that has permissions to access recordings.
2. In Connect Customer choose **Analytics and optimization**, **Contact search**.
3. Filter the list of contacts by date, agent login, phone number, or other criteria. Choose **Search**.
4. Conversations that were recorded have icons in the **Recording/Transcript** column. If you don't have the appropriate permissions, you won't see these icons.

   The following image shows what the icons look like for a voice recording. Note the play icon that indicates it's a voice recording.

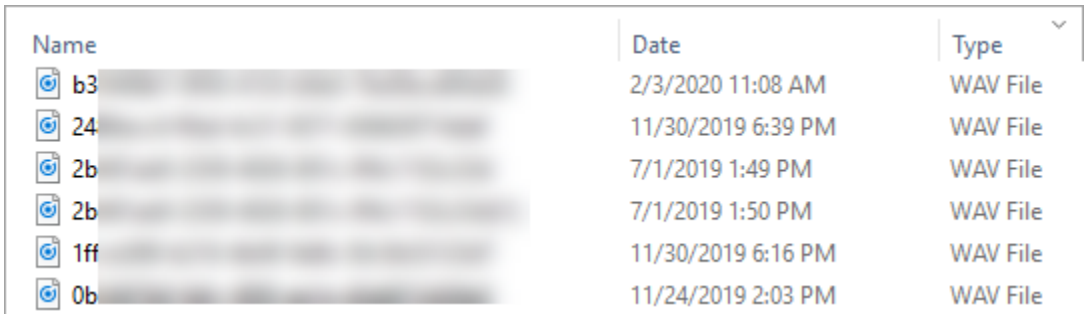


5. Choose the **Download** icon, as shown in the following image.



6. A voice recording is saved automatically to your **Downloads** folder as a .wav file.

   The following image shows a list of .wav files in a Downloads folder. The name of the .wav file is the contact ID.



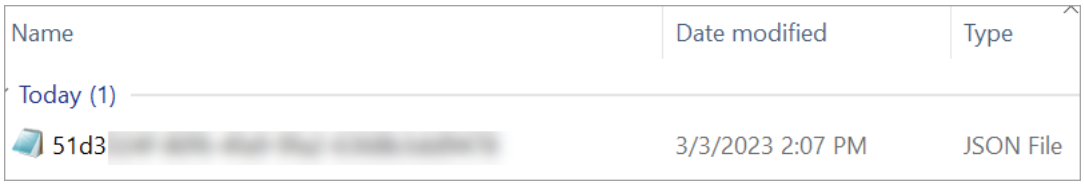
> **Tip**
>
> In the recording, you might hear only the agent, only the customer, or both the agent and customer. This is determined by how the Set recording and analytics behavior block is configured.

Download a chat transcript as a .json file

1. The following image shows what the icons look like for a chat transcript.

   A chat transcript is saved to the Downloads folder as a .json file.

The following image shows a .json file in the Downloads folder. The name of the .json file is the contact ID.



2. To view a downloaded chat transcript, open the context menu for the .json file, and then open it with another app that you can use to view the contents in a readable format.

   The following image shows a sample downloaded transcript that has been opened using Firefox. The image shows the middle of the transcript, where the agent and customer are chatting.

Events in a chat transcript

If you have a process that consumes events in S3 transcripts, note that chat transcripts contain the following event content types if the event has occurred during the chat session:

- `application/vnd.amazonaws.connect.event.participant.left`
- `application/vnd.amazonaws.connect.event.participant.joined`
- `application/vnd.amazonaws.connect.event.chat.ended`
- `application/vnd.amazonaws.connect.event.transfer.succeeded`

- `application/vnd.amazonaws.connect.event.transfer.failed`
- `application/vnd.amazonaws.connect.event.participant.invited`

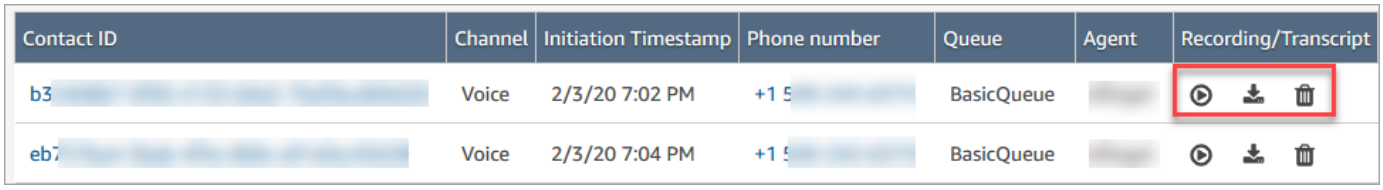
Search for recordings of conversations by a customer's contact ID in Connect Customer

To find a recording of a specific contact, you only need the contact ID. You don't need to know the date range, agent, or any other information about the contact.

> **Tip**
>
> We recommend using the contact ID to search for recordings.
> Even though many call recordings for specific contact IDs might be named with the contact ID prefix itself (for example, 123456-aaaa-bbbb-3223-2323234.wav), there is no guarantee that the contact IDs and name of the contact recording file always match. By using **Contact ID** for your search on the **Contact search** page, you can find the correct recording by referring the audio file on the contact's record.

To search for recordings

1. Log in to Connect Customer with a user account that has permissions to access recordings.
2. In Connect Customer choose **Analytics and optimization**, **Contact search**.
3. In the **Contact ID** box, enter the contact ID, and then choose **Search**.
4. Conversations that were recorded have icons in the **Recording/Transcript** column. The following image shows the play, download, and delete icons. If you don't have the appropriate permissions, you won't see these icons.



To learn more about searching, see Search for completed and in-progress contacts in Connect Customer.

Troubleshoot agent conversation monitoring ability in Connect Customer

The following table explains how to resolve error messages (exception messages) that might be displayed when you use Connect Customer to monitor live agent conversations with contacts.

Error message	Resolution	Exception type	Exception code
You do not have access to the agent. Contact your admin to learn more.	You must enable the service linked role for the instance. See Use service-linked roles and role permissions for Connect Customer for information about enabling the role.	AccessDeniedException	403
One or more of the input parameters are invalid	A developer needs to make sure that the input parameters for the `MonitorContact` action are valid. See MonitorContact Request Syntax.	InvalidRequestException	400
Monitoring failed, please enable call recording	In the flow, make sure that the Set recording and analytics behavior block is configured to allow call recording for both the agent and customer.	InvalidRequestException	400
User's phone number is invalid	Check that the phone number associate	InvalidRequestException	400

Error message	Resolution	Exception type	Exception code
	d with the agent's deskphone meets following requirements: 1. It is a valid phone number. 2. It is in the required E164 format. To express a US phone number in E.164 format, add the '+' prefix and the country code in front of the number. For example, for a US number +1-800-555-1212. A number such as 020 718 xxxxx in the UK would be formatted as +44 20 718 xxxxx. 3. It is in the list of countries that Connect Customer can call. For a list of countries allowed by default, see Countries that call centers using Connect Customer can call by default.		

Error message	Resolution	Exception type	Exception code
	For example, your Connect Customer instance is in the US East (N. Virginia) Region. Your agent has a deskphone in Germany, which is not a country that Connect Customer can call by default. By default the agent's deskphone would not be configured correctly to start the monitoring session so they would get an error. You would need to submit a service quota increase request to add Germany to your list of allowed countries that Connect Customer can call. 4. The queue that is associated with the agent's routing profile has an outbound caller ID number assigned		

Error message	Resolution	Exception type	Exception code
	to it. For instructions for setting the outbound caller ID number, see Set up outbound caller ID in Connect Customer.		
The contact or agent is not in the state that can be monitored	The contact is not in an active state. The agent or customer might have disconnected from the call or chat before the monitoring request could be processed. Choose another contact to monitor.	InvalidRequestException	400
Monitoring failed, please enable multi party conferencing feature	The Connect Customer instance must have the multi-party calls and enhanced monitoring feature enabled. In your instance settings, choose **Enable Multi-Party Calls and Enhanced Monitoring**. For instructions, see Update settings for your Connect Customer instance.	InvalidRequestException	400

Error message	Resolution	Exception type	Exception code
No AGENT participant found in the contact	The call or chat doesn't have an active agent who is connected to it and working on the contact. Choose another contact to monitor.	InvalidRequestException	400
MonitorContact is not supported for TASK contacts	The monitoring feature is supported only for voice and chat contacts. Choose a voice or chat contact to monitor.	InvalidRequestException	400
AllowedMonitorCapabilities must be provided and have `SILENT_MONITOR` value at the least	If your Connect Customer instance has the multi-party calls and enhanced monitoring feature enabled, the developer must make sure to pass the `AllowedMonitorCapabilities` input parameter with at least the `SILENT_MONITOR` value set. See MonitorContact Request Syntax.	InvalidRequestException	400

Error message	Resolution	Exception type	Exception code
One or more of the request resources were not found	A developer needs to make sure that the resources in the `MonitorContact` input request that's being passed exist in the Connect Customer instance.	ResourceNotFoundException	404
Internal service exception	The request processing has failed because of an unknown error, exception, or failure with an internal server. Wait a bit and then try again to monitor the contact.	InternalServiceException	500
Service quota has been exceeded	There are certain limits on how many contacts a supervisor can monitor at a time or how many supervisors can monitor one contact. Check the limits for the voice and chat contacts on the Connect Customer feature specifications page.	ServiceQuotaExceededException	402

Error message	Resolution	Exception type	Exception code
Another request with same clientToken is in progress	In the MonitorContact action, a `ClientToken` is a unique, case-sensitive identifier that developers provide to ensure the idempotency of the request. If not provided, the AWS SDK populates this field. For more information about idempotency, see Making retries safe with idempotent APIs.	IdempotencyException	409
Access denied	You don't have the appropriate permissions in your security profile to perform this action. For a list of the security profile permissions required for monitoring conversations see Assign permissions to monitor live conversations in the Connect Customer Contact Control Panel (CCP).	AccessDeniedException	403

Error message	Resolution	Exception type	Exception code
Too Many Requests	The API TPS quotas have been exceeded. Submit a request for a TPS quota increase. For instructions, see Requesting a quota increase.	ThrottlingException	429

Manage contacts from the Contact details page in Connect Customer

On the **Contact details** page, you can transfer, reschedule, end, or update the task template for an in-progress contact. You can also add or remove tags from an in-progress or completed contact that you can access.

You can also perform these actions programmatically using the TransferContact, UpdateContactSchedule, StopContact, UpdateContactTaskTemplate, TagContact, and UntagContact operations.

This section explains how to manage contacts by using the Connect Customer admin website.

Topics

- Transfer in progress contacts to a quick connect agent or a queue in Connect Customer
- Reschedule contacts from the Contact details page in Connect Customer
- End contacts from the Contact details page in Connect Customer
- Update the task template on an in-progress contact in Connect Customer
- Tag contacts on the Contact details page in Connect Customer

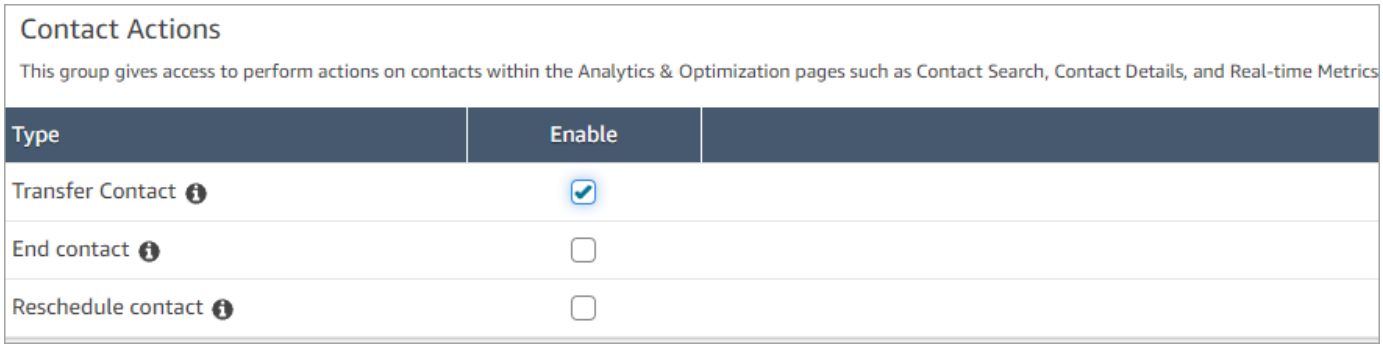
Transfer in progress contacts to a quick connect agent or a queue in Connect Customer

On the **Contact details** page of an in-progress contact, you can transfer a contact to a quick connect agent or queue. This capability supports task, email, or chat contacts.

To transfer contacts programmatically, use the TransferContact.

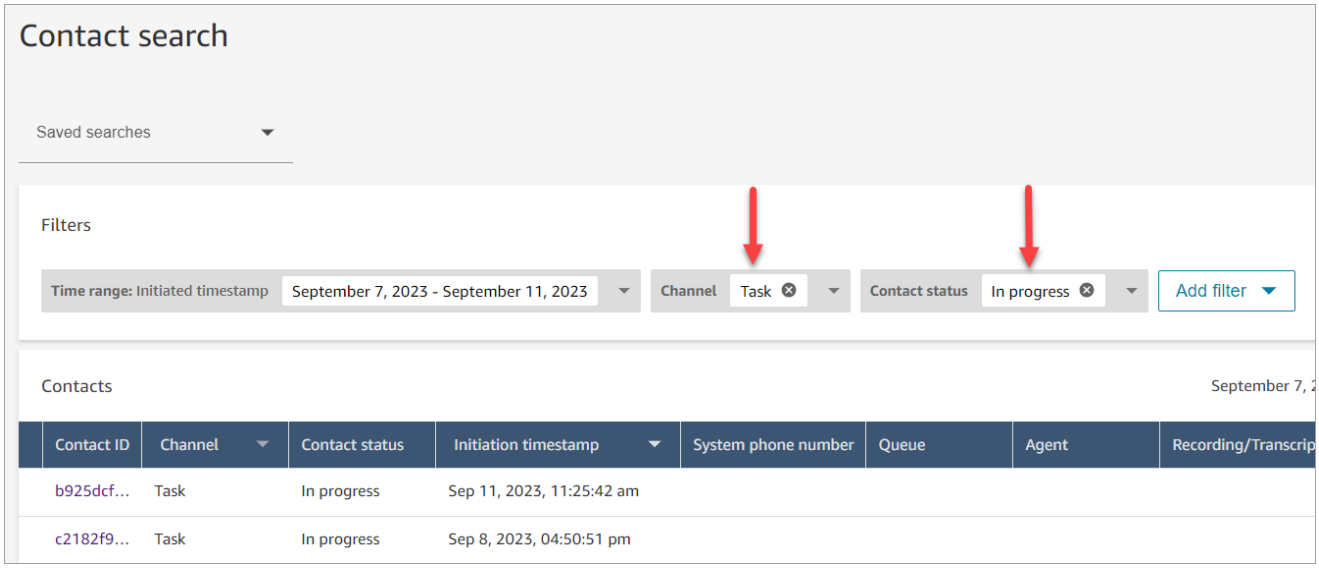
Required permissions

1. Enable one of the following permissions to view contacts on the **Contact search** and **Contact details** pages:
   a. **Contact search - View**: Allows a user to view all contacts
   b. **View my contacts - View**: Allows agents to view contacts that they themselves had handled
2. **Restrict contact access** (Optional): Restrict a user's access to contacts on the **Contact search** and **Contact details** pages within their own hierarchy group or any hierarchy groups below them. For more information about these permissions, see Manage who can search for contacts and access detailed information.
3. **Transfer Contact**: Enables a user to transfer contacts on the **Analytics & Optimization** pages. The following image shows the **Contact Actions - Transfer Contact** permission.



How to transfer a task, email, or chat contact

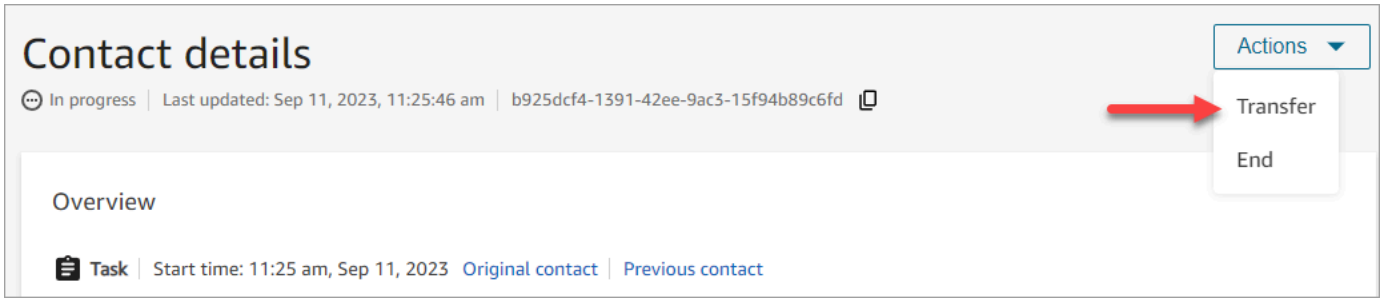
1. Log in to Connect Customer with a user account that has permissions to access contact records.
2. In Connect Customer choose **Analytics and optimization**, **Contact search**.
3. Search for an in-progress task or email contact to transfer:
   a. Select the **Contact status** filter and set it to **In progress**, as shown in the following image.



b. Set the **Channel** filter to **Tasks**, **Email**, or **Chat** to view only task, email, or chat contacts.

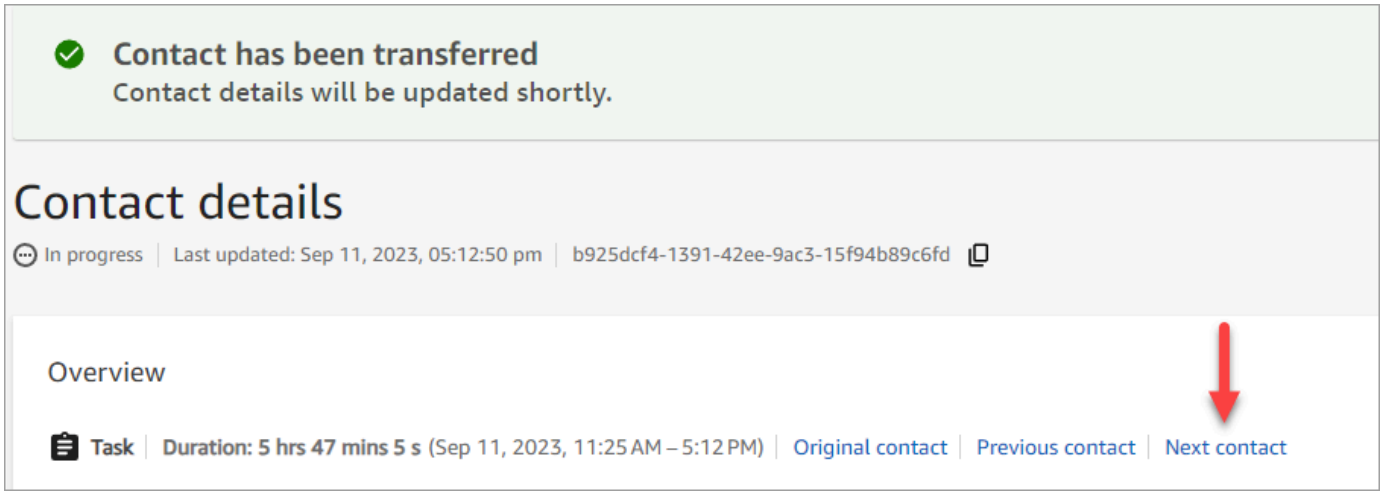
c. Choose the task, email, or chat contact to view its details.

4. On the **Contact details** page for the task, email, or chat contact, choose **Actions**, **Transfer**.



5. Select an agent or queue from a list of your quick connects and choose **Transfer**.

6. When the contact is transferred successfully, the page automatically refreshes with the **Next contact** link to the contact created as a result of the transfer. The following image shows the location of the **Next contact** link.



Reschedule contacts from the Contact details page in Connect Customer

On the **Contact details** page of an in-progress contact, you can reschedule a contact that was previously scheduled. This capability is currently supported only for task contacts.

To reschedule contacts programmatically, use the UpdateContactSchedule.

Required permissions

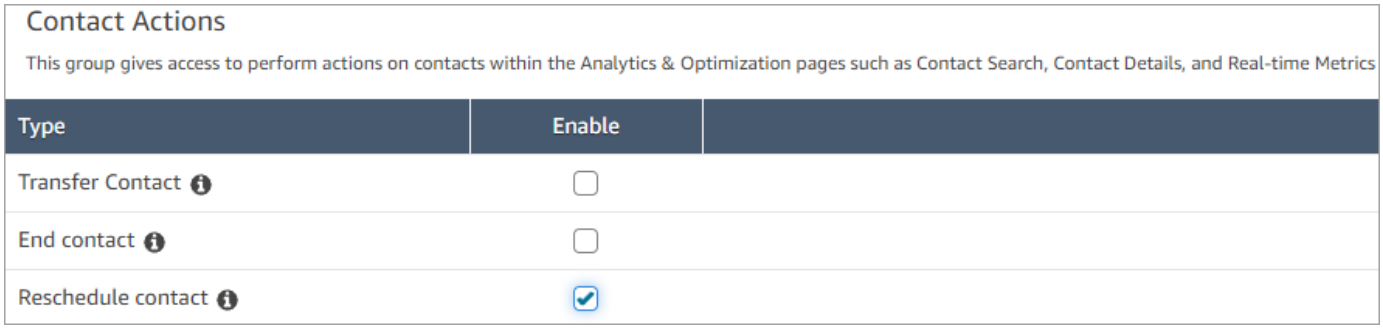
1. Enable one of the following permissions to view contacts on the **Contact search** and **Contact details** pages:

   a. **Contact search - View**: Allows a user to view all contacts

   b. **View my contacts - View**: Allows agents to view contacts that they themselves had handled

2. **Restrict contact access** (Optional): Restrict a user's access to contacts on the **Contact search** and **Contact details** pages within their own hierarchy group or any hierarchy groups below them. For more information about these permissions, see Manage who can search for contacts and access detailed information.

3. **Reschedule contact**: Enables a user to reschedule contacts on the **Analytics & Optimization** pages. The following image shows the **Contact Actions - Reschedule contact** permission.

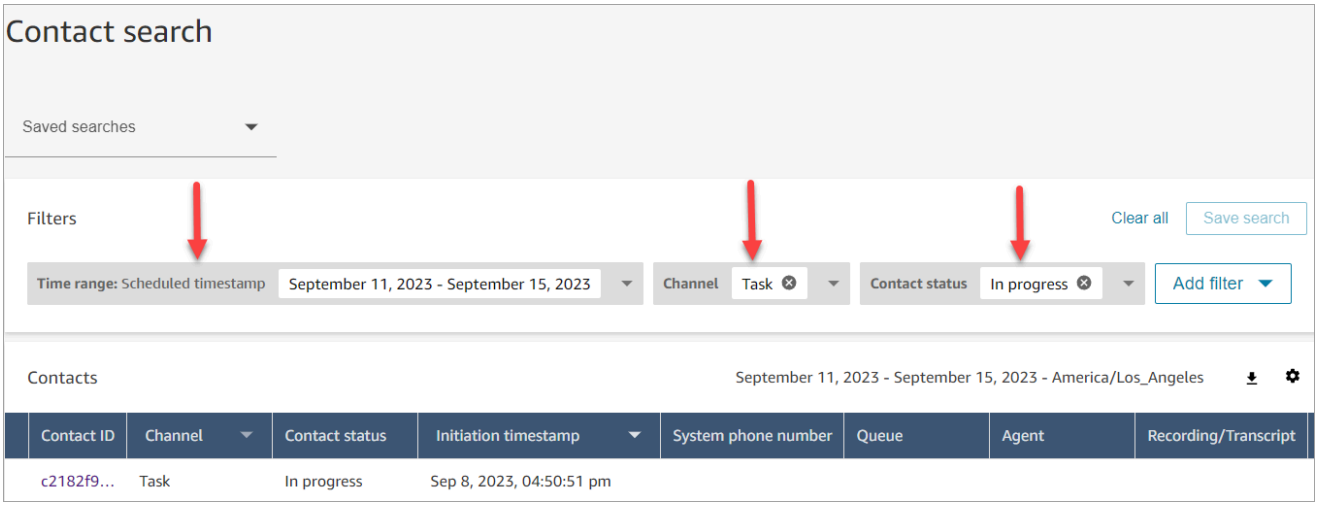


How to reschedule a contact

1. Log in to Connect Customer with a user account that has permissions to access contact records.
2. In Connect Customer choose **Analytics and optimization**, **Contact search**.
3. Search for an in-progress task contact to reschedule:

   a. Select the **Contact status** filter and change the selected value to **In progress**.

   b. Select the **Time range** filter. Set the **Timestamp type** to **Scheduled** to view only scheduled contacts. Filter for the time range. The following image shows these filters.



4. Choose the scheduled contact to view its details.
5. On the **Contact details** page of the task contact, choose **Actions**, **Reschedule**, as shown in the following image.

6. Select the time and range to reschedule the contact. The scheduled time must be within 90 days of when the task was initiated, and before the task's expiry time.
7. When the contact is rescheduled successfully, the page automatically refreshes with the new schedule time for the task.

End contacts from the Contact details page in Connect Customer

On the **Contact details** page of an in-progress contact, you can end a contact. Ending a contact results in the contact being disconnected. If the contact was already connected to an agent, ending the contact starts After Contact Work (ACW) for the contact.

To end contacts programmatically, use the StopContact.

Important things to know

- If you end a task contact after ACW is in progress, the contact is terminated. Voice and chat contacts that are in ACW state cannot be terminated by performing **End contact** action on the **Contact details** page.
- You cannot end voice contacts when they are initiated using the following methods:
  - DISCONNECT
  - TRANSFER
  - QUEUE_TRANSFER
- You can end chat and task contacts regardless of how they were initiated.

Required permissions

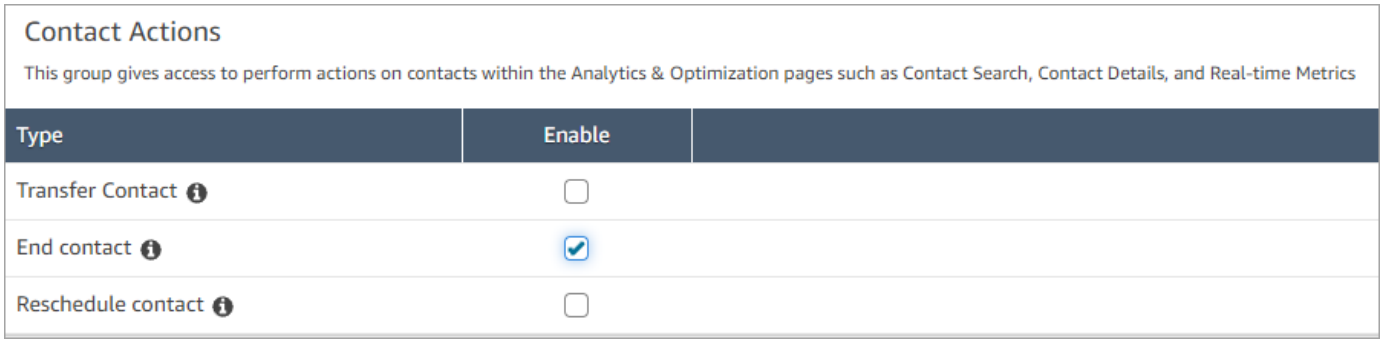
1. Enable one of the following permissions to view contacts on the **Contact search** and **Contact details** pages:

a. **Contact search - View**: Allows a user to view all contacts.

b. **View my contacts - View**: Allows agents to view contacts that they themselves had handled.

2. **Restrict contact access** (Optional): Restrict a user's access to contacts on the **Contact search** and **Contact details** pages within their own hierarchy group or any hierarchy groups below them. For more information about these permissions, see Manage who can search for contacts and access detailed information.

3. **End Contact**: Enables a user to end contacts on the **Analytics & Optimization** pages. The following image shows the **Contact Actions - End contact** permission.



How to end an in-progress contact

1. Log in to Connect Customer with a user account that has permissions to access contact records.
2. In Connect Customer choose **Analytics and optimization**, **Contact search**.
3. Select the **Contact status** filter and change the selected value to **In progress**.
4. Choose an in-progress contact to view its details.
5. On the **Contact details** page choose **Actions**, **End**.

6. Confirm the action to end the contact by choosing **End**.

7. When the contact is ended successfully, the page automatically refreshes.

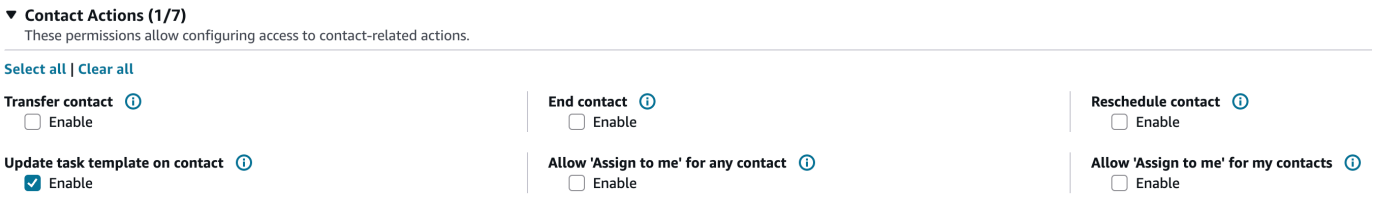
Update the task template on an in-progress contact in Connect Customer

On the **Contact details** page of an in-progress task contact that is not assigned to an agent, you can update the task template associated with the contact. This is useful when a task was created without a template, or when the task needs a different template to represent updated task data.

To update the task template programmatically, use the UpdateContactTaskTemplate operation.

Required permissions

1. Enable one of the following permissions to view contacts on the **Contact search** and **Contact details** pages:
   a. **Contact search - View**: Allows a user to view all contacts
   b. **View my contacts - View**: Allows agents to view contacts that they themselves had handled
2. **Restrict contact access** (Optional): Restrict a user's access to contacts on the **Contact search** and **Contact details** pages within their own hierarchy group or any hierarchy groups below them. For more information about this permission, see Manage who can search for contacts and access detailed information.
3. **Update task template on contact**: Enables a user to update the task template on contacts from the **Contact details** page. The following image shows the **Contact Actions - Update task template on contact** permission.



How to update template on a task contact

1. Log in to Connect Customer with a user account that has permissions to access contact records.
2. In Connect Customer choose **Analytics and optimization**, **Contact search**.

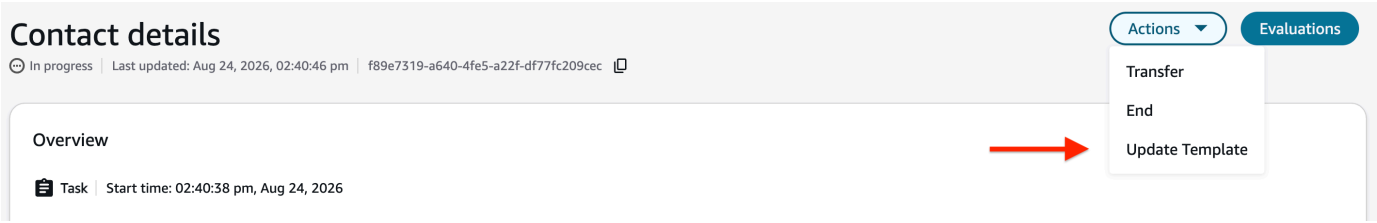
3. Search for an in-progress task contact to update the template:

   a. Select the **Contact status** filter and set it to **In progress**, as shown in the following image.

   b. Set the **Channel** filter to **Tasks** to view only task contacts.

   c. Choose the task contact to view its details.

4. On the **Contact details** page for the task contact, choose **Actions**, **Update Template**.



5. When the task template updates successfully, the page automatically refreshes to display the current task template in use.

Tag contacts on the Contact details page in Connect Customer

Tags are key-value pairs that help you categorize and organize contacts so you can find related contacts in **Contact search**. On the **Contact details** page, you can add up to 6 tags to an in-progress or completed contact that you can access.

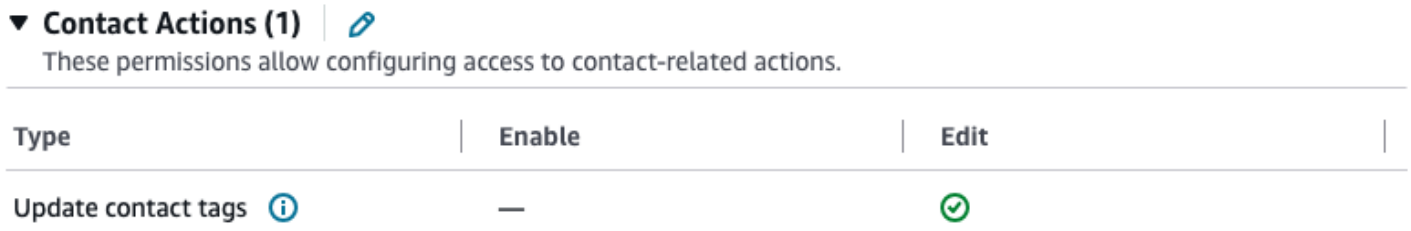
To add or remove tags programmatically, use the TagContact and UntagContact operations.

> **Note**
>
> Tag-based access control is not yet supported on contacts.

Required permissions

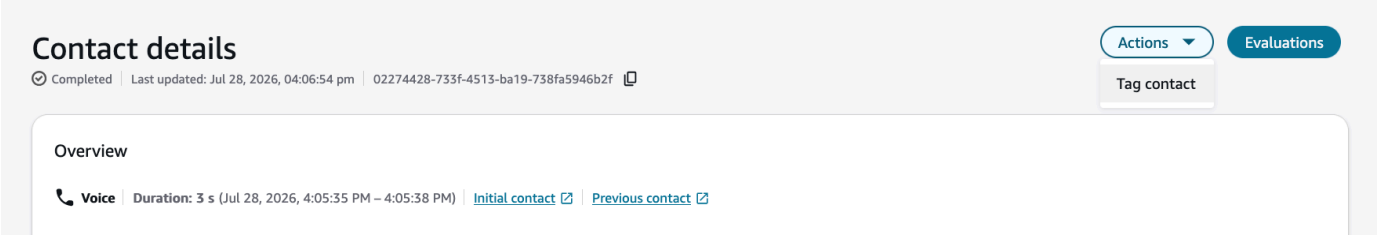
- Enable one of the following permissions to view contacts on the **Contact search** and **Contact details** pages:
  - **Contact search - View**: Allows a user to view all contacts.
  - **View my contacts - View**: Allows agents to view only those contacts that they handled.
- (Optional) **Restrict contact access**: Restricts a user's access on the **Contact search** and **Contact details** pages to contacts in their hierarchy group and any groups below it. For more information, see Manage who can search for contacts and access detailed information.
- **Update contact tags**: Allows a user to add and remove tags from contacts on the **Contact details** page.

The following image shows the **Contact Actions - Update contact tags** permission.

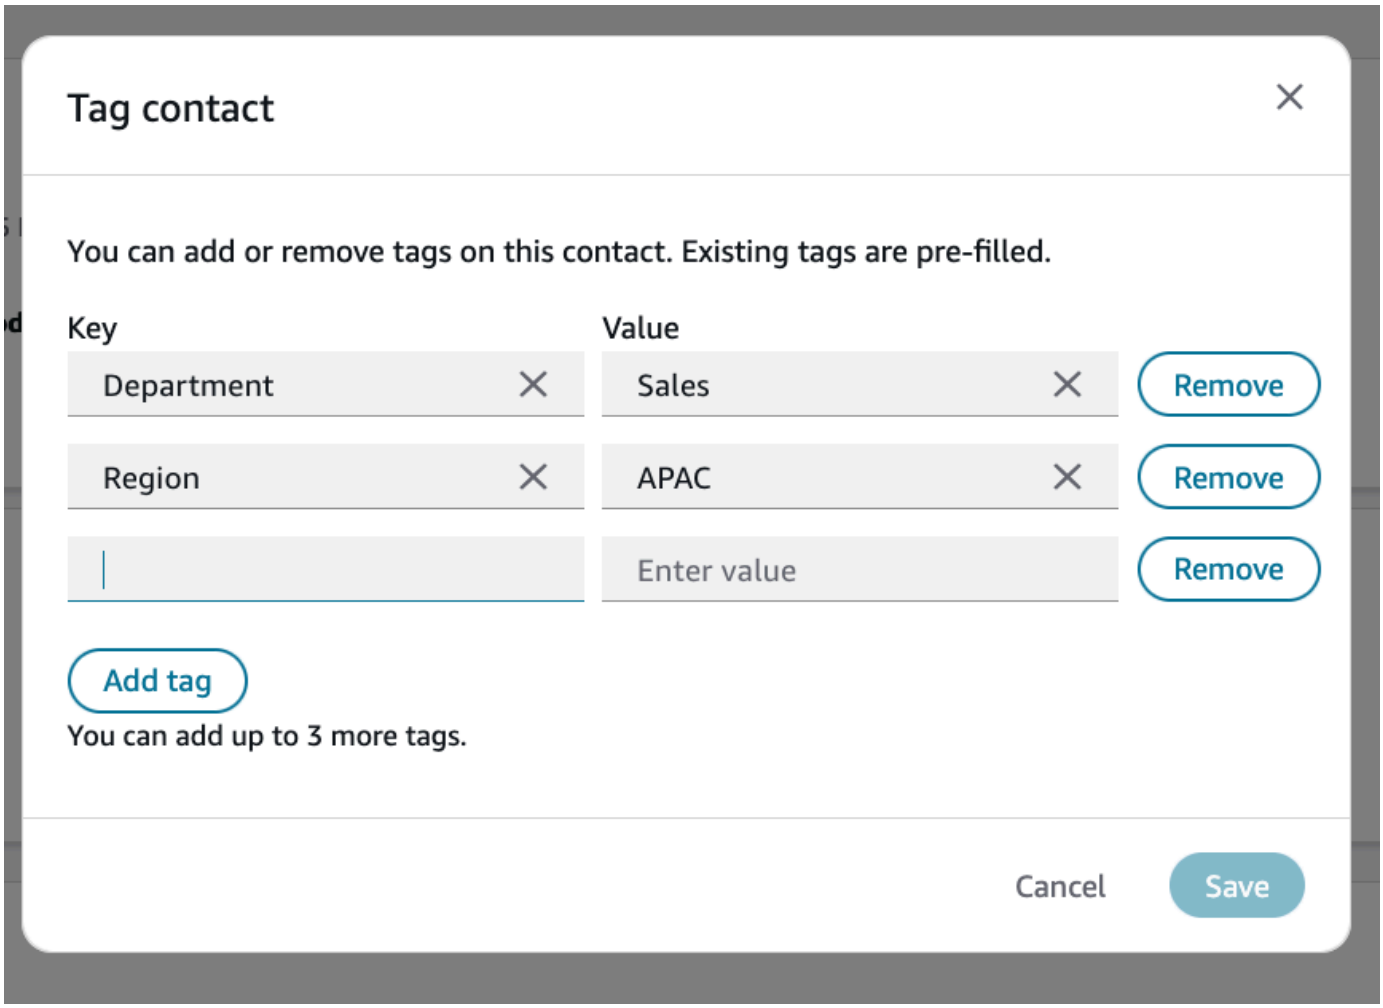


How to tag a contact

1. Log in to Connect Customer with a user account that has permissions to access contact records.
2. In Connect Customer, choose **Analytics and optimization**, **Contact search**.
3. Search for the contact you want to tag. The contact can be in-progress or completed.
4. Choose the contact to view its details.
5. On the **Contact details** page, choose **Actions**, **Tag contact**.



6. The **Tag contact** dialog opens. Existing tags on the contact are pre-filled.



7. Enter a **Key** and **Value** for the tag.
8. (Optional) To add another tag, choose **Add tag**, and then enter its **Key** and **Value**.
9. Choose **Save**.

How to remove a tag from a contact

1. On the **Contact details** page, choose **Actions**, **Tag contact**.
2. In the **Tag contact** dialog, choose **Remove** next to the tag you want to remove.

3. Choose **Save**.

Recording ingestion and conversational analytics

This guide provides instructions for importing voice recordings from third-party voice systems into Connect Customer and generating conversational analytics.

> **Note**
>
> Recording ingestion is only available in Amazon Connect Customer instances.

Common use cases

Recording ingestion and conversational analytics help address several customer needs:

- **Migration acceleration** – Customers moving to Connect Customer can ingest recordings from their existing voice system and start using conversational analytics insights without changing their voice traffic or agent experience.
- **Continuity during migration** – Customers actively migrating to Connect Customer can import recordings so that agents can find historical contacts directly in Connect Customer, without switching to the older system.
- **Unified analytics across systems** – Existing Connect Customer customers who also operate branch voice systems, meeting applications, or other telephony systems can import recordings from those systems for centralized and consistent contact tracking and conversational analytics within Connect Customer.

Getting started

Before using recording ingestion, complete the following configuration steps:

- **Service quotas** – Request increases for required API quotas
- **Prerequisites** – Verify your instance setup and permissions

Service quotas

The following service quotas apply to recording ingestion.

- **Rate of CreateAttachedFile API requests** – The default quota is 0 and must be increased before you can create contacts for recording ingestion.
- **Rate of StartContactConversationalAnalyticsJob API requests** – The default quota is 0 and must be increased before you can start analytics jobs.
- **Concurrent analysis jobs** – The default quota is 200 per account and can be increased upon request.

Prerequisites

- An Amazon Connect Customer instance.
- Conversational analytics enabled on your instance. To enable, open your instance in the AWS Console and navigate to **Applications**, **Analytics tools**.
- At least one active agent in your Connect Customer instance to associate with imported contacts. Depending on your requirements, you might want to do one of the following:
  - Assign all contacts to a single logical agent
  - Assign contacts to a single logical agent per line of business
  - Assign each contact to a specific individual agent
- Call recordings must be provided in the Connect Customer native format:
  - Format: Linear16 PCM WAV, 8 kHz, stereo, 16-bit
  - Channels: right = agent audio, left = customer audio (including conferenced participants)
  - Maximum recording duration: 4 hours
- Your recording source Amazon S3 bucket must be in the same AWS account and AWS Region as your Connect Customer instance.

  The recording Amazon S3 bucket is configured in your instance's **Data storage** settings. In the AWS Console, select your instance and navigate to **Data storage**, **Call recordings**.
- If call recording encryption is enabled, you must use a customer-managed AWS KMS key (CMK) — service-managed keys are not supported. Alternatively, you can disable call recording encryption.

Known limitations

- A contact can only have a recording attached to it once. Recordings cannot be replaced once attached to a contact.

- CreateAttachedFile and StartContactConversationalAnalyticsJob only operate on imported contacts. You cannot use these APIs on other Connect Customer contacts.
- A contact can only have conversational analytics processing performed once. If a contact already has conversational analytics results, initiating a new processing request will fail.
- Connect Customer does not transcode recordings. Recordings not matching the required format will be rejected.
- Contact timestamps (`InitiationTimestamp`, `DisconnectTimestamp`, `ConnectedToAgentTimestamp`) reflect the time the CreateContact API was called, not the original call time from the source system. You can use custom contact attributes to store original timestamps if needed.

Best practices

- Test the end-to-end workflow in a non-production Connect Customer instance before using in production.
- Ensure WAV files meet the format requirements before ingestion — invalid formats are rejected.
- Wait for the recording attachment to complete before calling StartContactConversationalAnalyticsJob. Monitor your contact trace record (CTR) delivery through Amazon Kinesis Data Stream or Amazon Kinesis Data Firehose to confirm attachment status. For more information, see Enable data streaming for your Connect Customer instance.
- Configure EventBridge to receive analytics job failure notifications. For more information, see Error notifications: When conversational analytics can't analyze a contact.

Configuration

Before you can use the recording ingestion APIs, configure the following:

- **Amazon S3 source bucket policy** – Grant Connect Customer permission to read recordings from your bucket
- **AWS KMS key policy** – Allow Connect Customer to decrypt recordings if encryption is enabled
- **IAM permissions** – Grant your users or roles permission to call the recording ingestion APIs

Amazon S3 source bucket policy

Your source Amazon S3 bucket must grant Connect Customer permission to read recordings from it.

Add the following policy to your source bucket, replacing the placeholder values:

```
{
  "Version": "2012-10-17",
  "Statement": [{
    "Effect": "Allow",
    "Principal": { "Service": "connect.amazonaws.com" },
    "Action": "s3:GetObject",
    "Resource": "arn:aws:s3:::SOURCE_BUCKET_NAME/*",
    "Condition": {
      "StringEquals": { "aws:SourceAccount": "YOUR_AWS_ACCOUNT_ID" },
      "ArnEquals": { "aws:SourceArn": "YOUR_CONNECT_INSTANCE_ARN" }
    }
  }]
}
```

Amazon S3 destination bucket policy

The destination bucket is the Amazon S3 bucket configured in the **Call Recording** section under the **Data Storage** tab of your Connect Customer console. Connect Customer needs permission to write recordings into this bucket.

Add the following policy to your destination bucket, replacing the placeholder values:

```
{
  "Version": "2012-10-17",
  "Statement": [{
    "Effect": "Allow",
    "Principal": { "Service": "connect.amazonaws.com" },
    "Action": ["s3:PutObject", "s3:ListBucket"],
    "Resource": [
      "arn:aws:s3:::DESTINATION_BUCKET_NAME",
      "arn:aws:s3:::DESTINATION_BUCKET_NAME/*"
    ],
    "Condition": {
      "StringEquals": { "aws:SourceAccount": "YOUR_AWS_ACCOUNT_ID" },
      "ArnEquals": { "aws:SourceArn": "YOUR_CONNECT_INSTANCE_ARN" }
```

```
    }
  }]
}
```

AWS KMS key policy (if encryption enabled)

If your Connect Customer instance has call recording encryption enabled, you must use a customer-managed AWS KMS key (service-managed keys are not supported). The key policy must grant the `connect.amazonaws.com` service principal the `kms:Decrypt`, `kms:Encrypt`, `kms:GenerateDataKey`, and `kms:DescribeKey` actions, scoped to your AWS account through the `aws:SourceAccount` condition.

Example key policy statement:

```
{
  "Sid": "AllowConnectServiceKMSAccess",
  "Effect": "Allow",
  "Principal": { "Service": "connect.amazonaws.com" },
  "Action": ["kms:Decrypt", "kms:Encrypt", "kms:GenerateDataKey", "kms:DescribeKey"],
  "Resource": "*",
  "Condition": {
    "StringEquals": { "aws:SourceAccount": "YOUR_AWS_ACCOUNT_ID" }
  }
}
```

IAM permissions to call APIs

The IAM principal making these API calls must have the following permissions:

- `connect:CreateContact`
- `connect:CreateAttachedFile`
- `connect:StartContactConversationalAnalyticsJob`

Transcoding (if required)

Connect Customer does not transcode recordings. Recordings that do not match the required format (Linear16 PCM WAV, 8 kHz, stereo, 16-bit) will be rejected.

If your source recordings are in a different format, you can use tools such as FFmpeg to transcode them before ingestion.

Example: Convert an MP3 to the required WAV format:

```
ffmpeg -i input.mp3 -acodec pcm_s16le -ar 8000 -ac 2 output.wav
```

Breakdown:

- `-acodec pcm_s16le` – Linear PCM, 16-bit, little-endian (Linear16)
- `-ar 8000` – 8 kHz sample rate
- `-ac 2` – stereo (2 channels)

This produces a WAV file matching the Connect Customer recording format. The channel mapping (left = customer, right = agent) depends on how your source MP3 is already laid out.

If you need to swap channels, add:

```
ffmpeg -i input.mp3 -af "pan=stereo|c0=c1|c1=c0" -acodec pcm_s16le -ar 8000 output.wav
```

This swaps left and right so you can get customer on the left and agent on the right.

API workflow

Recording ingestion and conversational analytics uses a workflow of three sequential API calls:

- CreateContact – Create a voice contact to represent the call
- CreateAttachedFile – Import a recording from your Amazon S3 bucket and attach it to the contact
- StartContactConversationalAnalyticsJob – Create the conversational analytics for the contact

Step 1: CreateContact

Use CreateContact to create a voice contact in `COMPLETED` state. The contact represents the call and is the anchor for the recording and analytics.

Request:

```
aws connect create-contact \
  --instance-id "instance-id" \
  --region "region" \
  --cli-input-json '{
```

```
    "InstanceId": "instance-id",
    "ClientToken": "unique-idempotency-token",
    "Channel": "VOICE",
    "InitiationMethod": "INBOUND",
    "InitiateAs": "COMPLETED",
    "Name": "descriptive-contact-name",
    "Description": "optional-description",
    "UserInfo": { "UserId": "agent-arn" }
  }'
```

Response:

```
{ "ContactId": "contact-id" }
```

Notes:

- `UserInfo.UserId` must be the ARN of an agent that exists in your Connect Customer instance.
- You will need the returned `ContactId` in Steps 2 and 3.

Step 2: CreateAttachedFile

Use CreateAttachedFile to import the recording from your Amazon S3 bucket into Connect Customer storage. Connect Customer performs an S3-to-S3 copy.

Request:

```
aws connect create-attached-file \
  --instance-id "instance-id" \
  --region "region" \
  --file-use-case-type "VOICE_RECORDING" \
  --file-source-uri "s3://source-bucket/path-to-recording.wav" \
  --associated-resource-arn "contact-arn" \
  --client-token "unique-idempotency-token"
```

Response:

```
{
  "CreationTime": "2026-03-31T00:00:00.000Z",
  "FileId": "file-id",
  "FileArn": "arn:aws:connect:region:account-id:instance/instance-id/file/file-id",
  "FileStatus": "PROCESSING"
```

```
}
```

Notes:

- Construct the `ContactArn` using the `ContactId` from Step 1:

  ```
  arn:aws:connect:region:account-id:instance/instance-id/contact/contact-id
  ```

- `ClientToken` enables safe retries — pass the same value to retry the request without creating duplicate resources.
- Attempting to attach a second recording to the same contact will be rejected.
- `FileStatus` will be `PROCESSING` initially. The copy completes asynchronously — monitor your CTR (delivered through Amazon S3 or Kinesis) for the final attachment status.
- Do not attempt Step 3 until the recording is attached.
- The external voice charge applies after the recording is attached. For pricing information, see Connect Customer Pricing.

Step 3: StartContactConversationalAnalyticsJob

Use StartContactConversationalAnalyticsJob to initiate conversational analytics on the imported recording.

Request:

```
aws connect start-contact-conversational-analytics-job \
  --instance-id "instance-id" \
  --contact-id "contact-id" \
  --region "region" \
  --cli-input-json '{
    "AnalyticsModes": ["PostContact"],
    "AnalyticsConfiguration": {
      "LanguageConfiguration": { "LanguageLocale": "en-US" },
      "RedactionConfiguration": { "Behavior": "Enable", "Policy":
 "RedactedAndOriginal" },
      "SentimentConfiguration": { "Behavior": "Enable" },
      "SummaryConfiguration": { "SummaryModes": ["PostContact"] },
      "RulesConfiguration": { "Behavior": "Enable" }
    }
  }'
```

Response:

```
{ "ContactId": "contact-id", "InstanceId": "instance-id" }
```

Notes:

- The contact must be in `COMPLETED` state with a recording attached.
- `RedactionConfiguration.Policy` options: `RedactedOnly`, `RedactedAndOriginal`.
- `RulesConfiguration` cannot be disabled — the rules configured in your account are executed.
- Analysis runs asynchronously. Results are delivered to your Connect Customer-configured Amazon S3 bucket.
- `ContactId` is used as the job identifier — duplicate analysis jobs on the same contact are not allowed.
- Subscribe to EventBridge to receive notifications when analysis fails. Successful completion is indicated by the conversational analytics output file being delivered to your configured Amazon S3 bucket. For more information, see Error notifications: When conversational analytics can't analyze a contact.

Verification

To confirm the workflow completed successfully, check the following in the Connect Customer console:

- The contact appears in the **Contact search** results with the expected name and description.
- The recording is playable in the **Contact Details** page.
- Conversational analytics (transcript, sentiment, categories, summary) are visible in the **Contact Details** page.

To retrieve details about the contact—such as its channel, initiation method, recording status, and contact attributes—you can call the DescribeContact API. For more information about the DescribeContact API, see DescribeContact.

In the following AWS CLI command, replace *instance-id*, *contact-id*, and *region* with your own values.

```
aws connect describe-contact \
```

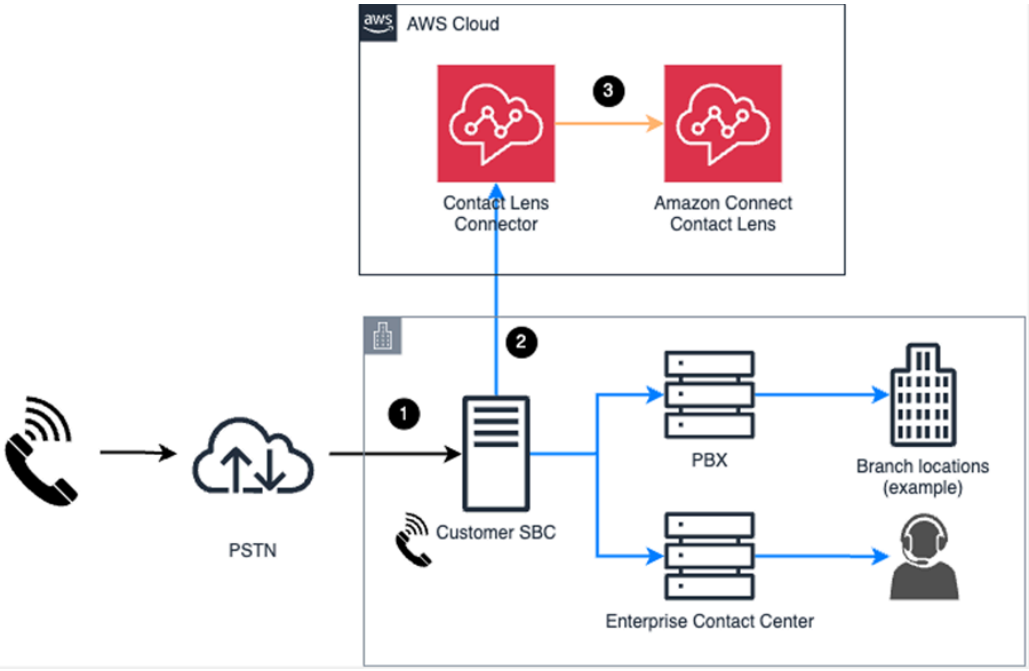
```
  --instance-id "instance-id" \
  --contact-id "contact-id" \
  --region "region"
```

Integrate Connect Customer conversational analytics with external voice systems

Migrating a contact center from an external system to the cloud can be complicated. It requires moving many different components such as telephony, IVR, ACD, call recording, call analytics, and more. By integrating your external system with conversational analytics for analytics, however, you can accelerate your migration to Connect Customer. Here's how this first step can benefit your business:

- Conversational analytics integration enhances your existing external contact center recording and analytics capabilities.
- It provides an opportunity to train your contact center administrators, managers, and agents on Connect Customer.
- Conversational analytics helps uncover key trends, issues, and themes from customer interactions happening across multiple voice systems such as external contact centers or customer facing voice solutions (for example, phone consults, financial advisors, or banking relationship managers).

The following diagram shows how the voice call audio flows between your external voice system and conversational analytics. You use the conversational analytics Connector to send a replica of your contact center audio to conversational analytics. The external call flow continues to operate as normal for your agents, while conversational analytics provides real-time and post-call analytics using the replicated call audio.



1. A call sent through PSTN lands on your external voice system.
2. A read-only copy of the call audio is forked into Connect Customer.
3. A flow is started for the call. The conversational analytics connector routes the call to Connect Customer conversational analytics.

Requirements

Before you start setting up conversational analytics integration, check that your Connect Customer and external systems meet the following requirements:

- Verify your Connect Customer instance is created in a supported AWS Region. Make sure your external voice system can connect to the Region.
- Make sure the external device that initiates the SIPREC session and the voice system that is used for the call are supported. For a list of supported systems, see `ContactCenterSystemTypes` and `SessionBorderControllerTypes` in the PutVoiceConnectorExternalSystemsConfiguration in the Amazon Chime API. Usually the SIPREC session is a Session Border Controller (SBC) and the voice system is your contact center.
- Verify you have SIPREC support or the ability to add SIPREC to the source system that will send the SIPREC replica call audio to conversational analytics.
- The maximum call duration that can be streamed into Connect Customer is 3 hours and 45 minutes. Audio beyond this duration is not streamed or analyzed.

Set up steps

Following is a summary of the steps you'll take to set up conversational analytics integration with your external voice system. The linked topics provide more detail.

- Create a Connect Customer instance if you don't already have one.
  - You don't need to claim a phone number to Connect Customer to integrate with conversational analytics.
  - Add agents and set up agent hierarchies. This will help you to attribute the analytics generated by conversational analytics to specific agents.

    Note

    If no agent is identified for a call, the replica call in conversational analytics terminates. No recording and conversation analytics are produced. For more information, see Provide call metadata for conversational analytics integration.

- Request service quota increases for the following quotas in your Connect Customer account:
  - **conversational analytics connectors per account**
  - **Maximum active recording sessions from external voice systems per instance**

    Important

    After your service quotas are requested and approved, conversational analytics integration will be visible in the Connect Customer console and the Connect Customer admin website.

- Create a conversational analytics connector in the Connect Customer console.
- Configure your SBC to send SIPREC audio to that connector host along with call metadata.
- Enable the conversational analytics connector on the Connect Customer admin website. You do this by assigning the following security profiles permissions to Admins and other users who need to access the conversational analytics connectors:
  - **Analytics and Optimization - conversational analytics connectors - View** and **Edit**. The **View** permission helps you see the list of available conversational analytics connectors. The **Edit** permission helps you associate flows with a conversational analytics connector.

- **Channels and Flows - Flows - View**: This permission helps you see the available flows you can associate with a conversational analytics connector.

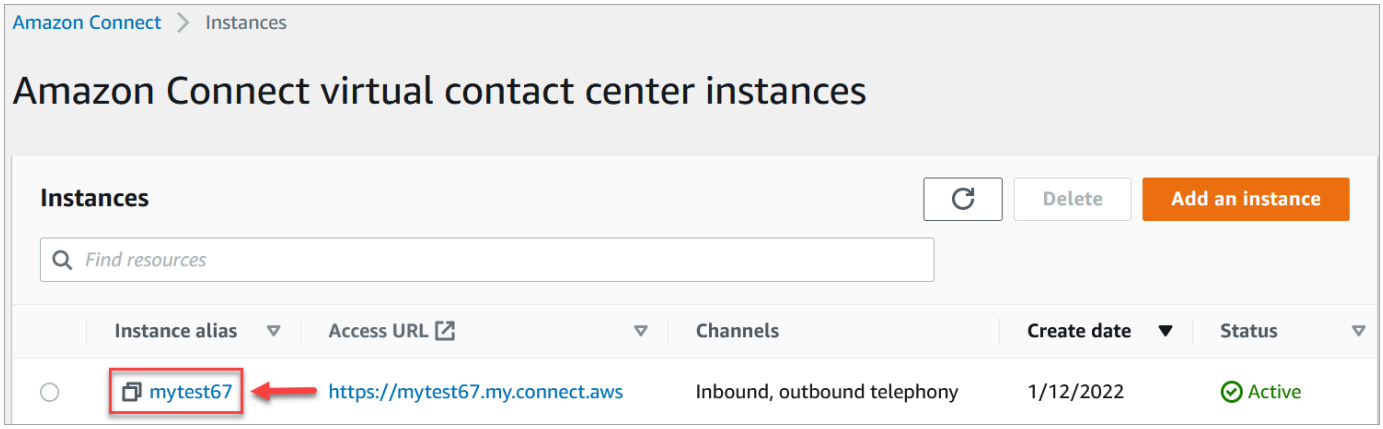
  Only users who have these permissions will be able to access the conversational analytics connector on the Connect Customer admin website.

- Create a flow to specify how to process the call audio including recording, live or post call analytics, and associate the flow with the conversational analytics connector.
- Optionally, create a Lambda that can be invoked when the Connect Customer flow is triggered. Use the Lambda to parse the SIPREC request and additional call meta data, and take actions. For more information, see Call metadata for conversational analytics integrations.

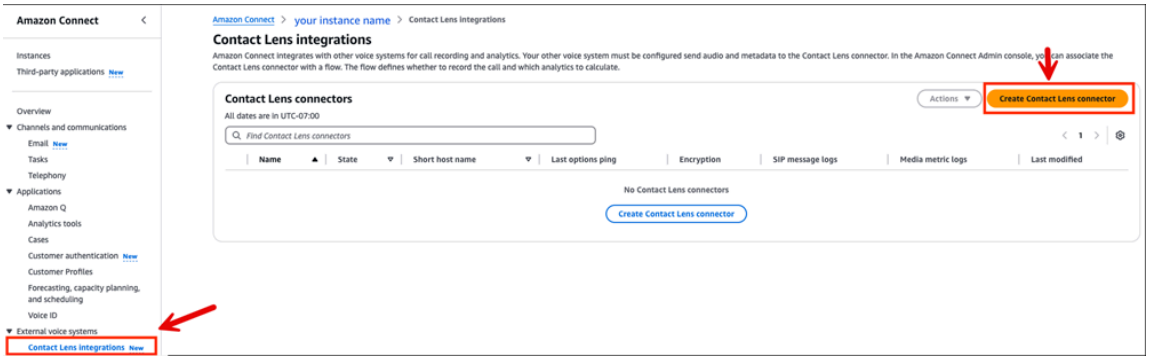
Create a conversational analytics connector to integrate with your external voice system

This topic explains how to create a conversational analytics connector to integrate with your external voice system. Complete the following steps.

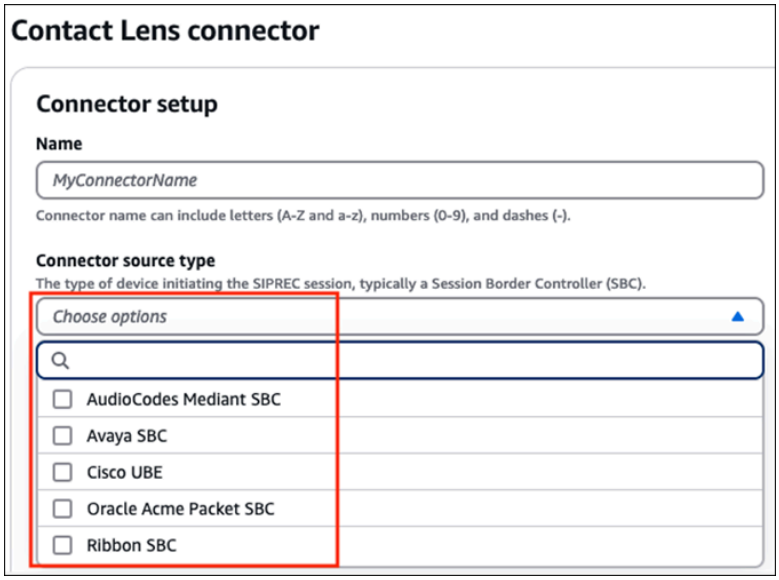
1. Open the Connect Customer console at https://console.aws.amazon.com/connect/.
2. On the instances page, choose the instance alias. The instance alias is also your **instance name**, which appears in your Connect Customer URL. The following image shows the **Connect Customer virtual contact center instances** page, with a box around the instance alias.



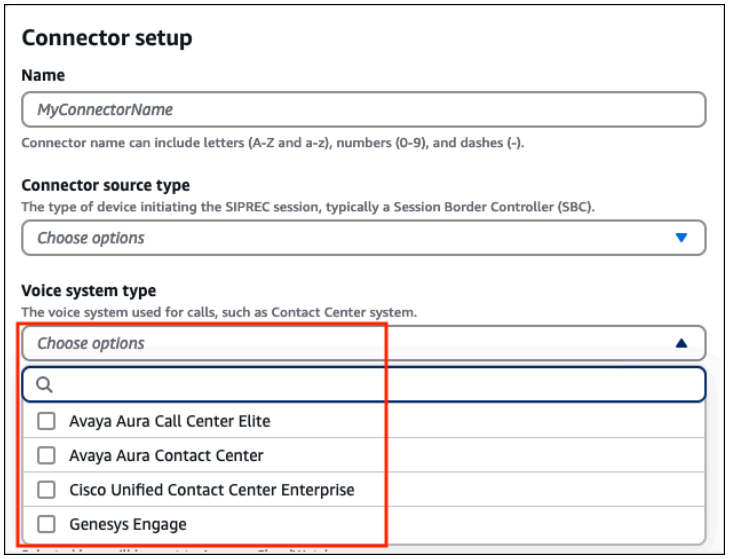
3. In the Connect Customer console, in the navigation pane, choose **External voice systems**, **conversational analytics integrations**, and then choose **Create conversational analytics connector**, as shown in the following image.



4. On the **conversational analytics connector** page, type a friendly name for the connector.
5. Under **Connector source type**, use the dropdown menu to select from a list of available connector source types. Usually this is an external Session Border Controller (SBC) that will initiate the SIPREC session. The following image shows a sample dropdown list of source types.



6. Under **Voice system type**, use the dropdown list to select the voice system used for the call. Usually this is your external contact center system. The following image shows a sample dropdown list of voice system types.



7. Enable **Encryption** and **Logging** of the SIP and Media metric messages.

   - Amazon Chime SDK Voice Connector uses TLS server certificates issued by Amazon Trust Services. Most modern operating systems trust Amazon Trust Services by default. If this is not the case for your SIP infrastructure and you enable encryption, you might need to add the Starfield and Amazon Trust Services root CA certificates, excluding the EU roots, to your trust stores. You can find these certificates here.
   - Although logging is optional, we recommend you enable it to help you debug integration issues.

8. In the **Source IP addresses** section, you can configure a range of Source IP addresses that are allowed to send voice to this connector.

9. In the **Credentials - optional** section, we recommend that you create credentials. They can help authenticate the SIPREC sessions.

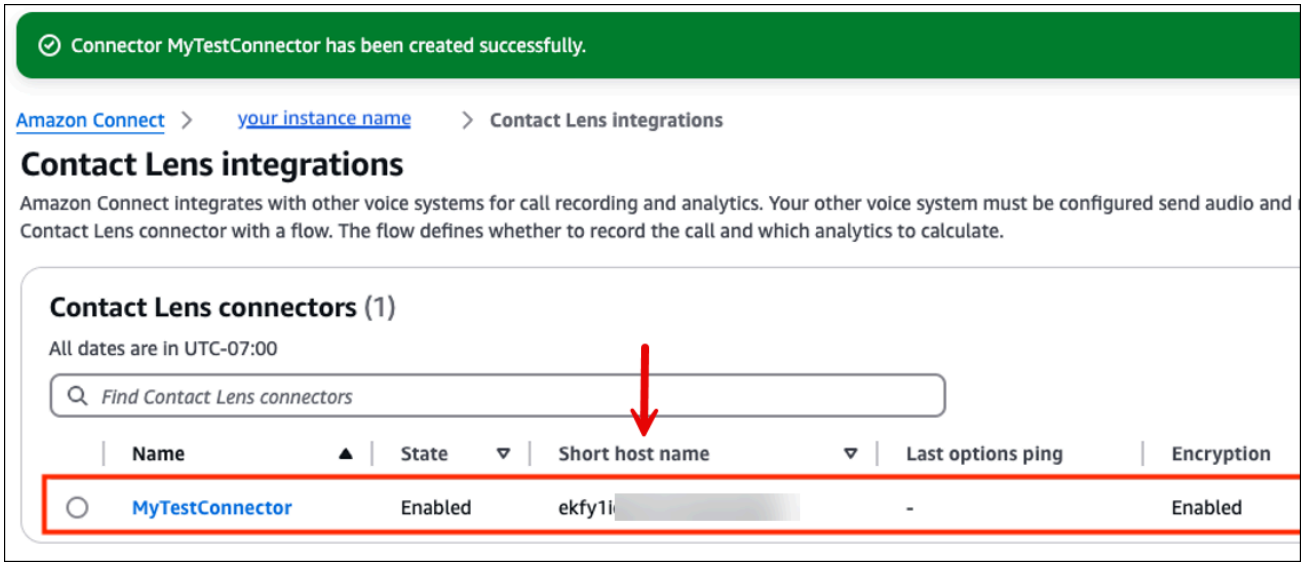
   > **Note**
   >
   > If you do this, you'll need to provide the same credentials when you configure your external system.

10. Optionally, add tags to identify, organize, search for, filter, and control who can access this connector. For more information, see Add tags to resources in Connect Customer.

11. Choose **Create conversational analytics connector** to create the connector. After the connector is created, a success message is displayed.

12. On the **conversational analytics integrations** page you'll see the short host name. This is the host that your external voice system will send SIPREC voice traffic to.

    When you configure your external voice system, you'll use the fully qualified domain name of the host, not this short host name.

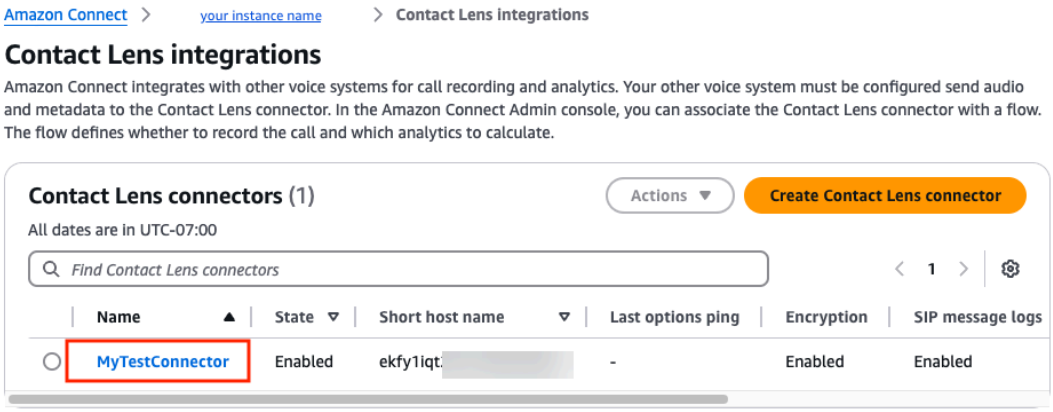


13. You're done creating the conversational analytics connector. Continue to the next step: Configure your external voice system for integration with conversational analytics.

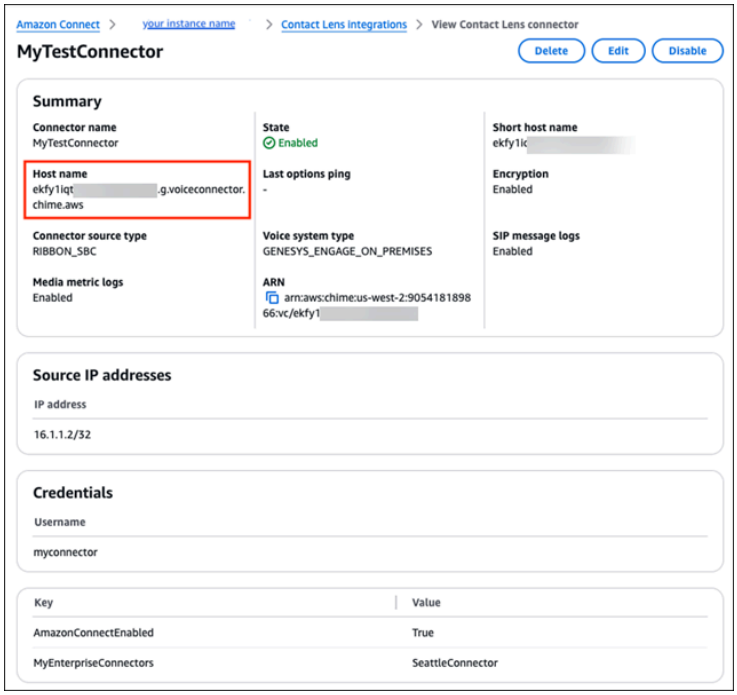
Configure your external voice system for integration with conversational analytics

After you create a conversational analytics connector you need to configure your external voice system to point to the connector. Complete the following steps.

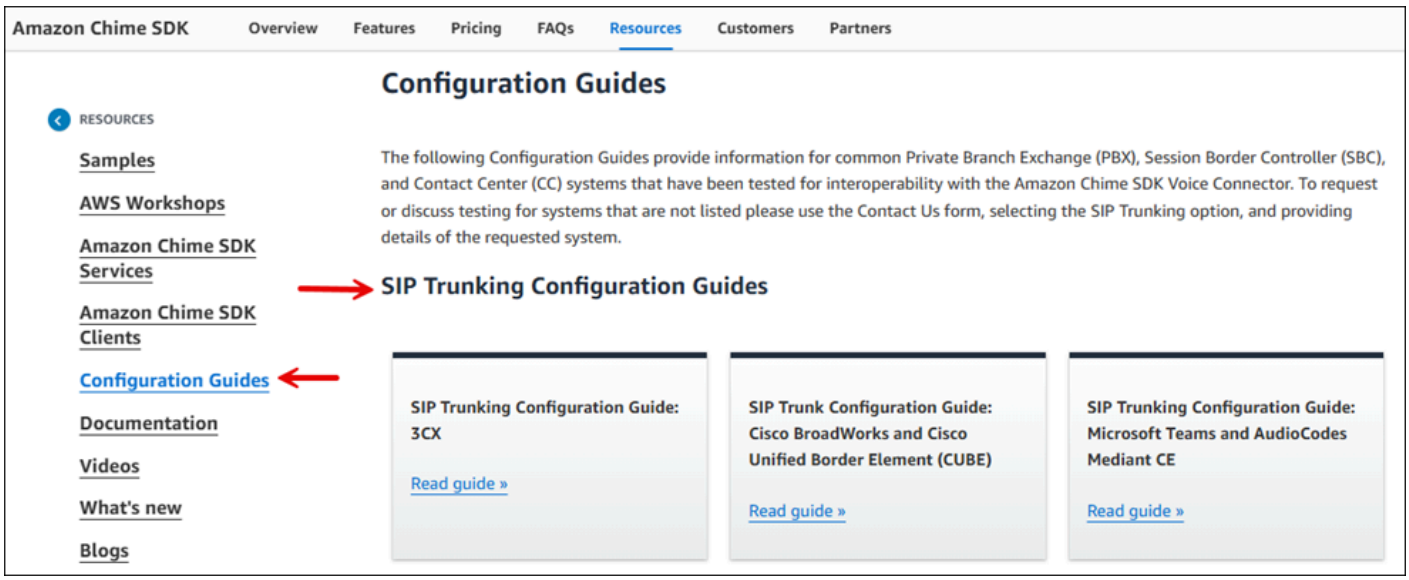
1. In the Connect Customer console navigation pane, choose **External voice systems**, **conversational analytics integrations**. You'll see the name of available conversational analytics connectors. Select the one you want to use. The following image shows an example conversational analytics connector named **MyTestConnector**.



2. On the connector details page, note the fully qualified host name. This is the name of the host in Connect Customer that will receive the SIPREC audio. The following image shows an example fully qualified host name.



3. For information about how to configure your external source system, go to the Amazon Chime SDK resources page, and choose **Configuration Guides**. Scroll down the page to **SIPREC/NBR Configuration Guides**, as shown in the following image.



> **Note**
>
> If you created credentials for the connector, you need to use the same credentials for your external system.

4. After you configure your external source system, continue to the next step: enable conversational analytics integration.

Model contact transfers and conferencing in Connect Customer

This topic is for developers who have integrated their external voice system with Connect Customer conversational analytics.

Your external voice system might support contact transfers (cold and warm) and conferencing multiple agents in a single call. You can signal these cases to Connect Customer by calling the CreateContact and StopContact APIs. These APIs create a contact chain similar to native Connect Customer voice contacts. Each leg of the call will get its own recording, contact record, and analytics, just like native Connect Customer voice contacts.

Each agent-customer interaction is modeled by an independent contact segment.

- To model adding an agent to an ongoing call, you create a new contact segment using the CreateContact API with initiation method TRANSFER. Transfer contacts are linked to the previous contact by their `previousContactId`.

- If enabled, call recordings are generated independently for each contact segment and delivered upon completion of that segment.
- Conversational analytics real-time and post-call analytics are generated for each contact segment independently.
- A contact record is generated for each independent contact segment.
- To model an agent leaving a call, you can end a contact segment by calling the StopContact API.

Workflow for warm transfer

Warm transfers involve putting the customer on hold as the agent makes an introduction about the caller to another party.

To model a warm transfer using the contact APIs, implement the following workflow:

1. A call in your external voice system creates an initial contact segment.
2. When the new agent joins the call, invoke the CreateContact API. Use the initial contact segment's `contactId` as the `PreviousContactId` parameter. Provide the new agent's ID in the `UserInfo` parameter.
3. Let the initial agent introduce the new agent to the call and then disconnect from the call.
4. When the initial agent disconnects from the call, invoke the StopContact API.
5. When the call ends in your external voice system (upon SIP BYE), the contact chain ends.

Workflow for cold transfer

Cold transfers involve directly transferring the customer from one agent to another without any introduction or context shared between them.

To model a cold transfer using the contact APIs, implement the following workflow:

1. A call in your external voice system creates an initial contact segment.
2. When the initial agent disconnects from the call, invoke the StopContact API.
3. When the new agent joins the call, invoke the CreateContact API. Use the initial contact segment's `contactId` as the `PreviousContactId` parameter. Provide the new agent's ID in the `UserInfo` parameter.
4. When the call ends in your external voice system (upon SIP BYE), the contact chain ends.

Contact segment limits

You can have up to two concurrent contact segments and 10 total contact segments in a chain.

Enable Connect Customer conversational analytics integration

After you create a conversational analytics connector, you need to enable the integration by assigning users security profile permissions so they can access it on the Connect Customer admin website.

1. Log in to the Connect Customer admin website at https://*instance name*.my.connect.aws/ using an Admin account.
2. On the navigation bar, choose **Security profiles**. On the **Manage security profiles** page, choose **Admin**, **Edit**.
3. On the **Edit security profile** page, choose **Channels and Flows** - **AnalyticsConnectors** - **View** and **Edit** permissions, and then choose **Save**.

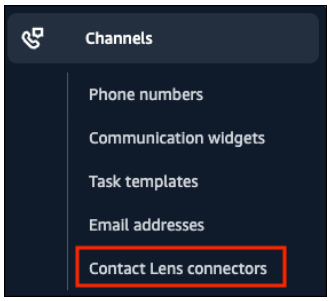
> **Important**
>
> If you don't see the conversational analytics connectors permission under **Channels and Flows**, request service quota increases for the following quotas in your Connect Customer account:
>
> - Conversational analytics connectors per account
> - Maximum active recording sessions from external voice systems per instance

4. Assign this permission to the security profiles for users who you want to access the conversational analytics connectors.

> **Note**
>
> You can only delete the last conversational analytics connector in your Connect Customer instance when the access to the conversational analytics connector is removed from the users of that instance.
> If you attempt to delete the last conversational analytics connector without first removing the conversational analytics connectors access from the users of that instance, the following error message is displayed: **error - Failed to delete connector {connector-**

name} with error: An analytics connector permissions is being used in a security profile.

5. After you apply the permission, users who have it will be able to see the **conversational analytics connectors** option in the Connect Customer admin website left navigation menu, as shown in the following image.



6. You're done enabling the conversational analytics connector. Continue to the next step: associate a conversational analytics connector with a flow.

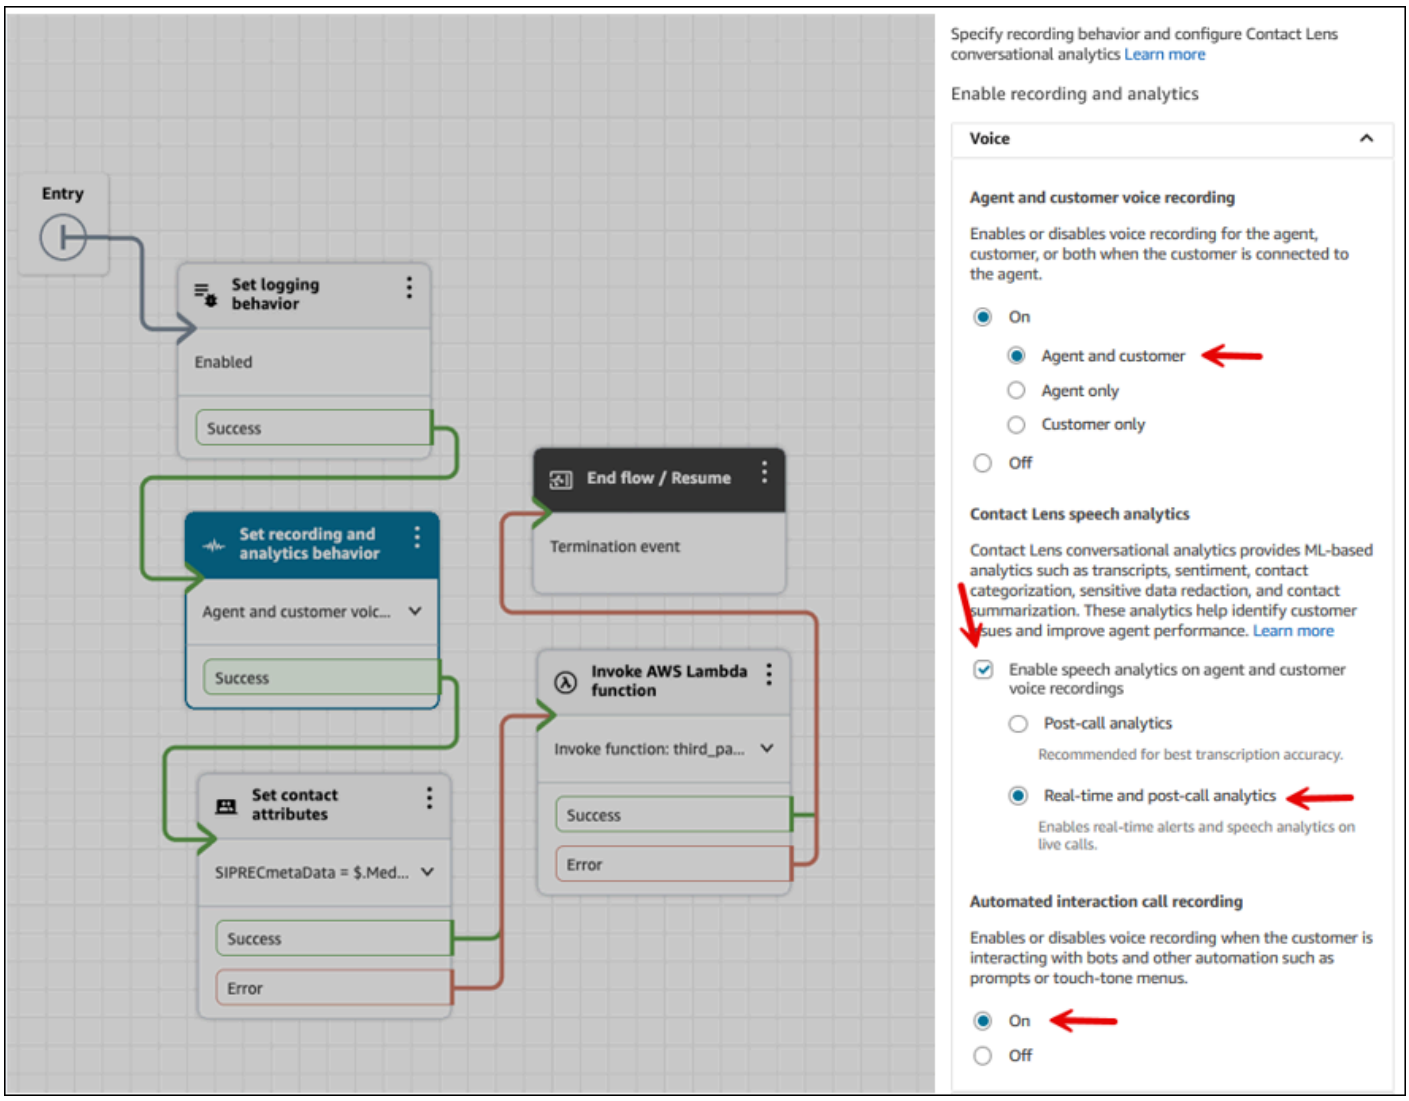
Associate a conversational analytics connector with a flow

After you have configured your external SBC to point to the conversational analytics integration connector host, you need to configure how the audio will be processed when it reaches Connect Customer conversational analytics. To do this, you define the audio processing steps in an Connect Customer flow. It specifies what steps the call audio will go through, including invoking conversational analytics.

Complete the following steps to create a flow that enables conversational analytics, and then associate the flow with the conversational analytics connector. This flow will be invoked when the conversational analytics connector receives call audio.

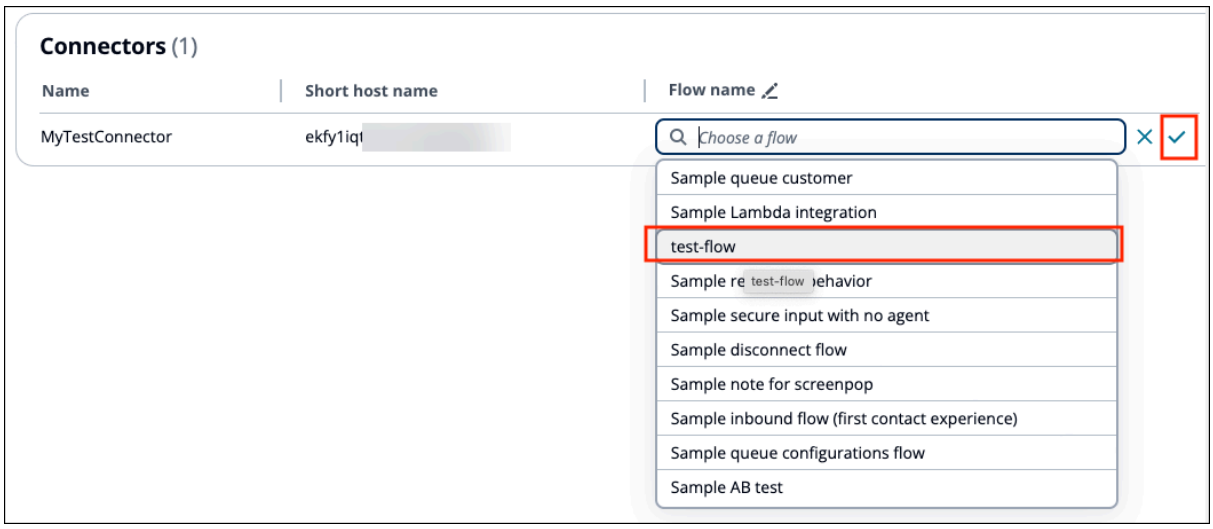
1. In the Connect Customer admin website, create a flow that uses the Set recording and analytics behavior. Configure the block to enable **Agent and customer voice recording**, **speech analytics**, and **Automated interaction call recording**. End the flow with the End flow / Resume block. This configuration is shown in the following image.

   For a list of blocks you can use in a conversational analytics integration, see Supported flow blocks for conversational analytics integration.



For detailed instructions, see Enable conversational analytics.

2. On the navigation menu, choose **Channels**, **conversational analytics connectors**. Choose the conversational analytics integration connector that you want to associate with the flow. In the **Flow name** field, start typing the name of your flow to display a list, and then choose the flow.



Provide call metadata for conversational analytics integration

In Connect Customer, each interaction with a customer is a Connect Customer contact. Each voice session that comes through the conversational analytics connector creates a Connect Customer contact. The connector creates a Connect Customer contact using the fields provided in the call metadata. The call metadata includes the agent user ID and agent queue ID for the streamed call in the call metadata.

You can provide the agent user ID and other call metadata to the conversational analytics connector by using supported SIPREC metadata parameters within the SIP INVITE of the audio stream session. The connector parses the following call metadata fields and adds this information to the Connect Customer contact.

Call State Field	SIPREC Metadata	Value	If not provided
Agent user id	`AmznConnectAgentUserId`	Connect Customer agent user id	Required
Queue id	`AmznConnectQueueId`	Connect Customer queue id	*Optional*. If not provided, the default queue of the Connect Customer instance is used.

Call State Field	SIPREC Metadata	Value	If not provided
Participant order	`AmznConnectParticipantOrder`	Valid values: `asc`, `desc`	*Optional*. If not provided, ascending order is used. Connect Customer sorts the SIPREC streams by using labels. The first stream in label order is the agent and the second is the caller.

A contact must have a Connect Customer agent user ID. conversational analytics starts capturing the streamed audio, and generating call recording and call analysis, only when the agentId is provided.

If agentid is missing then the Connect Customer conversational analytics connector session is terminated. If your SIPREC metadata was not parsed automatically by the Connect Customer conversational analytics connector and agent user ID is not set, you can create a flow lambda and access all the SIP and SIPREC metadata by using the following fields:

Attribute	Description	JSONPath Reference
SIPREC metadata	SIPREC metadata from the SIP event	$.Media.Sip.SiprecMetadata
SIP header	SIP header from the SIP event. {SIP header name} is the name of the SIP header provided in the SIP event. For example, "To", "From", and others.	$.Media.Sip.Headers.{SIP header name}

For more information, see Telephony call metadata attributes (call attributes).

How to use event metadata

Connect Customer publishes SIP, streaming, and contact events. These events include the metadata gathered from the SIPREC SIP INVITE of the calls. The metadata includes the SIPREC Metadata, SIP headers, fromNumber, toNumber, and others. Here are some things you can do with this event metadata:

1. You can process the metadata in these events to determine your own unique identifier for the calls and correlate the calls with your own system.
2. You can then add your unique identifier for the call into the call's contact attributes by using Set contact attributes block.
3. You can search by custom contact attributes in the Connect Customer admin website to find the contact for the third-party call in the two Connect Customer instances.

For information about how to create Connect Customer flow Lambda functions, see Grant Connect Customer access to your AWS Lambda functions. For a list of all the supported contact attributes that you can access in your flow Lambda, see List of available contact attributes in Connect Customer and their JSONPath references.

Supported flow blocks for conversational analytics integration

The following tables list the flow blocks that you can use to specify how Connect Customer processes the audio stream sessions.

Set blocks

Flow block	Effect	Description
Set Working Queue	No Effect	Sets Working Queue
Set Contact Attributes	Supported	Stores key-value pairs as contact attributes. You set a value that is later referenced in a flow.
Get Queue Metrics	No Effect	Gets queue metrics

Flow block	Effect	Description
Change routing priority/age	No Effect	change routing priority of contact
Set Hold Flow	No Effect	Specifies the flow to invoke when a customer or agent is put on hold.
Set Whisper Flow	No Effect	Specifies the flow to invoke when a customer or agent joined in a voice or chat conversation.
Set callback Number	No Effect	Specify the attribute to set the callback number.
Set Voice	No Effect	Sets the text-to-speech (TTS) language and voice to use for the contact flow.
Set Customer Queue	No Effect	Sets the customer queue for customer queue flow
Set Disconnect Flow	No Effect	Sets disconnect flow for disconnect queue flow
Set event flow	No Effect	Specifies which flow to run during a contact event.
Set routing criteria	No Effect	Sets the routing criteria for the contact.

Analyze blocks

Flow block	Effect	Description
Set Recording and Analytics behavior	Supported	Sets options for recording and enables features in conversat ional analytics.
Set logging behavior	Supported	Enable or disable flow logs

Logic blocks

Flow block	Effect	Description
Distribute by percentage	Supported	Routes contacts randomly based on a percentage
Loop	Supported	Executes looping branch for specified amount of times

Branch blocks

Flow block	Effect	Description
Check Queue Status	No Effect	Checks Queue Status
Check Staffing	No Effect	Checks staffing in queues
Check hours of operation	Supported	Branches based on specified hours of operation.
Check Contact Attributes	Supported	Branches based on a comparison to the value of a contact attribute.

Integrate blocks

Flow block	Effect	Description
Create Task	Supported	Creates a new task manually or by using a task template.
Customer profiles	Supported	You can retrieve, create, and update a customer profile.
Invoke AWS Lambda	Supported	Calls AWS Lambda, and optionally returns key-value pairs.
Invoke module	Supported	Calls a published module, which you can use to create reusable sections of a contact flow.

Terminate/Transfer blocks

Flow block	Effect	Description
Disconnect/Hangup	Supported	Disconnects the contact and end the audio stream session.
End Flow	Supported	Ends the current flow without disconnecting the contact.

Set up multi-region redundancy for conversational analytics integration

With multi-region redundancy, you can scale your external voice system for highest reliability, performance, and efficiency. You can support multi-region redundancy using Connect Customer replica instance.

Active/Passive redundancy configuration

You can create one Connect Customer instance in one Region (for example, US East (N. Virginia)) and a replica instance in another Region (for example, US West (Oregon)). You can then configure

your external voice system to send SIPREC SIP INVITE to the primary Region. When the Connect Customer instance in the primary Region fails, you can update your external voice system to failover to the replica Connect Customer instance in the passive Region.

Active/Active redundancy configuration

You can implement the active-active strategy by concurrently streaming audio to both Connect Customer instances. To implement this strategy, configure your external voice system to concurrently stream audio to the two separate Regions. In each Region, conversational analytics integration will do the following:

1. Create its own Connect Customer contact.
2. Captures the audio stream to create call recordings
3. Perform conversational analytics analysis

This approach requires you to replicate all the Connect Customer contact center configurations manually. However, you can use Connect Customer Global Resiliency and it will replicate all the Connect Customer instance settings across the Regions automatically. For more information, see Set up Connect Customer Global Resiliency.

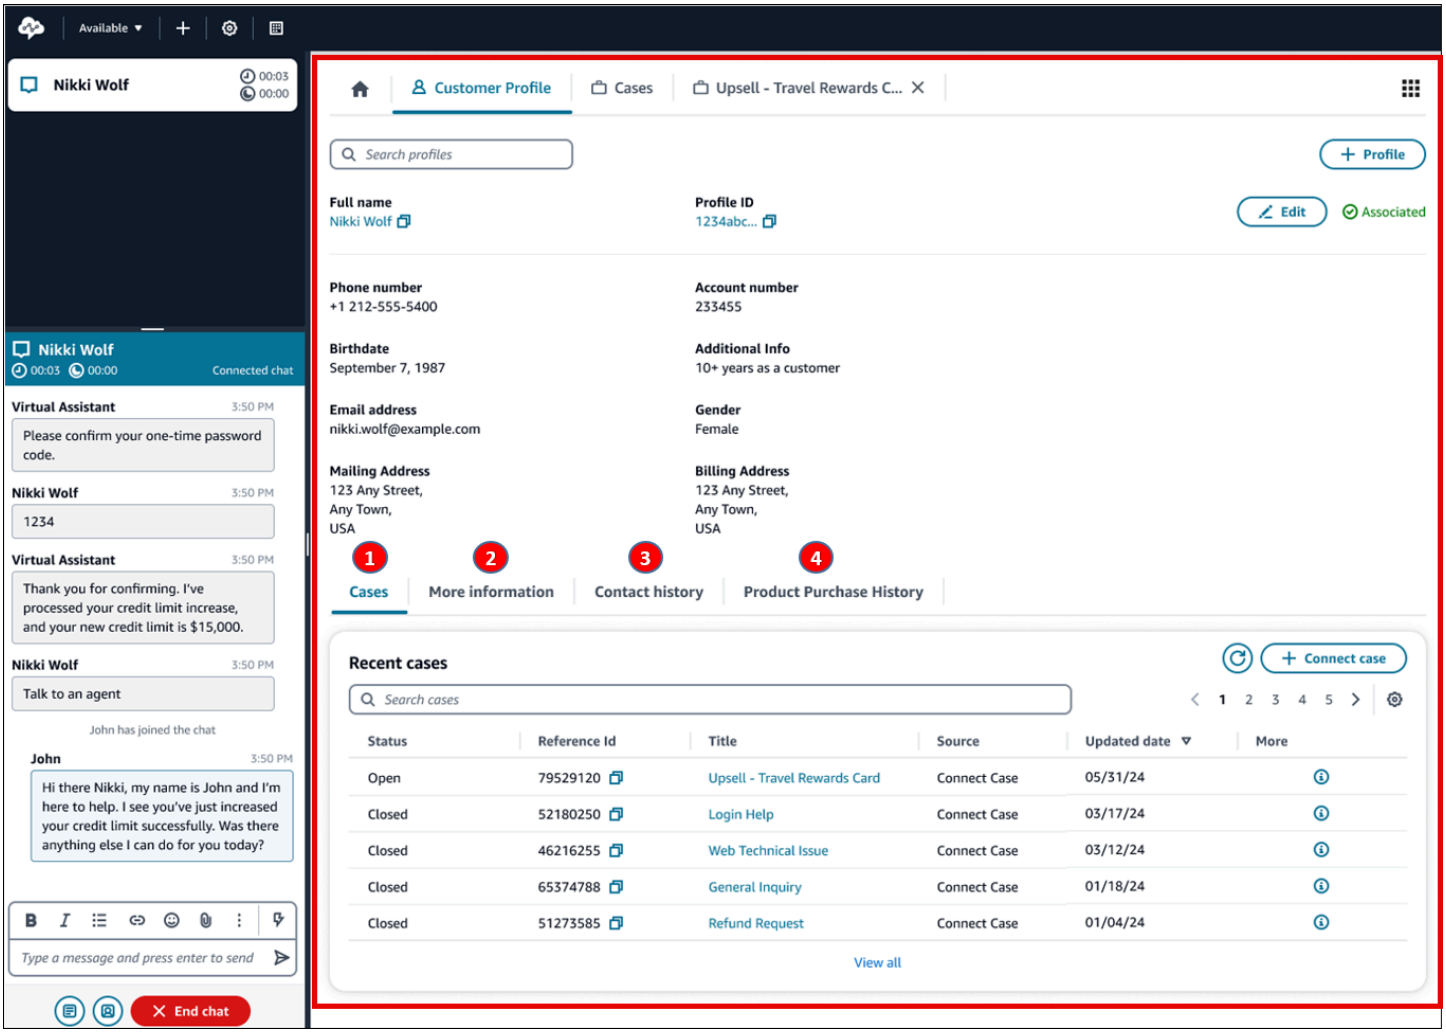
Customer Profiles in Connect Customer

To help agents deliver more efficient and personalized customer service, you can use Connect Customer to combine information from external applications, such as Salesforce, Zendesk, ServiceNow, or other Customer relationship management (CRM) products, with contact history from Connect Customer. This creates a customer profile that has all the information agents need during customer interactions in a single place.

With a single view of customer information including their product, case, and contact history, agents can quickly confirm the customer's identity and determine the reason for the call or chat.

Currently, Customer Profiles can be used in compliance with GDPR and is pending additional certifications held by Connect Customer.

The following image shows Customer Profiles in the agent workspace. The agent workspace contains all the tools your agents need to handle calls, chats, tasks, and emails, with quick access to information from Customer Profiles.



1. **Cases**: Status, reference Id, title, source, updated date, and more information related to cases ingested from 3P application such as Zendesk and ServiceNow, in addition to cases created and managed using Connect Customer Cases.
2. **More information**: Additional information contained in the customer defined *Attributes* field of the profile, as well as further profile information such as cell phone number and shipping address. This information will be sorted alphabetically to help an agent quickly locate the information they need.
3. **Contact history**: Date, channel, and duration of when this customer contacted your contact center in the past.
4. **Product purchase history**: All the assets purchased by a customer can be populated here. The data is ingested from an external app such as Salesforce or Zendesk that you've integrated with Customer Profiles.

What is a customer profile in Connect Customer?

A *customer profile* is a record that stores contact history combined with information about customers, such as account number, additional information, birth date, email, multiple addresses, name, and party type. An *account-based profile* is expected to have underlying sub-profiles.

After you enable Connect Customer Customer Profiles, a unique customer profile is created for every contact. With Connect Customer Customer Profiles, you can create a customer profile that has all the information agents need during customer interactions in a single place at no charge.

To access customer profiles in your flows, use the Customer profiles block. Agents access customer profiles in the agent workspace.

You can use the paid features of Customer Profiles to enrich your customer profiles by ingesting data from external applications. See pricing for details.

You can also add custom fields and objects to the customer profiles by using the Connect Customer Customer Profiles APIs.

How is customer profile data stored?

Connect Customer stores contact history in unique customer profiles. It parses data ingested from external applications and stores it as customer profile attributes.

Connect Customer does not replace or update the data in the external application. If a data source is removed, the data from the external application is no longer available in the customer profile for every voice contact.

For information about how customer profile data are secured, see Data protection in Connect Customer.

For more information about how to access the data that is stored in a customer profile, see Access Customer Profiles in the agent workspace or Use the Customer Profiles API.

Enable Customer Profiles for your Connect Customer instance

Connect Customer provides pre-built integrations so you can quickly combine customer information from multiple external applications, with contact history from Connect Customer. With these integrations, you can create a customer profile that has all the information agents need during customer interactions in a single place.

Before you begin

Following is an overview of key concepts and the information that you'll be prompted for during the setup process.

About the customer profiles domain

When you enable Connect Customer Customer Profiles, you create a customer profiles domain: a container for all data, such as customer profiles, object types, profile keys, and encryption keys. Following are guidelines for creating Customer Profile domains:

- Each Connect Customer instance can only be associated with one domain.
- You can create multiple domains, but they don't share external application integrations or customer data between each other.
- All the external application integrations you create are at a domain level. All of the Connect Customer instances associated with a domain inherit the domain's integrations.
- You can change the association of your Connect Customer instance from your current domain to a new domain at any time, by choosing a different domain. This isn't recommended, however, because the customer profiles from the earlier domain won't be moved to the new domain.

How do you want to name your customer profiles domain?

When you enable customer profiles, you are prompted to provide a friendly domain name that's meaningful to you such as your organization name, for example, *CustomerProfiles-ExampleCorp*. You can change the friendly name using the API at any time.

Data store

Data store is a long-term, service-managed data store of Customer Profiles data. It retains Customer Profiles data updated over the past 10 years. You must enable it to use segmentation powered by Spark SQL and predictive insights. Data store does not compute calculated attributes or populate the agent workspace.

After you enable Data store, it automatically stores the data you ingest into Customer Profiles. You cannot disable Data store after you enable it. To delete data from Data store, use the DeleteProfile API, or delete the object types or the Customer Profiles domain.

Do you want to use a dead-letter queue?

A dead-letter queue is used for reporting errors associated with processing data from external applications.

Amazon AppFlow handles connecting to the external application and moving data from it to Connect Customer Customer Profiles. Connect Customer then processes the file.

- If an error occurs during the connection or while transporting the data to Connect Customer, Amazon AppFlow surfaces the error but it doesn't write the error to the dead-letter queue.

  For example, a processing error could be that the external data didn’t match the specified schema or that the format of the external data format isn't correct (currently only JSON is supported).
- If Connect Customer encounters an error while processing the file, it writes the error to your dead-letter queue. You can look at the queue later and try to reprocess the error.
- You might find SQS messages in the dead-letter queue defined with your domain that includes the error message, along with the object.

Error Message	Recommendation
The UNIQUE key or PROFILE key does not exist in the profile object	Modify the data mapping or object, make sure keys marked as UNIQUE and PROFILE in data mapping exist in object. See **data mapping page** on how to set it up.
Too many objects ingested on profile per second	Too many objects assigned to same profile within short time. You can re-ingest the object or add wait time between calling the PutProfileObject API.
Customer Profiles cannot ingest the object due to the EncryptionKey does not exist in the Region, the EncryptionKey does not have a grant for Customer Profiles to use, or the EncryptionKey does not have the GenerateDataKey permission	Check your KMS permission, make sure Customer Profiles has the required access. Follow **Enable Customer Profiles, and specify a dead-letter queue and KMS key** section.

Error Message	Recommendation
KMS key is invalid	Check your KMS permission, make sure Customer Profiles has the required access. Follow **Enable Customer Profiles, and specify a dead-letter queue and KMS key** section.
Customer Profiles cannot ingest the object due to invalid KMS key	Check your KMS permission, make sure Customer Profiles has the required access. Follow **Enable Customer Profiles, and specify a dead-letter queue and KMS key** section.
Your data contains profile object larger than # bytes	Remove any unnecessary fields and reduce data size until it falls below the specified limit mentioned in the error message.
All keys of this object are binding to more than one profiles	Modify the data mapping or object, make sure at least 1 PROFILE key in the object binds to less than or equal to 1 existing profile.

When you enable Customer Profiles, you have the option of specifying an Amazon SQS queue as your dead-letter queue. If you select this option, add the following resource policy to Amazon SQS so Customer Profiles has permissions to send messages to that queue:

```
{
      "Sid": "Customer Profiles SQS policy",
      "Effect": "Allow",
      "Principal": {
        "Service": "profile.amazonaws.com"
      },
      "Action": "SQS:SendMessage",
      "Resource": "arn:aws:sqs:region:accountID:YourQueueName"
}
```

To prevent a confused deputy security issue, see Connect Customer Customer Profiles cross-service confused deputy prevention for an example policy to apply.

Step-by-step instructions for creating a dead-letter queue are provided later in this topic, in Enable Customer Profiles, and specify a dead-letter queue and KMS key.

Create a KMS key to be used by Customer Profiles to encrypt data (required)

> **Note**
>
> To maintain access to Customer Profiles APIs, entities using the Customer Profiles `profile` APIs must have explicit `kms:Decrypt` and `kms:GenerateDataKey` permissions in their IAM policies. This enables them to use `kms:Decrypt` and `kms:GenerateDataKey` for the KMS key associated with resources retrieved from the API related to Customer Profiles.

When you enable Customer Profiles, you are prompted to create or provide a AWS Key Management Service KMS key. Step-by-step instructions for creating a KMS key are provided later in this topic, in Enable Customer Profiles, and specify a dead-letter queue and KMS key.

All data at rest for Customer Profiles is encrypted under the KMS key you choose. Your customer managed key is created, owned, and managed by you. You have full control over the KMS key (AWS KMS charges apply).

If you choose to set up a KMS key where someone else is the administrator, it must have a policy that allows `kms:GenerateDataKey`, `kms:CreateGrant`, and `kms:Decrypt` permissions to the Customer Profiles service principal. For information about how to change a key policy, see Changing a key policy in the AWS Key Management Service Developer Guide. In addition, to prevent cross-service impersonation, see Cross-service confused deputy prevention in AWS for sample policies that you should apply.

Enable Customer Profiles, and specify a dead-letter queue and KMS key

Data store

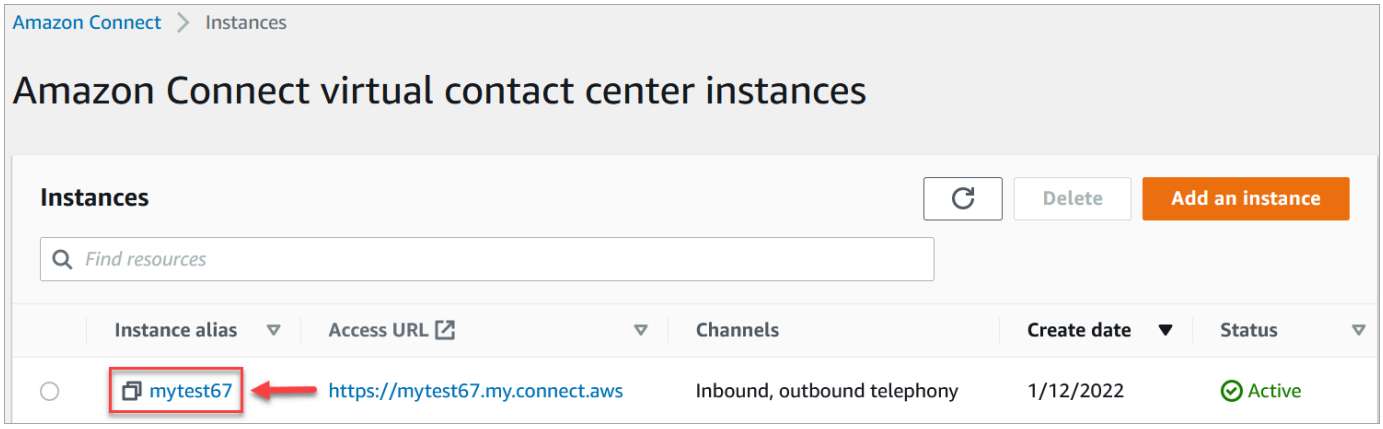
Choose whether to enable Data store. It is required to use segmentation powered by Spark SQL and predictive insights. If you choose not to enable Data store when creating a domain, you can enable it after the domain is created and being used. You cannot turn off Data store after it has been enabled.

You can enable Data store by choosing on the enable button in the blue banner on the Customer Profiles page (left hand panel > **Customer Profiles**). You will see this blue banner after you have created your domain.

Data store requires a Customer managed key (CMK) and will prompt you to create a Customer managed key (CMK) if you have not already enabled one for your domain.

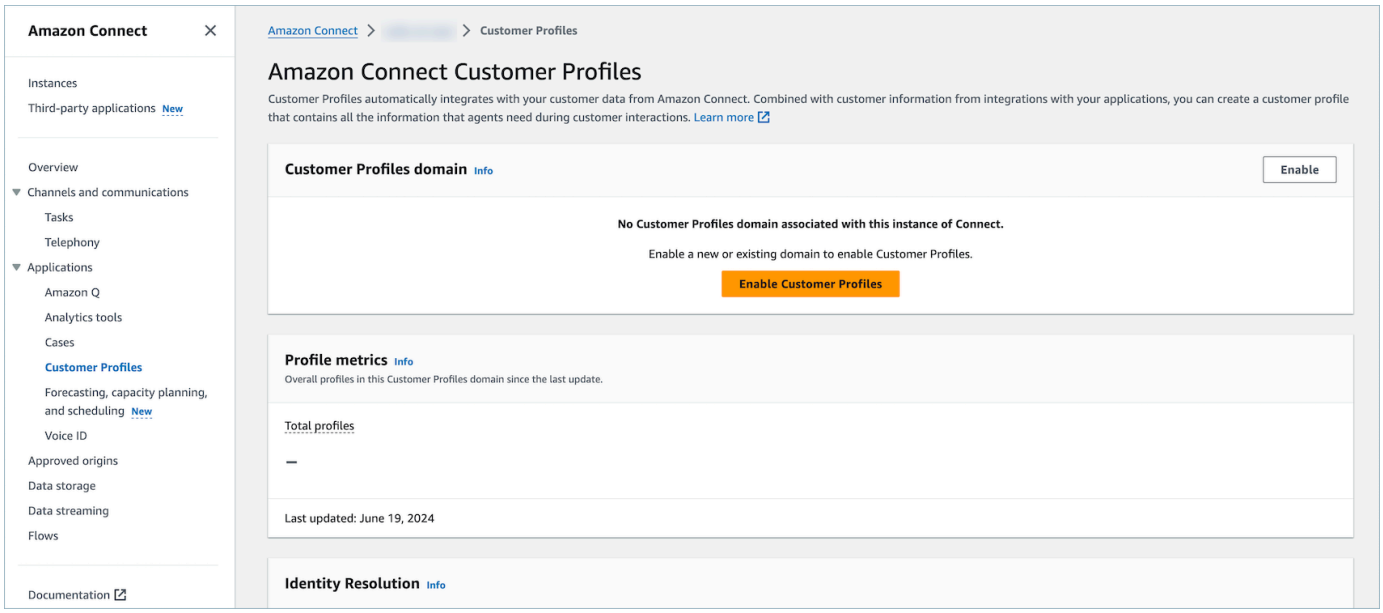
> **Important**
>
> When using Data Vault, Customer Profiles stores your data by object type and encrypts it using your AWS KMS key. Customer Profiles normalizes your object type names by:
>
> 1. Converting the name to lowercase
> 2. Converting hyphens - to underscores _
> 3. Appending "standard" to any Customer Profiles standard object type
> 4. Appending “domain” to any Customer Profiles domain object type
> 5. Appending “domain_standard” to any Customer Profiles standard domain object type
>
> You can't enable Data Store if Customer Profiles detects naming conflicts. After you enable Data Store, you can't create object types that conflict with existing object type names under these normalization rules.

1. Open the Connect Customer console at https://console.aws.amazon.com/connect/.
2. On the instances page, choose the instance alias. The instance alias is also your **instance name**, which appears in your Connect Customer URL. The following image shows the **Connect Customer virtual contact center instances** page, with a box around the instance alias.



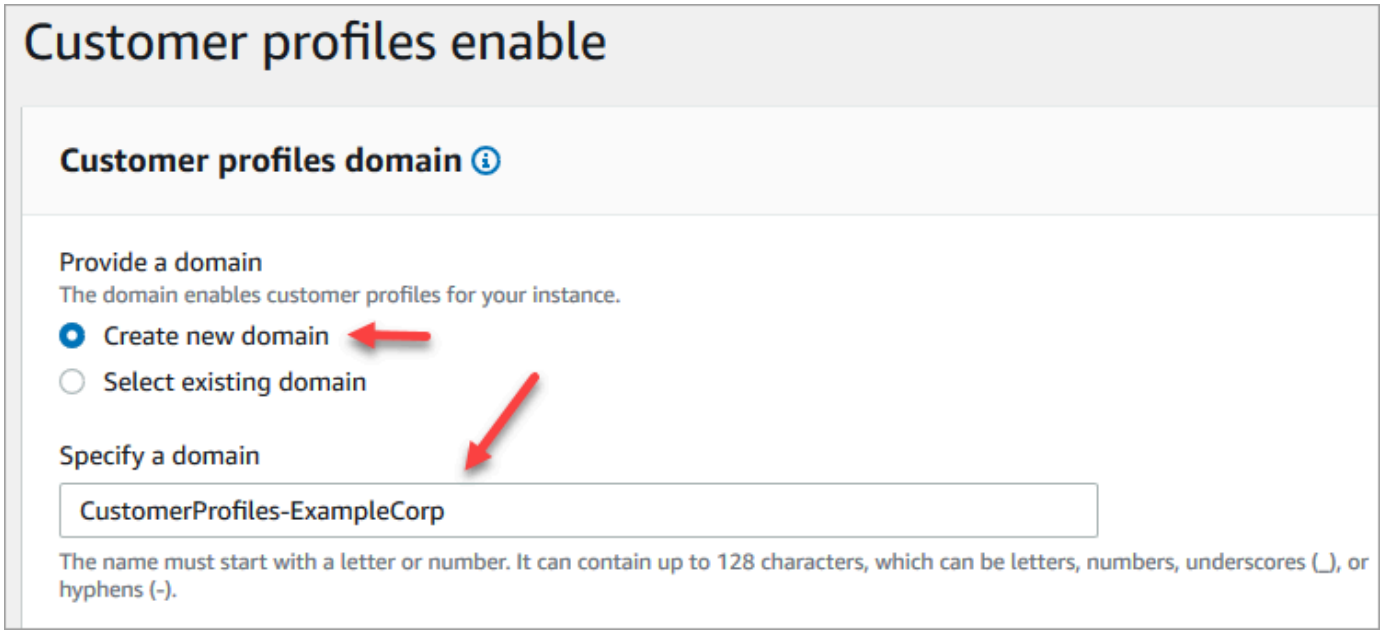
3. In the navigation pane, choose **Customer profiles**.

   The **Customer profiles domain** page lists the applications that are available for integration. In the following image, the page shows no customer profile domains have been enabled.



4. Choose **Enable customer profiles** to get started.

5. At the **Customer profiles enable** page, choose **Create new domain**. Under **Specify a domain**, enter a friendly name that's meaningful to you, such as your organization name, for example, *CustomerProfiles-ExampleCorp*.

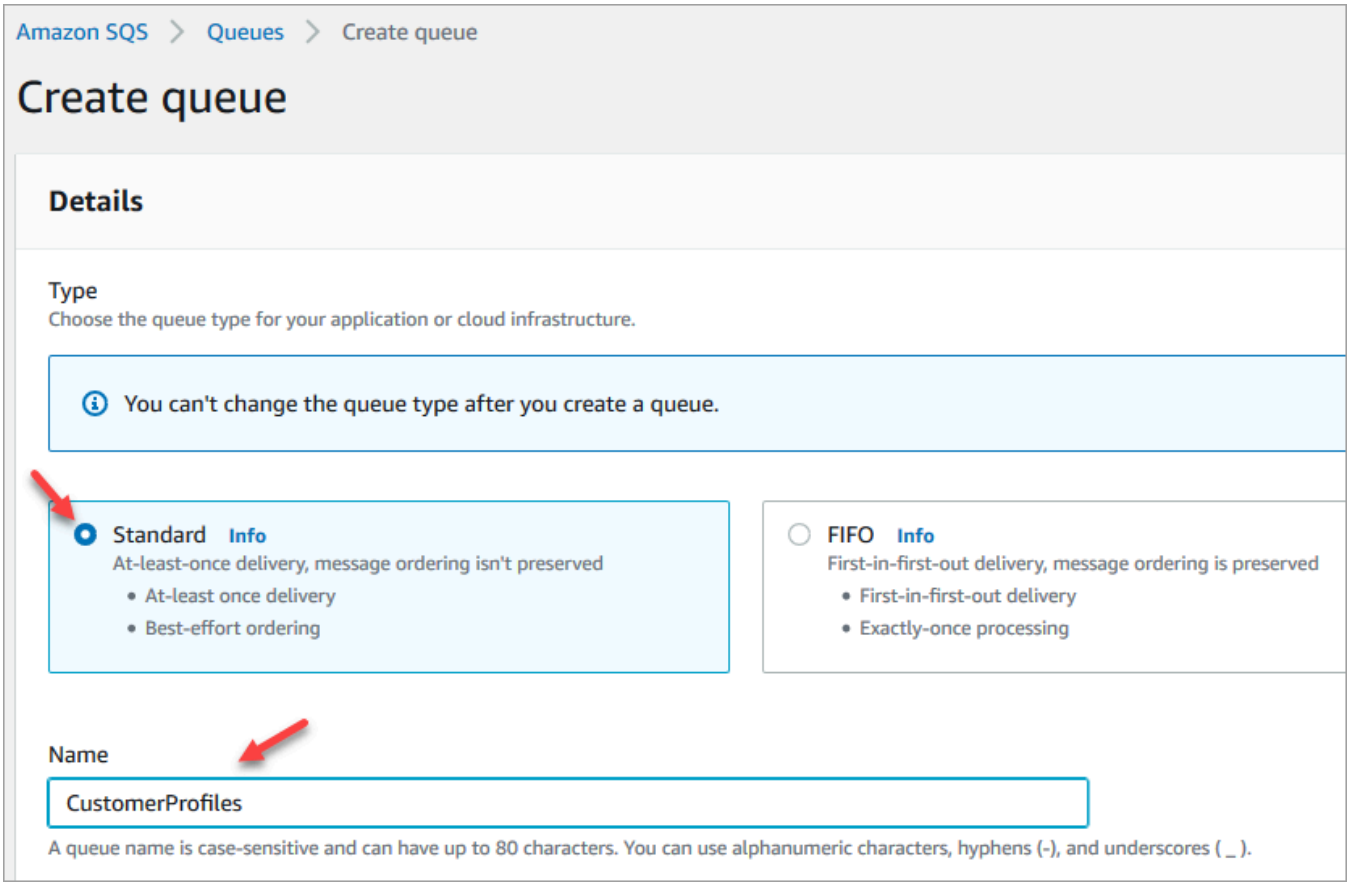


6. Under **Specify dead-letter queue**, choose whether to send failed events to a dead-letter queue. This is helpful if you want to get visibility into data that failed to be ingested. It also gives you the option to retry these failed data ingestions in the future.

   Following are the steps to create a dead-letter queue:

   - On the **Customer profiles enable** page, choose **Create new or select existing SQS queue** and then choose **Create a new Dead Letter Queue**.

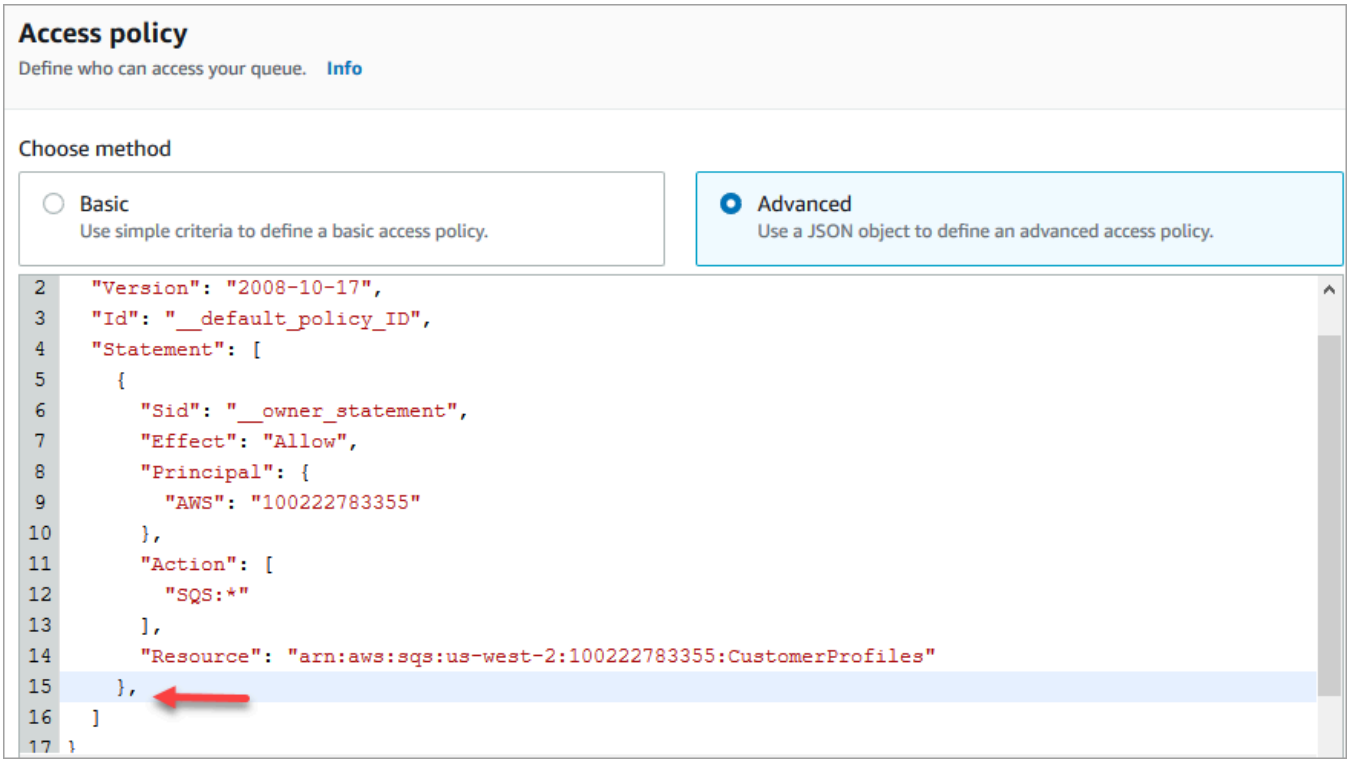
   - A new tab in your browser opens for the Amazon SQS console. Choose **Create queue**.
   - On the **Create queue** page, choose **Standard**, then assign a name to your queue.



- In the **Access policy** section, choose **Advanced**.

  The Version name, policy ID, and Statement appear. If needed, update this section to give access to only the appropriate roles.

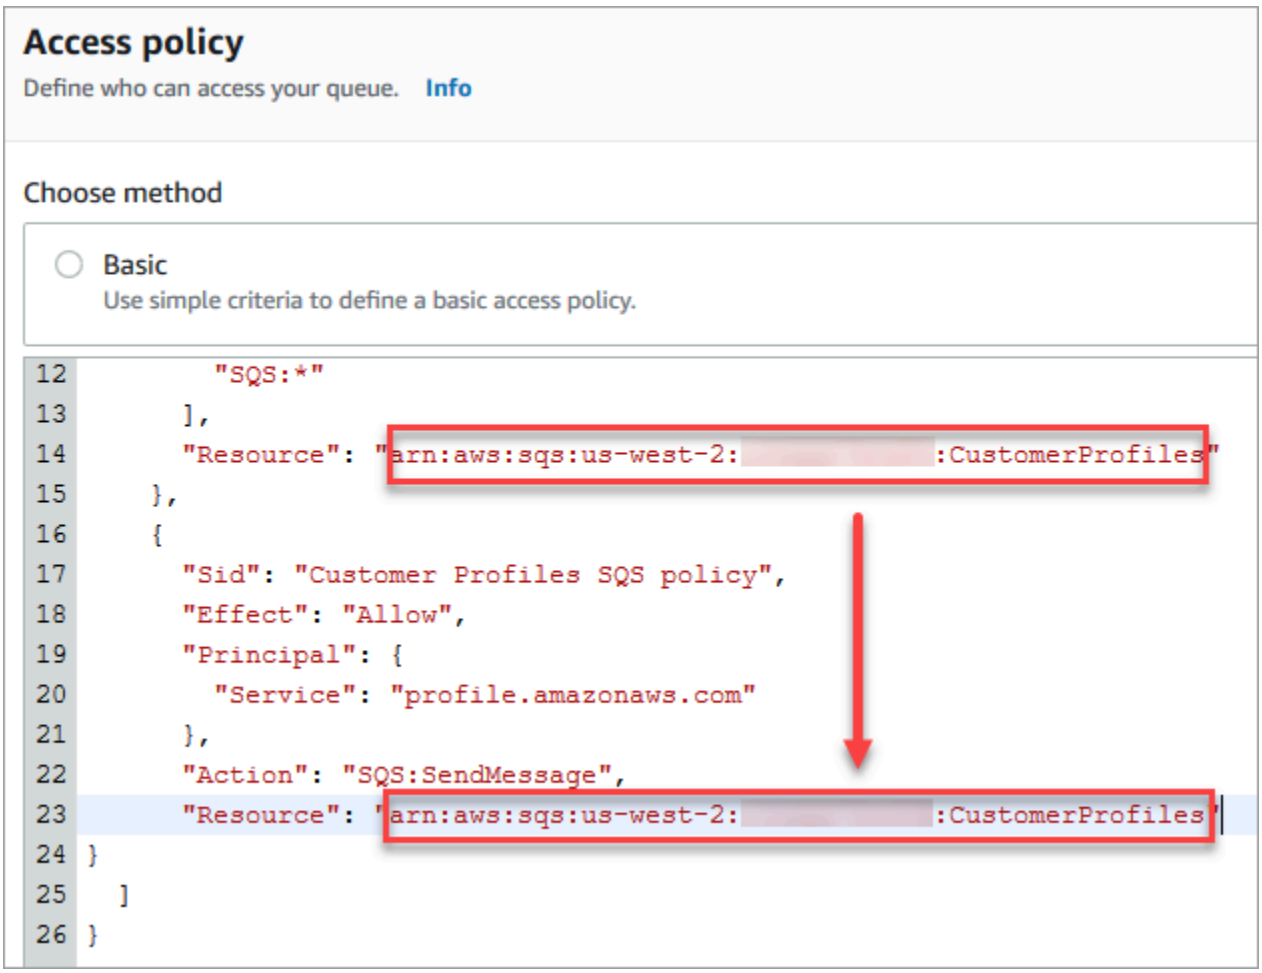
- At the end of the Statement section (line 15 in the following image) add a comma after }, and press `Enter`.



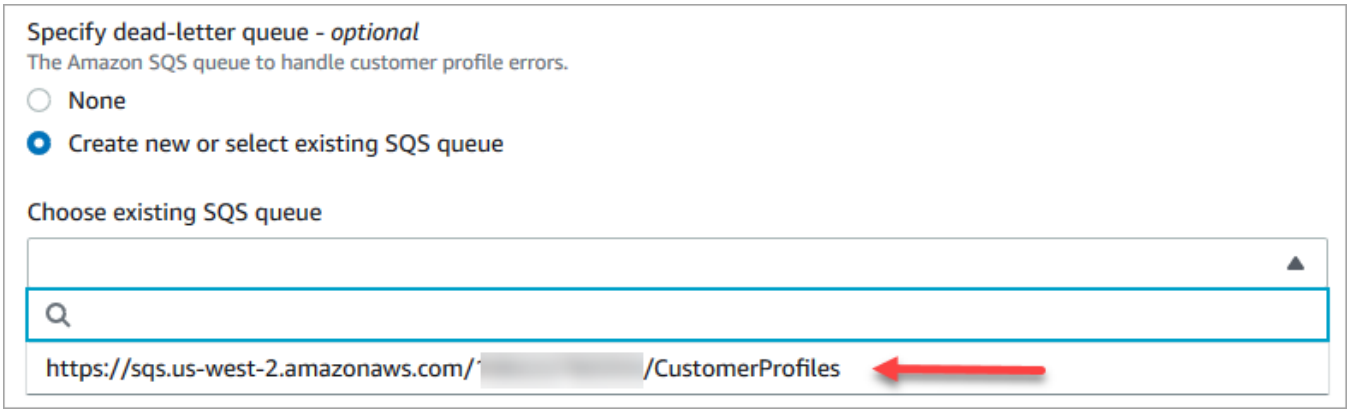
- Then copy and paste the following code:

```
{
      "Sid": "Customer Profiles SQS policy",
      "Effect": "Allow",
      "Principal": {
        "Service": "profile.amazonaws.com"
      },
      "Action": "SQS:SendMessage",
      "Resource": "arn:aws:sqs:region:accountID:YourQueueName"
}
```

- To replace *region*, *accountID*, and *YourQueueName* with your information, copy and paste the `Resource` information from line 14.

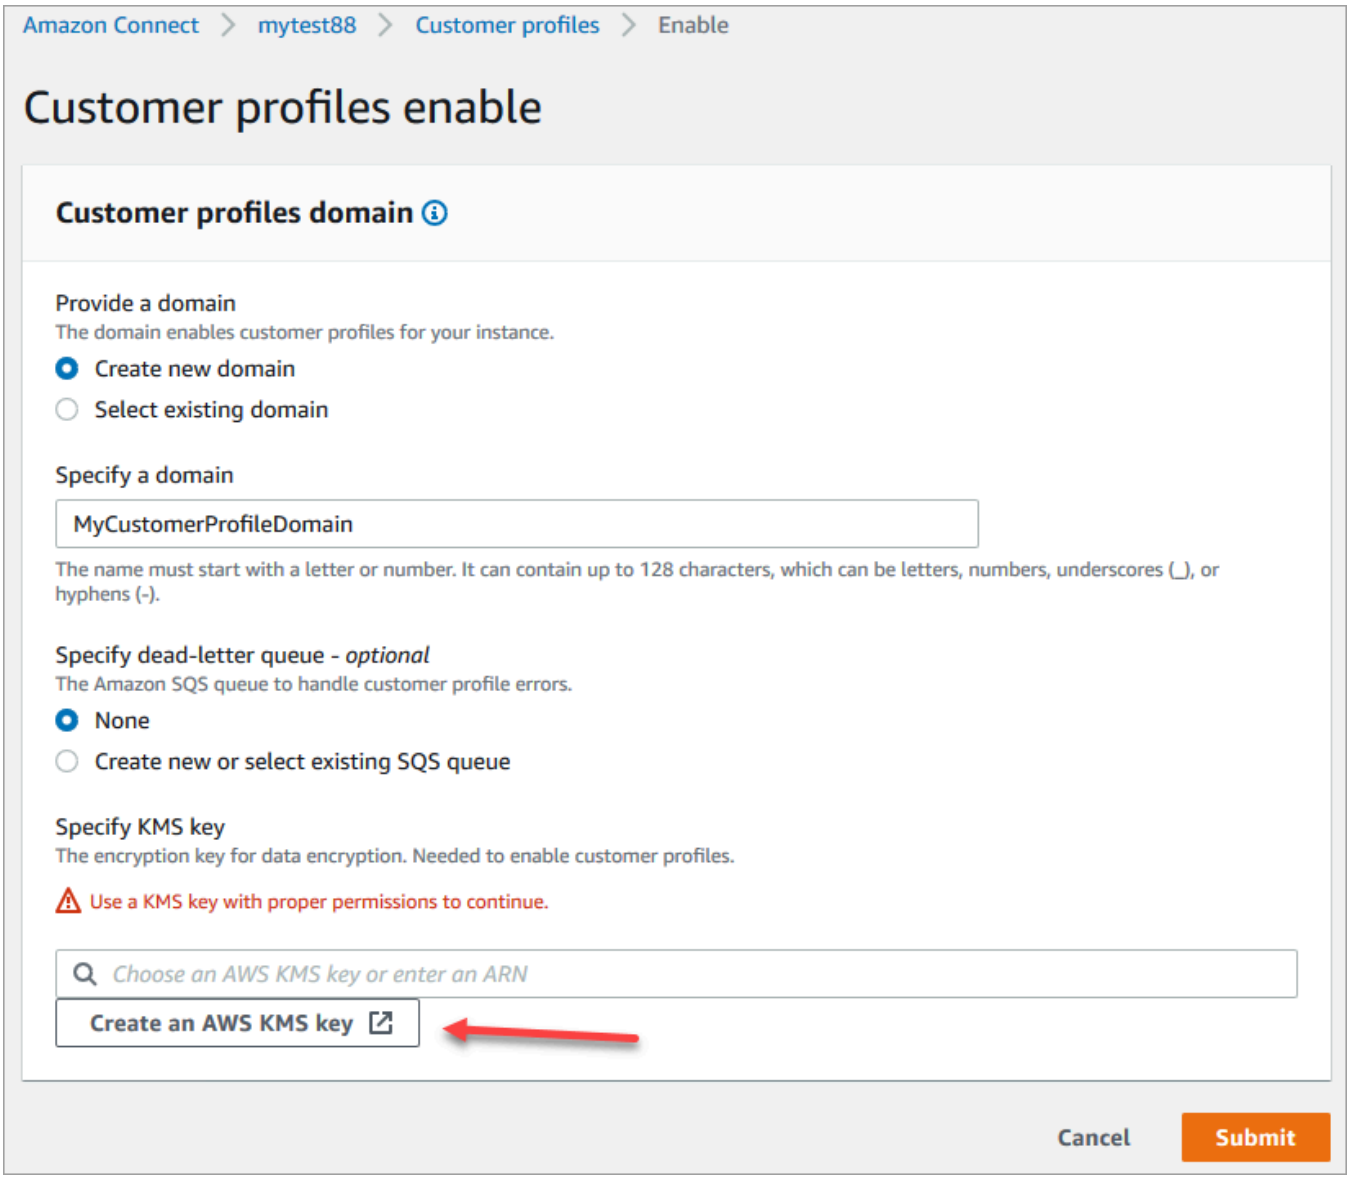


- Choose **Create queue**.
- Return to the tab in your browser for the Connect Customer console, **Customer profiles enable** page. Choose or tap in the **Choose existing SQS queue** box to select the queue you just created from the dropdown list.

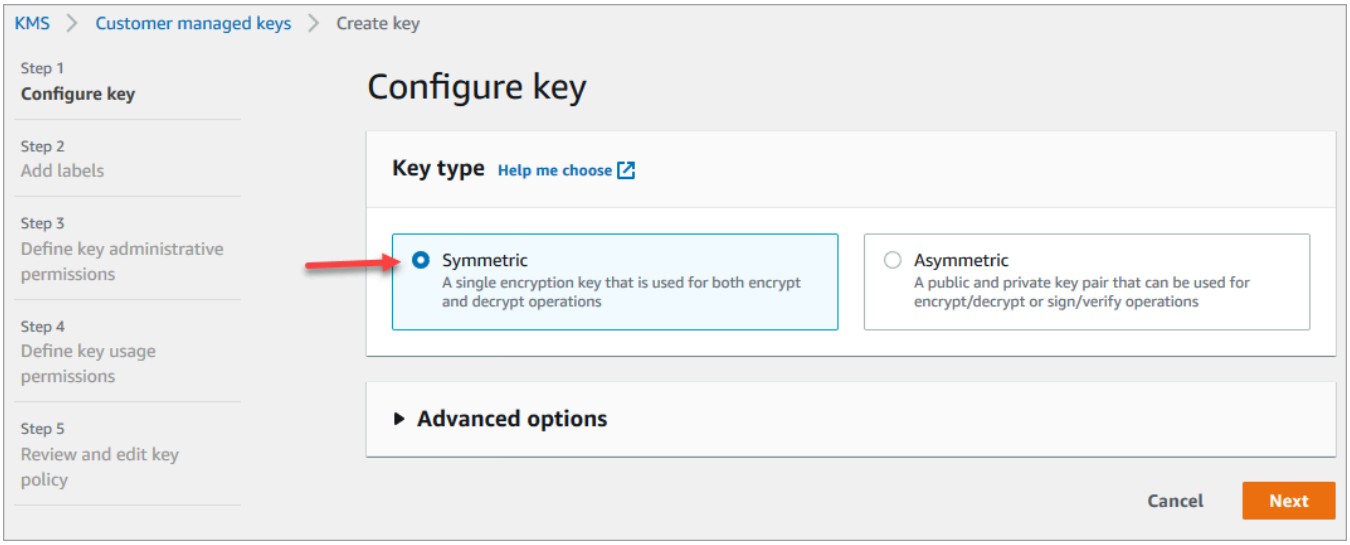


7. Under **Specify KMS key**, create or enter your own AWS KMS key for encryption. Following are the steps to create your AWS KMS key:

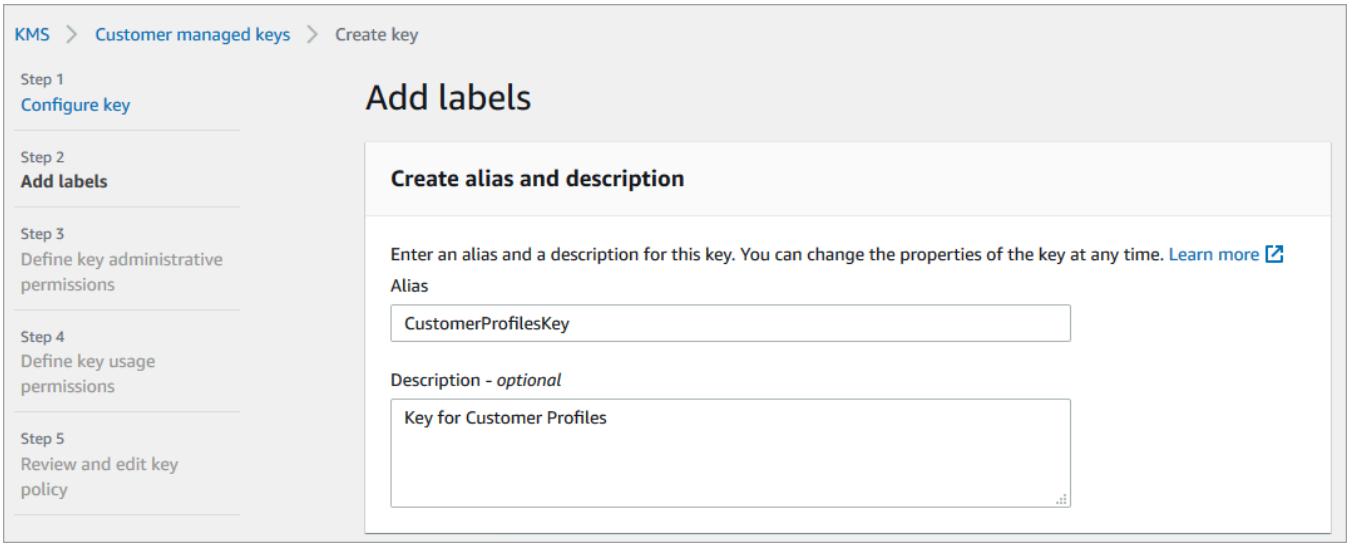
- On the **Customer profiles enable** page, choose **Create an AWS KMS key**.



- A new tab in your browser opens for the Key Management Service (KMS) console. On the **Configure key** page, choose **Symmetric**, and then choose **Next**.

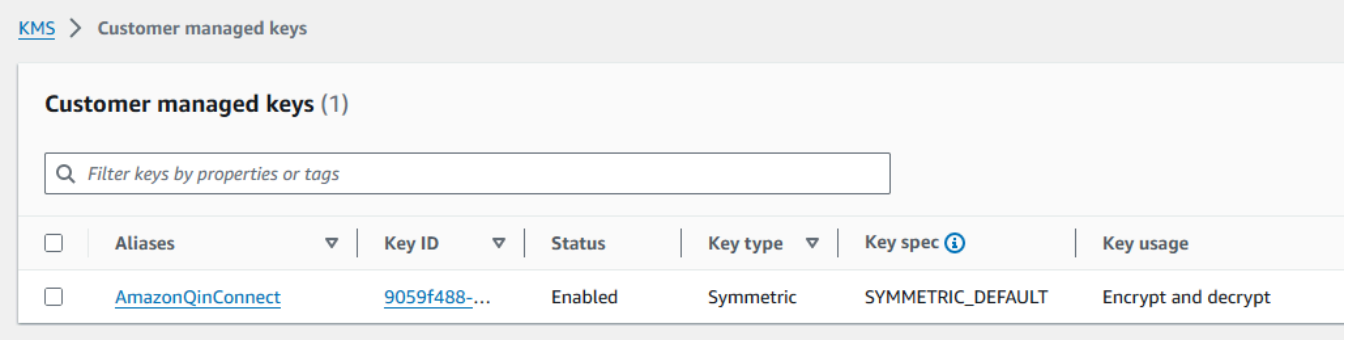


- On the **Add labels** page, add a name and description for the key, and then choose **Next**.

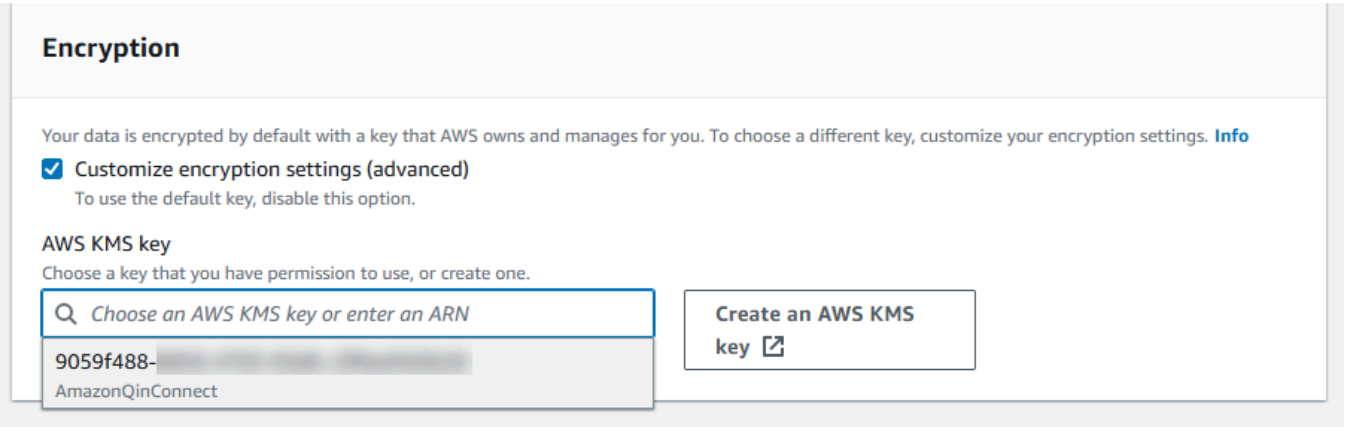


- On the **Define key administrative permissions** page, choose **Next**.
- On the **Define key usage permissions** page, choose **Next**.
- On the **Review and edit key policy** page, choose **Finish**.

  In the following example, the key ID starts with **bcb6fdd**:



- Return to the tab in your browser for the Connect Customer console, **Customer profiles enable** page. Choose or tap in the **Specify KMS key box** for the key you created to appear in a dropdown list. Choose the key you created.

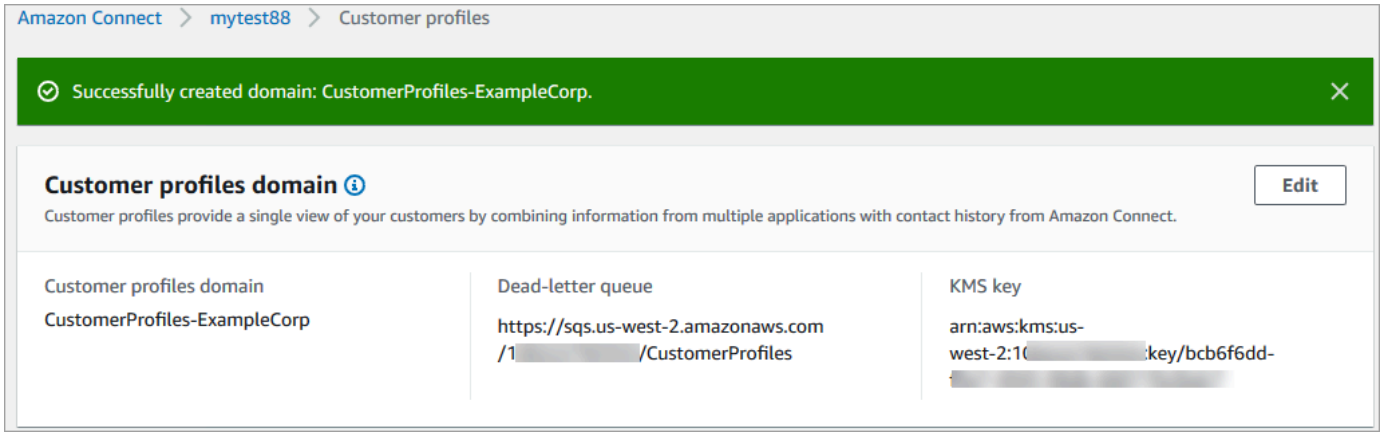


8. Under **Data store**, choose whether to enable Data store. It is required to use segmentation powered by Spark SQL and predictive insights. If you choose not to enable Data store when creating a domain, you can enable it after the domain is created and being used. You cannot turn off Data store after it has been enabled.

   If you have an existing domain without Data store, you can enable it by choosing on the enable button in the blue banner on the Customer Profiles page (left hand panel > Customer Profiles)

   Data store requires a Customer Managed Key (CMK) and will prompt you to create a Customer Managed Key (CMK) if you have not already enabled one for your domain.

9. Choose **Submit**. The completed page looks similar to the following image. It shows the name of the customer profiles domain, the dead-letter queue, and the KMS key.



You're done! Connect Customer Customer Profiles is enabled. Now with every new contact that comes in, Connect Customer creates a customer profile record. It then tracks the contact history for that phone number (voice) or email address (chat).

Your agents can create new customer profiles and view contact records for your customers.

Next steps

1. Make Customer Profiles available through the agent workspace.
2. Assign agents permissions to access Customer Profiles in the agent workspace.
3. Integrate with external applications that profile customer profile data (optional).
4. Enable Identity Resolution to identify two or more similar profiles, and consolidate them.

Getting started with industry resource templates

Connect Customer Customer Profiles provides industry resource templates to help you quickly set up your domain with calculated attributes, segments, and Profile Explorer layouts tailored to specific industries.

Before you begin

Before you enable industry resource templates, make sure you have:

- An Amazon Connect instance with Customer Profiles enabled
- Appropriate permissions to create resources in your Customer Profiles domain

About industry resource templates

When you enable an industry template, Customer Profiles automatically creates the following resources in your domain:

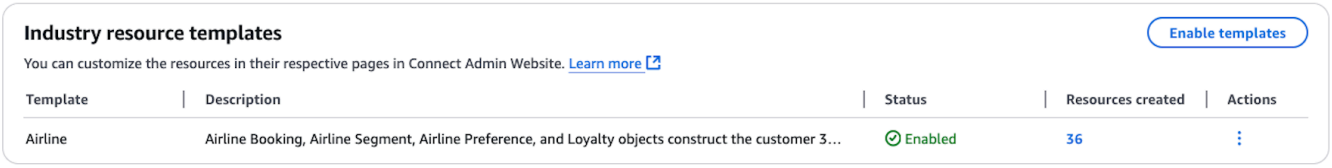
- Calculated attribute definitions - Pre-defined attributes derived from your customer data
- Segment definitions - Customer groupings based on common characteristics
- Profile Explorer layouts - Customized dashboard views for visualizing customer information

These resources are designed to help you quickly derive value from your customer data without having to manually create each resource.

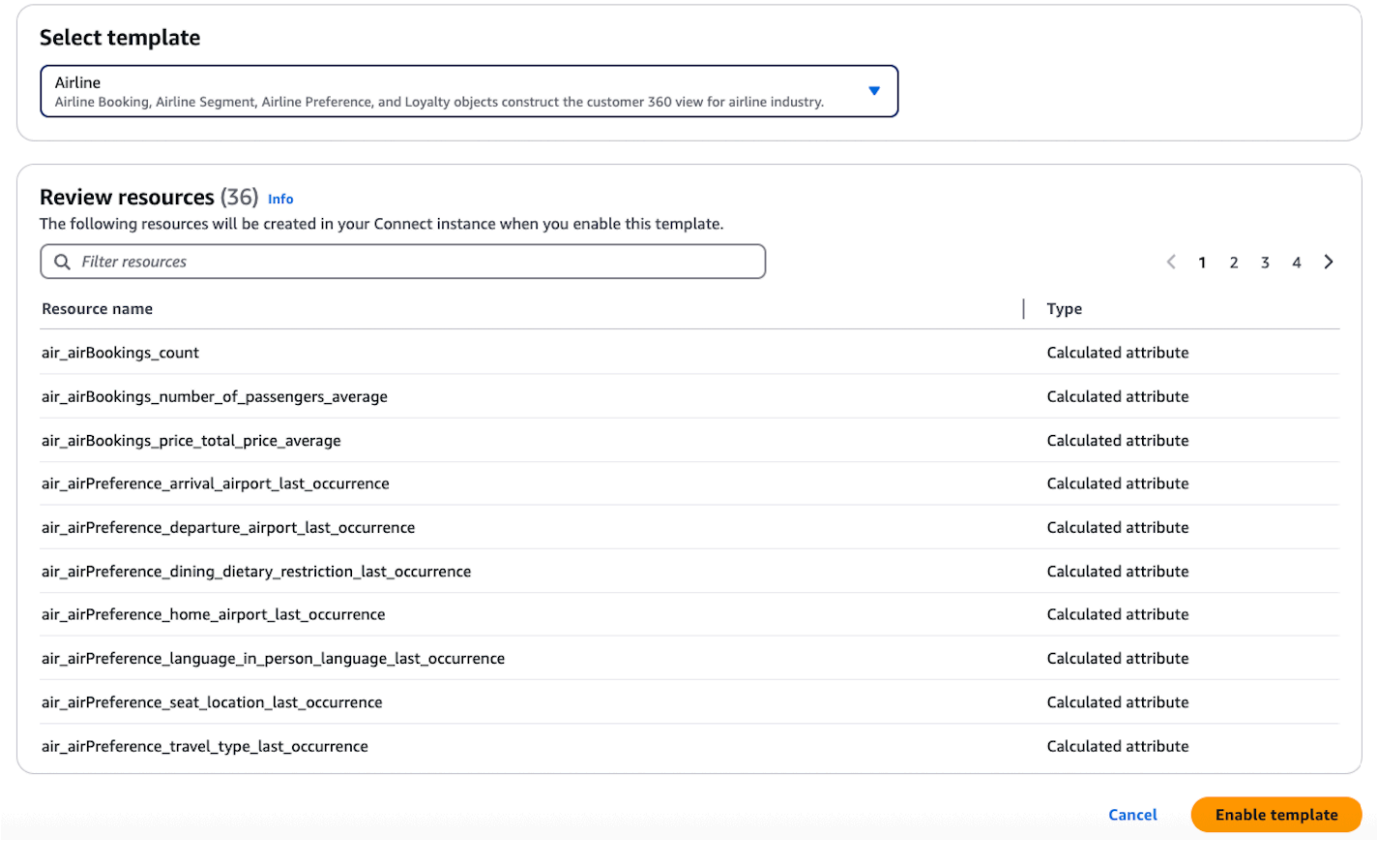
Enable industry resource templates

1. On the Customer Profiles homepage, locate the Industry templates section.
   - If this is your first time setting up Customer Profiles, an announcement appears at the top of the page.

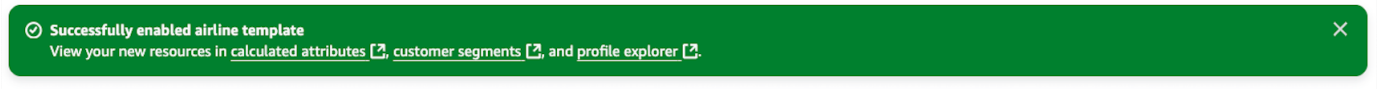
     
   - If you already have resources in your domain, the list of enabled templates appears in the Industry templates section.

2. To enable a template, choose **Enable a template**.
3. In the **Select template** dropdown, choose the industry that best matches your business:
   - **Airline** - For air travel businesses
   - **Hotel** - For hospitality businesses
4. Review the resources that will be created in the **Review resources** section.



5. Choose **Enable template**.
6. Wait for the resources to be created. Make sure to keep the browser tab open while the resource creation is in progress.
7. Once complete, you'll see a confirmation message and the template will appear in the Industry templates section with the number of resources created.



Resources created by industry templates

Airline Industry Template

Calculated Attributes

The airline template creates calculated attributes across several categories:

Airline Calculated Attributes

Calculated Attribute Name	Display Name	Description	Object type
air_airPreference_departure_airport_last_occurrence	Preferred departure airport	Returns customer's most recently configured preferred departure airport.	_airPreference
air_airPreference_arrival_airport_last_occurrence	Preferred arrival airport	Returns customer's most recently configured preferred arrival airport.	_airPreference
air_airPreference_travel_type_last_occurrence	Preferred travel type	Returns customer's most recently configured preferred type of travel.	_airPreference
air_airPreference_marketing_opt_in_last_occurrence	Marketing opt-in preference	Returns customer's most recently configured marketing opt-in setting.	_airPreference
air_airPreference_language_in_person_language_last_occurrence	Preferred in-person language	Returns customer's most recently preferred language for in-person interactions.	_airPreference
air_airPreference_seat_location_last_occurrence	Preferred seat location	Returns customer's most recently selected seat location preference.	_airPreference
air_airPreference_home_airport_last_occurrence	Preferred home airport	Returns customer's most recently specified home airport.	_airPreference
air_airPreference_dining_dietary_restriction_last_occurrence	Preferred dietary restriction	Returns customer's most recently specified dietary restriction.	_airPreference

Calculated Attribute Name	Display Name	Description	Object type
air_airBookings_number_of_passengers_average	Average passengers per booking	Returns average number of passengers across customer's bookings.	_airBooking
air_airBookings_price_total_price_average	Average booking price	Returns average cost across all customer's bookings.	_airBooking
air_airBookings_count	Count of bookings	Returns the count of bookings made by a customer.	_airBooking
air_airSegments_flight_delay_time_sum	Total flight delay duration	Returns total length of flight delays experienced by customer.	_airSegment
air_airSegments_cancelled_flights_count_30_days	Cancelled flights in past 30 days	Returns count of customer flights cancelled within the last 30 days.	_airSegment
air_airSegments_delayed_flights_count_30_days	Delayed flights in past 30 days	Returns count of customer flights delayed within the last 30 days.	_airSegment
air_airSegments_completed_flights_count_30_days	Completed flights in past 30 days	Returns count of customer flights completed within the last 30 days.	_airSegment
air_airSegments_completed_flights_count_1_year	Completed flights in past year	Returns count of customer flights completed within the last year.	_airSegment
air_airSegment_departure_date_last_occurrence	Last flight departure date	Returns departure date of customer's most recent flight.	_airSegment

Calculated Attribute Name	Display Name	Description	Object type
air_airSegments_miles_to_earn_sum	Total miles flown	Returns sum of all flight distances in miles for a customer.	_airSegment
air_airSegments_miles_to_earn_sum_1_year	Miles flown in past year	Returns sum of flight miles flown by customer in the past year.	_airSegment
air_airSegments_business_first_class_count	Count of premium class flights	Returns count of customer air segments booked as business-class or first-class.	_airSegment
air_loyalties_points_redeemed_sum	Total loyalty points redeemed	Returns total sum of points redeemed across all customer loyalty programs.	_loyalty
air_loyalties_count	Count of loyalty memberships	Returns number of loyalty program memberships held by the customer.	_loyalty
air_loyalty_tier_points_to_next_tier_last_occurrence	Points to next tier	Returns customer's most recent record of points needed to reach next loyalty tier.	_loyalty
air_loyalty_points_balance_last_occurrence	Current loyalty points balance	Returns customer's most recent loyalty points balance.	_loyalty
air_loyalty_membership_id_last_occurrence	Current loyalty membership ID	Returns customer's most recent loyalty membership identifier.	_loyalty
air_loyalty_program_name_last_occurrence	Current loyalty program name	Returns customer's most recent loyalty program name.	_loyalty

Calculated Attribute Name	Display Name	Description	Object type
air_loyalty_enrollment_date_last_occurrence	Most recent loyalty enrollment date	Returns customer's most recent loyalty program enrollment date.	_loyalty
air_loyalty_tier_current_tier_last_occurrence	Current loyalty tier	Returns customer's most recent loyalty program tier status.	_loyalty
air_loyalties_silver_gold_platinum_tier_count	Count of premium tier memberships	Returns count of customer loyalty programs with Silver	_loyalty
air_loyaltyPromotions_count	Count of loyalty promotions	Returns total number of loyalty promotions received by the customer.	_loyaltyPromotion

Segments

The airline template creates the following segments:

- [Airline] Marketing subscribers
- [Airline] Customers with cancelled flights in the past 30 days
- [Airline] Customers with delayed flights in the past 30 days
- [Airline] Customers with completed flights in the past 30 days
- [Airline] Dormant members

Profile Explorer Layout

A demo profile explorer layout is created with layout name: `DEMO-Airline-Layout` that consists of the following widgets:

- Customer details and contact information
- Loyalty program status and points
- Recent bookings and flights
- Customer preferences

- Customer value metrics
- Customer satisfaction indicators

Hotel Industry Template

Calculated Attributes

The hotel template creates calculated attributes across several categories:

Hotel Calculated Attributes

Calculated Attribute Name	Display Name	Description	Object type
hotel_hotelPreference_location_room_type_last_occurrence	Preferred room type	Returns customer's most recently configured preferred room type.	_hotelPreference
hotel_hotelPreference_cleaning_time_last_occurrence	Preferred cleaning time	Returns customer's most recently configured room cleaning time preference.	_hotelPreference
hotel_hotelPreference_location_view_last_occurrence	Preferred room view	Returns customer's most recently configured room view preference.	_hotelPreference
hotel_hotelPreference_check_in_type_last_occurrence	Preferred check-in method	Returns customer's most recently configured check-in method preference.	_hotelPreference
hotel_hotelPreference_check_out_type_last_occurrence	Preferred check-out method	Returns customer's most recently configured check-out method preference.	_hotelPreference
hotel_hotelPreference_special_request_last_occurrence	Last special request type	Returns customer's most recently requested special accommodation type.	_hotelPreference
hotel_hotelPreference_interest_name_	Most frequent interest	Returns customer's most frequently expressed	_hotelPreference

Calculated Attribute Name	Display Name	Description	Object type
of_interest_max_occurrence		interest or amenity preference.	
hotel_hotelPreference_marketing_opt_in_last_occurrence	Marketing opt-in preference	Returns customer's most recently configured marketing opt-in setting.	_hotelPreference
hotel_hotelReservations_number_of_nights_average	Average length of stay	Returns average duration of stay across all customer hotel reservations.	_hotelReservation
hotel_hotelReservations_number_of_nights_completed_sum_1_year	Total nights in past year	Returns total nights stayed in the past year across all customer reservations.	_hotelReservation
hotel_hotelReservations_number_of_nights_completed_sum	Total nights stayed	Returns total number of nights stayed across all customer hotel reservations.	_hotelReservation
hotel_hotelReservation_room_type_name_last_occurrence	Last room type booked	Returns customer's most recently booked room type.	_hotelReservation
hotel_hotelReservation_channel_method_last_occurrence	Last booking channel used	Returns customer's most recent channel used for hotel reservation.	_hotelReservation
hotel_hotelReservations_count	Count of reservations	Returns the count of hotel reservations made by a customer.	_hotelReservation
hotel_hotelReservations_total_amount_after_tax_average	Average reservation spend	Returns average amount spent per hotel reservation after taxes.	_hotelReservation

Calculated Attribute Name	Display Name	Description	Object type
hotel_hotelReservations_total_amount_after_tax_sum	Total hotel spend	Returns total amount spent across all customer hotel reservations after taxes.	_hotelReservation
hotel_hotelReservation_number_of_guests_max_occurrence	Most common group size	Returns customer's most frequently booked number of guests across all stays.	_hotelReservation
hotel_hotelReservations_business_travel_count	Count of business trips	Returns count of customer reservations marked as business travel.	_hotelReservation
hotel_hotelReservations_missed_checkin_count	Count of missed check-ins	Returns count of reservations where customer missed check-in.	_hotelReservation
hotel_hotelReservation_cancelled_count	Count of cancelled reservations	Returns count of hotel reservations that were cancelled by the customer.	_hotelReservation
hotel_hotelStayRevenues_amount_sum	Total revenue generated	Returns total revenue generated from all customer hotel stays.	_hotelStayRevenue
hotel_hotelStayRevenues_amount_average	Average revenue per stay	Returns mean revenue amount calculated across all customer stays.	_hotelStayRevenue
hotel_hotelStayRevenues_amount_maximum	Highest revenue amount	Returns largest single revenue amount generated from any customer stay.	_hotelStayRevenue
hotel_hotelStayRevenue_revenue_type_max_occurrence	Most common revenue source	Returns most frequent type of revenue generated across customer hotel stays.	_hotelStayRevenue

Calculated Attribute Name	Display Name	Description	Object type
hotel_loyalties_points_redeemed_sum	Total loyalty points redeemed	Returns total sum of points redeemed across all customer loyalty programs.	_loyalty
hotel_loyalties_count	Count of loyalty memberships	Returns number of loyalty program memberships held by the customer.	_loyalty
hotel_loyalty_tier_points_to_next_tier_last_occurrence	Points to next tier	Returns customer's most recent record of points needed to reach next loyalty tier.	_loyalty
hotel_loyalty_points_balance_last_occurrence	Current loyalty points balance	Returns customer's most recent loyalty points balance.	_loyalty
hotel_loyalty_membership_id_last_occurrence	Current loyalty membership ID	Returns customer's most recent loyalty membership identifier.	_loyalty
hotel_loyalty_program_name_last_occurrence	Current loyalty program name	Returns customer's most recent loyalty program name.	_loyalty
hotel_loyalty_enrollment_date_last_occurrence	Most recent loyalty enrollment date	Returns customer's most recent loyalty program enrollment date.	_loyalty
hotel_loyalty_tier_current_tier_last_occurrence	Current loyalty tier	Returns customer's most recent loyalty program tier status.	_loyalty
hotel_loyalties_silver_gold_platinum_tier_count	Count of premium tier memberships	Returns count of customer loyalty programs with Silver	_loyalty

Calculated Attribute Name	Display Name	Description	Object type
hotel_loyaltyPromotions_count	Count of loyalty promotions	Returns total number of loyalty promotions received by the customer.	_loyaltyPromotion

Segments

The hotel template creates segments such as:

- [Hotel] Preference Marketing Subscribers
- [Hotel] Solo travelers
- [Hotel] Couple or pair travelers
- [Hotel] Family or group travelers
- [Hotel] Customers with upcoming reservation in 30 days

Profile Explorer Layout

A customized layout that displays:

- Customer details and contact information
- Room preferences
- Stay history
- Revenue information
- Loyalty status

Disable industry templates

You can disable an industry template to remove the resources it created from your domain. To disable a template:

1. On the Customer Profiles homepage, locate the Industry templates section.
2. Find the template you want to disable and choose **Disable** action.
3. Review the confirmation message and choose **Confirm** to disable the template.

Important

When you disable a template, all resources created by that template will be deleted from your domain. If any of these resources are used in Customer Segments, Outbound Campaigns, or Contact Flows, disabling the template might impact them.
Before disabling a template, review the resources in use to understand the potential impact.

Troubleshooting

Troubleshooting Industry Templates

Error	Recommendation
Template resources failed to create	1. Check that you have the necessary permissions to create resources in your domain. 2. Verify that you haven't reached the limit for calculated attributes or segments in your domain. 3. Try enabling the template again. It will only attempt to create resources that don't already exist.
Created resources don't appear in Profile Explorer	1. Refresh your browser. 2. Verify that you have the necessary Security Profiles permissions to view the resources. 3. Check that the resources were successfully created in the Industry templates section.
Unable to enable multiple templates	Each domain can have multiple industry templates enabled. If you're experiencing issues, check that you haven't reached the resource limits for your domain.
Need to delete template resources	Currently, the Getting Started feature does not provide a way to automatically delete

Error	Recommendation
	all resources created by a template. You can manually delete individual resources through their respective management pages.

Next steps

After enabling an industry template, you can:

- Navigate to the Profile Explorer to see your new layout in action
- View and Edit calculated attributes to better fit your specific needs
- Manage customer segments in Amazon Connect
- Edit Profile Explorer Layout based on your business requirements
- Integrate external applications with Amazon Connect Customer Profiles to start populating profiles

Access Customer Profiles in the agent workspace

After you enable Customer Profiles, agents can begin using customer information to provide personalized service. This topic explains how to access Customer Profiles in the agent workspace.

> **Tip**
>
> Make sure your agents have **Customer profiles** permissions in their security profile so they can access Customer Profiles. For more information, see Security profile permissions for Connect Customer Customer Profiles.

Use Customer Profiles in the agent workspace

Customer Profiles is a native application in the agent workspace. Your agents can access contact controls, Customer Profiles, and Cases all in a single browser window.

> **Note**
>
> You can access the agent workspace by using the following URL:

- `https://instance-name.my.connect.aws/agent/`

If you access your instance using the **awsapps.com** domain, use the following URL:

- `https://instance-name.awsapps.com/connect/agent/`

For help finding your instance name, see Find your Connect Customer instance name.

Embed Customer Profiles into a custom agent application

You can embed Customer Profiles alongside the Contact Control Panel (CCP) in a custom agent application. You use the Connect Customer Streams library to embed the CCP and Customer Profiles into a custom agent application.

For information about embedding Customer Profiles, see the Streams documentation.

To build your own user interface for Customer Profiles information, see the documentation for the CustomerProfilesJS library on GitHub.

Tip

When you build a custom agent application, you determine the URL agents use to access it. That URL might be very different from the one provided by Connect Customer. For example, your URL could be https://example-corp.com/agent-support-app.

Automatically populate customer profiles

By default, Connect Customer Customer Profiles uses the following values to search for and autopopulate a customer profile in its user interface:

- For voice contacts: Phone number
- For chat contacts: Email

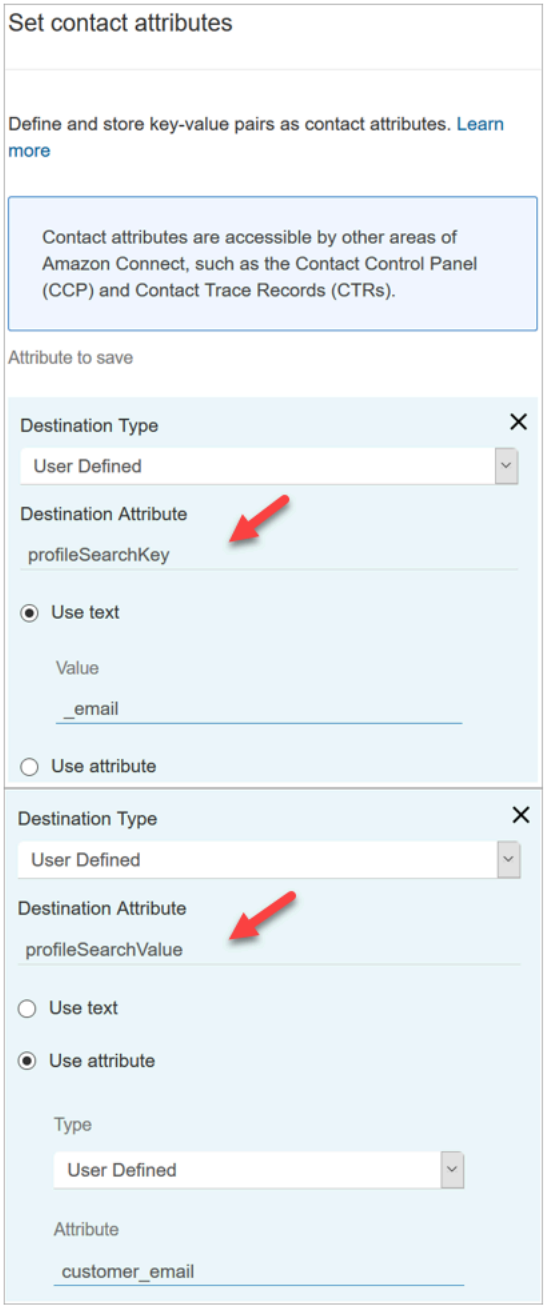
It autopopulates a customer profile by using the Customer Profiles flow block. To customize this behavior, use the Set contact attributes block (see below) for the following contact attributes

Attribute	Description	Type	JSONPath Reference
profileSearchKey	The name of the attribute you want to use to search for a profile.	User-defined	Not applicable
profileSearchValue	The value of the key you want to search for, such as customer name or account number.	User-defined	Not applicable

For example, to search by email for chat contacts, you can set the `profileSearchKey` attribute to the `_email` search key, and provide the email value as the `profileSearchValue`.

If you have defined custom keys in your profile objects, you can search by those search keys as well. To make sure your custom keys are searchable, see Key definitions in Customer Profiles object type mappings.

The following image shows how you might use these attributes in the Set contact attributes block.



Automatically associate a customer profile with a contact

By default, agents need to manually associate a customer profile with a contact based after they've verified the customer's identity. To change this behavior to automatically associate contacts with a profile based on the phone number, see Contact record templates in Connect Customer Customer Profiles.

If multiple profiles match a contact's phone number, the multiple matched profiles are shown to the agent. The agent needs to choose which profile to associate with the contact.

Security profile permissions for Connect Customer Customer Profiles

Assign permissions for your agents' security profiles so that they can perform such tasks as searching for profiles and viewing customer details, associating contact records to profiles, editing profiles, and creating and saving new profiles. The topics in the section help you assign permissions by updating permissions for agents, flows, and calculated attributes. There is also information to help you troubleshoot an error should you happen to encounter it while updating permissions.

Topics

- Update Customer Profiles permissions for agents
- Update Customer Profiles permissions for flows
- Update permissions for calculated attributes in Connect Customer Customer Profiles
- Assign security profile permissions to manage customer segments
- Assign new Customer Profiles permissions in case of error

Update Customer Profiles permissions for agents

Assign the following **Customer profiles** permissions as needed to the agent's security profile:

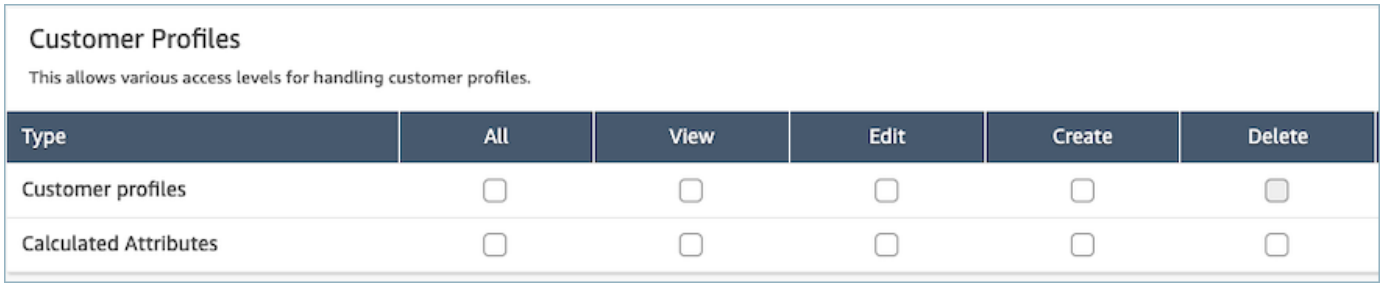
- **View**: Enables agents to see the Customer profiles application. They can:
  - View profiles that are autopopulated in the agent workspace.
  - Search for profiles.
  - View details stored in customer profiles (for example, Name, Address).
  - Associate contact records to profiles.
- **Edit**: Enables agents to edit details in the customer profile (for example, change address). They inherit **View** permissions by default.
- **Create**: Enables agents to create and save a new profile. They inherit **View** permissions by default, but don't inherit **Edit** permissions.

For information about how to add more permissions to an existing security profile, see Update security profiles in Connect Customer.

By default, the **Admin** security profile already has permissions to perform all Customer profiles activities.

Update Customer Profiles permissions for flows

1. Go to the Security profiles page, choose the security profile you would like to edit, or choose **Add new security profile**.

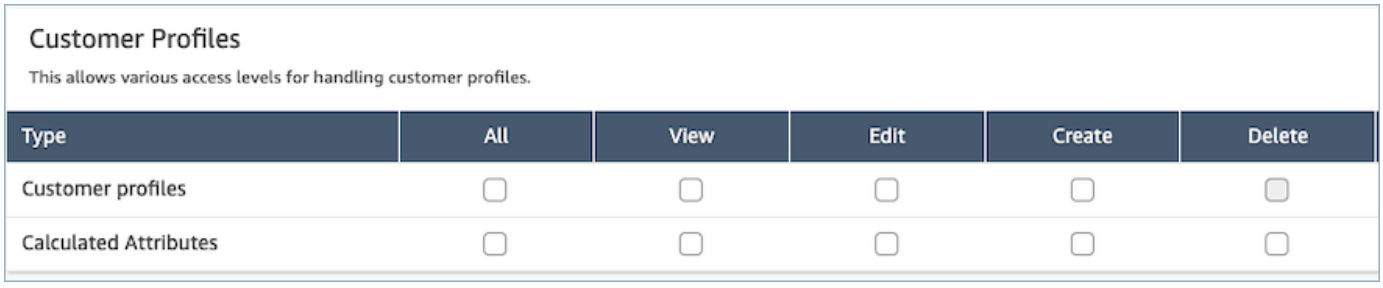


2. Select the **View** permission for Customer Profiles.

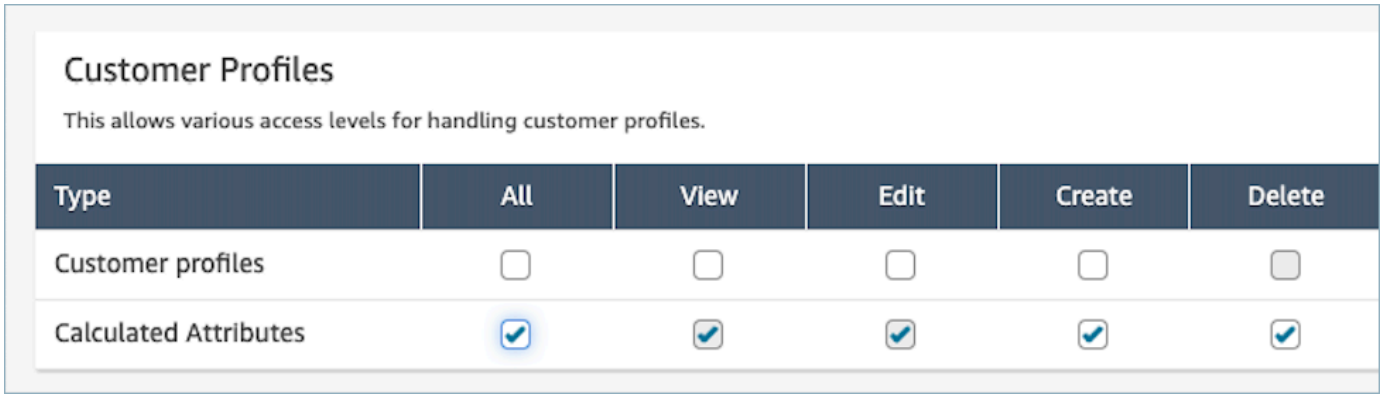
3. Choose **Save**. You can now navigate to the **User management** section and provide this security profile to the users of your choice.

Update permissions for calculated attributes in Connect Customer Customer Profiles

1. Go to the Security profiles page, choose the security profile you would like to edit, or choose **Add new security profile**.



2. Select **All** or **View**,**Edit**, **Create**, and **Delete** permission for calculated attributes.



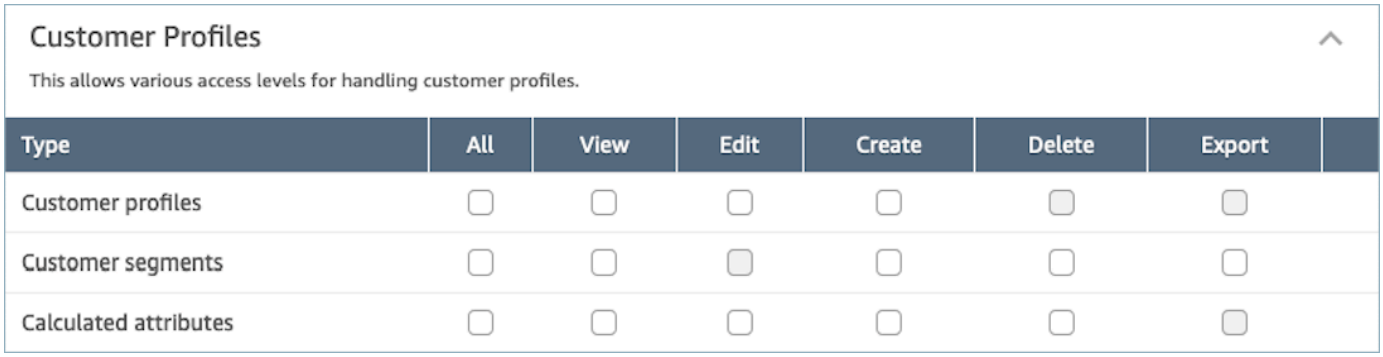
3. Choose **Save**. You can now navigate to the **User management** section and provide this security profile to the users of your choice.

For more information about calculated attributes, see the section called “Calculated Attributes”.

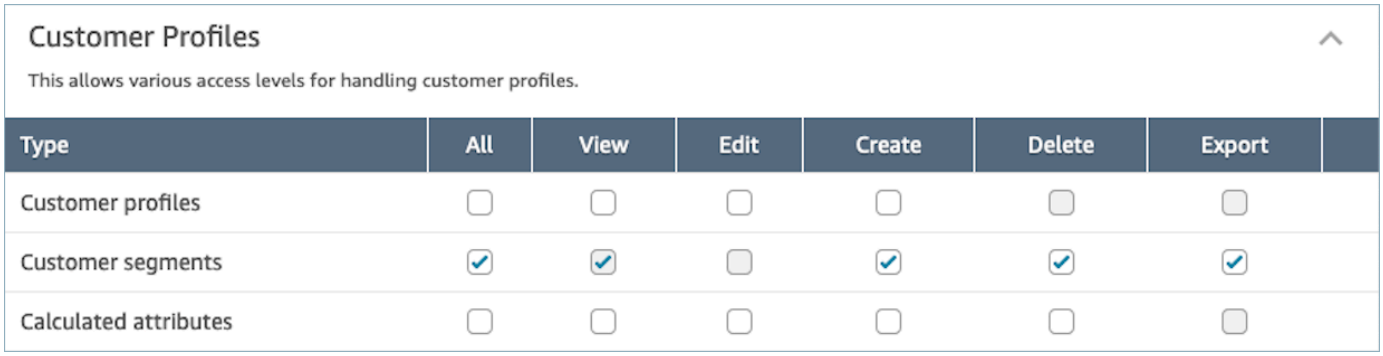
Assign security profile permissions to manage customer segments

Assign the following customer segments permissions as needed to the user’s security profile. For more details on security profiles, see Security profiles for Connect Customer and Contact Control Panel (CCP) access.

1. Go to the Security Profiles page, choose the security profile you would like to edit, or choose **Add new security profile**.



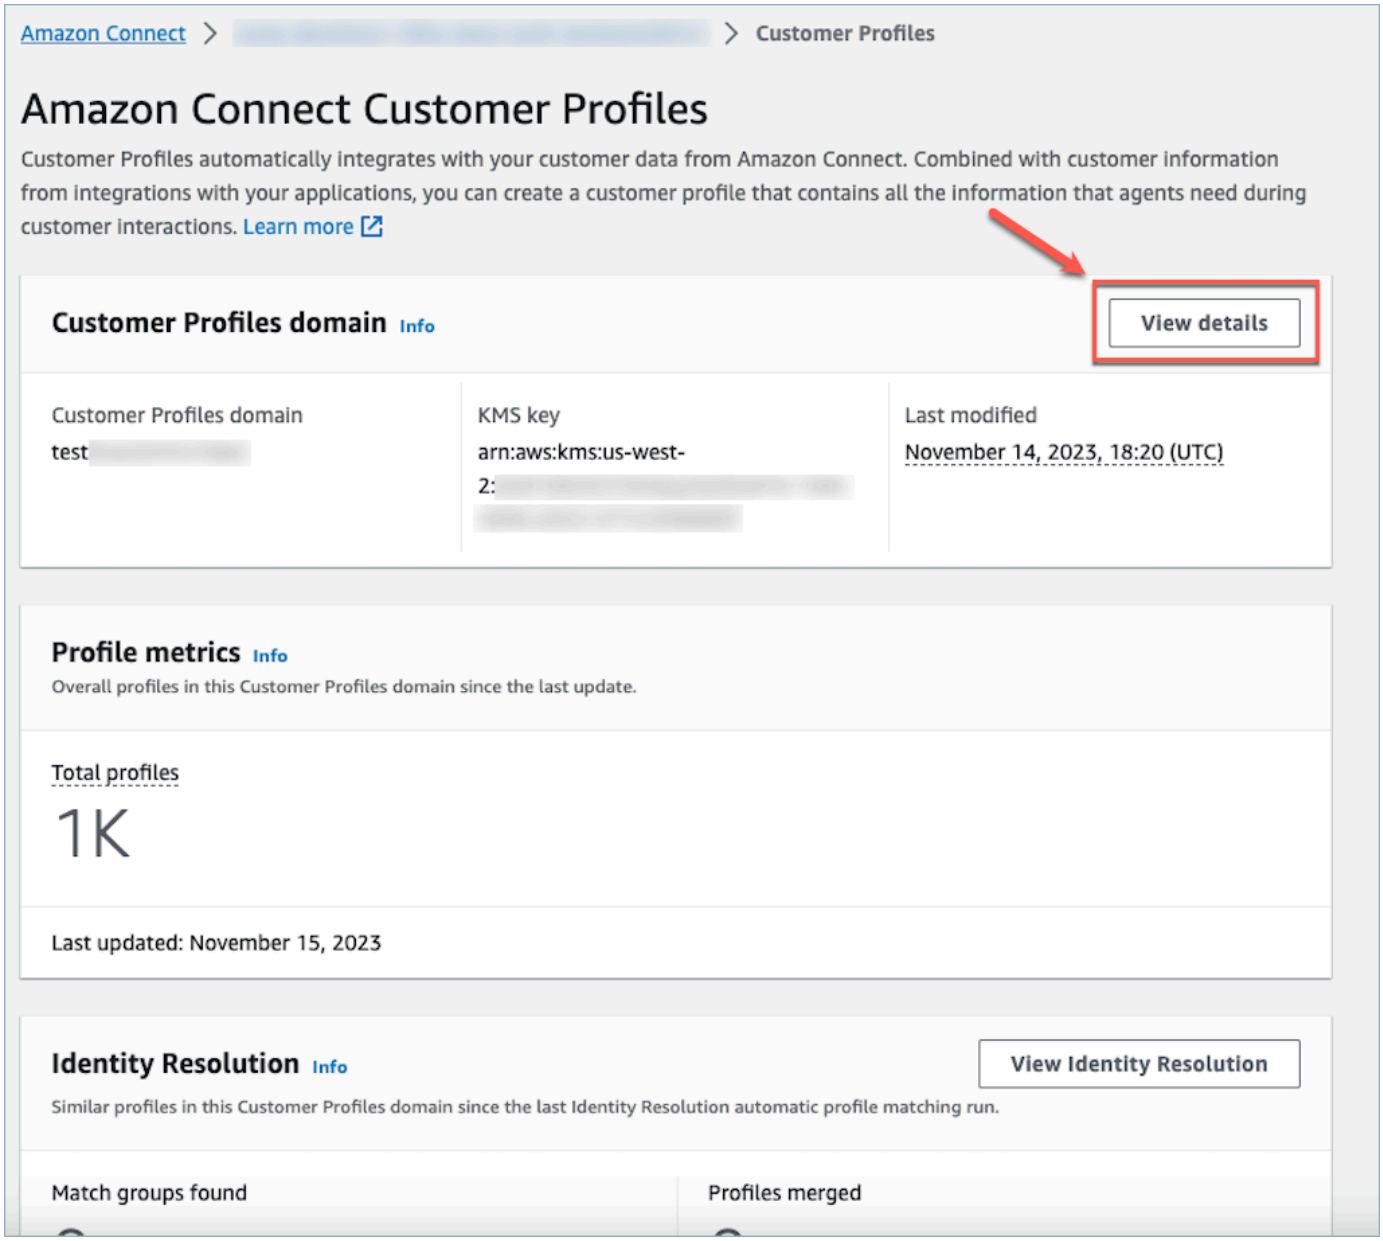
2. Select **All** or **View**, **Create**, **Delete**, and **Export** permission for customer segments.



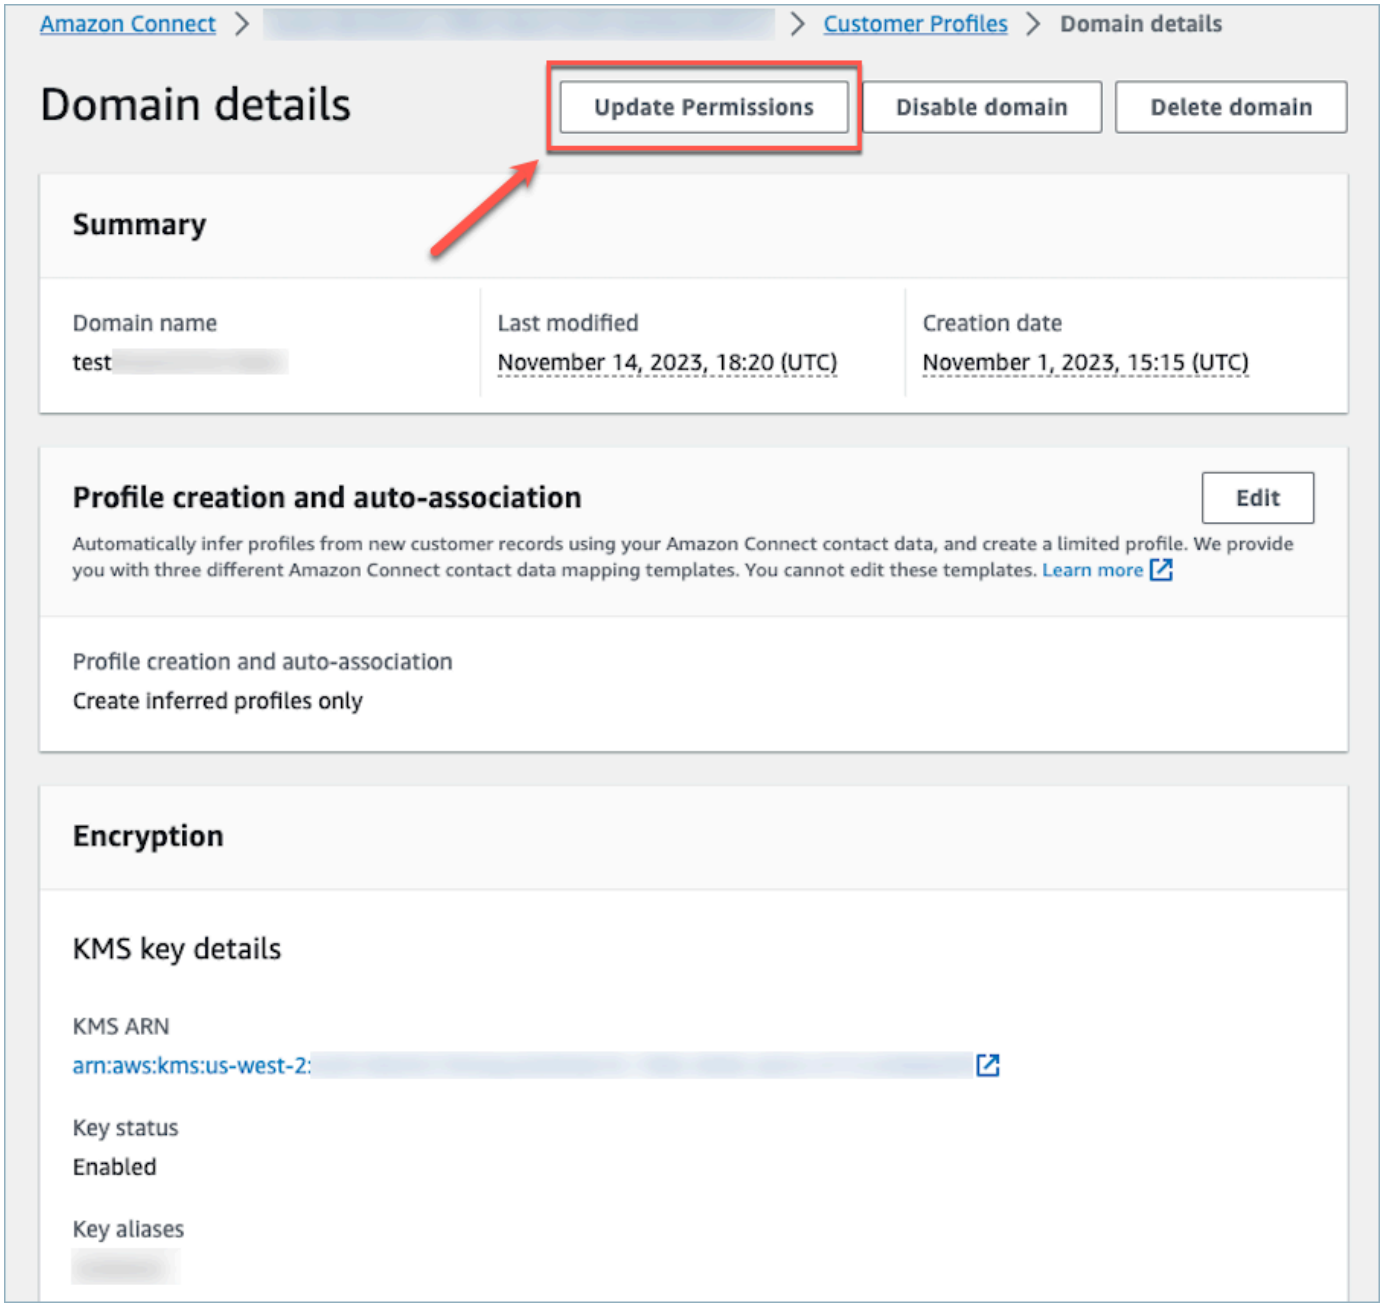
3. Choose **Save**. You can now navigate to the **User management** section and provide this security profile to the users of your choice.

Assign new Customer Profiles permissions in case of error

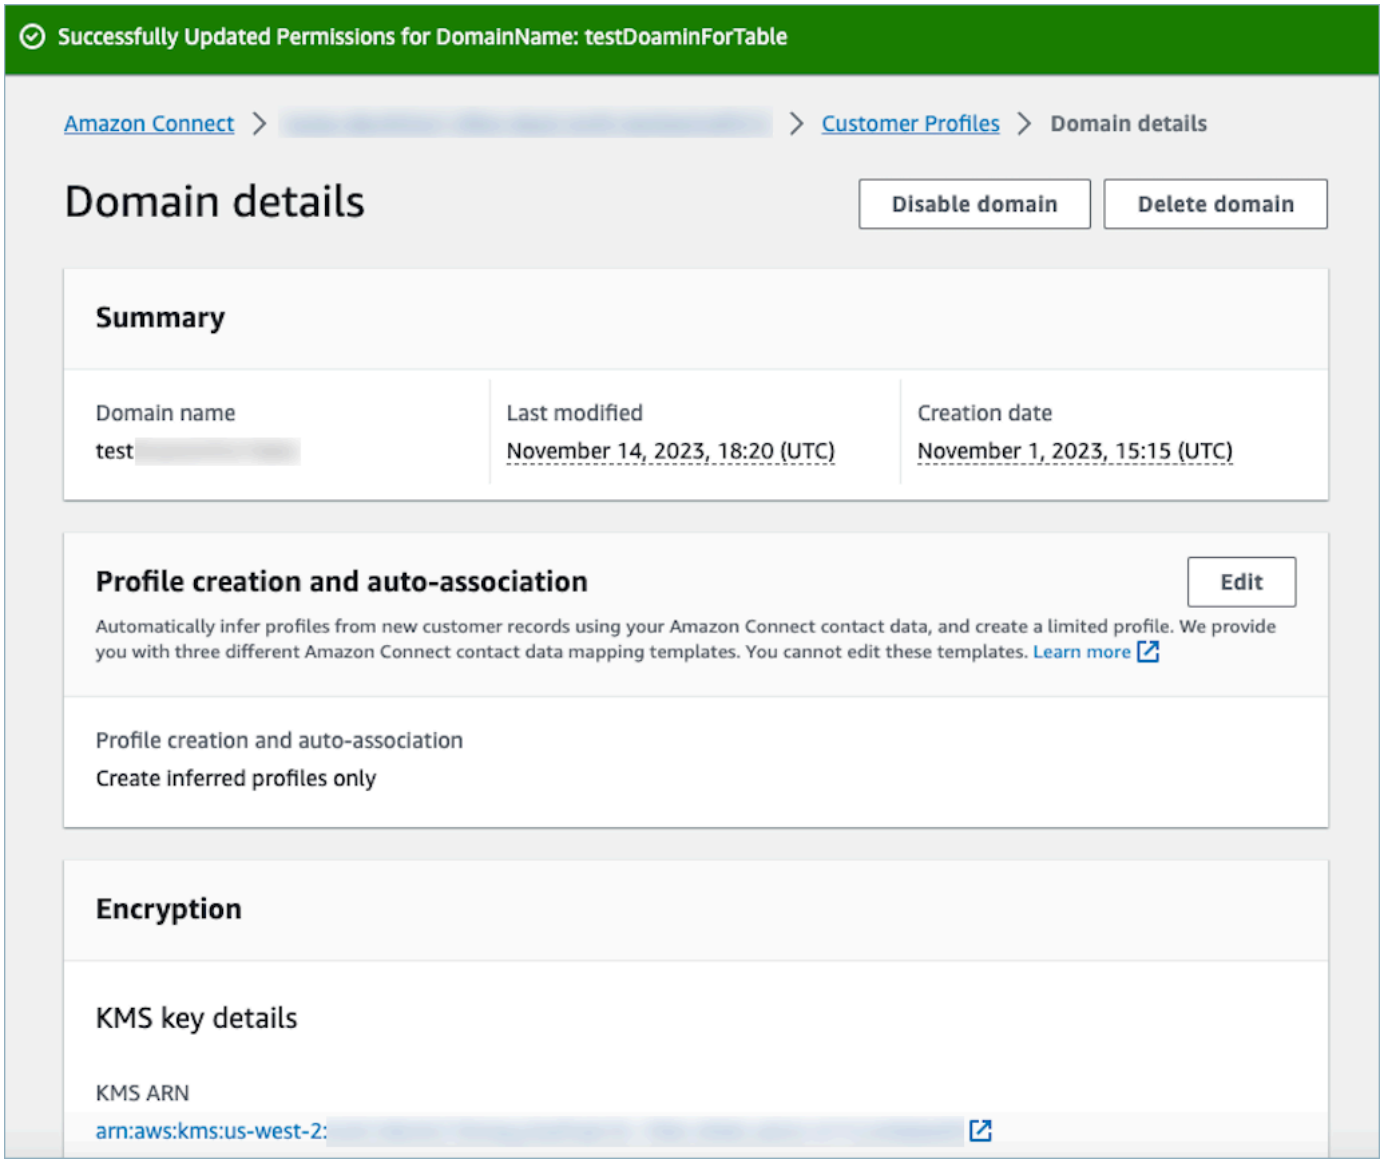
1. To update permissions in case of a 403 forbidden call error for any of the backend APIs, navigate to the domain section of the Connect Customer Customer Profiles console and choose **View details**.



2. Choose **Update Permissions** in the view domain details section.



3. After this is done, the permissions will be successfully updated and the **Update Permissions** button will no longer be visible in the domain details section. This will mitigate the 403 forbidden error issue and you will be able to make API calls successfully.



Connect Customer Customer Profiles data expiration

If a profile has not been updated within a specified amount of time, it will expire. This will cause the profile to be cleaned up, and removed from the Customer Profiles domain.

The time for Customer Profiles Data expiry can be broken down into two different categories:

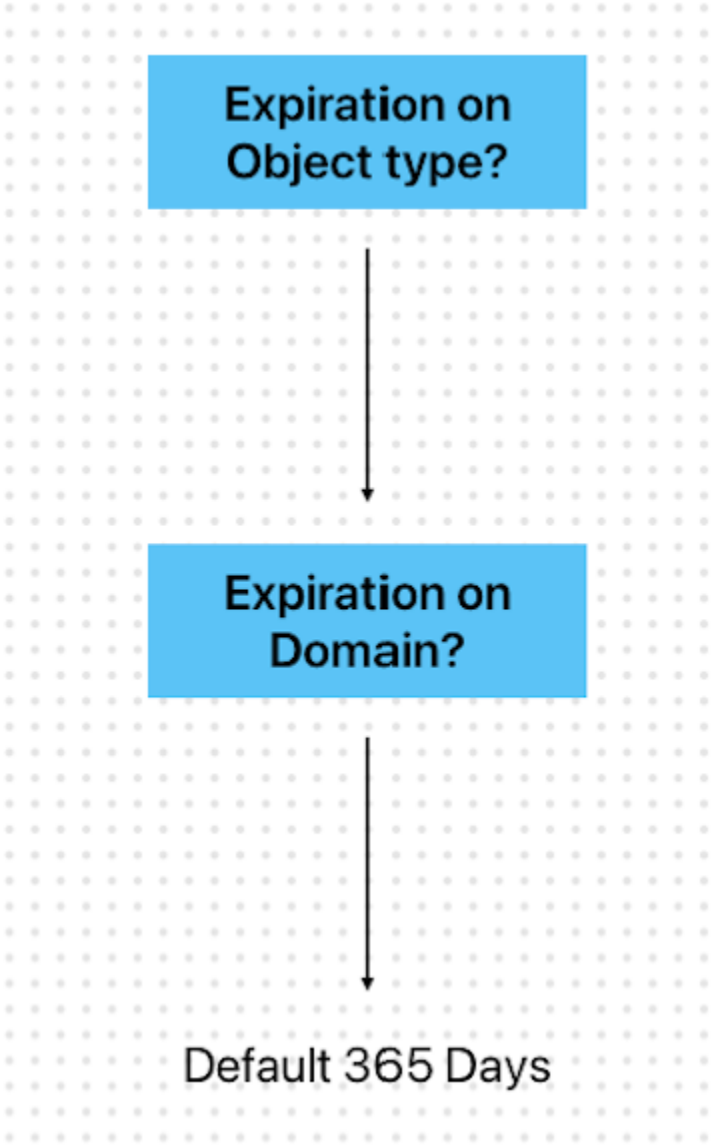
Profiles created through CreateProfile

Profiles created by using the `CreateProfile` API will expire based on the timestamp assigned by **DefaultExpirationDays** on a Customer Profiles Domain. If no Expiration has been configured it will default to 365 days.

Profiles created or updated through PutProfileObject

Profiles created or updated by using `PutProfileObject` will always respect the **ExpirationDays** defined on the object type associated to them. If no Expiration is defined on the object type, the Customer Profiles domain expiration date will be used. Finally, if neither are provided, the profile or profile object will expire to the default 365 days.

Mental model visualized



Import profile expiration

If a profile has been imported into a Customer Profile domain by using Segment Import, its expiry will fall into two different scenarios.

1. **Explicit definition of expiry when calling CreateUploadJob**

   By default profiles imported by using Segment import will expire in 14 days if no updates have been performed. This number can be defined by using the API, or within the Connect Customer admin website during import creation, with a max of 90 days.

2. **Importing profiles that already exist within your Customer Profiles Domain from a previous import job**

   If two import jobs have been ran, and a duplicate profile has been found, Customer profiles will always respect the longest expiry time.

Use Identity Resolution to consolidate similar profiles in Connect Customer

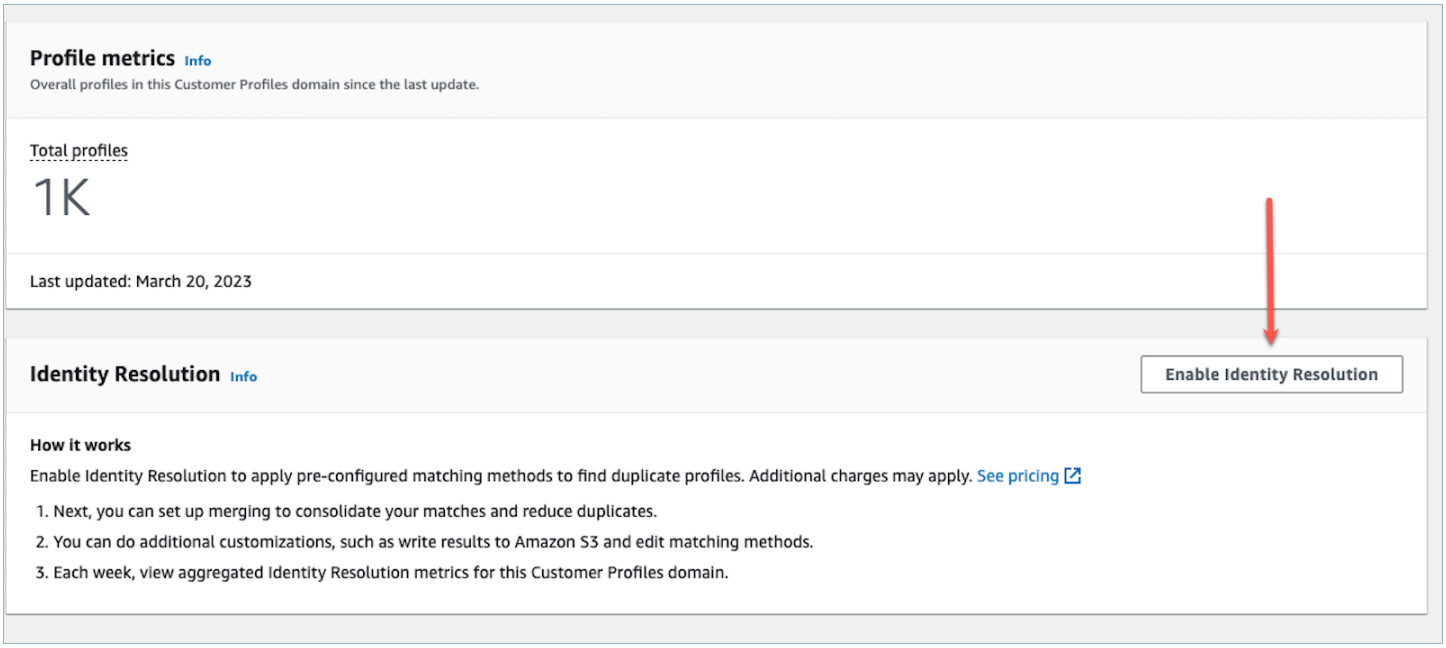
A *similar profile* is when two or more profiles are determined to be for the same contact. There can be multiple profiles when customer records are captured across multiple channels and applications for the same customer, and do not share a common unique identifier.

Identity Resolution automatically finds similar profiles and helps you consolidate them. It runs an Identity Resolution Job on a weekly basis, which performs the following steps:

1. Automatic profile matching
2. Automatic merging of similar profiles based on your consolidation criteria

Each time an Identity Resolution Job runs, it displays metrics on the **Customer Profiles** page. The metrics show the number of profiles it reviewed, the number of match groups found, and the number of profiles consolidated.

Additional charges might apply for enabling Identity Resolution. For more information, see Connect Customer pricing.



Enable Identity Resolution for your Connect Customer Customer Profiles domain

When you enable Identity Resolution you specify the following information:

- When the Identity Resolution Job should run on a weekly basis. By default, it runs Saturdays at 12AM UTC.
- The Amazon S3 bucket where the Identity Resolution Job should write the results of the automatic profile matching process. If you don't have an S3 bucket, you'll have the option to create one during the enablement process.

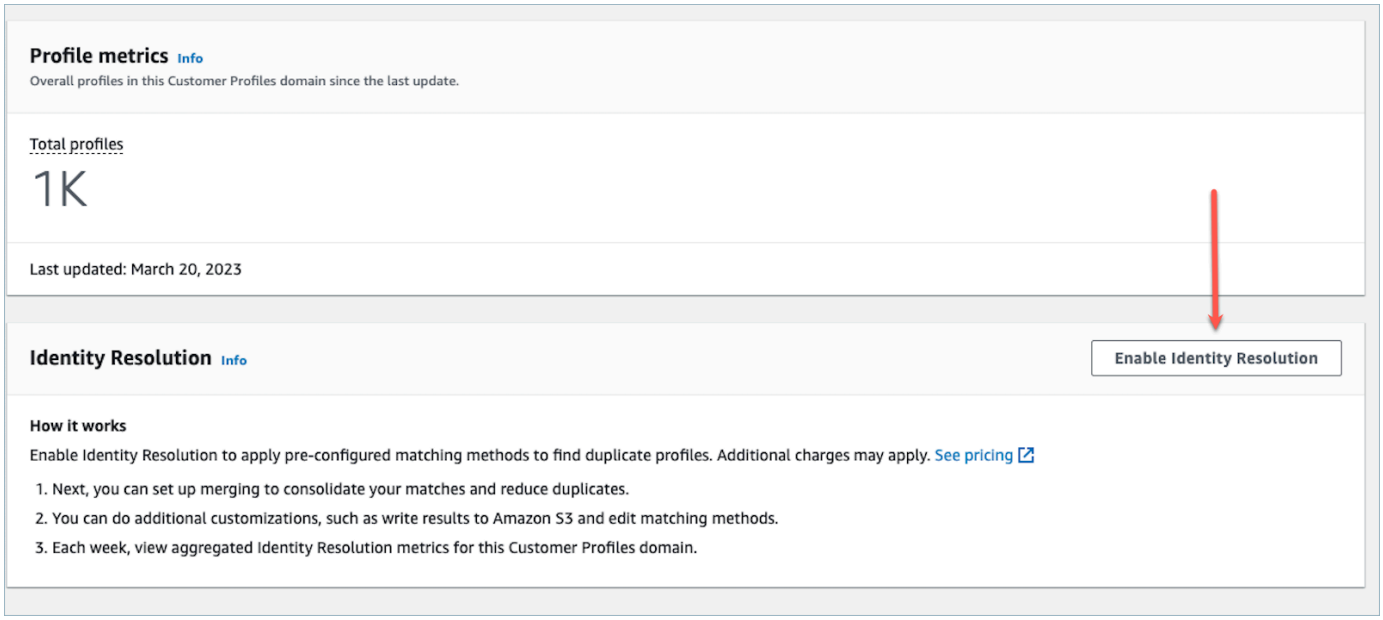
  You can query the Amazon S3 bucket or use the GetMatches API to filter results based on confidence scores.

After you enable Identity Resolution you'll see the option to create consolidation criteria for the optional auto-merging process.

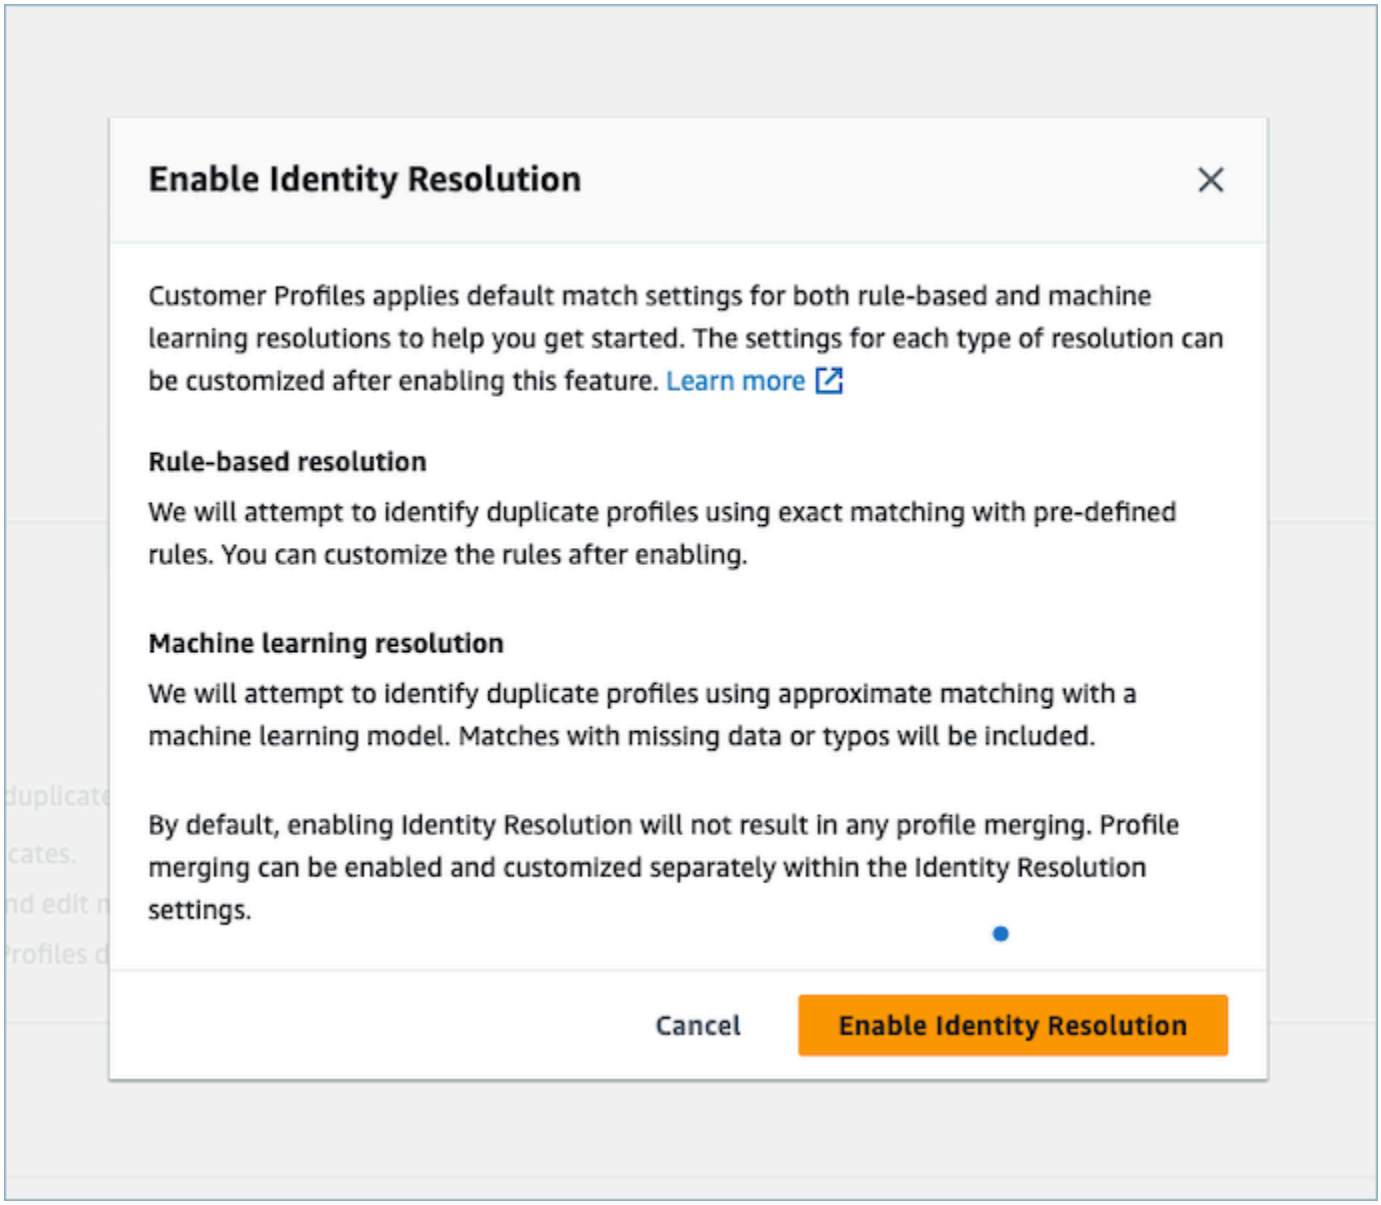
To enable Identity Resolution

1. You must have a Customer Profiles domain enabled for your instance. For instructions, see Enable Customer Profiles for your Connect Customer instance.
2. In the navigation pane, choose **Customer profiles**.

3. In the **Identity Resolution** section, choose **Enable Identity Resolution**.



4. In the **Identity Resolution** pop-up box, choose **Enable Identity Resolution**.



5. On the **Enable Identity Resolution** page, specify the date and time when you want the Identity Resolution Job to run.
6. If you want to review the matched profile IDs from an Amazon S3 bucket, select **Write profile ID matches to Amazon S3**. Otherwise, you can use the GetMatches API to review matching profiles.

> **Note**
>
> If you auto-enable merges, you will not receive matched profile IDs.

- Specify the Amazon S3 bucket where the Identity Resolution Job should write the profile matches.

  We recommend applying a policy to prevent a confused deputy security issue. For more information and a sample policy, see Connect Customer Customer Profiles cross-service confused deputy prevention.

7. When done, choose **Enable Identity Resolution**. Both rule-based matching and ML-based matching are enabled after you enable Identity Resolution. You can disable one of them or both from the Identity Resolution page. For more information, see Disable Identity Resolution in Connect Customer Customer Profiles.
8. Rule-based matching for Identity Resolution:

   a. After you enable the rule-based matching with a new domain the matching will start immediately if you set up an integration and the integration is running.

   b. After you enable the rule-based matching with an existing domain, the matching process will start within one hour.
9. ML-based matching for Identity Resolution:

   a. After you enable Identity Resolution the Identity Resolution Job runs for the first time within 24 hours.

   > **Note**
   >
   > Before running an Identity Resolution Job for the first time on a new Customer Profiles domain, we recommend checking your profile metrics to make sure that profiles have been created. Otherwise, there won't be any matching results.

   b. You might want to set up consolidation criteria for auto-merging matching profiles. If so, see Set up consolidation criteria for Identity Resolution in Connect Customer.

Set up consolidation criteria for Identity Resolution in Connect Customer

> **Note**
>
> You must enable Identity Resolution in order to access the option to create consolidation criteria using the Connect Customer admin console.

When similar profiles are detected by an Identity Resolution Job, the process can automatically merge them into a unified profile based on consolidation criteria that you specify.

The attributes that you select are compared across all similar profiles in a match group for exact match. For example, if you specify `email` as an attribute in the criteria, then all similar profiles in a match group that have exact same value of `email address` are merged into a unified profile.

> **Tip**
>
> If you want to set up your own merging logic, use the MergeProfiles API.

Limits

You can select any attribute from the standard profile to compare similar profiles. For example, you might choose phone number, email address, and name, as well as custom attributes.

You can specify up to:

- 10 consolidation criteria
- 20 attributes per criteria

Tips for creating strong criteria

To improve the targeting of unique profiles and to avoid consolidating profiles that are not duplicates, we recommend the following steps:

- Select attributes that can uniquely identify a customer and are not likely to be the same across customers, such as an account number or a form of government ID.

- Avoid single attribute criteria. Select multiple attributes to create a combination of attributes to improve targeting. For example:
  - **Phone number** with **First name**, **Middle name**, **Last name** is stronger criteria

  than
  - **Phone number** alone, or
  - The combination of **First name, Middle, name, Last name** alone
- Select all attributes within a specific attribute group, when applicable. For example, if you want to use name, select all the related name attributes: **First name, Middle name, Last name**. If you want to use business address, select all the related business address attributes.
- Include one of the following attributes likely to uniquely identify a customer in combination with other attributes in the criteria:
  - Account number
  - Phone number
  - Email

How to set up auto-merging criteria

Before setting up your consolidation criteria for automatic merging, or auto-merging, we recommend reviewing How the auto-merging process works.

1. After you enable Identity Resolution, on the **Identity Resolution** page you'll have the option of setting up auto-merging criteria. Choose **Create consolidation criteria**.
2. If you receive a **Missing timestamp** dialog box, we recommend adding new timestamp attributes to your custom object types before continuing. See Missing timestamp for profile conflicts.
3. In the **Profile conflicts** section, choose how profile conflicts should be resolved when two or more records have conflicts.
4. In the **Consolidation criteria** section, create one or more criteria. We recommend including at least two or more attributes per criteria.

Missing timestamp for profile conflicts

The **Missing timestamp** message is displayed if you have custom object type mappings.

Use the PutProfileObjectType API to add the following new attributes to your custom object type:

- `Fields.sourceLastUpdatedTimestamp`
- `sourceLastUpdatedTimestampFormat`

If the timestamp attribute is not specified, you can continue to create consolidation criteria, however, a default timestamp of when the records were ingested into Customer Profiles is used. We recommend adding the new attributes before creating your consolidation criteria.

If you have already defined a custom object type and want to update your custom object type, we run a scheduled backfill every week to update your existing profiles with the `Fields.sourceLastUpdatedTimestamp`. To opt in to the scheduled backfill:

1. Update your custom profile object type by using the PutProfileObjectType API.
2. After you update your custom profile object type, open an Support ticket and we'll schedule the backfill for you. The scheduled backfill runs until end of February 2022.

Alternatively, you can delete and then re-create the ingestion/connector you have for your domain that uses the custom object type. All of your data will be re-ingested using your updated object type and `Fields.sourceLastUpdatedTimestamp` will be parsed from it.

Example: How sample criteria are applied

In this example there are three criteria:

- **Resolve profile conflicts** is set to **Use last updated timestamp**. This means when two fields have conflicting values, Identity Resolution is going to use the last updated timestamp to determine which value to use.
- Criteria 1:
  - First name, Last name
  - Email
- Criteria 2:
  - Phone number

These criteria are applied to the following profiles:

- Profile A

  - John Doe [last updated **05:00**a]
  - doefamily@anyemail.com [last updated **05:00**a]
  - 555-555-5555 [last updated **07:00**a]
- Profile B
  - John Doe [last updated **04:00**a]
  - doefamily@anyemail.com [last updated **06:00**a]
  - 555-555-555**6** [last updated *04:00*a]
- Profile C
  - **Jane** Doe [last updated **06:00**a]
  - doefamily@anyemail.com [last updated **07:00**a]
  - 555-555-5555 [last updated **06:00**a]

Following are the results when Criteria 1 is applied:

- Profile A and B are merged = Profile AB

This results in ProfileAB, which looks like the following:

- John Doe [last updated **05:00**a]
- doefamily@anyemail.com [last updated **07:00**a]
- 555-555-555**5** [last updated **06:00**a]

Because there's a conflict between the phone numbers, Identity Resolution uses the last timestamp to choose the 555-555-555 number.

Next, Criteria 2 is applied. Following are the results:

- Profile AB and C are merged = Profile ABC

This results in Profile ABC, which looks like the following:

- **Jane** Doe [last updated **06:00**a]
- doefamily@anyemail.com [last updated **07:00**a]
- 555-555-555**5** [last updated **07:00**a]

Identity Resolution uses the First name, Last name, and Email from Profile C because they have the most recent timestamps.

Machine learning for Identity Resolution in Connect Customer

Identity Resolution in Connect Customer automatically finds similar profiles and helps you consolidate them. The topics in this section describe how to set up machine learning matching to consolidate duplicate profiles as part of the automatic merging process.

Topics

- How machine learning Identity Resolution works in Connect Customer
- Set up machine learning for Identity Resolution in Connect Customer

How machine learning Identity Resolution works in Connect Customer

This topic describes how Identity Resolution performs automatic profile matching, and if set up, how it automatically merges similar profiles.

Automatic profile matching

To identify similar profiles, Identity Resolution uses machine learning to review the following Personal Identifiable Information (PII) attributes in each profile:

- Name: All names are reviewed for similarity, including first name, middle name, and last name.
- Email: All email addresses are reviewed for similarity, including personal email and business email. They are not case sensitive.
- Phone number: All phone numbers and formats are reviewed for similarity, including home phone, mobile phone, and business phone.
- Address: All address types and format are reviewed for similarity, including business address, mailing address, shipping address, and billing address.
- Date of birth: All birth dates and formats are reviewed for similarity.

It uses this information to create match groups of similar profiles.

Match groups

A match group consists of all similar profiles which represents a customer. Each match group contains the following information:

- A match ID, which uniquely identifies the group of two or more similar profiles that represent a contact
- The number of profile IDs in the match group
- A confidence score associated with the match group

Confidence scores

After the auto-matching process runs, you can query the S3 bucket or use the GetMatches API to filter results based on confidence scores. For example, you can filter out high confidence matches for a further review.

A confidence score is a number between 0 and 1 that represents the confidence level of assigning profiles to a match group. A score of 1 likely indicates an exact match.

Automatic merging of similar profiles

After the profiles are matched, the Identity Resolution Job can optionally merge similar profiles based on your criteria. If you delete or update criteria, the updated criteria is applied to similar profiles in the next run.

Important

You cannot undo the consolidation process. We strongly recommend using the GetAutoMergingPreview API to do a dry run of the automatic merging process before running the Identity Resolution Job.

Note

When merging two profiles, profile fields manually populated through an API call or in the agent workspace will not be overwritten by profile fields automatically ingested from an integration or custom object type mapping.
For example, suppose a profile is created with FirstName “John” manually by an agent in the agent workspace. Another profile is created using an S3 integration with FirstName “Peter”. If these profiles are automatically merged, the FirstName “John” will be preserved.

How the auto-merging process works

- **All selected attributes in a consolidation criteria are connected with AND criteria with exact value comparison before merging**.
  - For example, when multiple attributes are specified in the criteria, such as `email address` and `phone number`, then all similar profiles in a match group that have the exact same value of `email address` and `phone number` are merged.
  - If one or more of the similar profiles in a match group have a different value or missing value for one or more of the attributes in a criteria, the similar profiles are merged.

    For example, one match group might be five similar profiles out of which three profiles are consolidated, because these three profiles meet the criteria. The other two profiles are not merged, because they do not meet the criteria.
- **Multiple criteria are evaluated in the order of priority starting with Criteria 1**.
  - The sequence in which consolidation criteria are applied. It starts with Criteria 1 as the highest priority to Criteria 10 as the lowest priority.
  - After the Identity Resolution Job applies one criteria, it applies the next criteria to the consolidated profiles and the remaining similar profiles in a match group.
  - You can have a maximum of 10 consolidation criteria.
- **Each criteria runs independently and operates as an OR with other criteria**.
  - When you have multiple criteria, each criteria is applied individually and in the sequence of priority order before the Identity Resolution Job moves on to the next criteria.
  - All criteria is applied in the sequence in which you listed them. It doesn't matter whether the criteria fails or succeeds to consolidate similar profiles in a match group.
- **By default, profile conflicts are managed by recency**.
  - When two or more similar profiles in a match group meet a consolidation criteria, the resulting consolidated profile is created by comparing each value of the profile attributes constituent similar profiles.
  - Each attribute might have an exact match in value. In this case, any value might be selected for that attribute.
  - If there is a conflict between values of two or more constituent similar profiles, the most recently updated attribute is chosen.

For example, if Jane Doe has three different values in the `Address` attribute of the constituent similar profiles, Identity Resolution picks the most recent addressed to create the unified profile.

  - By default, the **Last updated timestamp** is used to determine the record that was most recently updated.

- **Profile conflicts are managed by source object type and recency**.
  - You can also change default behavior of conflict resolution to choose a similar constituent profile from a specific source as the source of truth to inform conflict resolution.
  - If you want to specify a data source to use for profile conflicts, you can choose one of your object types as a data source if you select **Source with last updated timestamp**.
  - The most recently updated record from the specified object type is used for resolving profile conflicts.
- **Last updated timestamp identifies which record was most recently updated**.
  - The timestamp attribute associated with the source record's object type is used to identify which record was most recently updated.
  - If the timestamp attribute is not available for the object type, the timestamp on which the record was ingested into your Customer Profiles domain is used.
  - If you have custom object types, you need to add timestamps. See Missing timestamp for profile conflicts for more information.
- **Consolidation is a one-way process and cannot be undone**.
  - Choose your criteria carefully before starting the consolidation process. For more information, see Tips for creating strong criteria.
  - Use the GetAutoMergingPreview API to test the auto-merging settings of your Identity Resolution without merging your data.

For an example that shows how criteria is applied, see Example: How sample criteria are applied.

Rule-based matching for Identity Resolution in Connect Customer

Identity Resolution in AC automatically finds similar profiles and helps you consolidate them. The topics in this section describe how to set up rule-based Identity Resolution to consolidate duplicate profiles as part of the automatic merging process.

Topics

- How rule-based Identity Resolution works in Connect Customer
- Set up rule-based matching for Identity Resolution in Connect Customer
- Set up matching rules for rule-based Identity Resolution in Connect Customer

How rule-based Identity Resolution works in Connect Customer

This topic describes how rule-based Identity Resolution performs automatic profile matching and how it automatically merges similar profiles.

Automatic profile matching

To identify similar profiles, the rule-based Identity Resolution uses a list of matching rule attributes to match each profile. Up to 15 MatchingRule attributes are supported in the MatchingRules.

Matching rules

The following is a list of the MatchingRule attributes that can be used. You can configure up to 15 matching rule levels. For each matching rule, you can use the following Personal Identifiable Information (PII) attributes in each profile:

- **AccountNumber**
- **Address.Address**: All addresses specified in the Attribute Type Selector are reviewed for similarity, including Address, BusinessAddress, MaillingAddress, and ShippingAddress
- **Address.City**: All addresses specified in the Attribute Type Selector are reviewed for similarity, including Address, BusinessAddress, MaillingAddress, and ShippingAddress
- **Address.Country**: All addresses specified in the Attribute Type Selector are reviewed for similarity, including Address, BusinessAddress, MaillingAddress, and ShippingAddress
- **Address.County**: All addresses specified in the Attribute Type Selector are reviewed for similarity, including Address, BusinessAddress, MaillingAddress, and ShippingAddress
- **Address.PostalCode**: All addresses specified in the Attribute Type Selector are reviewed for similarity, including Address, BusinessAddress, MaillingAddress, and ShippingAddress
- **Address.State**: All addresses specified in the Attribute Type Selector are reviewed for similarity, including Address, BusinessAddress, MaillingAddress, and ShippingAddress
- **Address.Province**: All addresses specified in the Attribute Type Selector are reviewed for similarity, including Address, BusinessAddress, MaillingAddress, and ShippingAddress
- **PhoneNumber**: The phone numbers specified in the Attribute Type Selector are reviewed for similarity, including PhoneNumber, HomePhoneNumber, and MobilePhoneNumber.
- **EmailAddress**: All email addresses specified in the Attribute Type Selector are reviewed for similarity, including EmailAddress, BusinessEmailAddress, and PersonalEmailAddress
- **BirthDate**
- **BusinessName**
- **FirstName**

- **LastName**
- **MiddleName**
- **Gender**
- **Any customized profile attributes with the *Attributes* prefix**

Matching rules are processed by priority. For example, the first rule should be the most optimized rule you want to define and should be used to achieve the most accurate result.

Attribute Type Selector

The Attribute Types Selector holds vital configuration information for rule-based identity resolution, facilitating profile matching. You can use this to fine-tune the comparison of profiles across attribute types and select the key attributes for matching within each type. Within this feature, you have the flexibility to configure three distinct attribute types, enabling precise control over the matching process.

- **Email type**
  - You can choose from EmailAddress, BusinessEmailAddress, and PersonalEmailAddress
- **PhoneNumber type**
  - You can choose from PhoneNumberNumber, HomePhoneNumber, and MobilePhoneNumber
- **Address type**
  - You can choose from Address, BusinessAddress, MaillingAddress, and ShippingAddress

You can either choose `ONE_TO_ONE` or `MANY_TO_MANY` as the AttributeMatchingModel.
When choosing `MANY_TO_MANY`, the system can match attributes across the sub-types of an attribute type. For example, if the value of the EmailAddress field of Profile A and the value of BusinessEmailAddress field of Profile B matches, the two profiles are matched on the EmailAddress type. When choosing `ONE_TO_ONE`, the system can only match if the sub-types are exact matches. For example, only when the value of the EmailAddress field of Profile A and the value of the EmailAddress field of Profile B matches, the two profiles are matched on the EmailAddress type.

Max allowed rule level for matching

You can configure the max rule level you want to use to match similar profiles. For example, if your max allowed rule level for matching is 5, the system will not find similar profiles using the rule level 6.

Match groups

A match group consists of all similar profiles which represent a customer. Each match group contains the following information:

- A match ID, which uniquely identifies the group of two or more similar profiles that represent a contact
- The number of profile IDs in the match group

Match status

- **PENDING**

  The first status after the configuration of a rule-based Matching rule. If it is an existing domain, the rule-based Identity Resolution waits 1 hour before creating the matching rule. If it is a new domain, the system will skip the **PENDING** stage.

- **IN_PROGRESS**

  The system is creating the rule-based Matching rule. Under this status, the system is evaluating the existing data and you can no longer change the rule-based matching configuration.

- **ACTIVE**

  The rule is ready to use. You can change the rule a day after the status is in an **ACTIVE** state.

How the auto-matching process works

After you create a new Connect Customer Customer Profiles domain with the rule-based matching rule, the rule-based Identity Resolution will match similar profiles based on the rule you specified while you are ingesting the profiles. If you update the configuration of the rule-based matching, Customer Profiles will start to re-evaluate the profiles in your domain using the new configuration in an hour.

If you are enabling the rule-based matching with an existing domain, the system will move to a **PENDING** state and will start to evaluate the existing profiles in your domain using the new configuration in an hour. The time it takes to finish evaluating profiles is dependant on how many profiles exist.

- **By default, the default rule will be applied if no custom rule specified.**

  - Connect Customer Customer Profiles provides a default matching rule if you do not provide a custom matching rule. You can check the custom matching rule here.
- **All the records will go through the rule-based matching rules.**
  - The system assesses each matching rule level until a match is identified or until the maximum allowed rule level for matching is reached. The evaluation process commences at rule level 1, where the record is analyzed. If no matching group is discovered, the system proceeds to evaluate the subsequent rule levels, searching for a match group until either a match is found or the maximum allowed rule level for matching is reached.
- **All attributes in a single matching rule level are connected using an *AND* relationship**
  - When multiple attributes are present within a single rule level, they are interconnected by an AND relationship. During profile matching, all attribute values must align for profiles to be assigned to the same match group. For example, only when the values of all attributes are identical, profiles are considered as matches and grouped together for further processing.
- **All attributes in an attribute type selector are connected with an *OR* relationship**
  - When specifying attributes within the attribute type selector, attributes of the same type are linked through an OR relationship. For instance, consider the PhoneNumber Type where HomePhoneNumber and BusinessPhoneNumber are used. In this scenario, two profiles can be matched if either their HomePhoneNumber or BusinessPhoneNumber aligns. Consequently, the matching process allows for flexible matches based on either home or business phone numbers.
- **The match result is eventually optimized.**
  - Due to the near real-time nature of profile matching in the system, there is a possibility that a match group for your profile might be found at a lower (less optimized) rule level. Nevertheless, if a match is available at a higher (more optimized) rule level, the system will assign the profile to that particular group.

> **Note**
>
> When Identity Resolution performs rule-based matching, the order in which the rules that you have configured will be processed is dependant on how the data is ingested. For example, If you configure rules 1 and 2, rule 2 might be processed before rule 1. The processing order might change, but the end result will always be the same.

Automatic merging of similar profiles

After the profiles are matched, the Identity Resolution Job can optionally merge similar profiles based on the MaxAllowedRuleLevelForMerging you specify in the rule-based matching configuration.

> **Important**
>
> You cannot undo the consolidation process. It is recommended to turn on matching only first to evaluate the match result using the ListMatches and GetSimiliarProfiles APIs. You can turn on merging by setting the MaxAllowedRuleLevelForMerging using the UpdateDomain API.

> **Note**
>
> When merging two profiles, profile fields manually populated through an API call or in the agent workspace will not be overwritten by profile fields automatically ingested from an integration or custom object type mapping.
> For example, suppose a profile is created with FirstName “John” manually by an agent in the agent workspace. Another profile is created using an S3 integration with FirstName “Peter”. If these profiles are automatically merged, the FirstName “John” will be preserved.

Set up rule-based matching for Identity Resolution in Connect Customer

This topic provides an illustrative walkthrough of the steps that you use to edit rule-based matching attribute types, rule-based matching rules, rule-based matching merge rules, and rule-based match locations. It also shows how to reset rule-based matching rules.

Edit rule-based matching attribute types

Set up matching rules for rule-based Identity Resolution in Connect Customer

Limits

You can select any attribute from the standard profile to compare similar profiles. For example, you might choose phone number, email address, and name, as well as custom attributes.

You can create a rule-based matching rule with the following limitations:

- 15 rule levels
- Each rule level can contain up to 15 profile attributes

Tips

To improve the targeting of unique profiles and to avoid consolidating profiles that are not duplicates, the following tips are recommended:

- Include at least one high cardinality attribute that can uniquely identify a customer and that is not likely to be the same across customers, such as a phone number, an email address or an account number.
- Avoid using profile attributes that can belong to different identities without a high cardinality attribute.

  - **Phone number** with **First name**, **Last name** is a stronger rule than the combination of **First name**, **Last name** alone.
- If at one rule level, all of the profile attributes of that rule are low cardinality attributes (the attribute that can belong to more than 500 different profiles), Customer Profiles does not attempt to match the profile. You will receive the following SQS message in your DLQ if you setup one during the domain creation:
  - All attributes at rule level x are associated with more than 500 records.
- Always enable **Match only** first, check the match results, and only enable the merging by setting the **MaxAllowedRuleLevelForMerging** if you are satisfied with the match results.

Resolve profile conflicts for profile merging

You can define which record to use when the value of an attribute from two or more similar profiles is different, such as conflicting address records.

Last updated timestamp

By default, profile conflicts are managed by recency. When there is a conflict between the values of two or more similar profiles, the most recently updated attribute will be chosen.

Source with last updated timestamp

You can prioritize records from a specific object type as your data source for managing profile conflicts. When there is a conflict between the values of two or more similar profiles, the most recently updated attribute from the specified object type will be chosen.

If a timestamp is not specified in your object type, the date the record was ingested into Customer Profiles will be used. Source with last updated timestamp is unavailable when you don't have any integrations set up. When you add an integration, your object types will be available as a source for this option.

Missing timestamp for profile conflicts

The Missing timestamp message is displayed if you have custom object type mappings.

Use the PutProfileObjectType API to add the following new attributes to your custom object type:

- `Fields.sourceLastUpdatedTimestamp`

- `sourceLastUpdatedTimestampFormat`

If the timestamp attribute is not specified, you can continue to create consolidation criteria, however, a default timestamp of when the records were ingested into Customer Profiles is used. It is recommended to add the new attributes before creating your consolidation criteria.

If you have already defined a custom object type and want to update your custom object type, we run a scheduled backfill every week to update your existing profiles with the `Fields.sourceLastUpdatedTimestamp`. To opt in to the scheduled backfill, use the following steps:

1. Update your custom profile object type by using the PutProfileObjectType API.
2. After you update your custom profile object type, open an AWS Support ticket.
3. AWS will schedule the backfill on your behalf. The scheduled backfill runs until end of February 2022.

Alternatively, you can delete and then re-create the ingestion/connector you have for your domain that uses the custom object type. All of your data will be re-ingested using your updated object type and `Fields.sourceLastUpdatedTimestamp` will be parsed from it.

Example: How matching works

Example for ONE_TO_ONE

You can choose `ONE_TO_ONE` as the `AttributeMatchingModel`. When choosing `ONE_TO_ONE` the system can only match if the sub-types are exact matches.

For example:

You are using the `EmailAddress` and `BusinessEmailAddress` to represent the `EmailAddress` types. The `AttributeMatchingModel` is `ONE_TO_ONE`.

Your matching rule is:

```
Rule Level 1: EmailAddress, LastName, FirstName
Rule Level 2: AccountNumber
```

```
Profile A:
EmailAddress: 1@email.com
BusinessEmailAddress: john@company.com
LastName: Doe
FirstName: John
AccountNumber: account1234
```

```
Profile B:
EmailAddress: 2@email.com
BusinessEmailAddress: john@company.com
LastName: Doe
FirstName: John
AccountNumber: account1234
```

The Profile A and Profile B matches at rule level 1 since the `EmailAddress` type, `LastName`, and `FirstName` match.

Example for MANY_TO_MANY

You can choose `MANY_TO_MANY` as the `AttributeMatchingModel`. When choosing `MANY_TO_MANY`, the system can match attributes across the sub-types of an attribute type.

For example:

You are using the `EmailAddress` and `BusinessEmailAddress` to represent the `EmailAddress` types. The `AttributeMatchingModel` is `MANY_TO_MANY`.

Your matching rule is:

```
Rule Level 1: EmailAddress, LastName, FirstName
Rule Level 2: AccountNumber
```

```
Profile A:
```

```
EmailAddress: 1@email.com  (match with Profile B’s BusinessEmailAddress)
BusinessEmailAddress: john@company.com
LastName: Doe
FirstName: John
AccountNumber: account1234
```

```
Profile B:
EmailAddress: 2@email.com
BusinessEmailAddress: 1@email.com (match with Profile A's EmailAddress)
LastName: Doe
FirstName: John
AccountNumber: account1234
```

The Profile A and Profile B matches at rule level 1 since the `EmailAddress` type, `LastName`, and `FirstName` match.

View Identity Resolution metrics in Connect Customer Customer Profiles

Whenever Identity Resolution matches or merges profiles, metrics about the process are displayed on the Customer Profiles dashboard. You can review metric for the pass week on the **Identity Resolution** summary page.

The following metrics are generated each time the Identity Resolution Job runs:

- **Match groups found**: The number of match groups that were found.
  - Available for both ML-based and rule-based Identity Resolution.
- **Profiles Merged**: The number of profiles that were merged.
  - Available for both ML-based and rule-based Identity Resolution.
- **Match Group by rule**: The number of match group that were created by each rule level.
  - Only available for rule-based Identity Resolution.

Disable Identity Resolution in Connect Customer Customer Profiles

Disable machine learning-based

You can disable machine learning-based matching when you no longer want it to automatically find similar profiles. If you have consolidation criteria, all your criteria will be deleted and your profiles will no longer be automatically consolidated. Profiles that have already been consolidated will remain consolidated.

Disable rule-based matching

You can disable rule-based matching when you no longer want it to automatically find similar profiles. If you have a custom matching rule, the matching rule will be deleted and your profiles will no longer be automatically consolidated. Profiles that have already been consolidated will remain consolidated.

Resolution with AWS Entity Resolution

Amazon Connect Customer Profiles offers a *managed connector* that you can use to directly import matching results from AWS Entity Resolution. With this integration, you can use the powerful matching capabilities of AWS Entity Resolution while maintaining your customer profiles in Connect Customer.

AWS Entity Resolution helps you match and link related records across your various data sources using flexible matching techniques including rules, machine learning, or third-party data providers. By connecting Entity Resolution results to Customer Profiles, you can:

- Consolidate customer records from multiple systems more accurately
- Apply sophisticated matching logic based on your specific business needs
- Enhance customer profiles with linked data from various applications and channels
- Maintain consistent customer views across your organization

To get started using AWS Entity Resolution with Customer Profiles, you'll need to first set up your matching workflows in the AWS Entity Resolution console. Learn more about AWS Entity Resolution.

To set this up you need the following prerequisites:

- Active Amazon Connect instance with Customer Profiles enabled
- Customer data stored in Amazon S3
- Appropriate IAM permissions to access AWS Entity Resolution

To set up follow these steps:

1. Create a Customer Profiles domain
    - If you haven't already, create a Customer Profiles domain in your Connect instance
    - Navigate to the Customer Profiles section in your Amazon Connect console
    - Note: You'll see a new section for AWS Entity Resolution after domain creation
2. Configure AWS Entity Resolution
    - In your Customer Profiles domain, locate the AWS Entity Resolution section
    - Choose "Set up AWS Entity Resolution"
    - You'll be redirected to the AWS Entity Resolution console.
        - Create a matching workflow
        - Configure your S3 data sources
        - Define matching criteria
        - Review and activate your matching workflow

3. Connect Entity Resolution results to Customer Profiles

   - Return to your Customer Profiles domain
   - Select your Entity Resolution workflow
   - Configure how matched records should be consolidated
   - Enable the integration

Integrate external applications with Connect Customer Customer Profiles

Connect Customer provides a set of pre-built integrations powered by Amazon AppFlow and Amazon EventBridge. After you enable Connect Customer Customer Profiles, you can use these integrations to combine information from external applications such as Salesforce or Zendesk, with contact history from Connect Customer. This creates a customer profile that has all the information agents need during customer interactions in a single place.

You can also use Customer Profiles in Amazon AppFlow. Amazon AppFlow supports `CustomerProfiles` as a destination. You can use Amazon AppFlow APIs to send data into Customer Profiles using `CustomerProfiles` as the destination name.

Before you begin, make sure you are using a customer managed key. For more information about configuring KMS keys, see Create a KMS key to be used by Customer Profiles to encrypt data (required).

Set up integrations

You can setup an integration using either featured applications in Connect Customer or external applications using Amazon AppFlow by choosing the method that best fits your use-case below. For more detailed information on the integration of ServiceNow and Slack, see the blog post Combine data from multiple sources using Amazon AppFlow and build a unified Connect Customer Customer profile for contact center agents.

Topics

- Set up integration for featured applications in Connect Customer
- Set up integration for external applications using Amazon AppFlow
- Delete Customer Profiles or stop integrations

Set up integration for featured applications in Connect Customer

These integrations use Connect Customer featured applications to provide periodic updates to Connect Customer Customer Profiles.

Before you begin

Bulk ingestion of data

When you set up your integration, you are prompted to enter a date how far back you want to go to ingest data. If you choose a date that is more than two months ago, Customer Profiles automatically enables bulk ingestion by creating multiple flows. It does this so you don't have to calculate how many flows you need to ingest data.

When automatic bulk ingestion is enabled, Customer Profiles does the following:

- Sets the batch size to two months.
- Retries on transient failures up to three times before failing.

You can use the CreateIntegrationWorkflowRequest API to call your own batch size.

Why am I asked to select or create an IAM role?

For Salesforce, Marketo, and ServiceNow, Customer Profiles helps improve the historical ingestion of these sources by using your IAM role to create several workflows to ingest your data quickly and efficiently.

For these sources, if you select more than 60 days back in the **Date for importing records** date picker, you will be prompted to create a new IAM role or select an existing one. This role allows Customer Profiles to manage your integration. It provides Customer Profiles with the necessary permissions to update and create a workflow to ingest your data. After the workflow is complete, Customer Profiles creates a standard, continuous integration that ingests your new data as it is updated in your source.

The role created in the console is only usable by the domain it was created on. This is because Connect Customer limits the access of the role to only the KMS key used by the domain.

For more information, see Grant least privilege access to your Customer Profiles execution role.

Grant least privilege access to your Customer Profiles execution role

If you want to create your own IAM role, we recommend using the permissions shown in the following code to limit the role to the least permissions needed. Use the snippet below to create your role manually. Use your own KMS key and specify your Region where needed.

                    "kms:GrantOperations": [
                        "Decrypt"
                    ]
                }
            },
            "Effect": "Allow",
            "Sid": "KMSCustomerProfiles"
        }
    ]
}
```

Monitor your Customer Profiles integrations

After your connection is established, if it stops working, delete the integration and then re-establish it.

What to do if objects aren't being sent

If an object fails to be sent, choose **Flow details** to learn more about what's gone wrong.

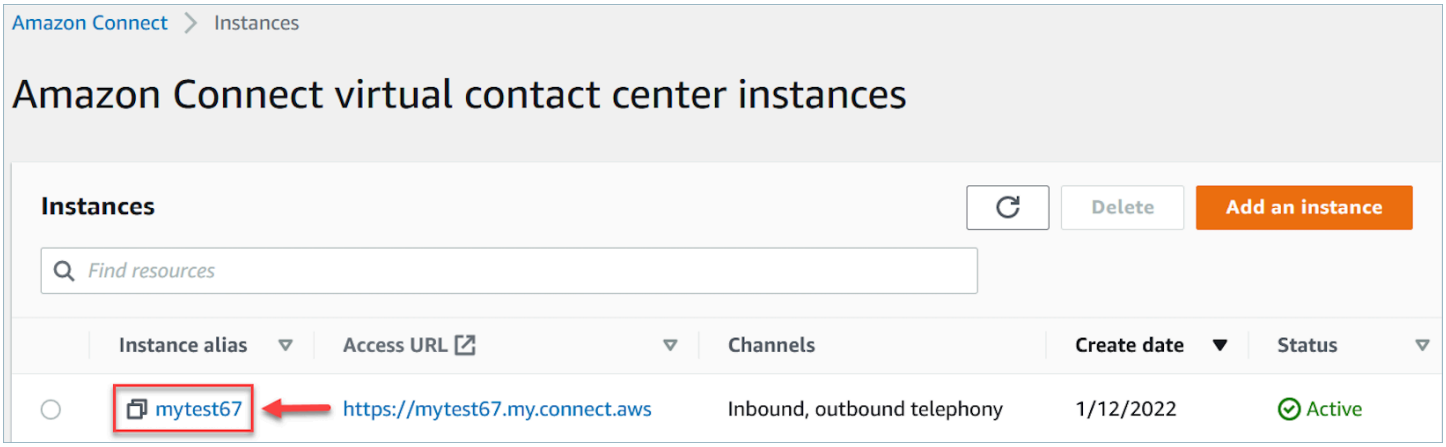
You might need to delete the configuration and re-connect to the external application.

Set up integration for Connect Customer Cases

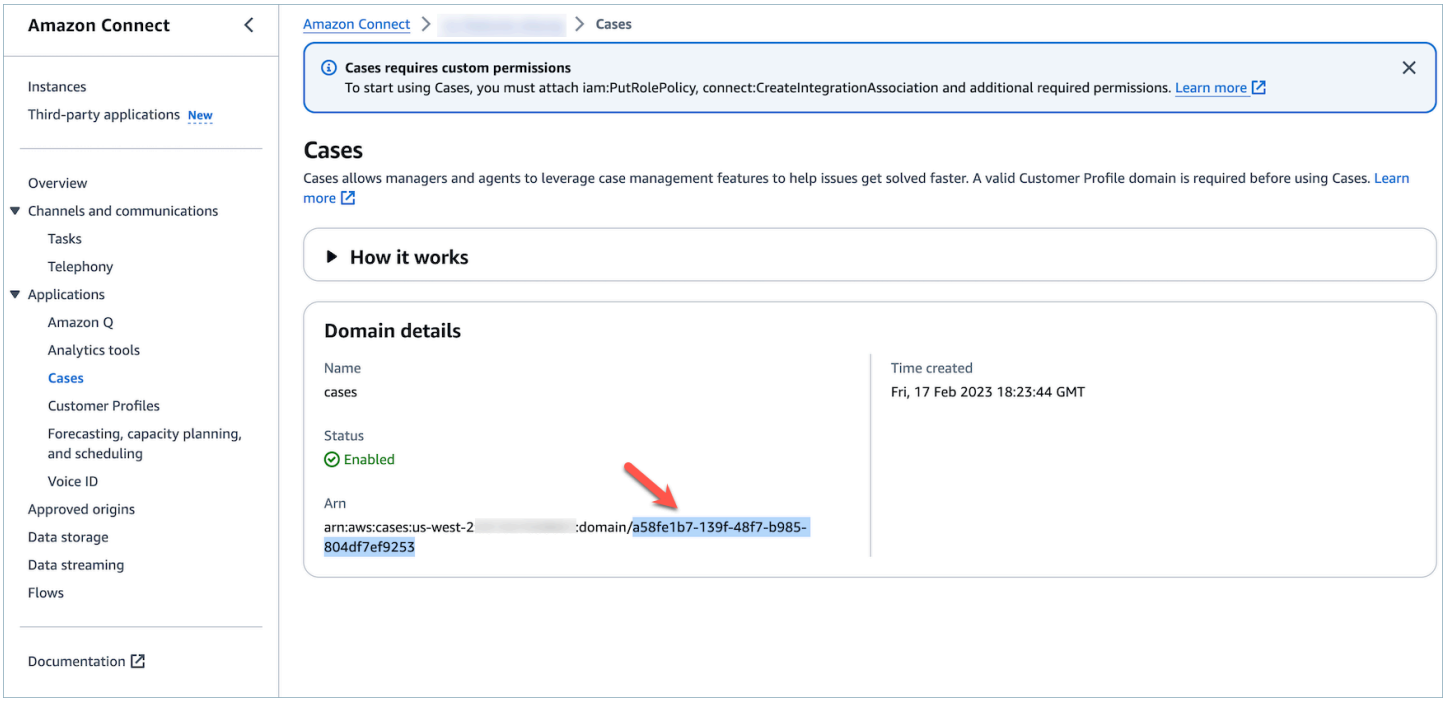
To update your Connect Customer Cases data in Connect Customer Customer Profiles and use features like calculated attributes, you can integrate using Amazon AppIntegrations. Start by setting up a Cases event stream to send system fields to an EventBridge bus, then use Amazon AppIntegrations to forward these events to Customer Profiles.

Stream data from Connect Customer Cases to Event Bridge

1. Open the Connect Customer console at https://console.aws.amazon.com/connect/.
2. On the instances page, choose the instance alias. The instance alias is also your **instance name**, which appears in your Connect Customer URL. The following image shows the **Connect Customer virtual contact center instances** page, with a box around the instance alias.



3. In the navigation pane, choose **Cases** and note your Cases domain ID from the **Domain details** section.

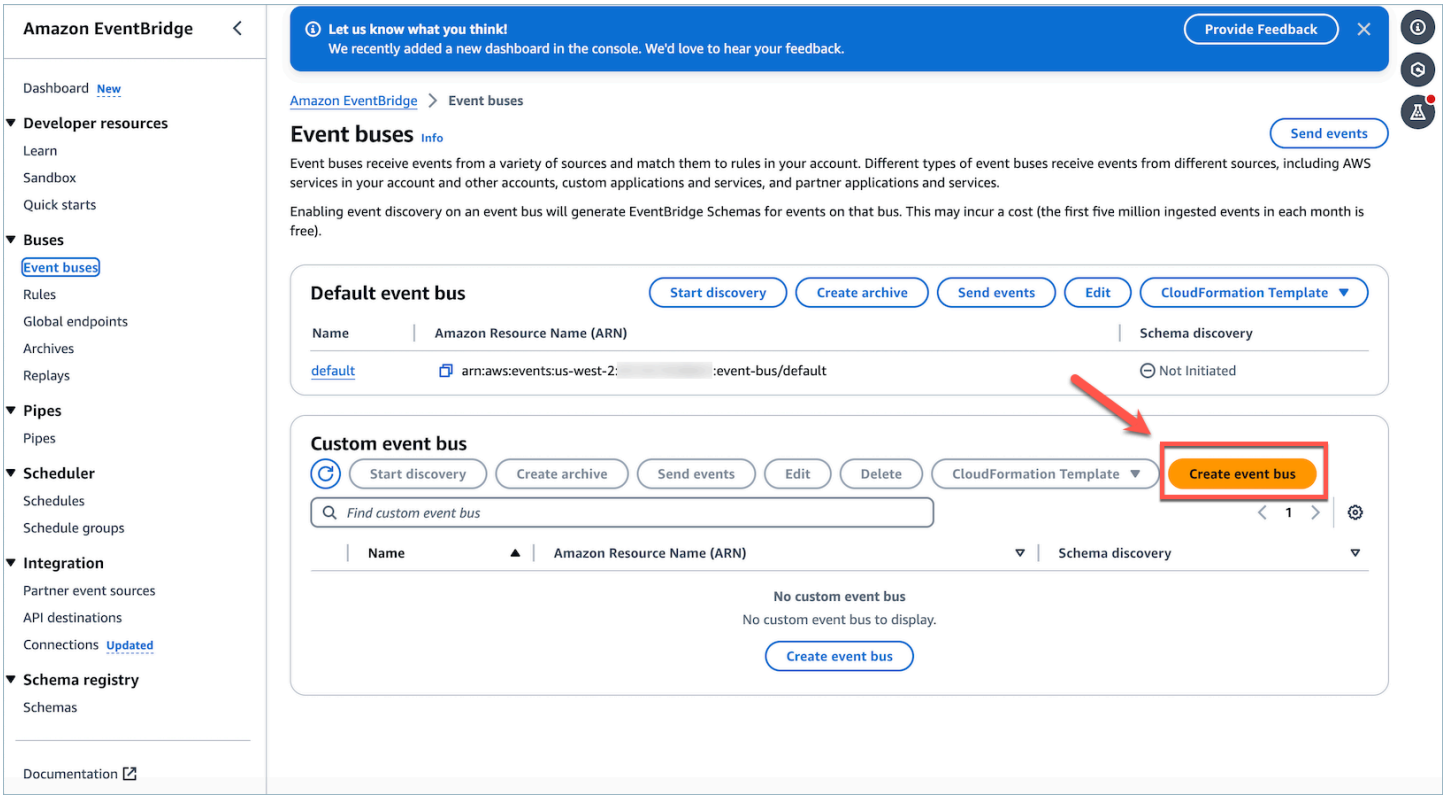


4. Using the AWS CLI, create a Case event configuration to send Connect Customer Cases Events to the default EventBridge bus for your AWS account.

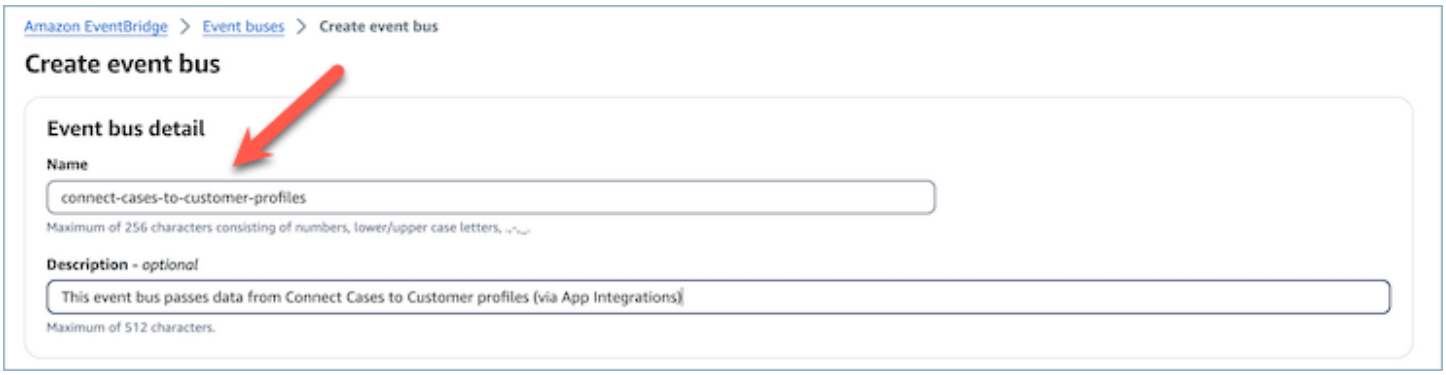
```
// set up Case Event Configuration including all system fields
aws connectcases put-case-event-configuration --domain-id <YOUR_CASES_DOMAIN_ID> --
region <YOUR_AWS_REGION> --event-bridge "{
    \"enabled\": true,
```

```
    \"includedData\": {
       \"caseData\": {
          \"fields\": [
          {
          \"id\": \"status\"
          },
          {
          \"id\": \"title\"
          },
          {
          \"id\": \"summary\"
          },
          {
          \"id\": \"reference_number\"
          },
          {
          \"id\": \"created_datetime\"
          },
          {
          \"id\": \"last_updated_datetime\"
          },
          {
          \"id\": \"last_closed_datetime\"
          },
          {
          \"id\": \"customer_id\"
          }
        ]
      }
    }
  }"
```

5. Open the Event Bridge console for your AWS Region. For example, https://us-west-2.console.aws.amazon.com/events/home?region=us-west-2#/eventbuses
6. Choose **Create event bus**.



7. Create an event bus with name `connect-cases-to-customer-profiles`.



8. Go back to your **default event bus** and create a rule with name `connect-cases-to-customer-profiles-rule`.

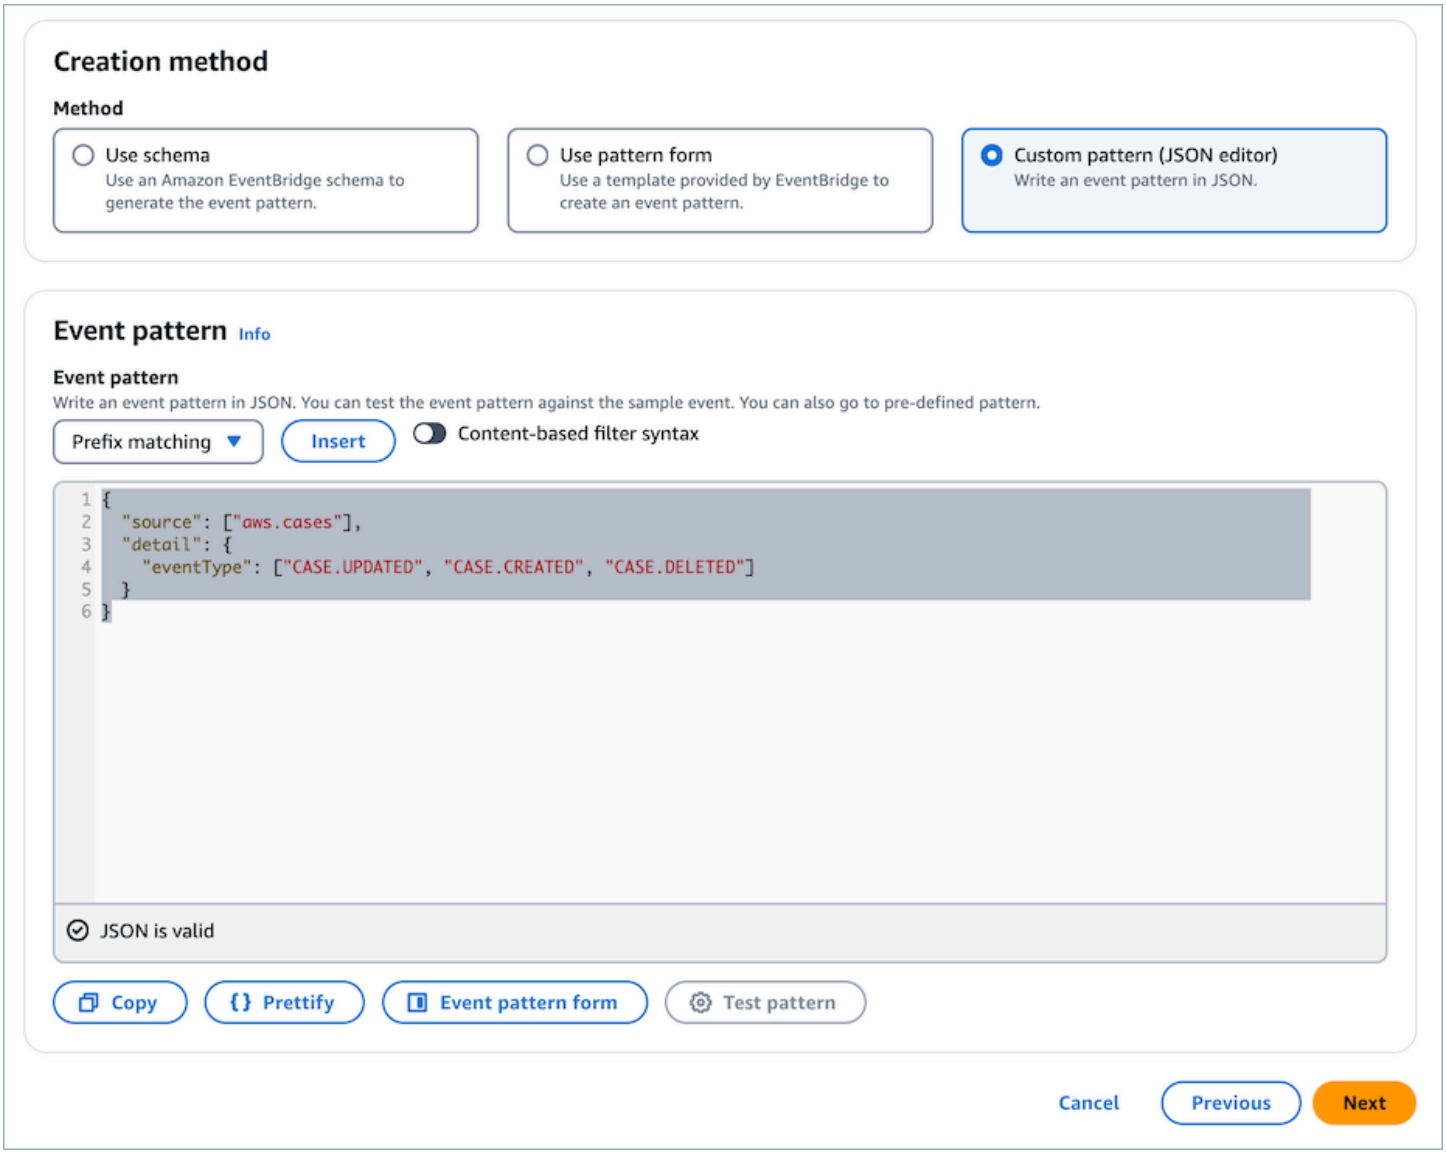
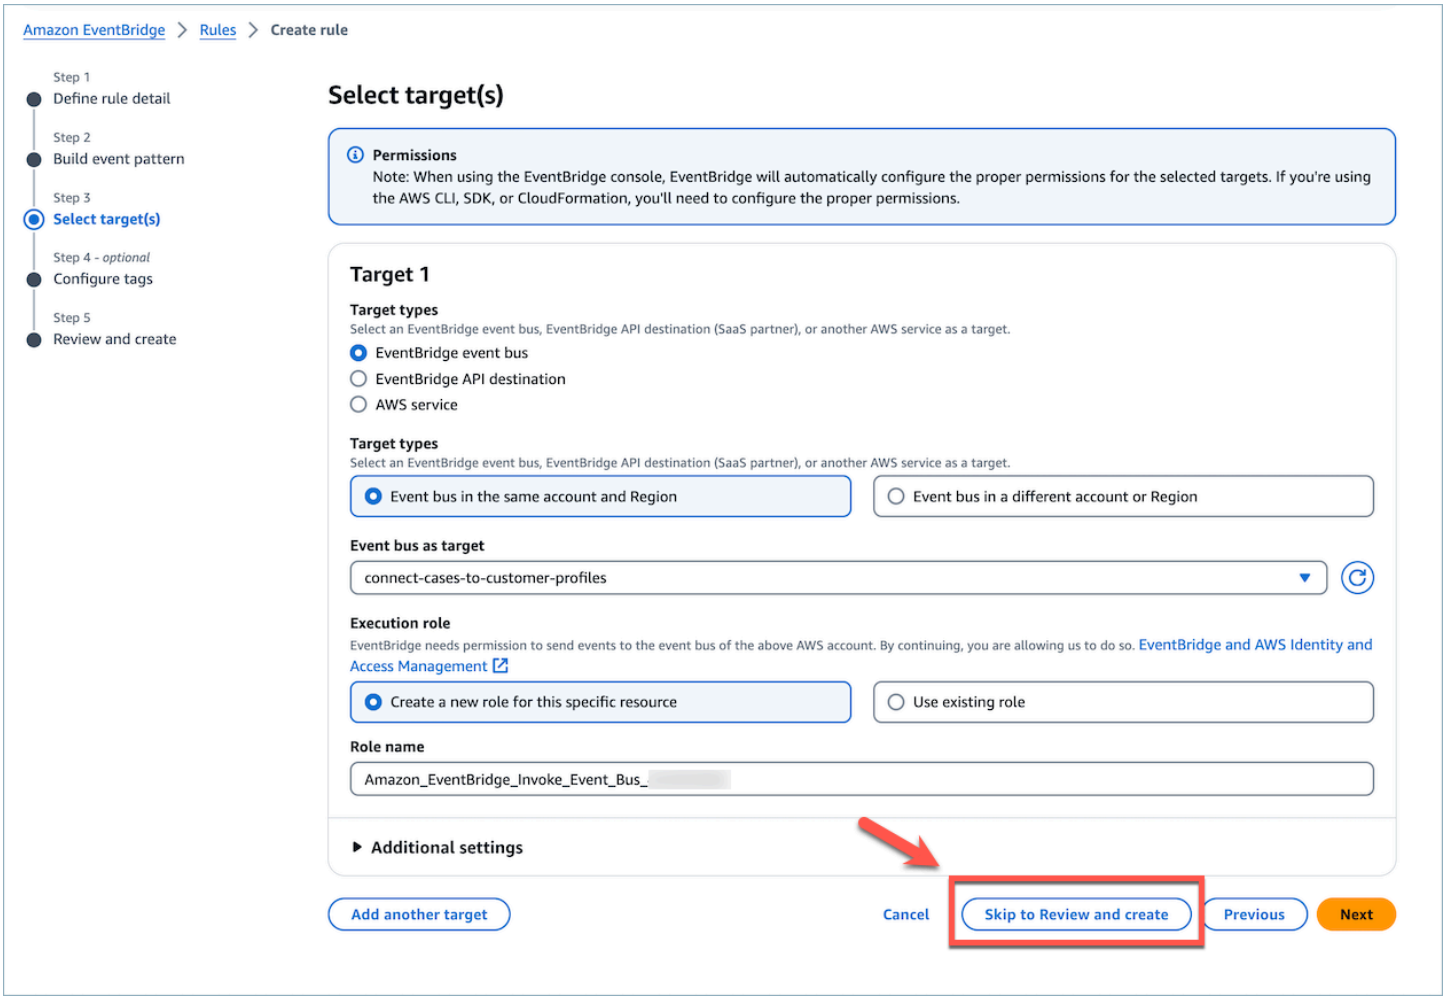
  }
}
```



- Choose **Skip to Review and Create** and then **Create rule**.



Ingest Event Bridge case data to Customer Profiles by using AppIntegrations

1. Using the AWS CLI, create an Event Integration with AppIntegrations and record the ARN output. This represents a source data that a Connect Customer instance can use.

```
aws appintegrations create-event-integration --region
    <YOUR_REGION> --name Connect-Cases-Event-Integration
    --event-bridge-bus connect-cases-to-customer-profiles --event-filter
    "{\"Source\": \"aws.cases\" }"
    --description "Event Integration for Cases Event Bus"
```

2. Using the AWS CLI, create an integration with Customer Profiles using the put-integration API. This will start the flow of data to Customer Profiles, replacing the placeholder values with your Event Integration ARN and Customer Profile domain name.

```
aws customer-profiles put-integration --region
    <YOUR_REGION> --domain-name <YOUR_CP_DOMAIN_NAME>
    --uri <YOUR_EVENT_INTEGRATION_ARN> --object-type-name Connect-case
```

Verify your Cases integration

1. Create a case in Connect Customer Cases.
2. The event delivery should be almost instantaneous but allow a minute for it to be delivered and associate with the customer profile.
3. Using the AWS CLI, find the Connect-case object under the profile, replacing the placeholders with the correct values.

```
aws customer-profiles list-profile-objects --domain-name
    <YOUR_CP_DOMAIN_NAME> --region <YOUR_REGION>
    --object-type-name Connect-case --profile-id <YOUR_PROFILE_ID>
```

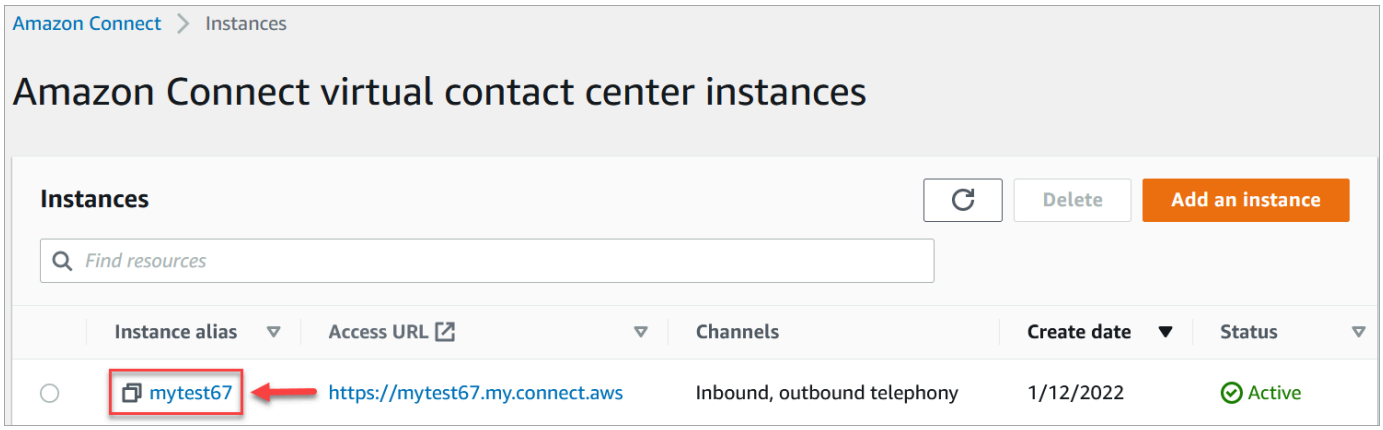
6. If you don't find an item in the response of the above API call, then there is a problem with your integration. To troubleshoot:
   a. Go to the Amazon EventBridge console.
   b. Check whether the EventSource is Active and the matching EventBus exists and is running.
   c. Check whether your Case Event Configuration is correctly configured.
   d. If these are working, contact Support for assistance investigating the issue.

Set up Connect Customer integration with Salesforce, ServiceNow, Marketo, or Zendesk

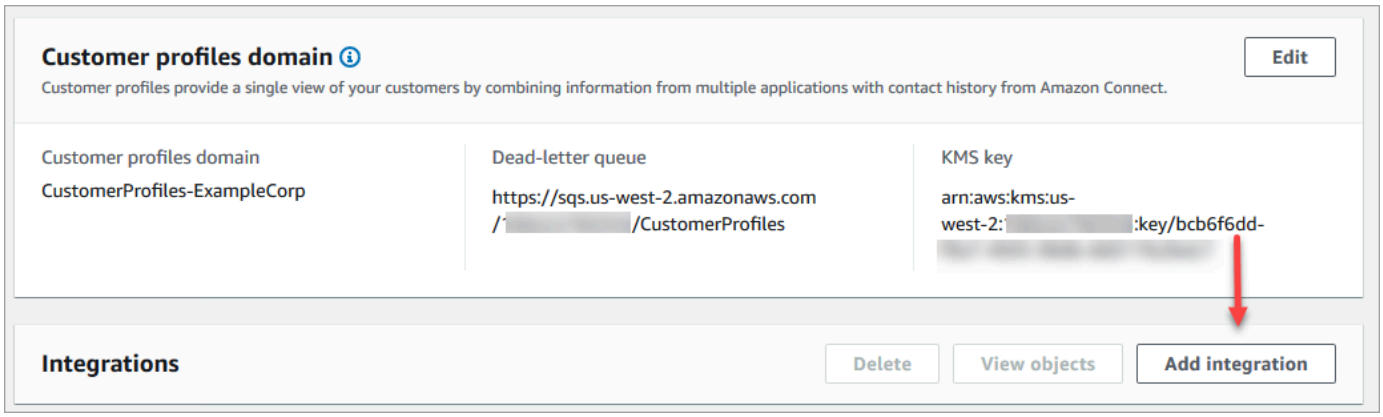
To provide periodic updates to Connect Customer Customer Profiles, you can integrate with Salesforce, ServiceNow, Marketo, or Zendesk using Amazon AppFlow. You first set up the connection in Connect Customer and the application of your choice, and then verify the integration.

Set up the connection in Connect Customer and Salesforce, ServiceNow, Marketo, or Zendesk

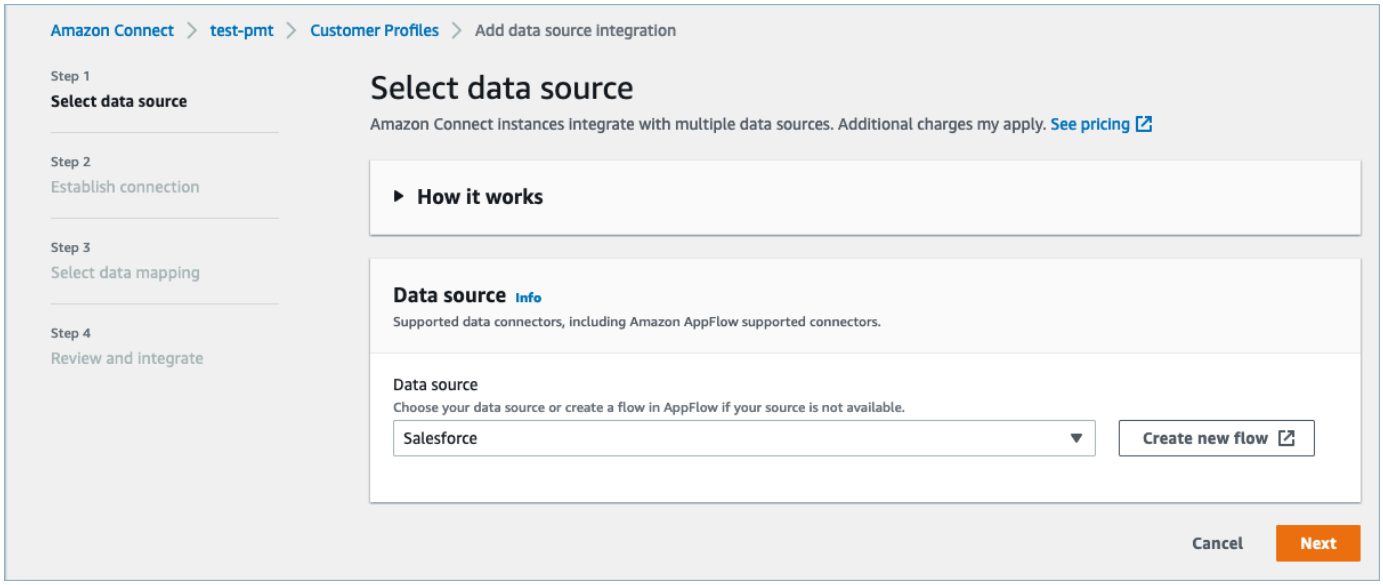
1. Open the Connect Customer console at https://console.aws.amazon.com/connect/.
2. On the instances page, choose the instance alias. The instance alias is also your **instance name**, which appears in your Connect Customer URL. The following image shows the **Connect Customer virtual contact center instances** page, with a box around the instance alias.



3. In the navigation pane, choose **Customer profiles**.
4. On the **Customer profiles configuration** page, choose **Add integration**, as shown in the following image.

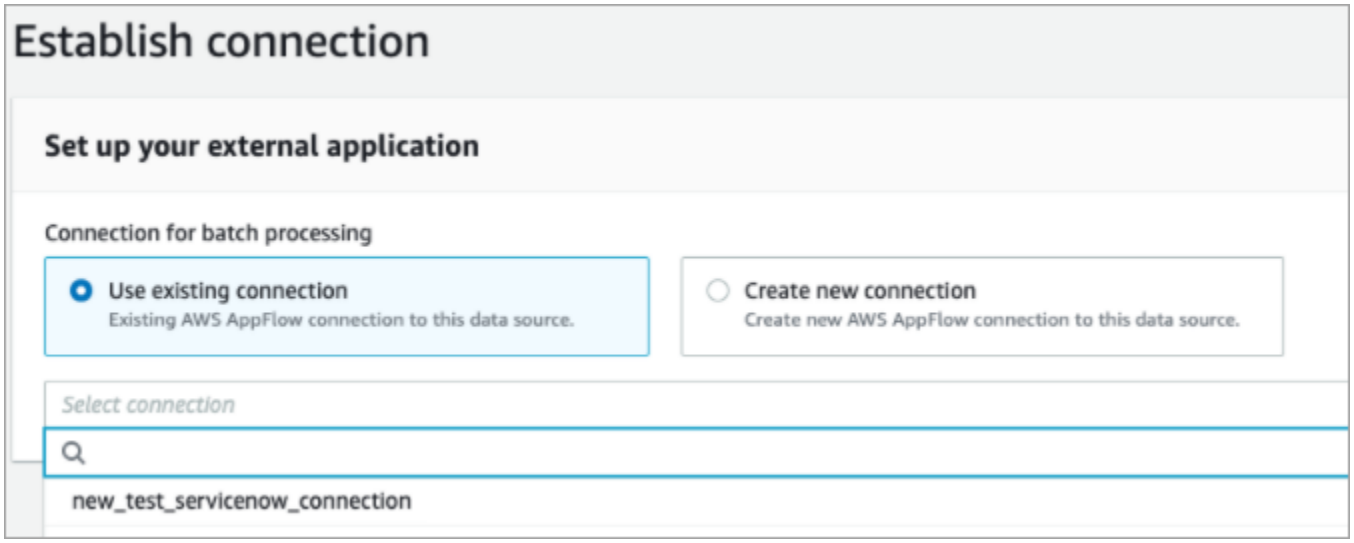


5. On the **Select data source** page, choose which external application you want to get customer profiles data from. You can view the integration requirements to better understand the connection requirements needed for your application.



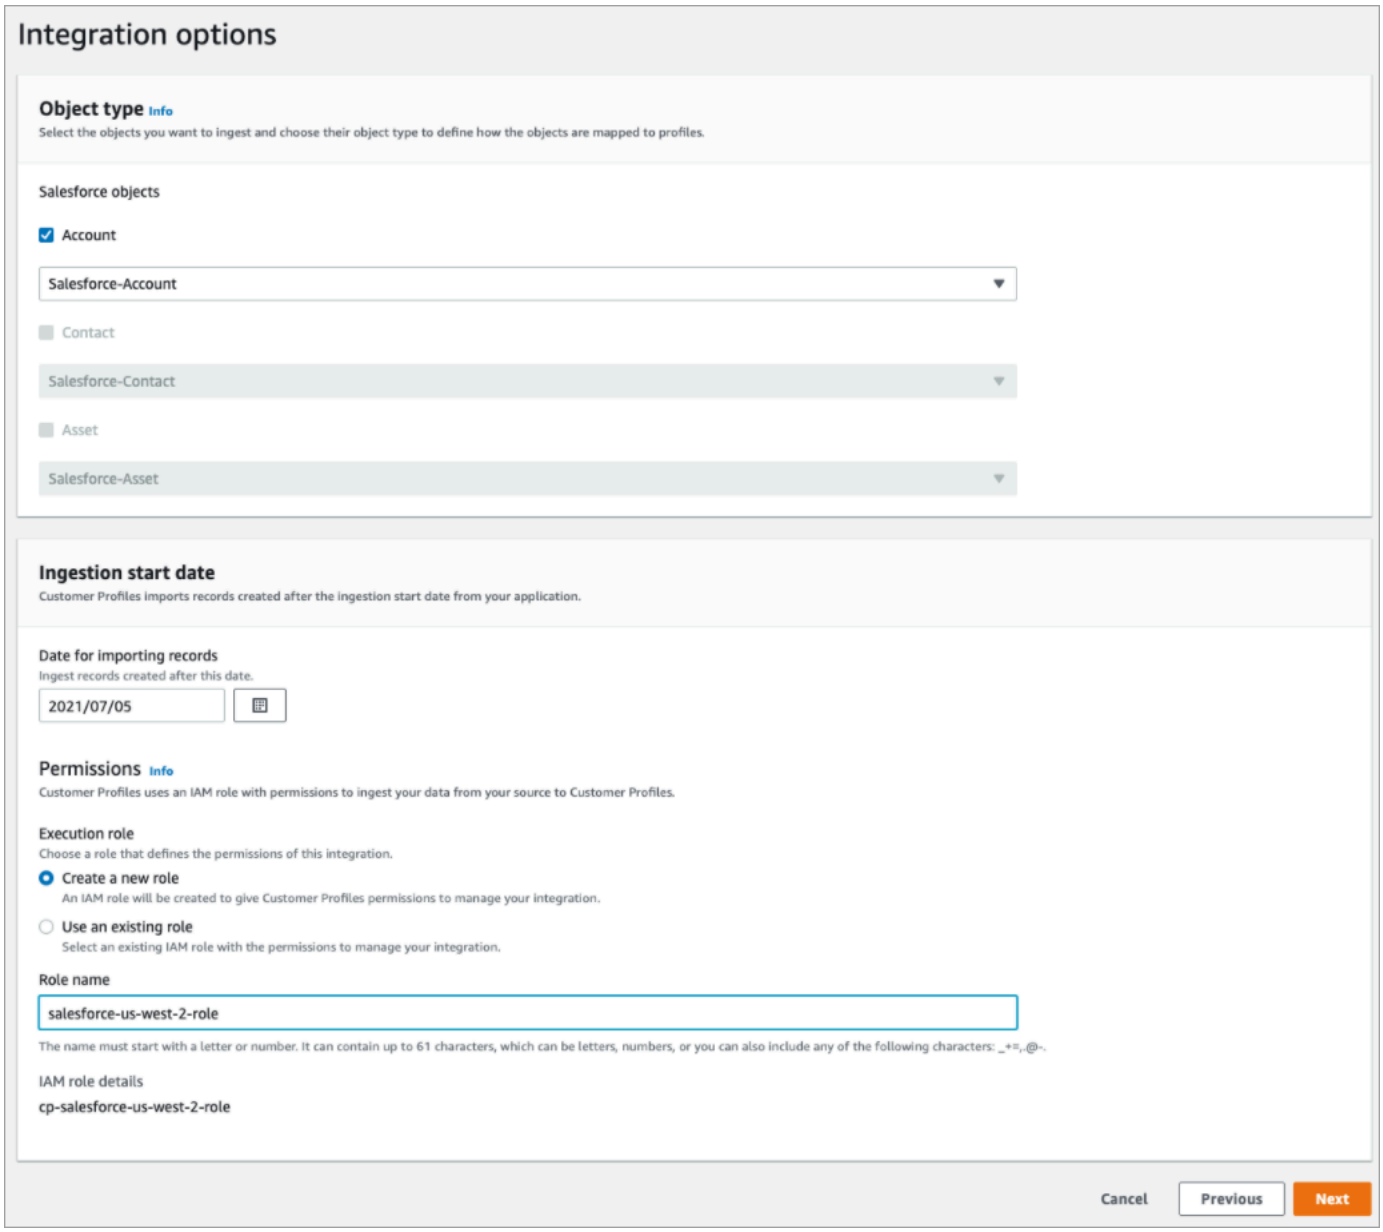
6. On the **Establish connection** page, choose one of the following:

   - **Use existing connection**: This allows you to reuse existing Amazon AppFlow resources you might have created in your AWS account..
   - **Create new connection**: Enter the information required by the external application.



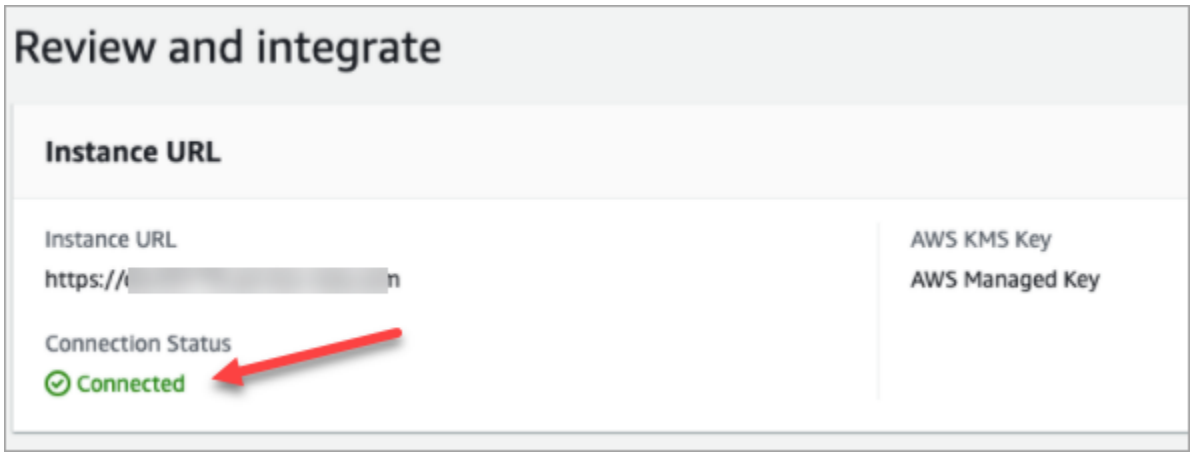
7. On the **Integration options** page, choose which source objects you want to ingest and select their object type.

Object types store your ingested data. They also define how objects from your integrations are mapped to profiles when they are ingested. Customer Profiles provides default object type templates you can use that define how attributes in your source objects are mapped to the standard objects in Customer Profiles. You can also use the object mappings that you've created from the PutProfileObjectType. When adding or creating the Salesforce integration for the user created data mapping, you need to specify the specific data mapping, otherwise it will choose the Salesforce default data mapping for object type. You can create your data mapping and use it when setting up a featured data connector.

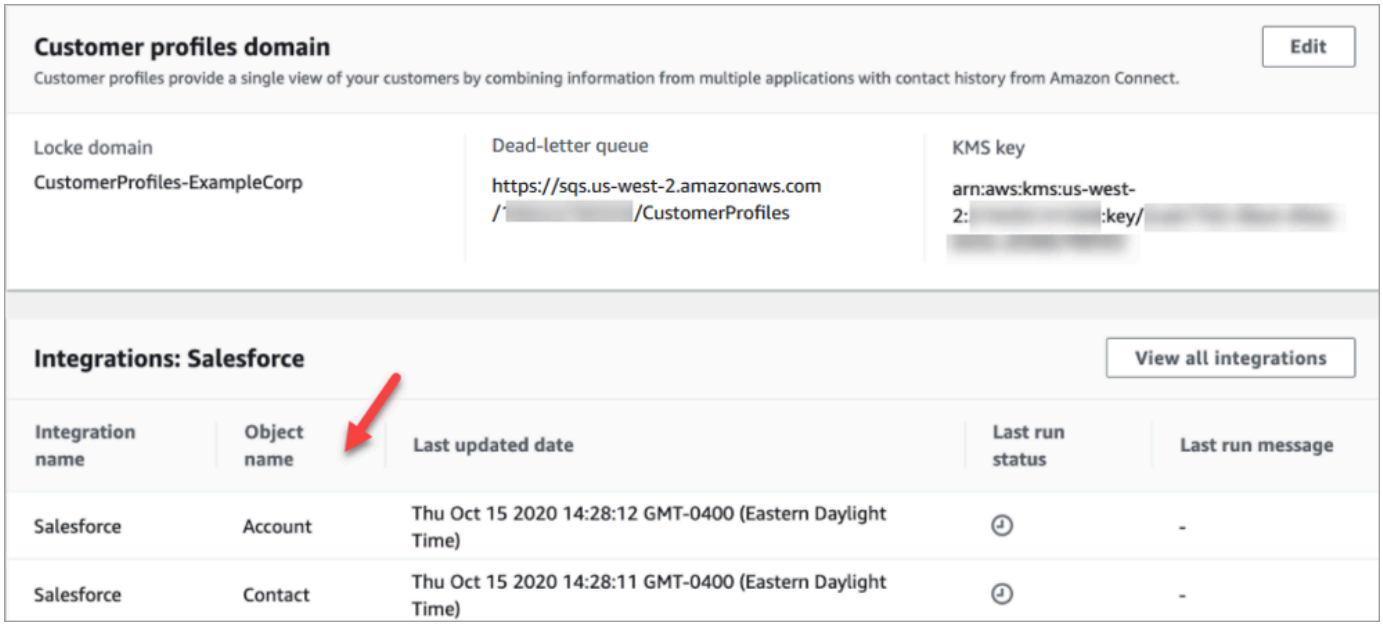


8. For the **Ingestion start date**, Customer Profiles starts ingesting records created after this date. By default, the date for importing records is set at 30 days prior.

9. On the **Review and integrate** page, check that the **Connection status** says **Connected**, and then choose **Create integration**.



10. After the integration is set up, back on the **Customer profiles configuration** page, choose **View objects** to see what data is being batched and sent. Currently, this process ingests records that were created or modified in the last 30 days.

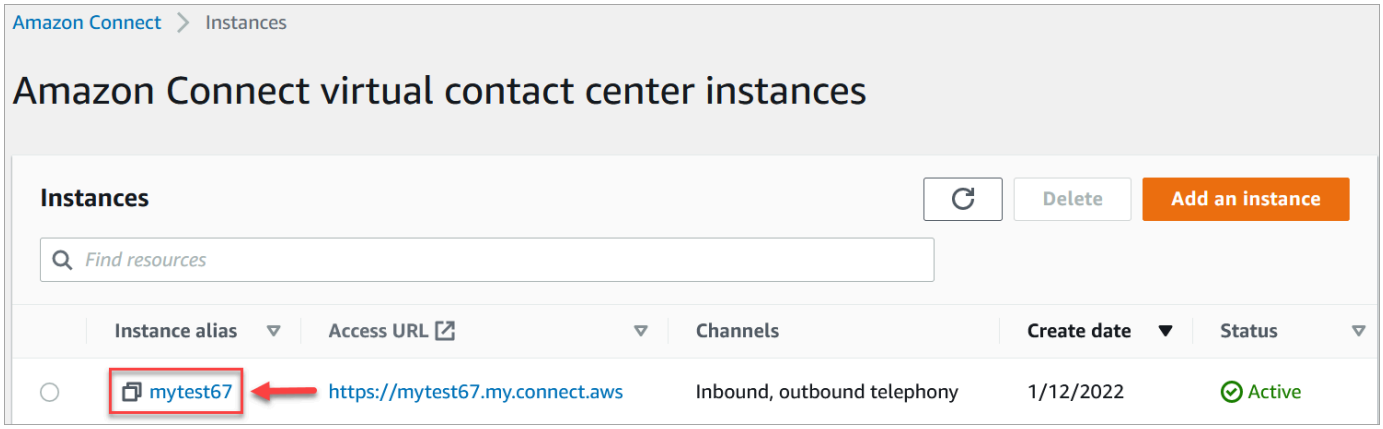


Set up integration for Segment to provide periodic updates to Connect Customer Customer Profiles

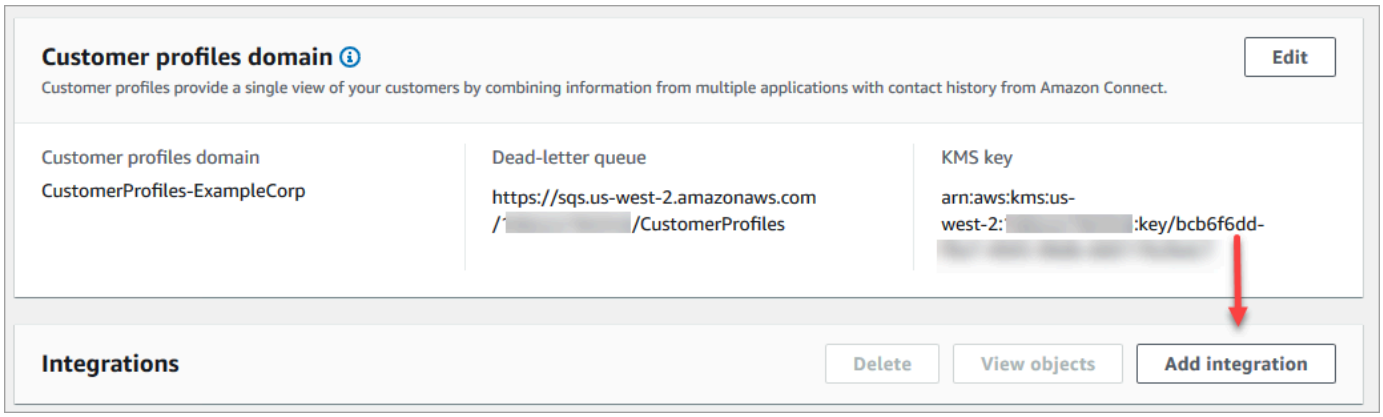
To provide periodic updates to Connect Customer Customer Profiles, you can integrate with Segment using Amazon EventBridge. You first set up the connection in Connect Customer and Segment, and then verify the Segment integration.

Set up the connection in Connect Customer and Segment

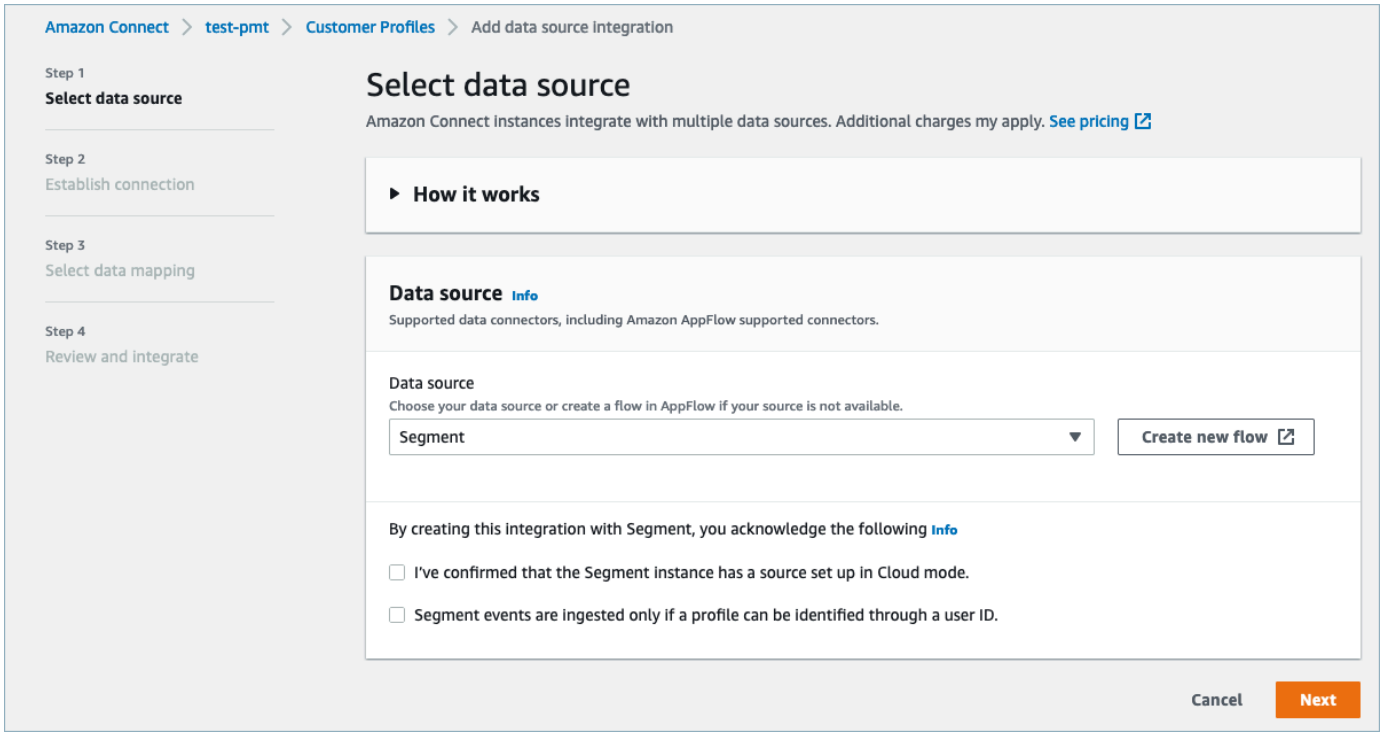
1. Open the Connect Customer console at https://console.aws.amazon.com/connect/.
2. On the instances page, choose the instance alias. The instance alias is also your **instance name**, which appears in your Connect Customer URL. The following image shows the **Connect Customer virtual contact center instances** page, with a box around the instance alias.



3. In the navigation pane, choose **Customer profiles**.
4. On the **Customer profiles configuration** page, choose **Add integration**.

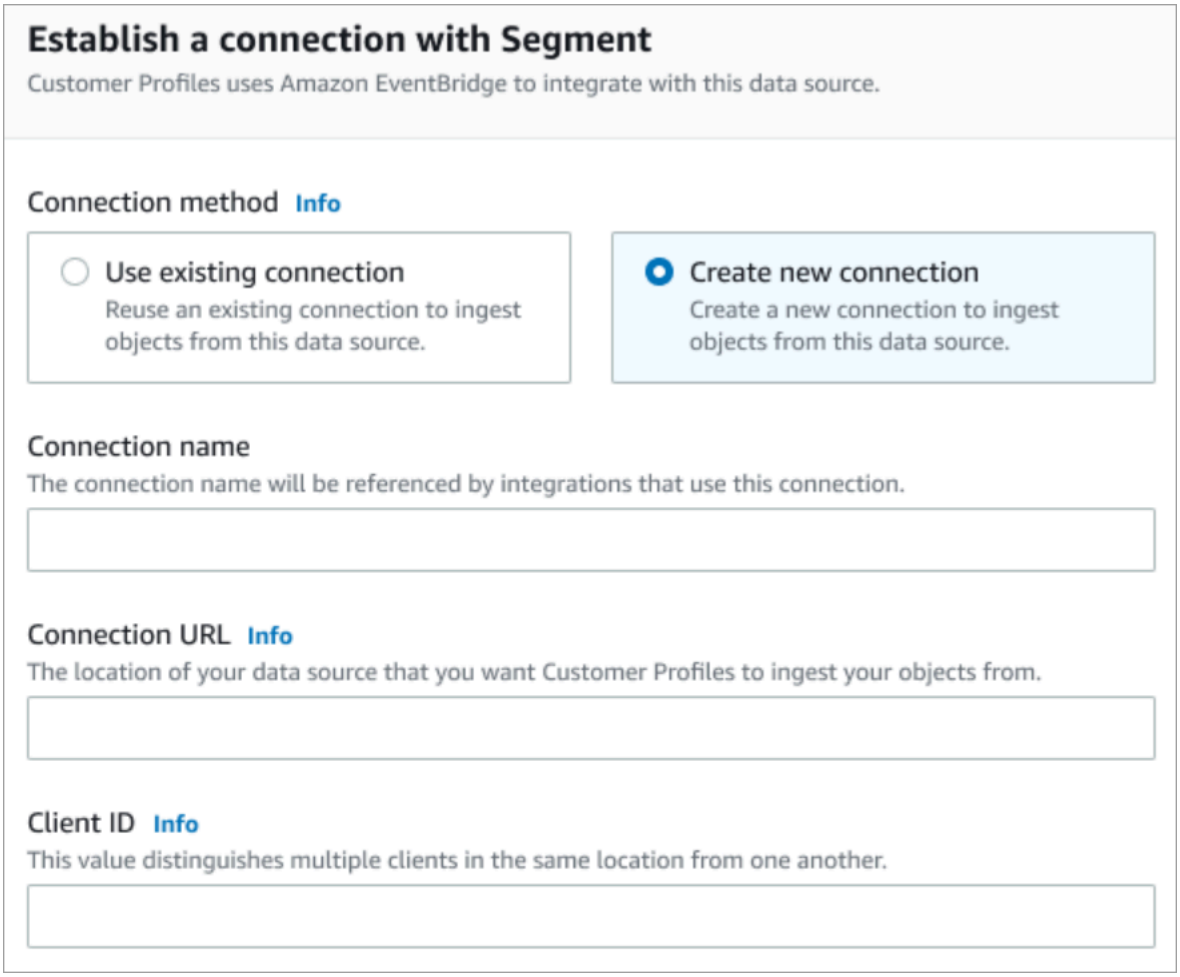


5. On the **Select data source** page, choose **Segment**. Review the application requirements that are listed on the **Select application** page.



6. On the **Establish connection** page, choose one of the following:

   - **Use existing connection**: This allows you to reuse existing Amazon EventBridge resources that you might have created in your AWS account.
   - **Create new connection**: Enter the information required by the external application.



- **Connection name**: Provide a name for your connection. The connection name is referenced by integrations that use this connection.
- **Connection URL**: Enter your application connection URL. This URL is used for deep-linking into the objects created in your external application. The connection URL is the Segment workspace URL available on the application website.

  To find your workspace URL:

  1. Log in to your segment.com account.
  2. Go to **Settings**, **General settings**.
  3. Copy the URL from your browser.

7. Customer Profiles uses Amazon EventBridge for integrations with Segment. On the **Source set up** page, copy your AWS account ID to your clipboard, and then choose **Log in to Segment** to configure Amazon EventBridge.
8. Use the following instructions to set up Segment:

a. Log in to Segment.

b. In your application, select a source to set up the destination to Amazon EventBridge.

c. Paste in your AWS account ID and select your AWS Region.

d. Toggle **ON**, to activate your partner event source.

9. Go to **Event Tester**, and send a test event to complete activating your partner event source.

10. **Client ID**: This is a string that uniquely distinguishes the client in your external application. This client ID is the Source Name available on the application website. You use the ID that you specify to identify the client that you want Customer Profiles to ingest your objects from.

    To find your source ID:

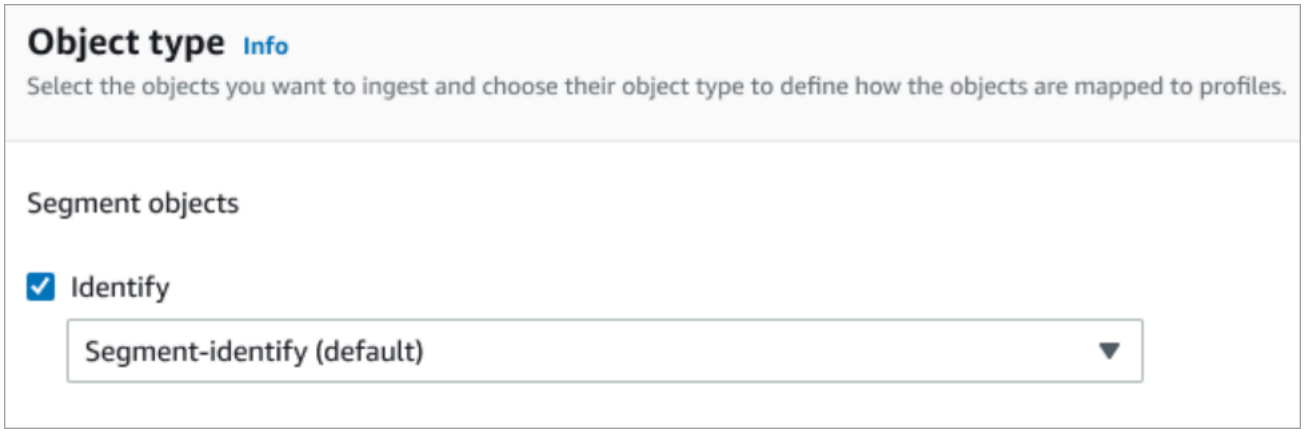
    1. Go to **Sources**, and choose a source.
    2. Go to **Settings**, **API Keys**.
    3. Copy your **Source ID**.

    After you set up the event source destination, return to the Customer Profiles console and paste the Client ID.

11. You will see an alert that indicates Connect Customer has successfully connected with Segment.

12. On the **Integration options** page, choose which source objects you want to ingest and select their object type.

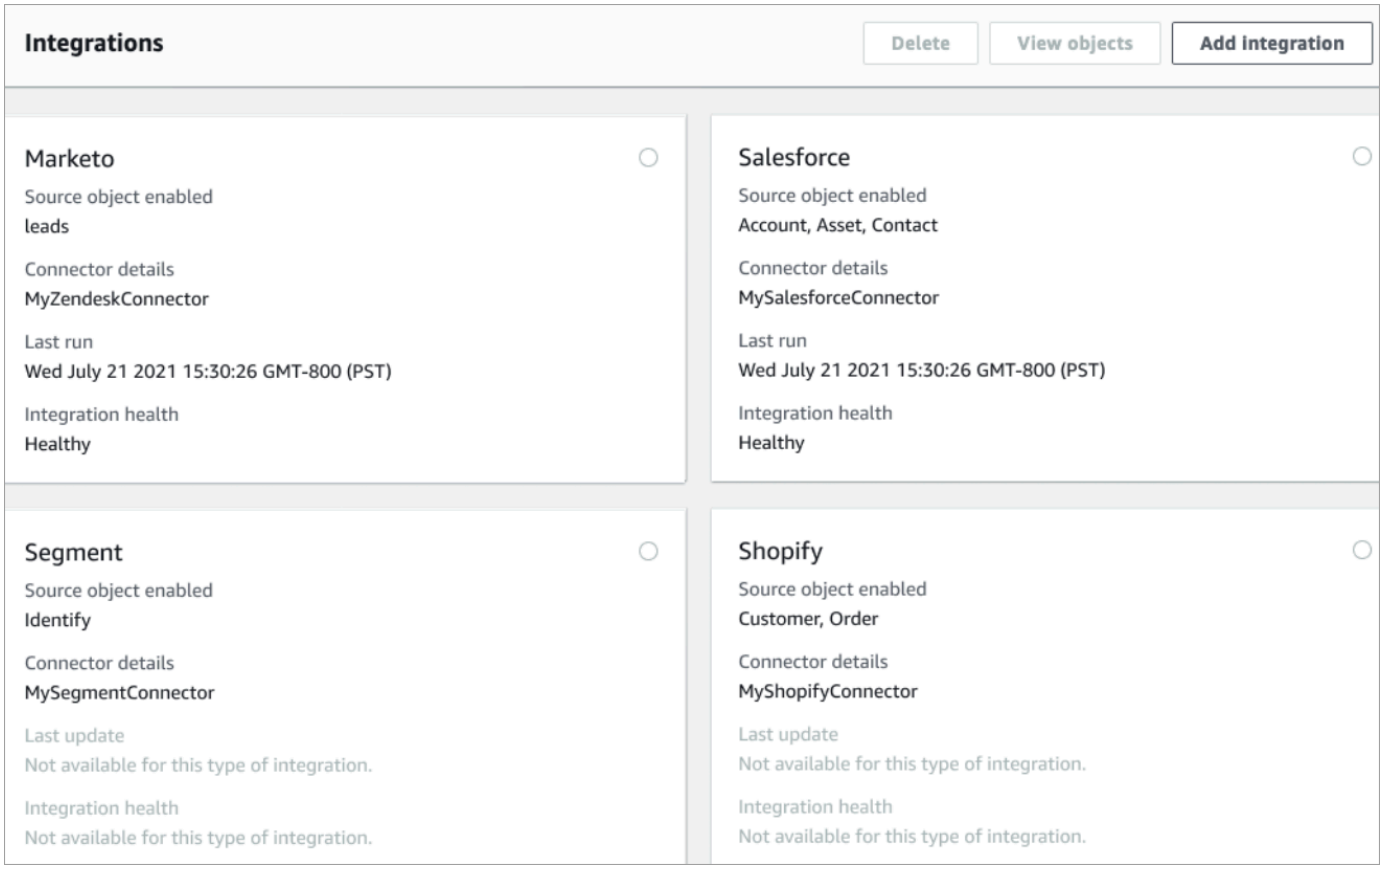
    Object types store your ingested data. They also define how objects from your integrations are mapped to profiles when they are ingested. Customer Profiles provides default object type templates you can use that define how attributes in your source objects are mapped to the standard objects in Customer Profiles. You can also use the object mappings that you've created from the PutProfileObjectType.



13. For the **Ingestion start date**, Customer Profiles starts ingesting records created after the integration is added.

> **Note**
>
> If you need historical records, you can use Amazon S3 as an integration source to import them.

14. On the **Review and integrate** page, check that the **Connection status** says **Connected**, and then choose **Add integration**.
15. After the integration is set up, back on the **Customer profiles configuration** page, the **Integrations** page displays which integrations are currently set up. The **Last run** and **Integration health** are not currently available for this type of integration.



To see what data is being sent, choose the integration and+ then choose **View objects** .

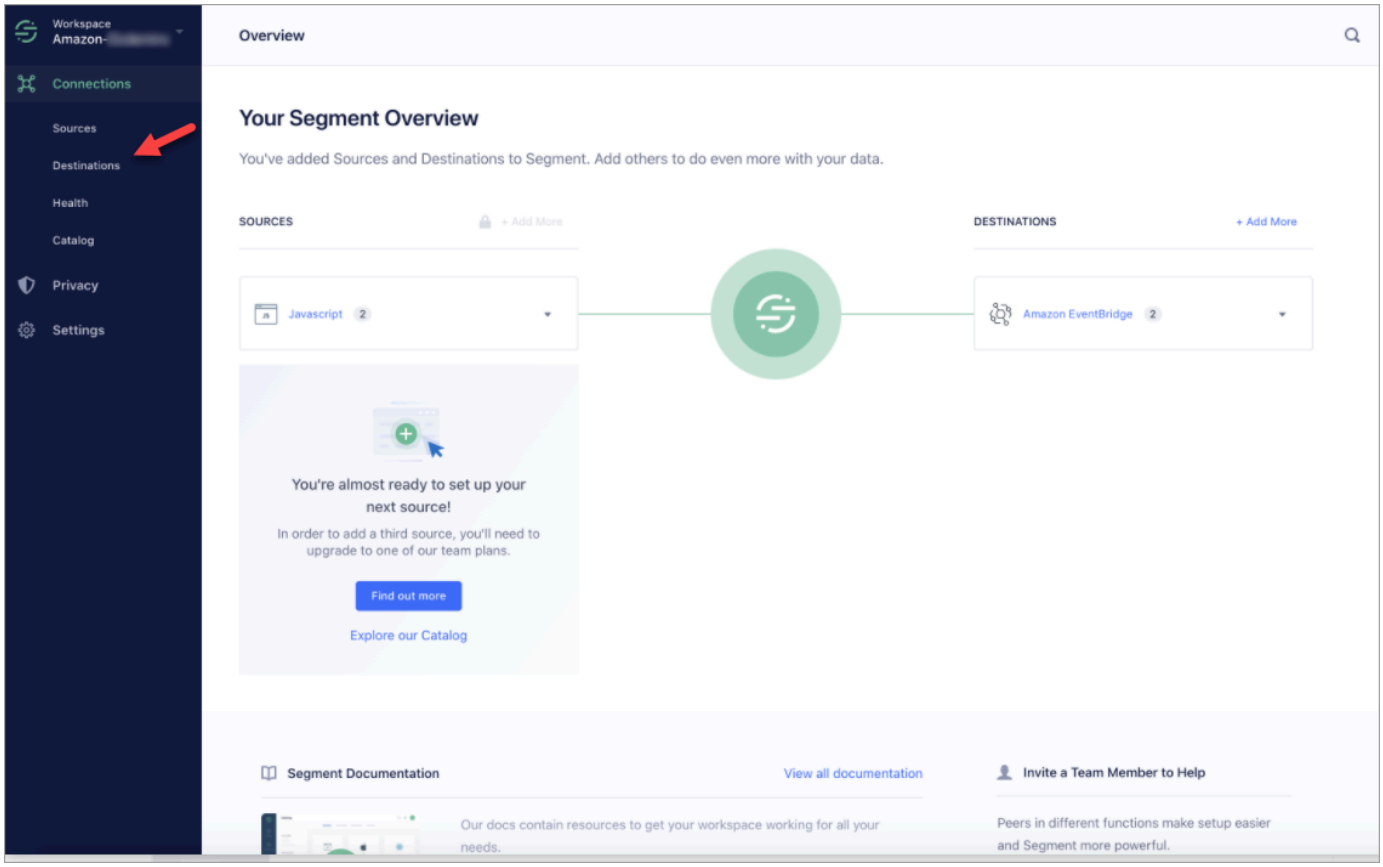
Verify your Segment integration

To perform this step you need the following prerequisites:

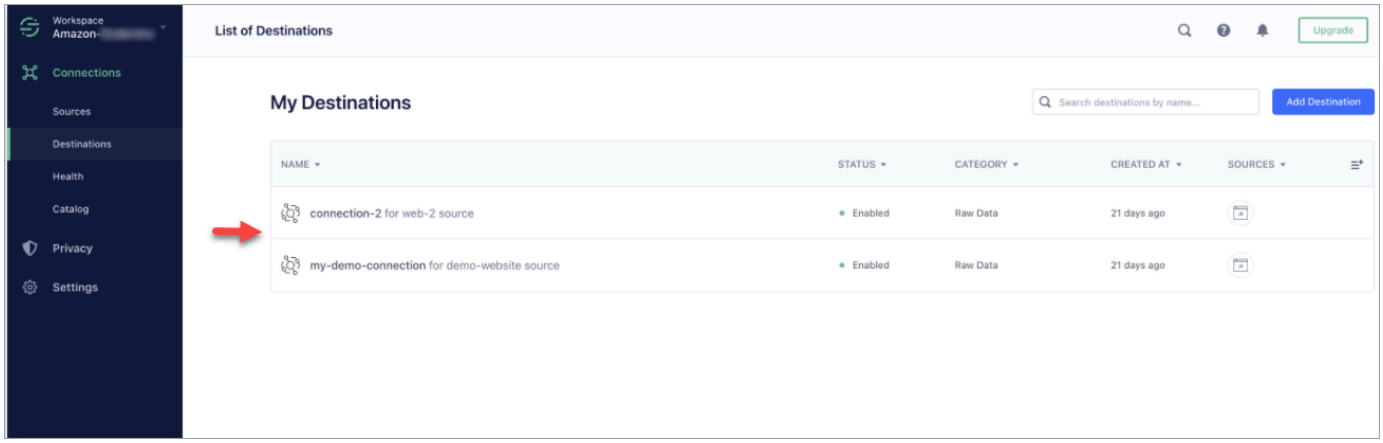
- Access to your Segment workspace.
- Access to the Connect Customer Contact Control Panel.

To verify your Segment integration

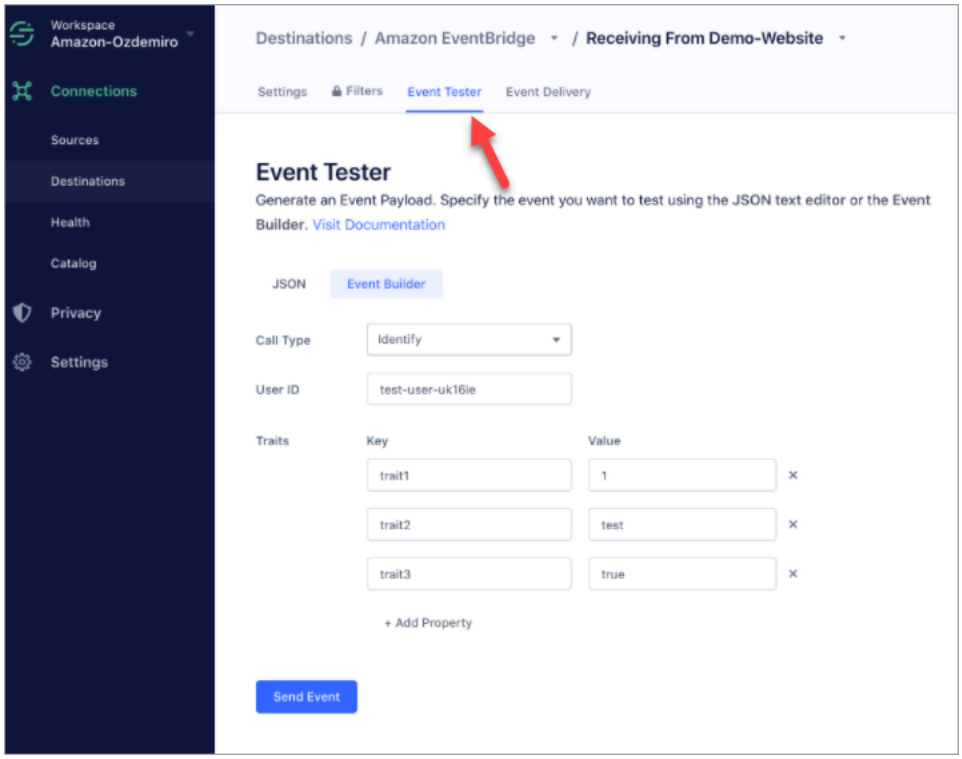
1. Go to your Segment workspace dashboard and choose **Destinations**.



2. You will see a list of destinations where that Segment sends data. Choose the EventBridge destination for Customer Profiles.



3. Choose the **Event Tester** tab. From this page you will send a test event to Customer Profiles. The event is ingested and turned into a customer profile that you can view in the Connect Customer agent workspace.



4. Select **Identify** as the event type, and select **Event Builder** as your input method.
5. You can specify a **User ID** and some traits. Agents can search for these traits in the agent workspace.
6. Choose **Send Event**.
7. The event delivery should be almost instantaneous but allow it a minute for it to be delivered and create a customer profile.
8. Open the Connect Customer agent workspace. Search for the user ID you entered in the **Event Builder**. You should be able to see the customer profile with the user ID and the traits you entered.
9. If you cannot see the customer profile, then there is a problem with your integration. To troubleshoot:

    1. Go to the Amazon EventBridge console.
    2. Check whether the EventSource is Active and the matching EventBus exists and is running.

    If these are working, contact Support for assistance investigating the issue.

Monitor your Customer Profiles integrations

After your connection is established, if it stops working, delete the integration and then re-establish it.

What to do if objects aren't being sent

If an object fails to be sent, choose **Flow details** to learn more about what's gone wrong.

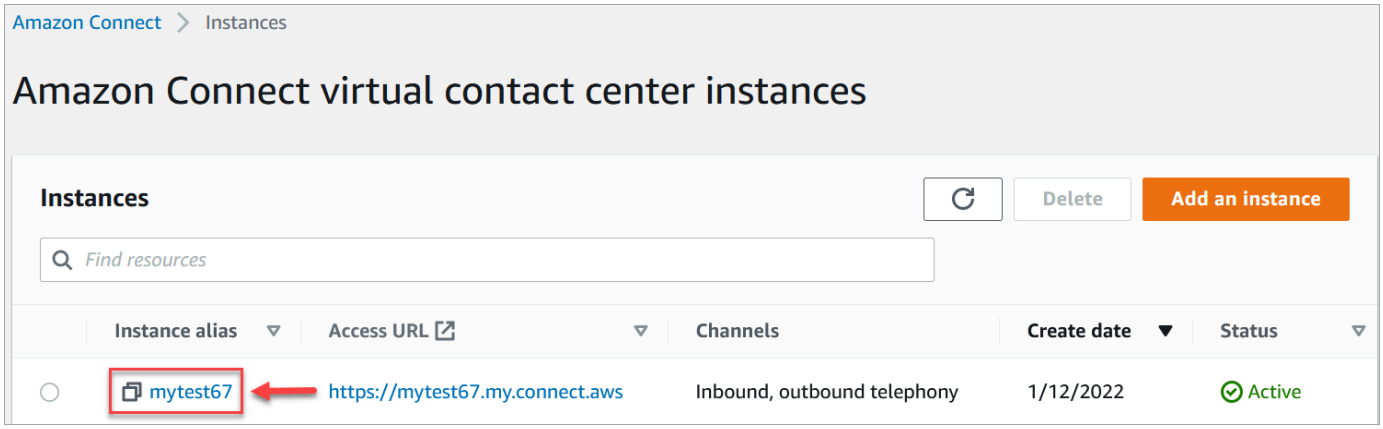
You might need to delete the configuration and re-connect to the external application.

Set up integration for Shopify to provide periodic updates to Connect Customer Customer Profiles

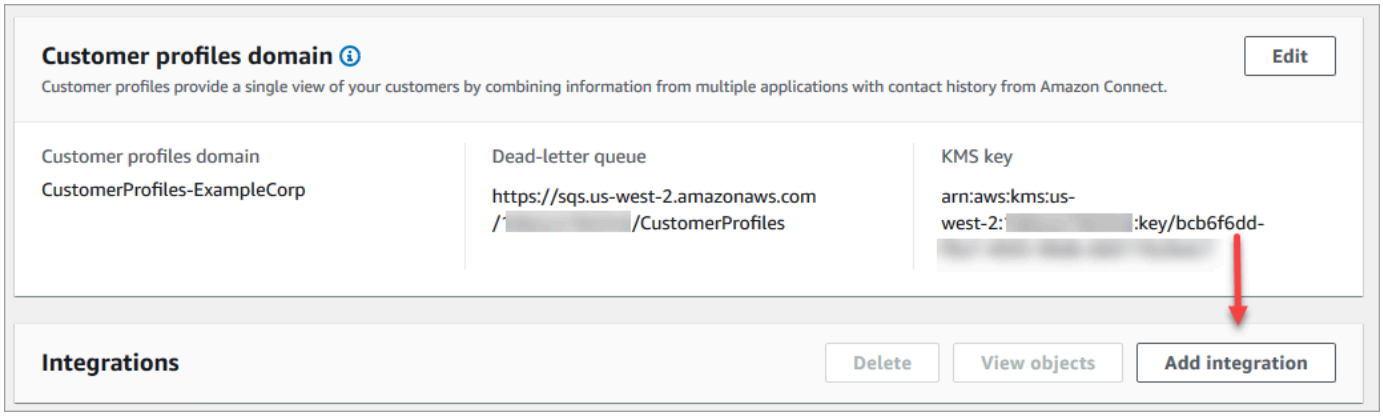
To provide periodic updates to Connect Customer Customer Profiles, you can integrate with Shopify using Amazon AppIntegrations. You first set up the connection in Connect Customer and Shopify, and then verify the Shopify integration.

Set up the connection in Connect Customer and Shopify

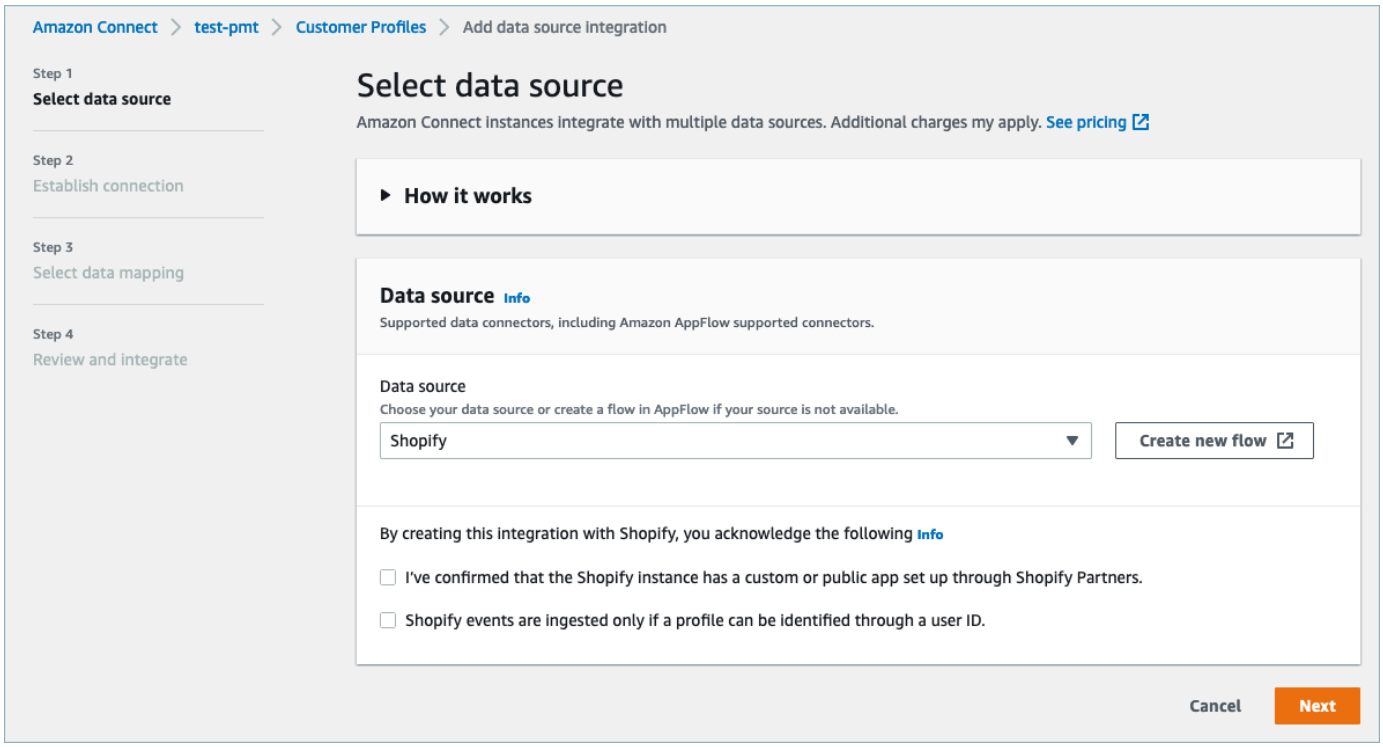
1. Open the Connect Customer console at https://console.aws.amazon.com/connect/.
2. On the instances page, choose the instance alias. The instance alias is also your **instance name**, which appears in your Connect Customer URL. The following image shows the **Connect Customer virtual contact center instances** page, with a box around the instance alias.



3. In the navigation pane, choose **Customer profiles**.
4. On the **Customer profiles configuration** page, choose **Add integration**.

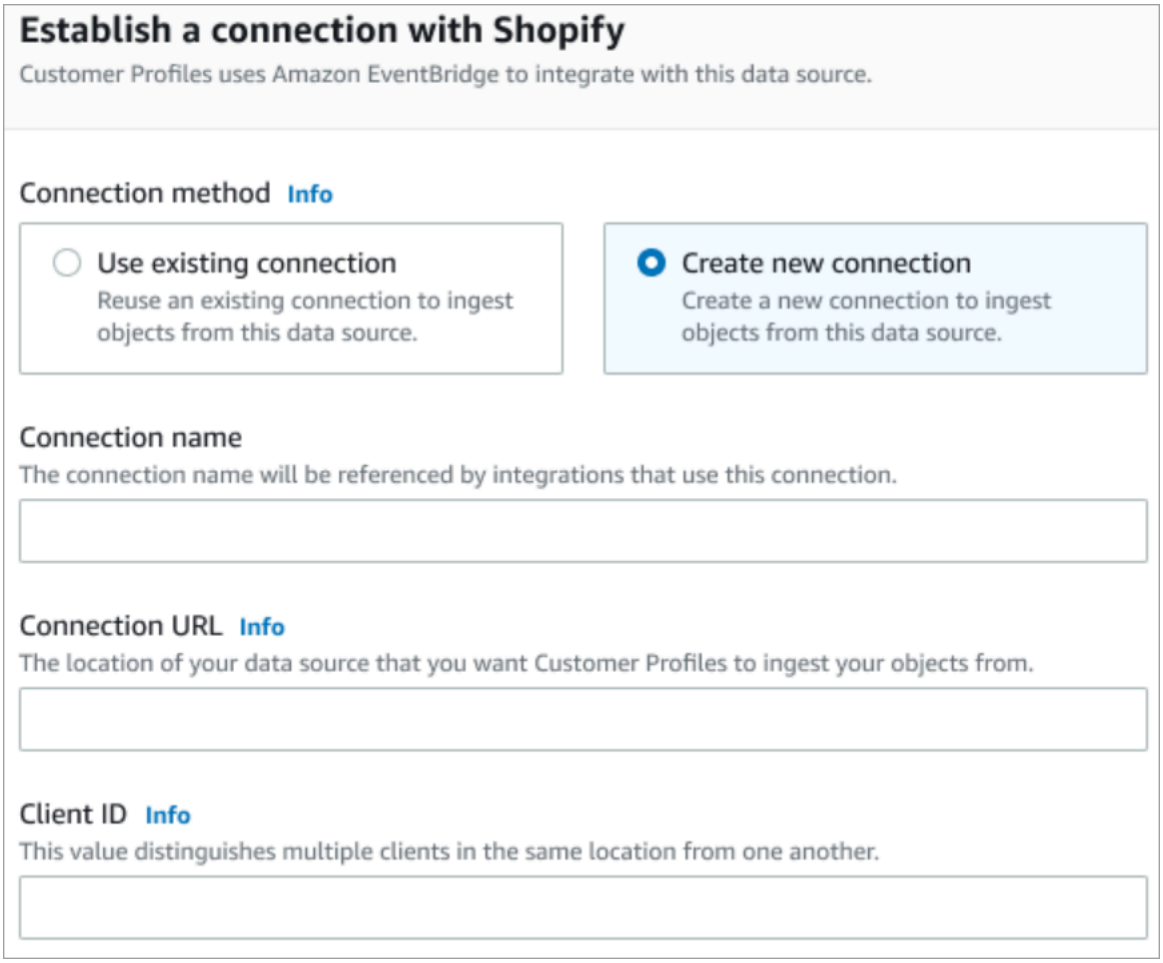


5. On the **Select source** page, choose **Shopify**. Review the application requirements that are listed on the **Select application** page.



6. On the **Establish connection** page, choose one of the following:

   - **Use existing connection**: This allows you to reuse existing Amazon EventBridge resources that you might have created in your AWS account.
   - **Create new connection**: Enter the information required by the external application.



- **Connection name**: Provide a name for your connection. The connection name is referenced by integrations that use this connection.
- **Connection URL**: Enter your application connection URL. This URL is used for deep-linking into the objects created in your external application. The connection URL is the Shopify Partner app URL available on the application website.

  To find your Shopify Partner app URL:

  - Log in to your partners.shopify.com account.
  - Go to your app.
  - Copy the URL from your browser.
- **Client ID**: Enter your application client ID. This is a string that uniquely distinguishes the client in your external application. This client ID is the Source Name available on the application website. You use the ID that you specify here to identify the client that you want Customer Profiles to ingest your objects from. Your client ID might be available after following the Source setup steps.

To find your source name:

- Log in to your partners.shopify.com account.
- Go to your app.
- Copy the source name from your Amazon EventBridge event source.

7. On the **Source set up** page, copy your AWS account ID to your clipboard, and then choose **Log in to Shopify**.
8. Use the following instructions to set up Shopify:

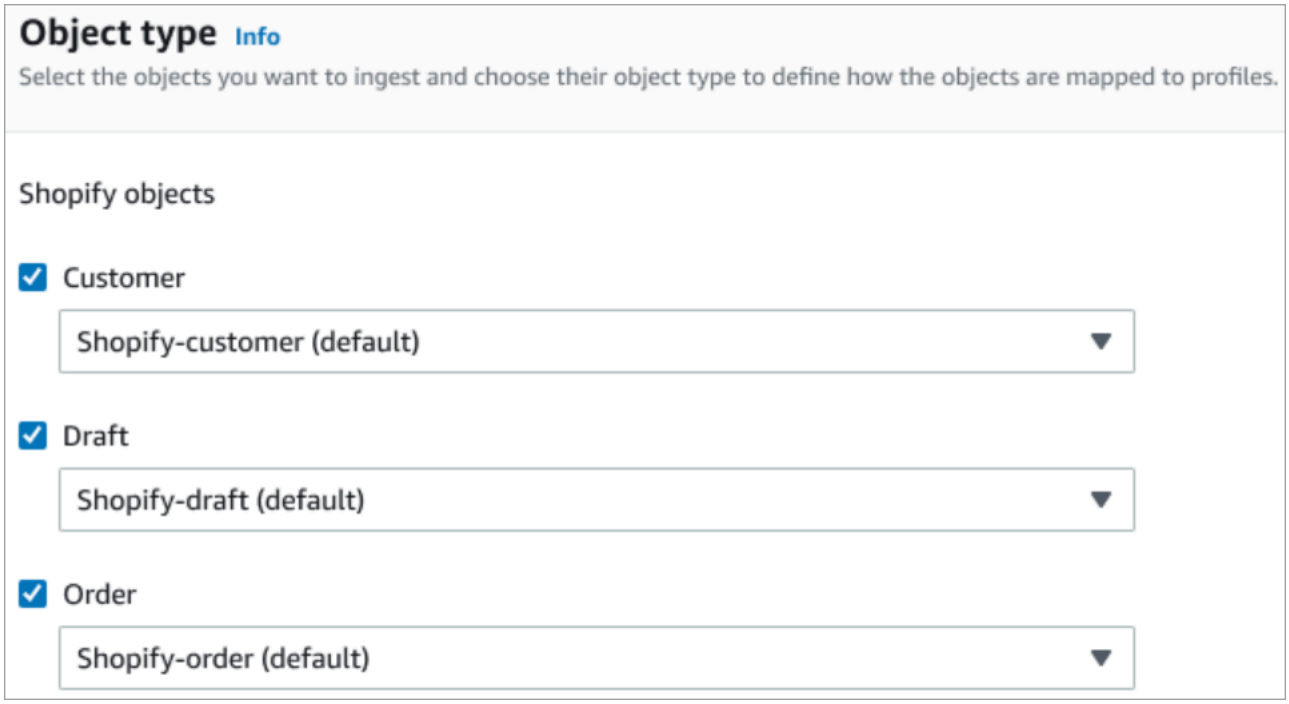
   a. Log in to partners.shopify.com.

   b. Under Amazon EventBridge, choose **Create source**.

   c. Paste in your AWS account ID and select your AWS Region.

   d. After you set up the event source destination, return to Customer Profiles. You will see an alert that indicates Connect Customer has successfully connected with Shopify.
9. On the **Integration options** page, choose which source objects you want to ingest and select their object type.

   Object types store your ingested data. They also define how objects from your integrations are mapped to profiles when they are ingested. Customer Profiles provides default object type templates you can use that define how attributes in your source objects are mapped to the standard objects in Customer Profiles. You can also use the object mappings that you've created from the PutProfileObjectType.

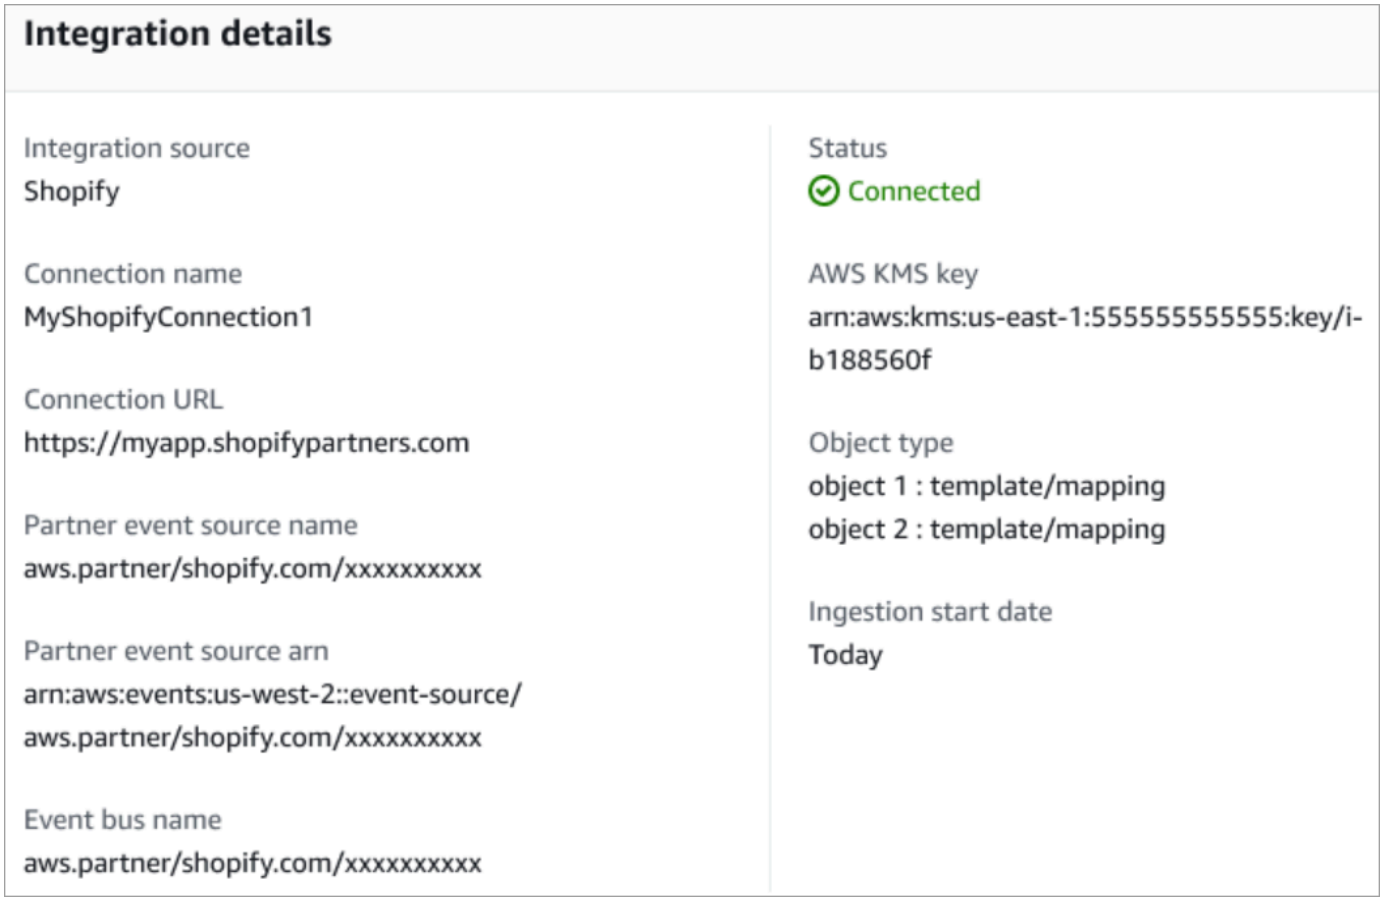


10. For the **Ingestion start date**, Customer Profiles starts ingesting records created after the integration is added.

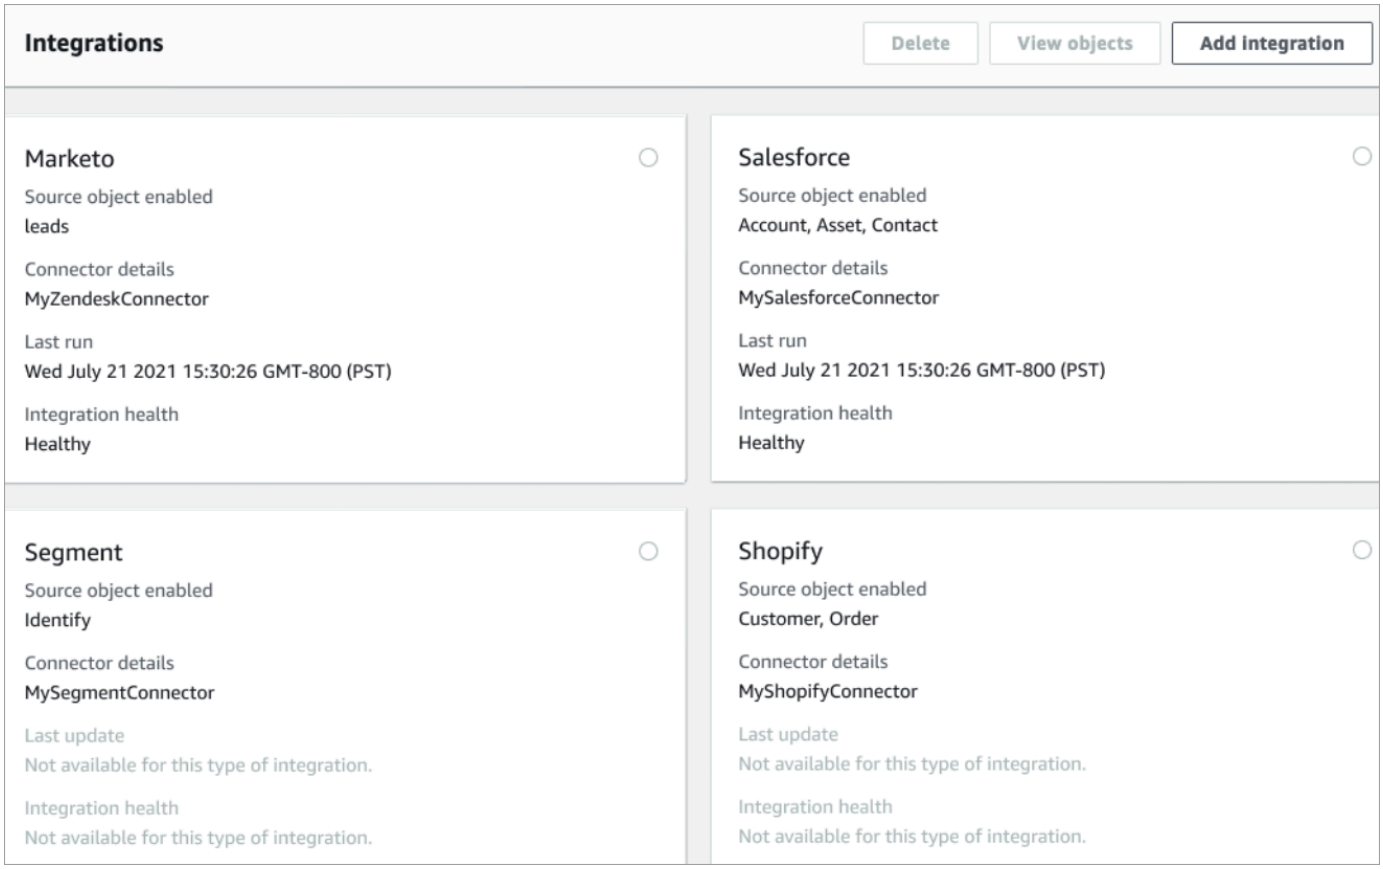
> **Note**
>
> If you need historical records, you can use Amazon S3 as an integration source to import them.

11. On the **Review and integrate** page, check that the **Connection status** says **Connected**, and then choose **Add integration**.

> **Note**
>
> After adding this integration, you need to set up webhook subscriptions to allow events to start flowing into this integration.



12. After the integration is set up, back on the **Customer profiles configuration** page, the **Integrations** section displays which integrations are currently set up. The **Last run** and **Integration health** are not currently available for this type of integration.



To see what data is being sent, choose the integration and then choose **View objects**.

13. Go to the next step to use the API to set up **webhook subscriptions** so events can start flowing into this integration.

Set up webhook subscriptions

1. Use the following URL to make sure your app has the required permissions:

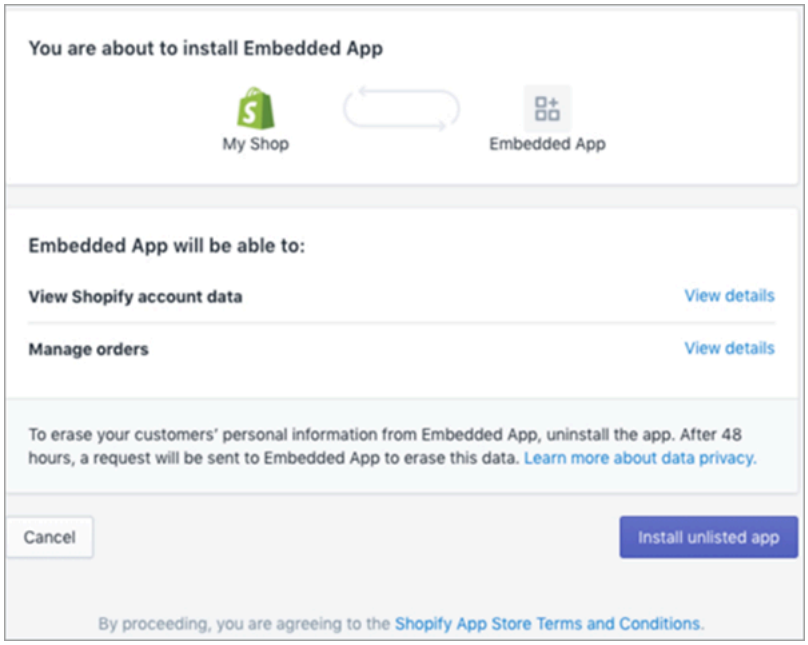
```
https://{shop}.myshopify.com/admin/oauth/authorize?
client_id={api_key}&scope={scopes}&redirect_uri={redirect_uri}&state={nonce}
```

Where:

- shop is the name of your Shopify store.
- `api_key` is the API Key of your Shopify app. You can find this on the Shopify **App** details page.

- `scopes` should have the value `read_customers,read_orders,read_draft_orders`.
- `redirect_uri` is the redirect URI you specified for your app when you created it. For our purposes it can be any valid URL.
- `nonce` can be any unique value to identify a given authorization request from others. We recommend using a timestamp.

After you have constructed the URL, paste it into your browser. An installation/authorization page similar to the following image is displayed, asking the store owner to give permissions for the defined scope.



2. Choose **Install unlisted app** to install and authorize the app on behalf of your store.

   You will be taken to the redirect URI that you entered with an authorization code appended to redirect URI as a query parameter. For example:

   ```
   https://example.org/some/redirect/uri?
   code={authorization_code}&hmac=da9d83c171400a41f8db91a950508985&host={base64_encoded_hostna
   ```

3. Copy the `authorization_code` from this URI. You're going to use it to get a permanent access token in the next steps.
4. Go to whatever tool you use to make API calls. For example, CURL or POSTMAN.
5. To get a permanent access token, make a POST request to the Shopify `Admin` API to this endpoint:

```
https://{shop}.myshopify.com/admin/oauth/access_token
```

with the following request body:

```
{
    "code": "authorization_code_received_from_redirect_uri",
    "client_id": "your_app_api_key",
    "client_secret": "your_app_api_secret"
}
```

This request returns the following response:

```
{
    "access_token": "permanent_access_token",
    "scope": "read_customers,read_orders,read_draft_orders"
}
```

6. Note the `access_token`. This is a permanent token that has the provided scope from a previous step. Now you are ready to create webhook subscriptions.
7. For the following API calls, make sure you set the HTTP header key `X-Shopify-Access-Token` to the `access_token` you received from the earlier call's response.
8. To setup webhook subscriptions, make the following POST request for each of the `topic` values listed in the next step:

   Endpoint: `https://{shop}.myshopify.com/admin/api/2021-04/webhooks.json`

   Request Body:

```
{
    "webhook": {
        "topic": "replace_this_with_one_of_the_topics_in_the_list_below",
        "address":
 "this_is_the_event_source_arn_generated_when_you_created_the_event_integration",
        "format": "json"
    }
}
```

9. For each subscription replace the value for `topic` with the following values:

- customers/create
- customers/enable
- customers/update
- draft_orders/create
- draft_orders/update
- orders/cancelled
- orders/create
- orders/fulfilled
- orders/paid
- orders/partially_fulfilled
- orders/updated

You're now all set to receive events from your Shopify store. Next, verify your Shopify integration.

Verify your Shopify integration

1. Sign in as Admin to your Shopify Store.
2. In the left navigation menu, choose **Customers**.
3. Select **Add Customer**.
4. Enter your customer details. Be sure to enter a phone number and email. These don’t have to belong to a real customer. You will delete this customer entry after verifying the integration.
5. Save the customer object.
6. The event delivery should be almost instantaneous but allow a minute for it to be delivered and to create a customer profile.
7. Open the Connect Customer agent workspace and look up the user by the email or phone number you entered into the Shopify Store. You should be able to see the customer profile with the same email or phone number.
8. If you cannot see the customer profile, then there is a problem with your integration. To troubleshoot:

    1. Go to the Amazon EventBridge console.
    2. Check whether the EventSource is Active and the matching EventBus exists and is running.

If these are working, contact Support for assistance investigating the issue.

Monitor your Customer Profiles integrations

After your connection is established, if it stops working, delete the integration and then re-establish it.

What to do if objects aren't being sent

If an object fails to be sent, choose **Flow details** to learn more about what's gone wrong.

You might need to delete the configuration and re-connect to the external application.

Set up integration for external applications using Amazon AppFlow

These integrations use Amazon AppFlow to provide periodic updates to Connect Customer Customer Profiles. The below steps provide guidance on configuring a connector of your choosing using Amazon AppFlow, configure data mappings, and configure integrations to ingest your customer data.

For more information on Amazon AppFlow pricing, see Amazon AppFlow pricing.

For more information on Amazon AppFlow supported connectors see Supported source and destination applications.

Before you begin

When you enable Connect Customer Customer Profiles you create a Customer Profiles domain, which is a container for all data, such as customer profiles, object types, profile keys, and encryption keys. The following are guidelines for creating Customer Profile domains:

- Each Connect Customer instance can only be associated with one domain.
- You can create multiple domains, but they don't share external application integrations or customer data between each other.
- All the external application integrations you create are at a domain level. All of the Connect Customer instances associated with a domain inherit the domain's integrations.

Prerequisite: Enable Customer profiles in your Connect Customer instance

1. Open the Connect Customer console at https://console.aws.amazon.com/connect/.
2. On the instances page, choose the instance alias. The instance alias is also your **instance name**, which appears in your Connect Customer URL. The following image shows the **Connect Customer virtual contact center instances** page, with a box around the instance alias.
3. In the navigation pane, choose **Customer profiles**.
4. Choose enable Customer Profiles

In the form, you will be required to complete all the mandatory fields to create a Customer Profiles domain by following the steps below:

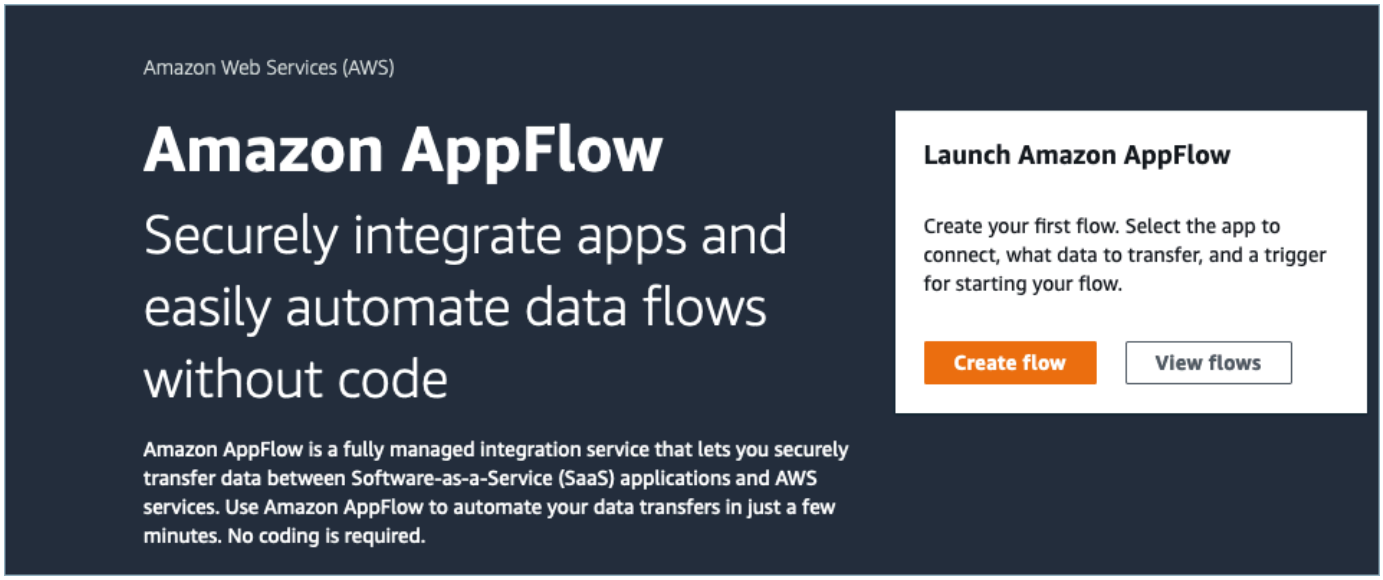
1. **Domain Setup**. You can Create New Domain and provide a name.
2. **Encryption**. Under Specify KMS key, you can enable encryption by either selecting an existing AWS KMS key, creating a new AWS KMS key, or you can choose **Select existing domain**.
3. **Error Reporting**. You can provide a Dead letter queue, which is an SQS queue to handle customer profile errors
4. Choose **Submit** and Customer Profiles will be get created using the Contact History information of your instance.

Set up an external application using Amazon AppFlow

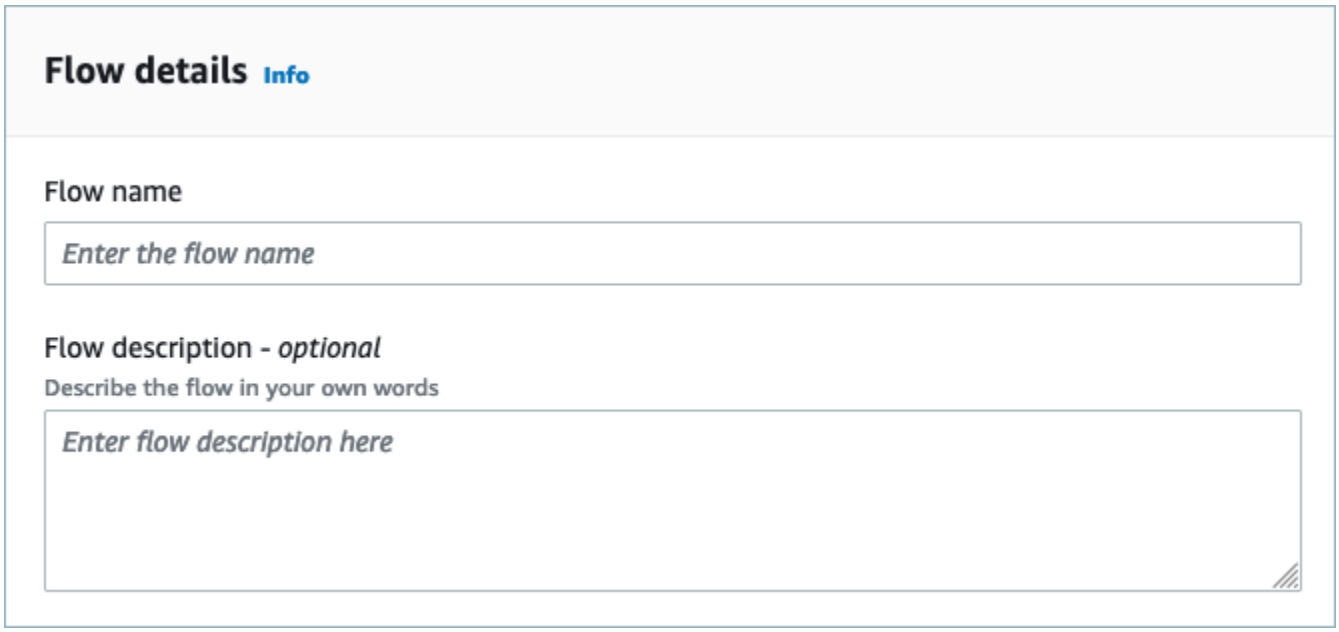
You can add an external application integration to a Connect Customer Customer Profiles domain by using Amazon AppFlow by following steps below. You must create a flow for your data source in the Amazon AppFlow console and set Connect Customer Customer Profiles as the destination before continuing in the Customer Profiles console. If you created a flow more than 14 days ago, it has expired and you will need to create a new flow for your integration.

You can optionally perform data transformations such as `Arithmetic`, `Filter`, `Map`, `Map_all`, `Mask`, `Merge`, `Truncate`, and `Validate` when using the CloudFormation `AWS::AppFlow::Flow Task` resource before ingestion.

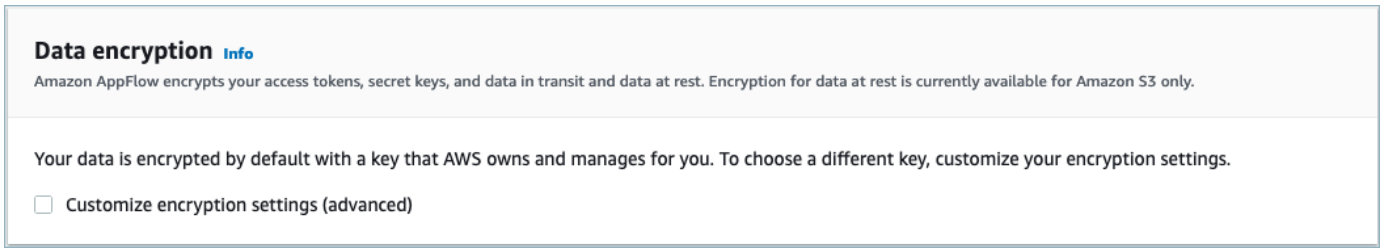
1. Log into your AWS Management Console, select Amazon AppFlow, and choose **Create flow**.



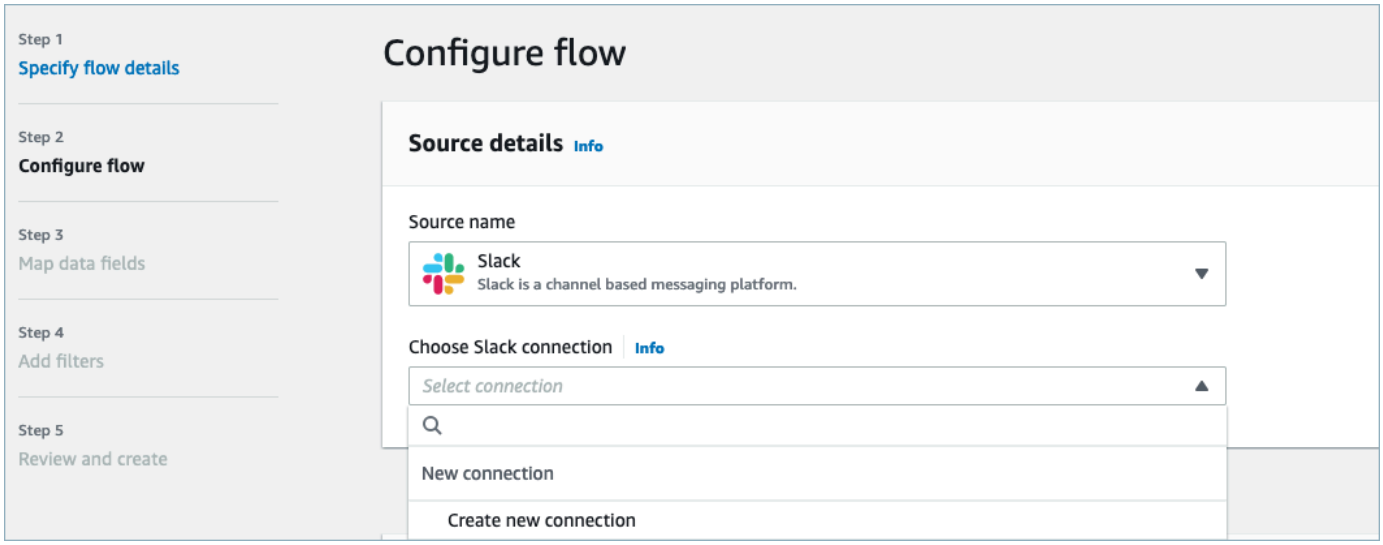
2. Enter the flow name and an optional flow description.



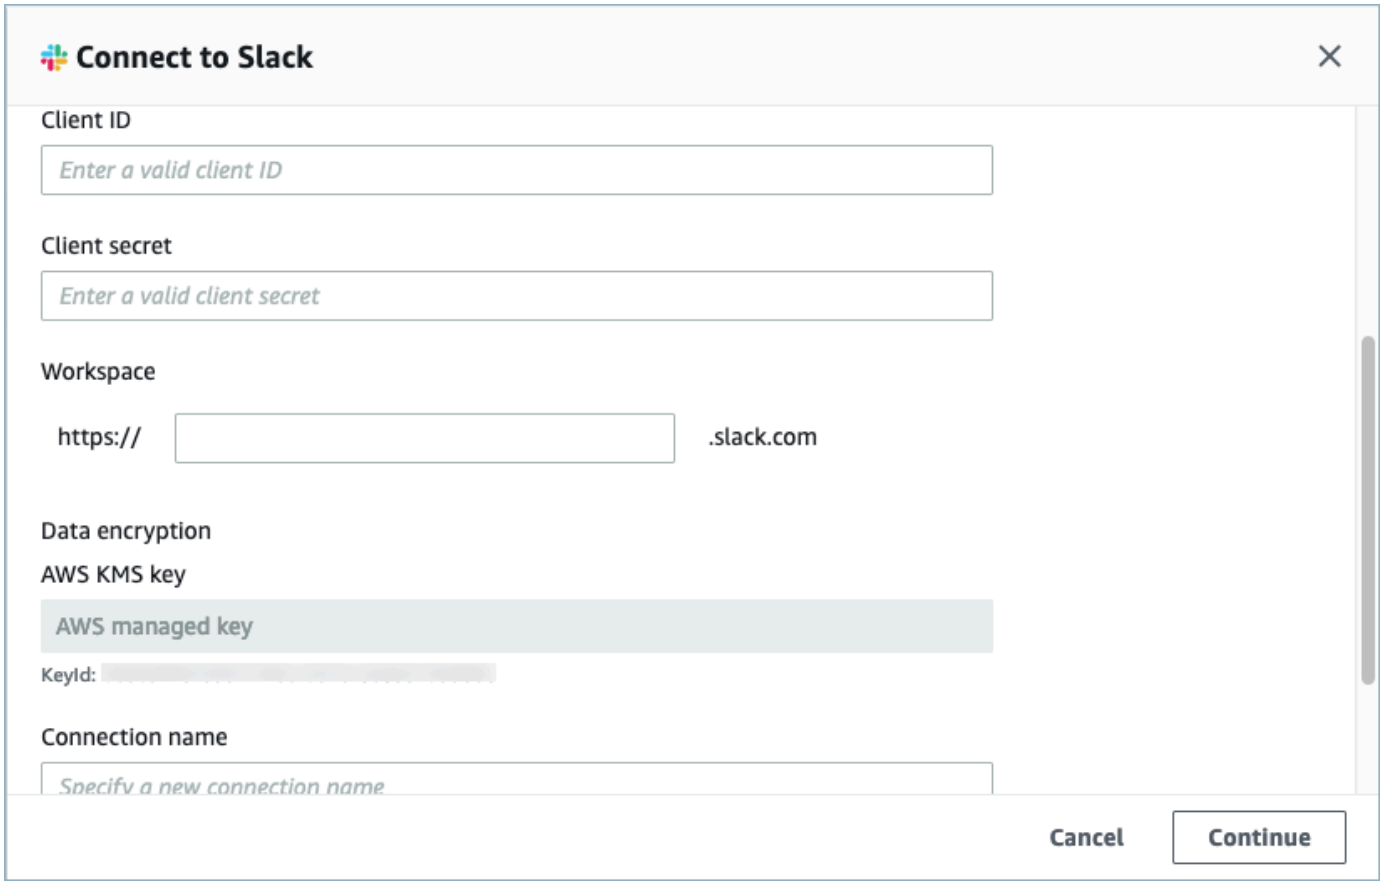
3. You can leave the **Data encryption** section as it is since your Connect Customer Customer Profiles domain already has an existing AWS KMS key that will be used for this Flow. You can optionally create tags and then choose **Next**.



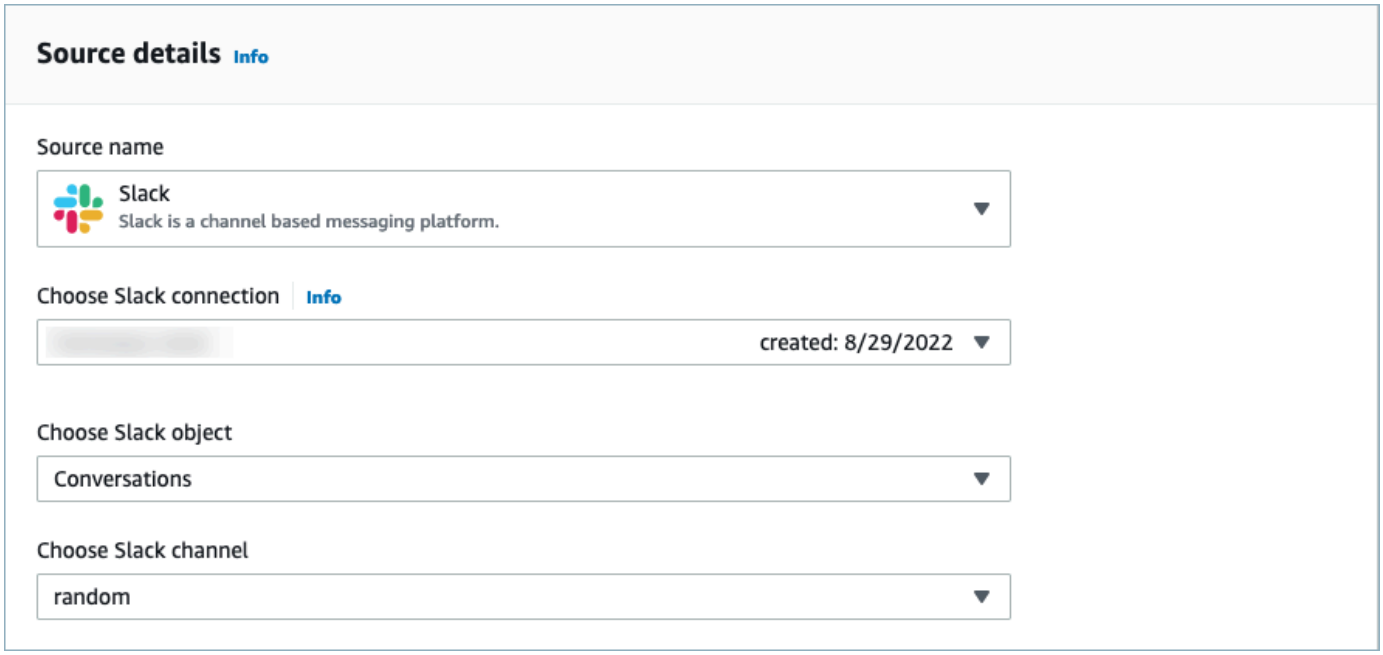
4. Select an external application of your choice in the **Source name** dropdown and then select the next relevant field. For example, if you wish to configure Slack, select Slack from the **Source name** dropdown. You can then either select an existing Slack flow or create a new connection.



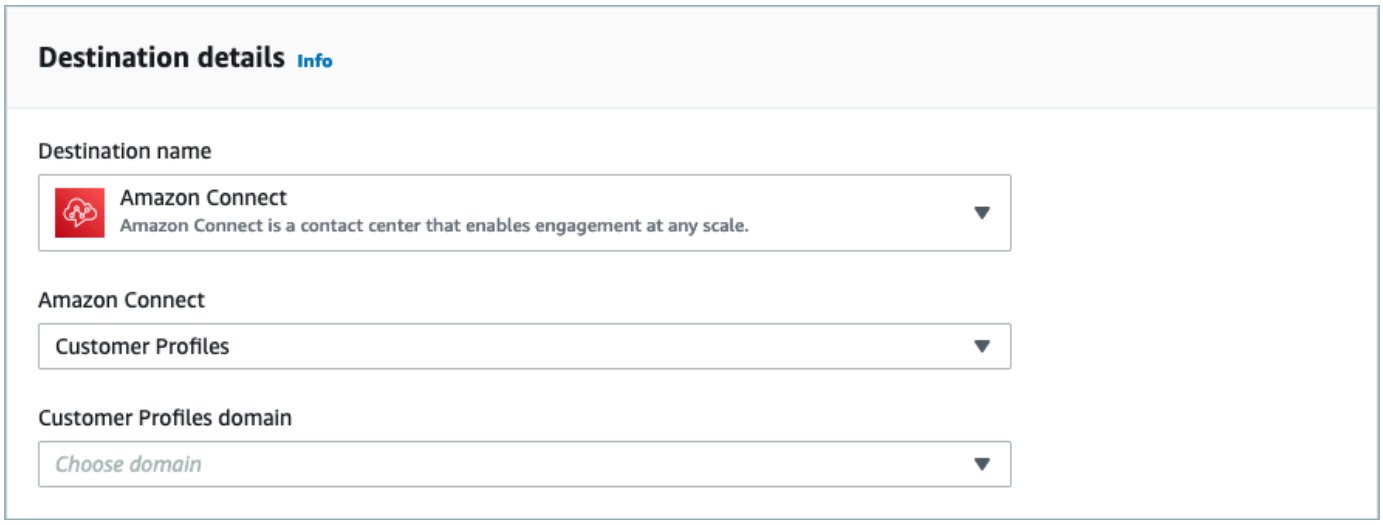
5. If you chose to create a new connection, you can then enter the external application's details such as user name, password and subdomain. You can also select the AWS KMS key for data encryption and enter the connection name to identify this connection.



6. If you choose to use an existing connection you can select the specific external application object from dropdown. For example, If choosing an existing Slack connection, you can select **Conversations** as the object and then choose the specific Slack channel that will be used.

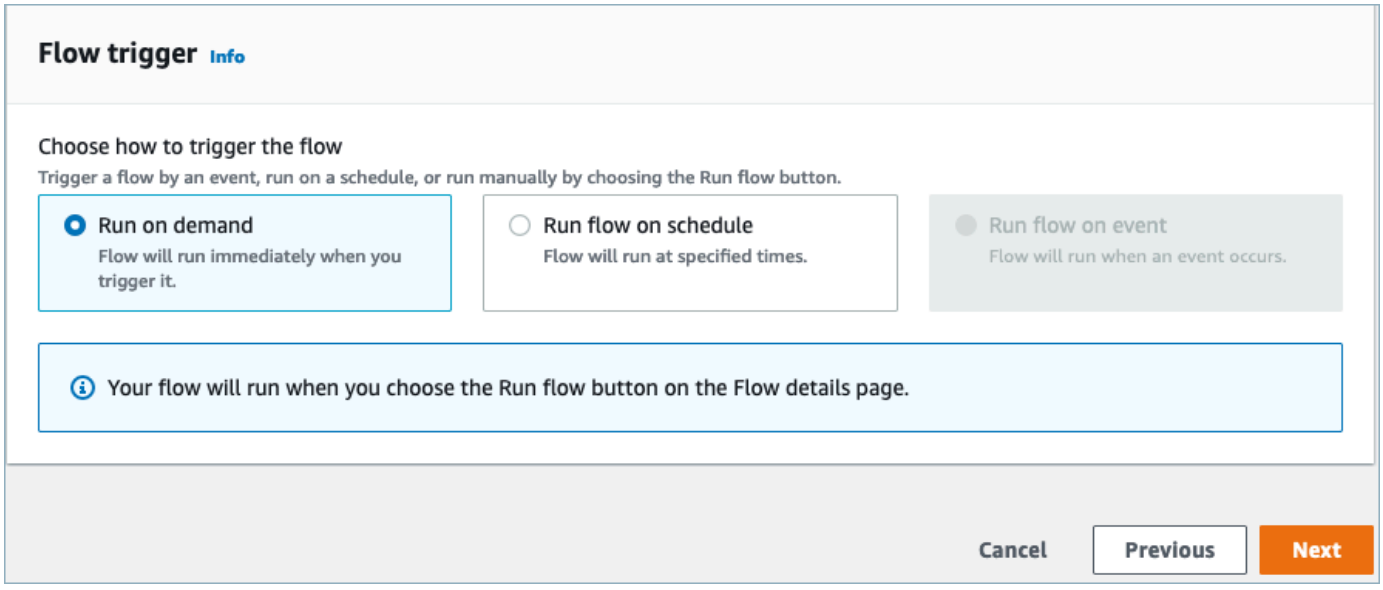


7. In the **Destination details** section, select Connect Customer as the Destination name in the dropdown and select the Customer profile domain created in the previous prerequisite step.

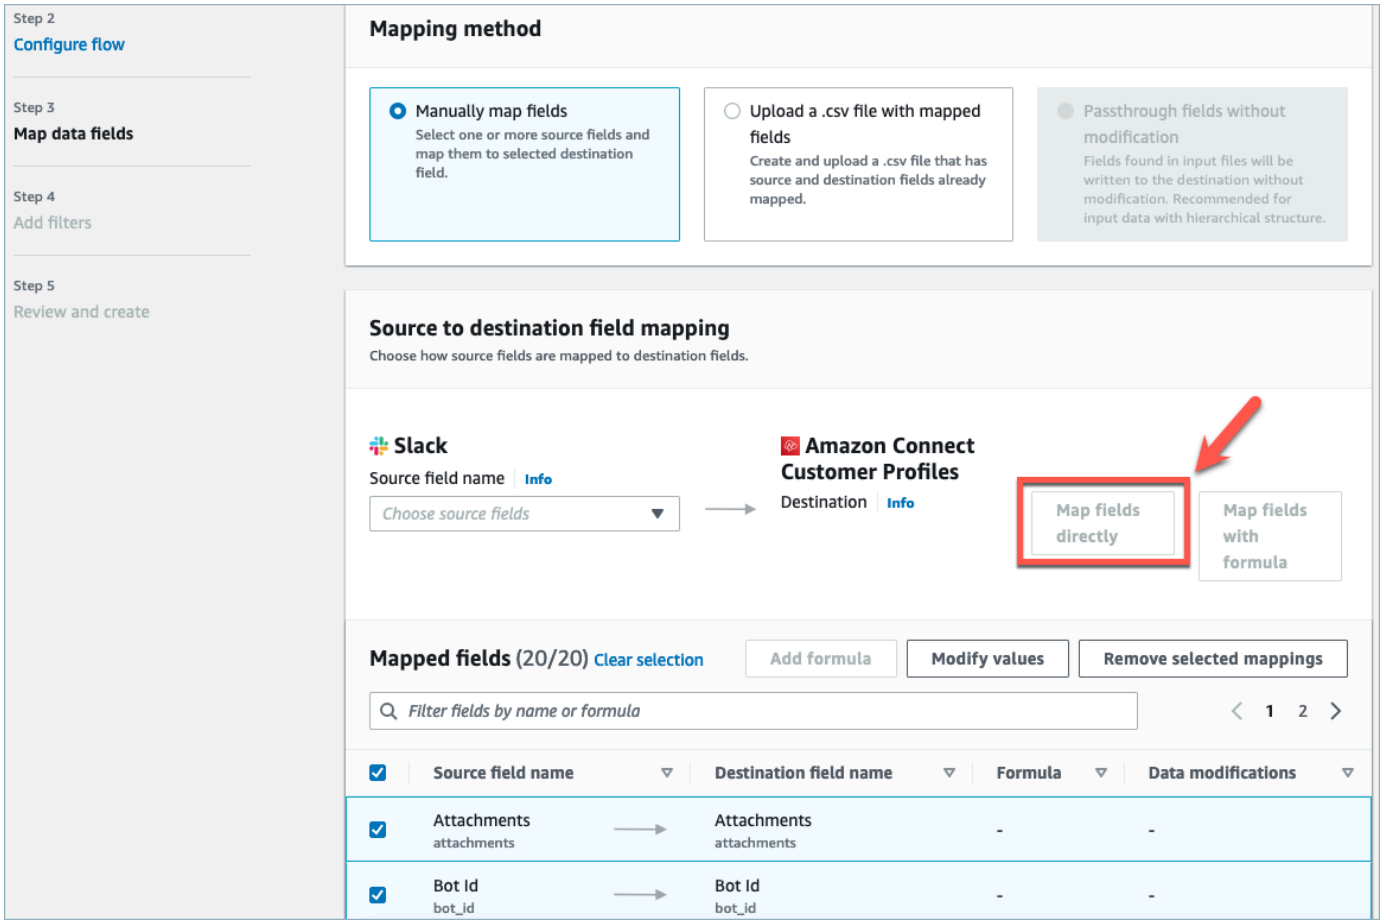


8. Select a flow trigger by choosing **Run on demand** or **Run flow on schedule**. Choose **Next**.

   - **Run on demand** runs the flow only when you trigger it.
   - **Run flow on schedule** runs the flow at a specific time by using a schedule. The schedule frequency is limited to 5 minutes, 15 minutes, or 1 hour.



9. Choose **Manually map fields** under **Mapping method**. Choose the source fields from external application and then choose **Map fields directly**.



10. Review and choose **Create flow**.

For more information on creating flows in the Amazon AppFlow console, see Creating flows in Amazon AppFlow.

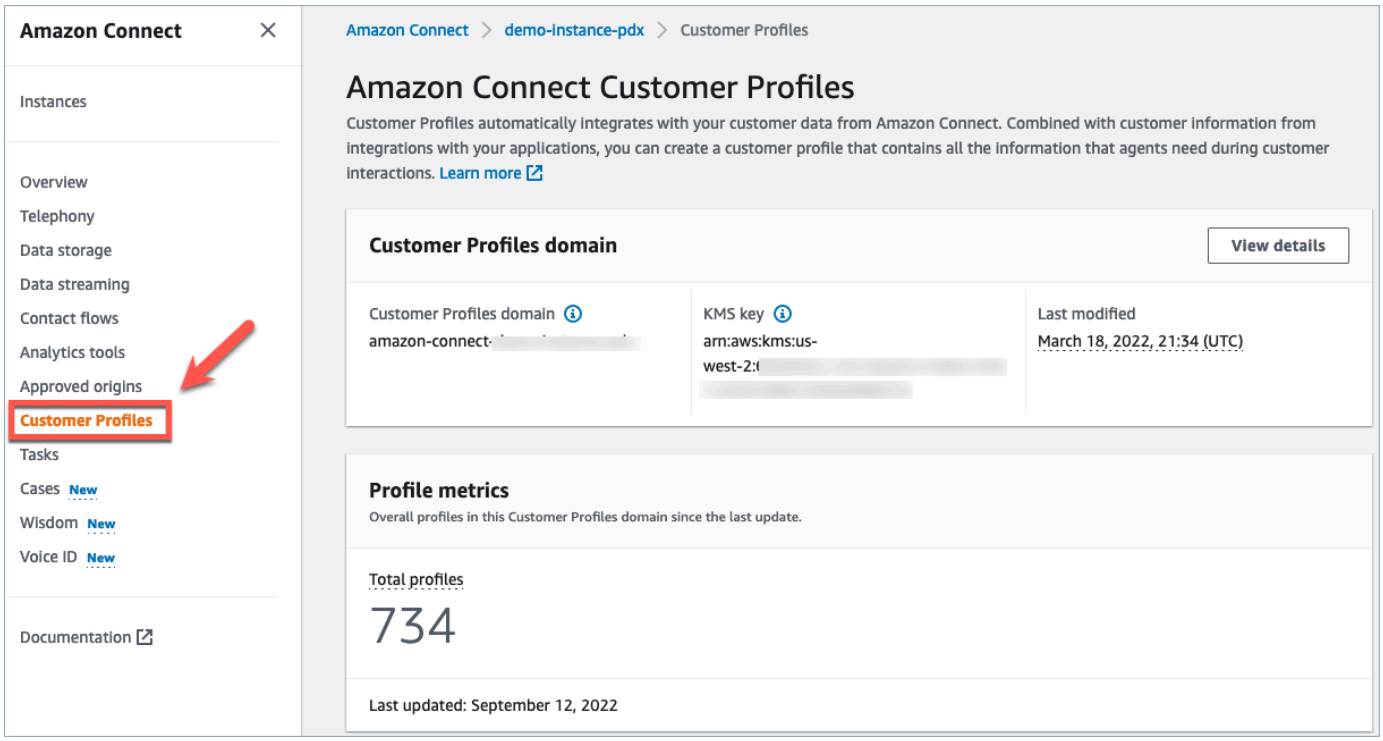
For more information on the setup of external application and many other supported applications in Amazon AppFlow, see Supported Amazon AppFlow source and destination applications.

Set up data mappings to define how external application data is mapped to a Customer Profile

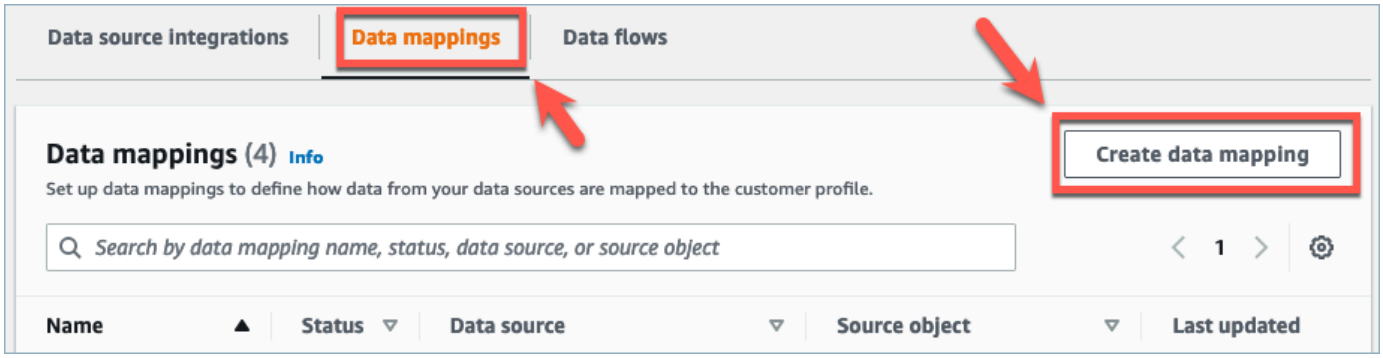
Once Amazon AppFlow integration has been set up, you need to set up data mappings in Customer Profiles to define how data from the external application will be mapped to the Customer Profile. With data mappings, you can customize the data that you want to use to build your unified customer profile. Choose your mapping carefully, as you will not be able to choose a different mapping after creating the integration.

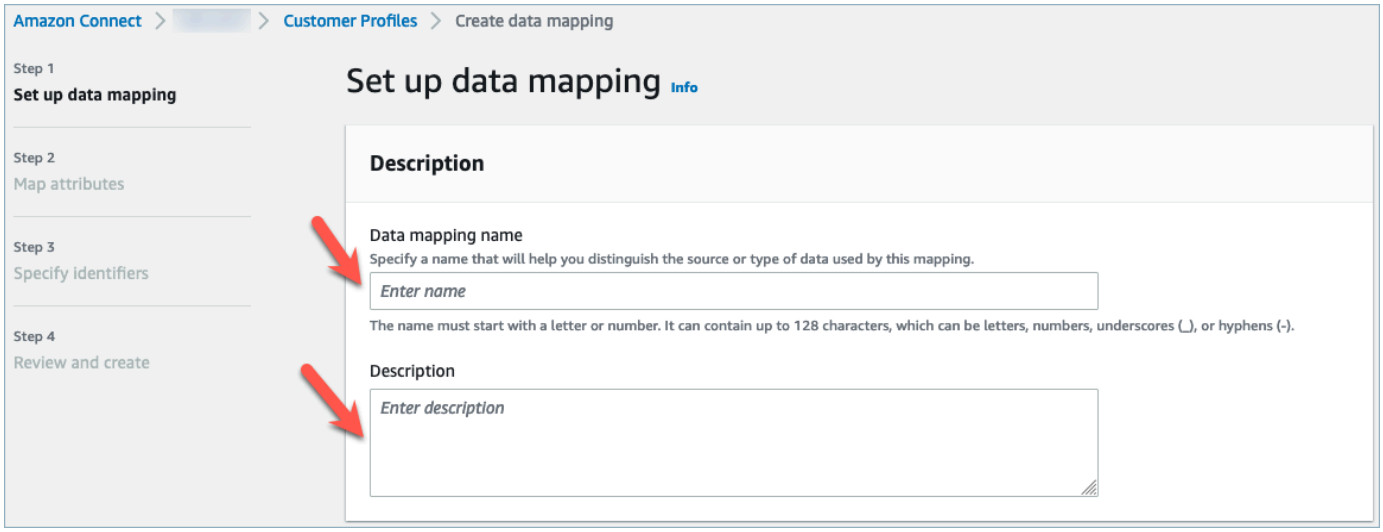
For more detailed information on data mappings, see Object type mapping.

1. Log into your AWS Management Console, select **Connect Customer**. and choose Customer Profiles under your connect instance alias.

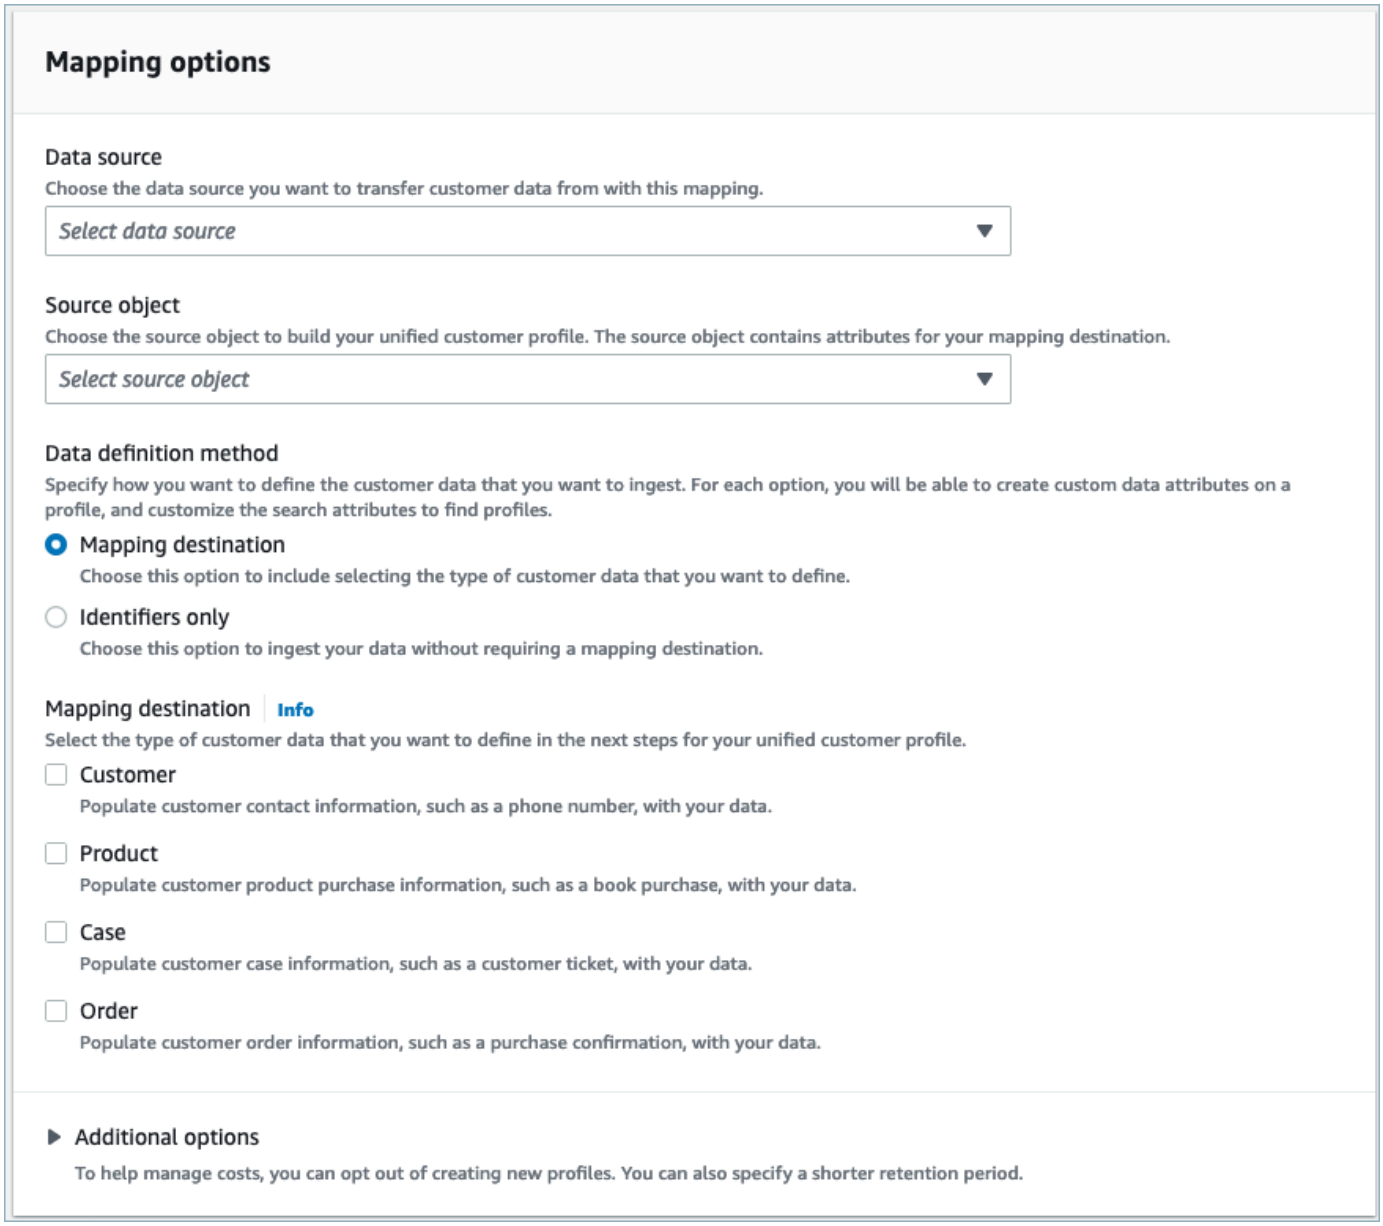


2. Choose **Data mappings** and then choose **Create data mapping**. Provide a Data Mapping name and a description.

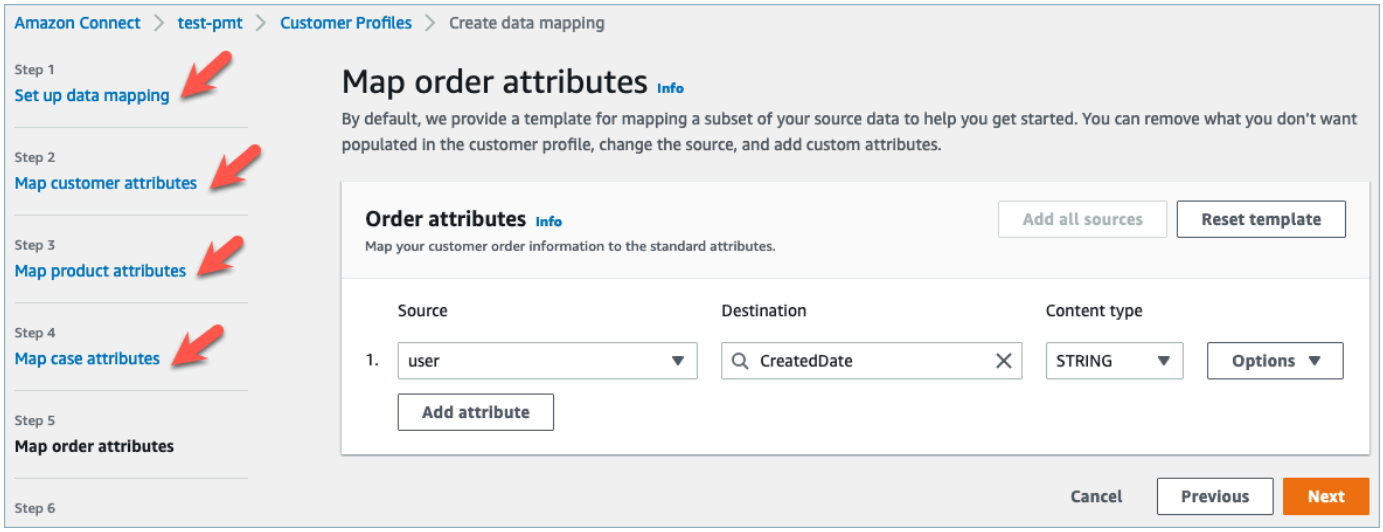




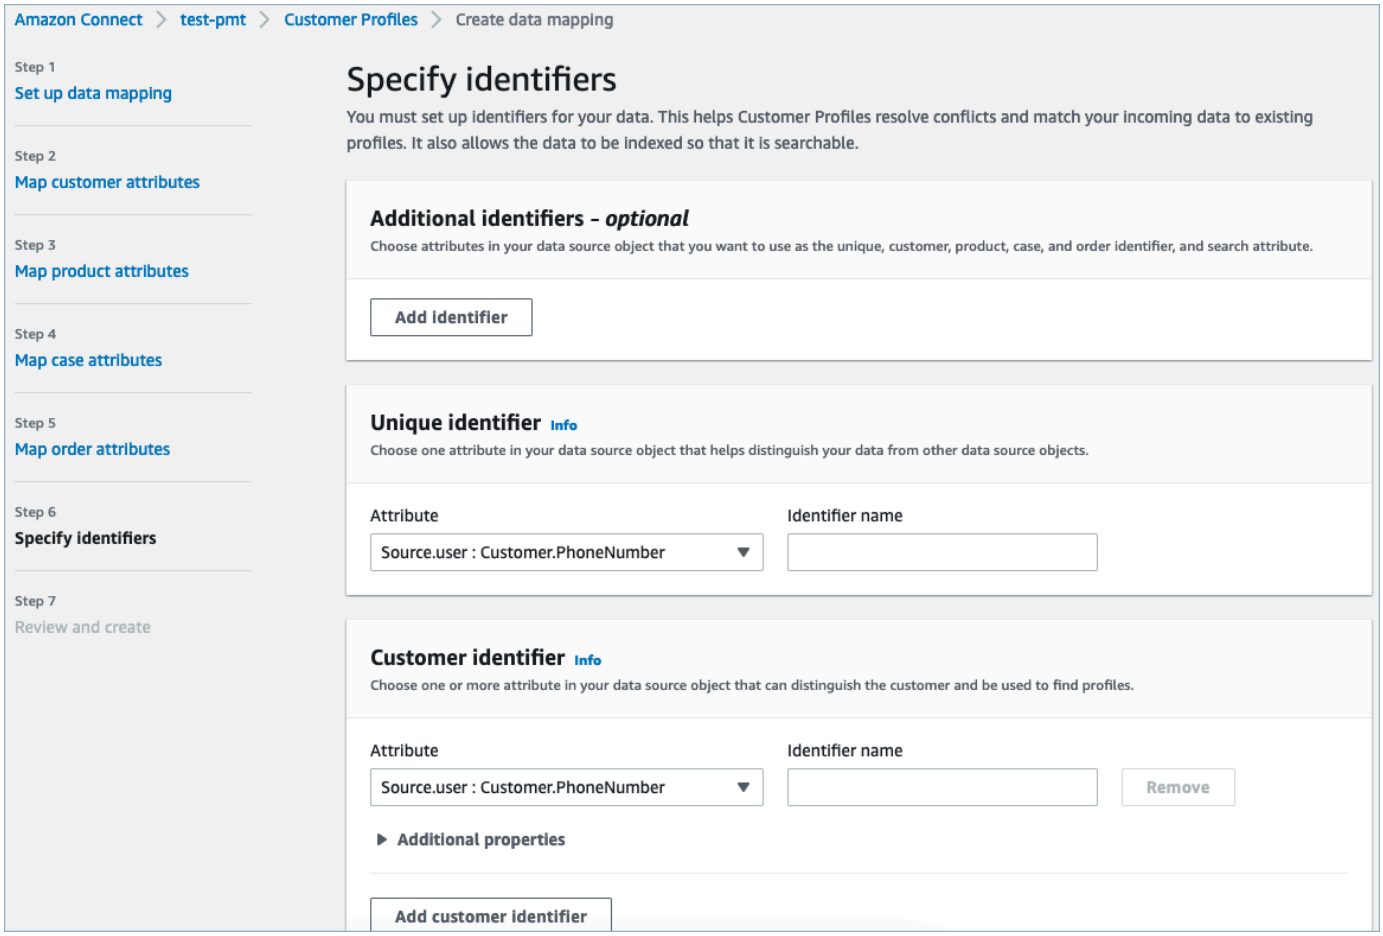
3. Under **Mapping options**, you can choose your **Data source** as the external application, the **Flow name** that you created in the previous section, and the **Data definition method** as *Mapping destination*. Under **Mapping destination** you can choose the types of customer data that wish to define for your unified customer profiles. Choose **Next**.



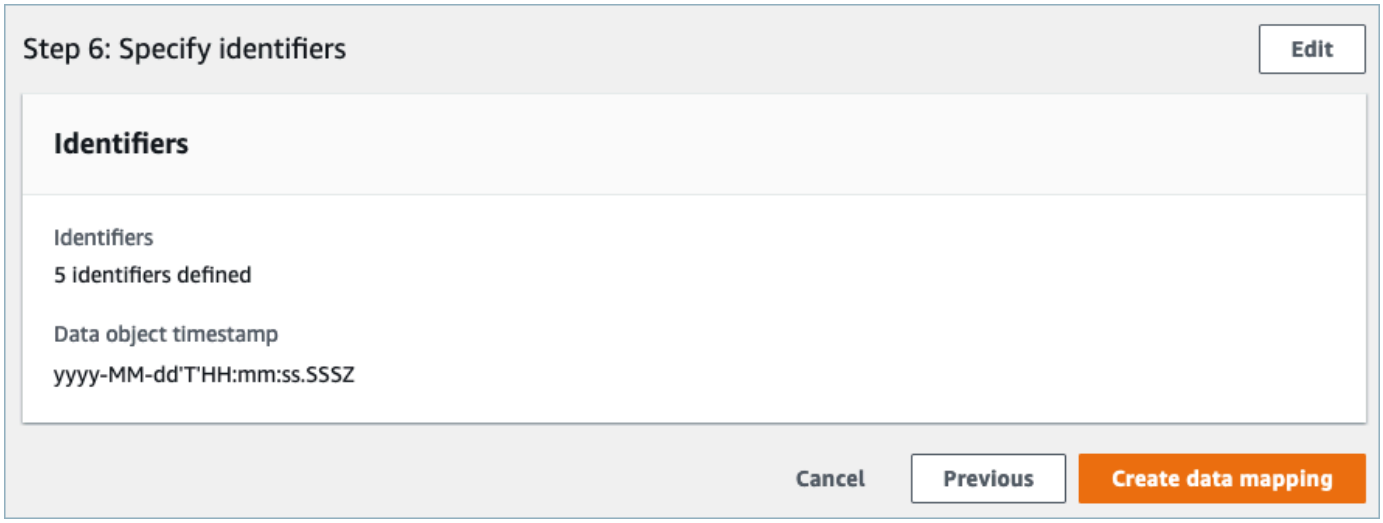
4. Add customer, product, case and order attributes with source, destination, and content type, then choose **Next**.



5. Under **Specify identifiers**, you can select various attributes from your data source object that helps distinguish your data from other data source objects. You can select attributes from unique, customer, product, case and order identifiers. For more information about identifiers, see Standard identifiers in Customer Profiles.



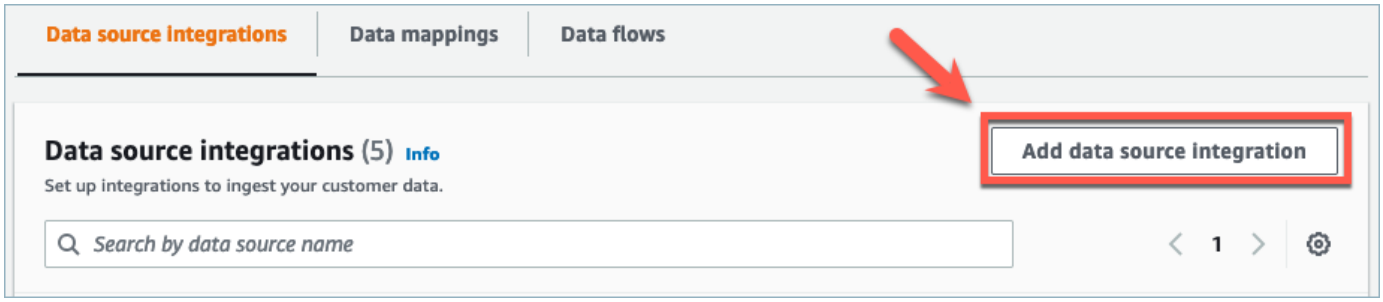
6. Review and choose **Create Data Mapping**. The Data Mapping status will show as *Active*.



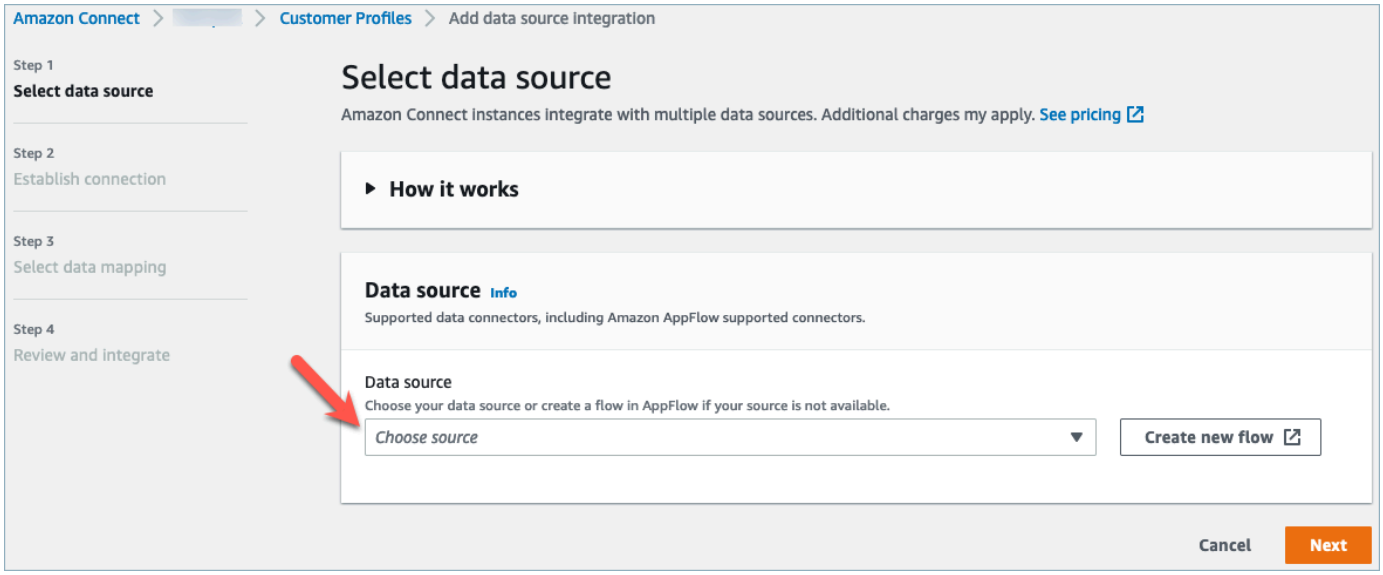
Set up integrations to ingest your customer data from an external application

After the data mapping set up is done for an external application, you will set up the Data source integration to ingest your customer data.

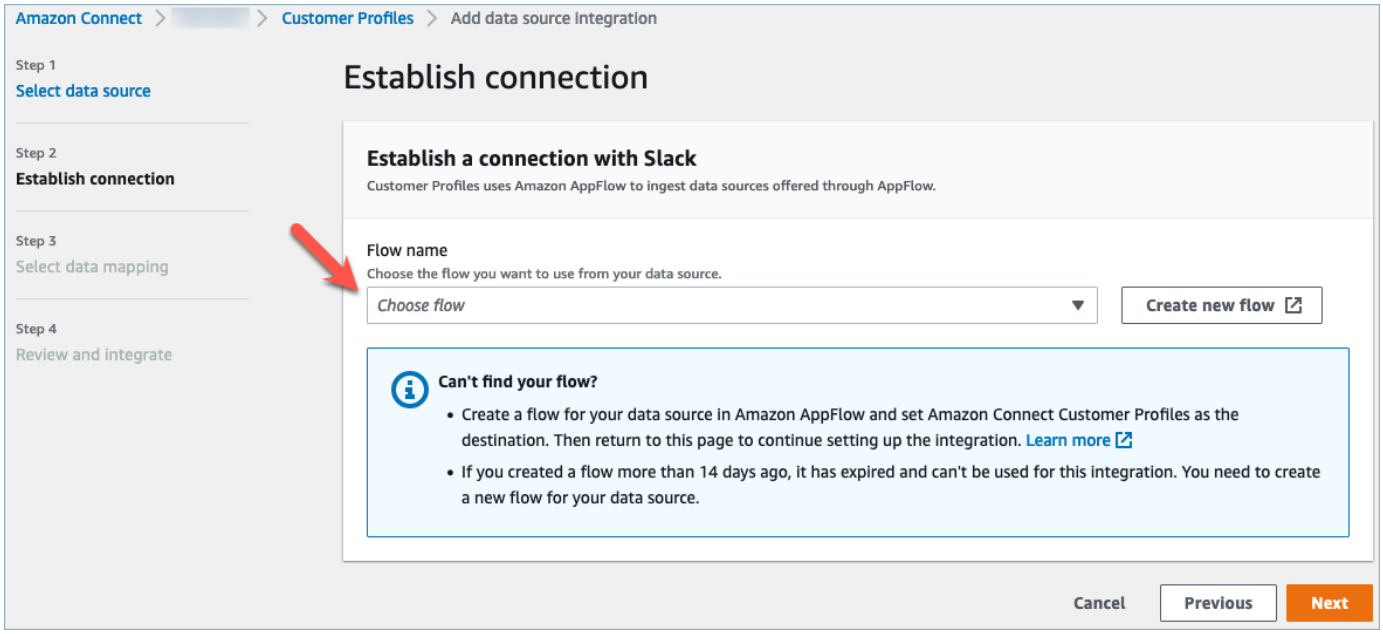
1. Log into your AWS Management Console, select **Connect Customer**. and choose Customer Profiles under your connect instance alias.
2. Under the **Data source integrations** section choose **Add data source integration**.



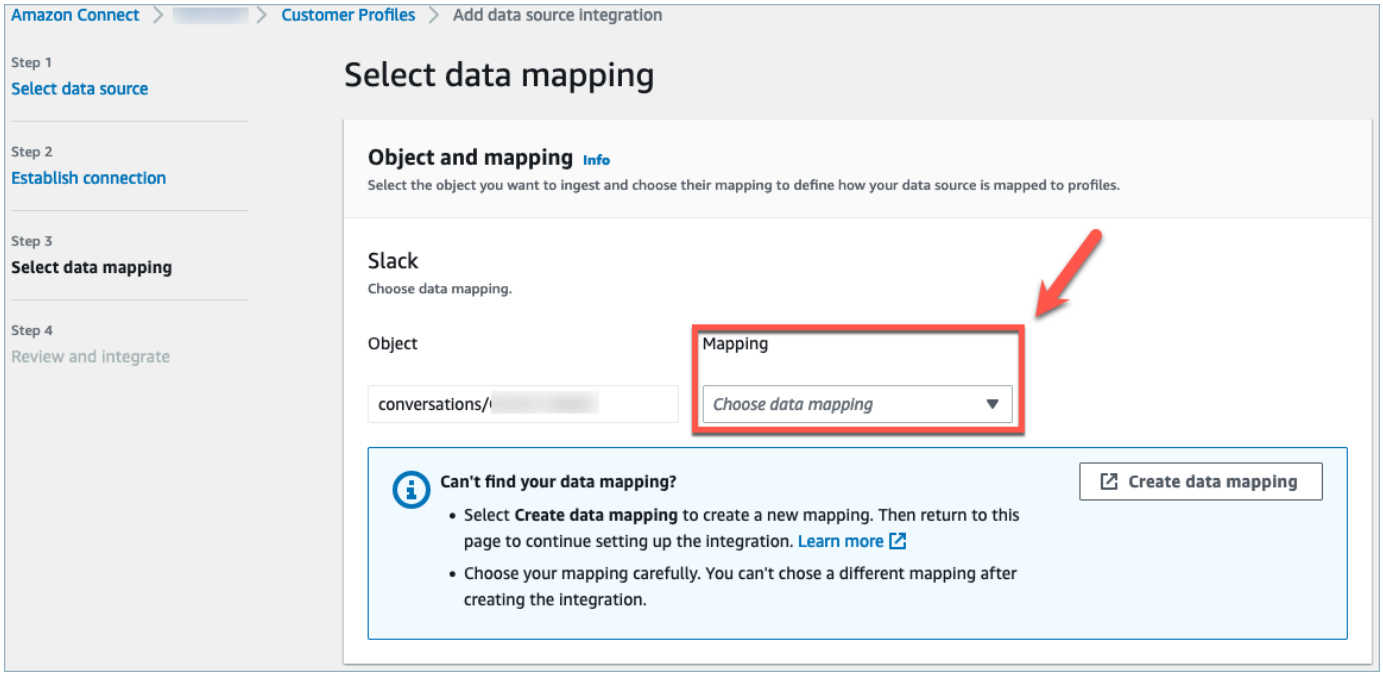
3. Under the **Data source** dropdown, select the external application and choose **Next**. You also have the option to choose **Create new flow** which will open the Amazon AppFlow console in a new tab.



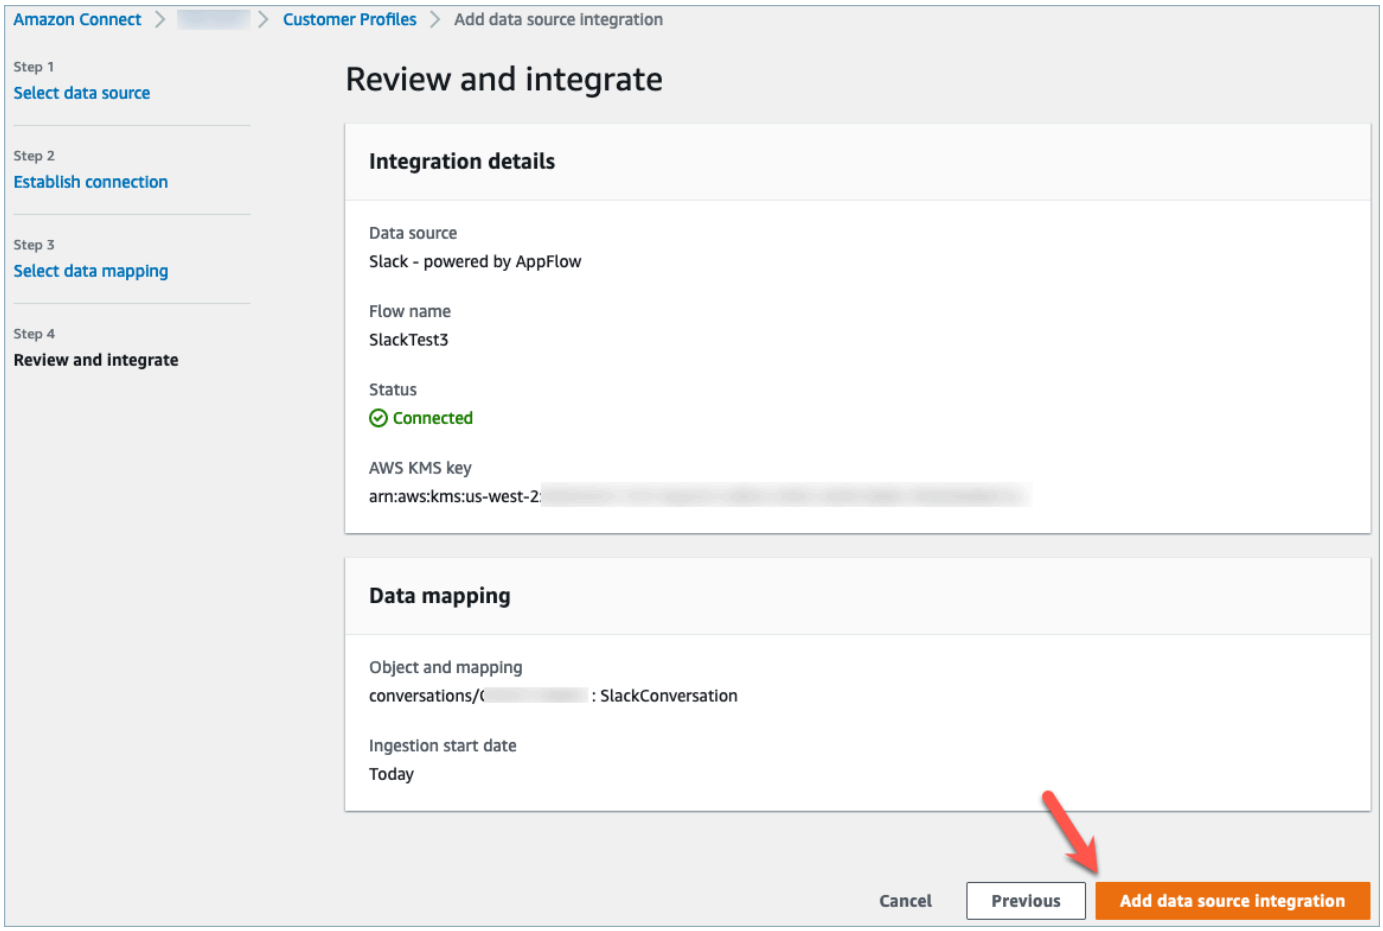
4. Under the **Flow name** dropdown, select the flow you want to use from your data source and choose **Next**.



5. Under the **Data Mapping** dropdown, select the external application data mapping for the object to define how your data source is mapped to profiles. Choose **Next**.



6. Review and choose **Add data Source Integration**. The datasource integration of the external application will initially show as pending before moving to an active state.



View the unified customer profile in Connect Customer Customer Profile Agent CCP

Your agents will now be able to view customer data that has been imported from an external application by logging in to the Connect Customer Agent CCP. For more information on connecting to the Connect Customer Agent CCP, see Agent application: Everything in one place.

Your agent will need to have the appropriate security profile permissions to view Customer Profiles and will be able to perform searches using a key name and value in the profiles search bar.

For more information on security profile permissions, see Security profiles.

Users who want to build their own custom agent application and embed customer profiles can use StreamsJS which provides more customization over the agent workspace.

Delete Customer Profiles or stop integrations

> **Note**
>
> Deleting mappings will only delete objects and data associated with that specific mapping. If there are multiple objects associated with a profile, then deleting a specific mapping might not clear the profile data. If you want to delete specific data, then you would delete the mapping, but your profiles might still exist if they contain data from other mappings. This could result in additional charges for the existing profiles. You can delete a domain and all data from Customer Profiles, including all profiles, by using the Connect Customer console or the DeleteDomain API.

Console method

- If at any time you want to stop the ingestion of customer profile data, choose the integration/mapping and then choose **Delete**.
- To delete the integrations, customer profiles, and all the customer profile data, you can delete your customer profiles domain in the Connect Customer console. For more information, see Delete a Connect Customer Customer Profiles domain.

API method

- To delete customer profiles data for a specific integration, use the `DeleteProfileObjectType` API.

- To delete the integrations, customer profiles, and all the customer profile data, use the `DeleteDomain` API.

To re-enable the ingestion of customer profile data, go through the setup steps again.

Object type mapping in Connect Customer Customer Profiles

Object type mapping tells Customer Profiles how to ingest a specific type of data into a unified customer profile. A mapping provides Customer Profiles with two essential pieces of information:

- How values from a source object populate **standard objects**—the standard profile, and (optionally) other standard objects such as assets, orders, cases, and loyalty records. For more information, see Reference for standard objects in Customer Profiles.
- Which fields to index for searching, and how those fields are used to assign objects of this type to a specific profile (and, when applicable, to a specific standard object such as an asset or order).

With a mapping in place, you can ingest data from sources such as Salesforce, Zendesk, ServiceNow, Marketo, Amazon S3, or your own applications, and present a single unified view of each customer to your agents, flows, and downstream applications.

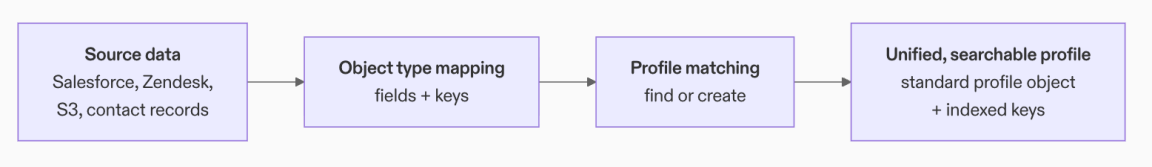
How object type mapping works in Customer Profiles

This topic describes what happens to your data from the moment it's ingested to the moment it becomes part of a unified, searchable profile. Understanding this flow helps you design mappings that match objects to the right profiles and avoid unwanted duplicate profiles.

How your data flows through Customer Profiles

An object type mapping is the bridge between your raw data and a unified profile. At a high level, data moves through four stages:

1. **Source data** arrives from a connector (Salesforce, Zendesk, Amazon S3, Connect Customer contact records, your own application, and so on).
2. The **object type mapping** defines fields that extract values from the source object and keys that identify which profile (and which standard objects, if any) the data belongs to.
3. Customer Profiles uses the keys to look up an existing profile or create a new one, populates the **standard profile object** (and any other targeted standard objects, such as `_asset` or `_order`) from the field targets, and stores the original source data as a profile object.
4. The resulting **unified profile** is searchable by every key you defined and is available to downstream applications.



The ingestion sequence

Each ingested object moves through three conceptual stages:

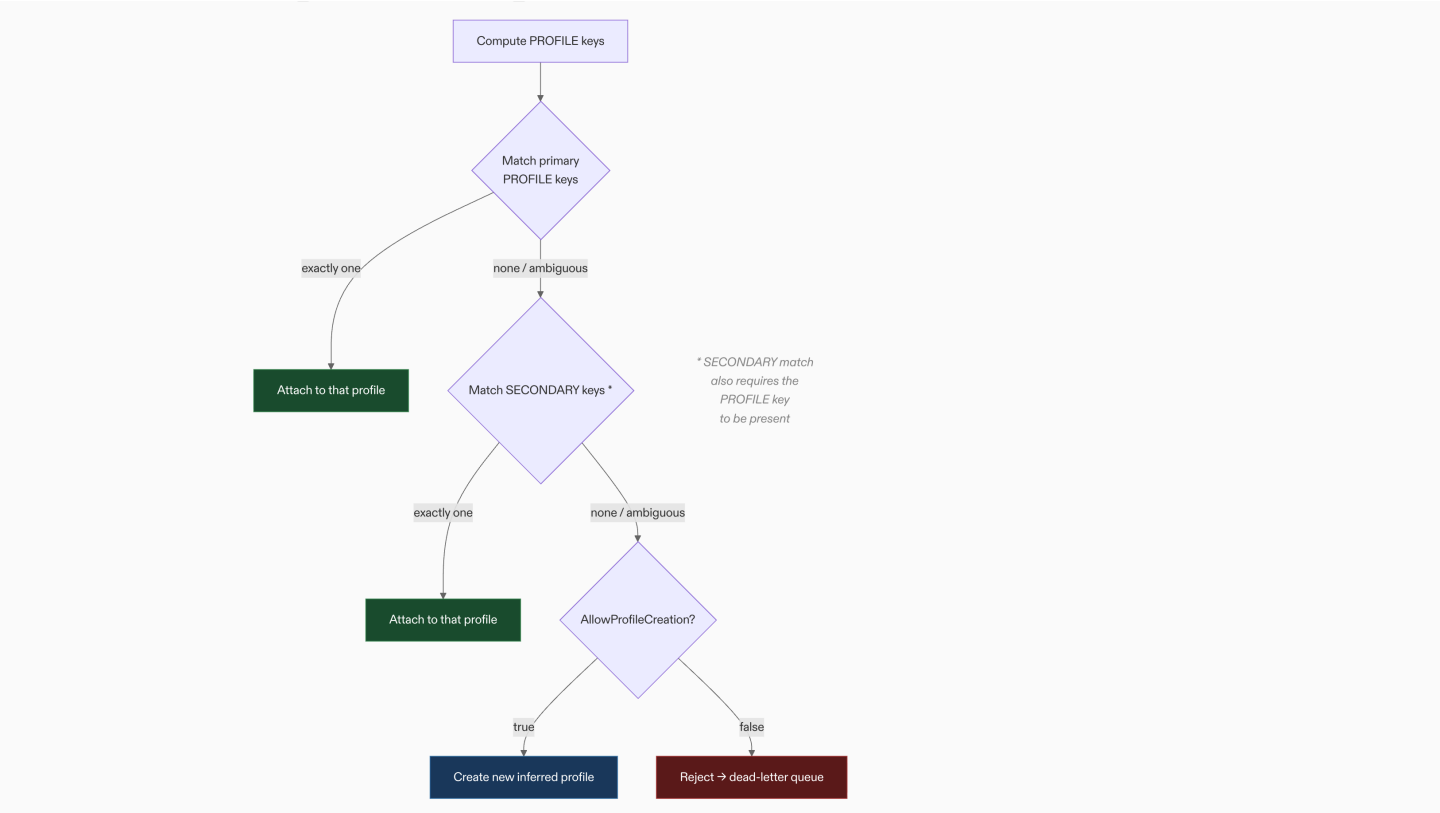
1. **Field extraction**: Customer Profiles reads each field's `Source` expression from the object type mapping and pulls the corresponding value out of the incoming JSON. Fields that define a `Target` are written to the standard object the target points to—the standard `_profile`, or another standard object such as `_asset`, `_order`, or `_loyalty`. For most fields, the `Source` is a JSON accessor (for example, `_source.FirstName`); advanced cases can use Handlebars to combine or transform values. For more information, see Field definitions in Customer Profiles object type mappings and Reference for standard objects in Customer Profiles.
2. **Key computation**: For each key defined in the mapping, Customer Profiles combines the referenced field values and normalizes them according to each field's `ContentType` (for example, phone numbers and email addresses are normalized so different formats match). This produces a comparable value for each key, categorized by its standard identifier role—`UNIQUE`, `PROFILE`, `SECONDARY`, and so on. For more information, see Standard identifiers in Customer Profiles.

3. **Profile resolution**: Customer Profiles uses the computed key values to decide which profile the object belongs to, following the decision tree below.

Profile resolution decision tree

Customer Profiles resolves the target profile in this order:

1. Evaluate each primary `PROFILE` key against the domain's existing keys:
   - If exactly one profile matches, the object is attached to that profile.
   - If more than one profile matches, the match is **ambiguous**—that key is discarded and the next key is tried.
   - If no profile matches, the next `PROFILE` key is tried.
2. If no primary `PROFILE` key produces an unambiguous match, repeat the evaluation with any secondary keys—keys whose standard identifiers include both `PROFILE` and `SECONDARY`.
3. If no key—primary or secondary—produces a single match, the outcome depends on the object type's `AllowProfileCreation` setting:
   - `AllowProfileCreation = true`: a new inferred profile is created and the object is attached to it.
   - `AllowProfileCreation = false`: the object is rejected and sent to the domain dead-letter queue.



> **Note**
>
> An *ambiguous* match (a key value that points to more than one profile) is never used to attach an object. This prevents a common value—such as a shared email address—from silently writing to unrelated profiles. For more information, see Profile matching and inferred profiles in Customer Profiles.

What happens after a profile is resolved

- The source object is stored as a profile object on the resolved profile. This profile object is identified by its `UNIQUE` key—re-ingesting an object with the same `UNIQUE` value replaces the previous profile object wholesale.
- Field values that define a `Target` are written to the corresponding standard object (the standard profile, or a non-profile standard object such as `_asset`, `_order`, or `_loyalty`). Standard objects are not replaced wholesale—each ingestion contributes only the fields it carries, and many profile objects can write to the same standard object over time.

- Targets that were set manually by an agent or by the UpdateProfile API aren't overwritten by ingestion by default. To let an ingested value take precedence over a manual update, configure `SourcePriority` on the object type. When several sources write to the same standard field, `SourcePriority` determines which value wins. For more information, see Merging behavior and source priority.
- All `PROFILE` and `SECONDARY` keys are stored so the profile can be found by those values later. `LOOKUP_ONLY` keys are not stored.

> **Note**
>
> **Wholesale replace compared with incremental update**
> A *profile object* (what you ingested) is replaced wholesale by the next object with the same `UNIQUE` key. A *standard object* (such as `_profile`, `_asset`, or `_order`) accumulates: it keeps fields previously written and updates only the fields the new object provides. This is why the same asset can be enriched over time by data from multiple object types.

For details on the merge and overwrite rules, see Profile matching and inferred profiles in Customer Profiles.

Object type mapping terminology and concepts

The following terms are central to understanding object type mapping in Connect Customer Customer Profiles. Each term links to the topic where it's covered in depth.

Domain

A *domain* is the top-level container for your unified customer data. Each domain belongs to a single AWS account and holds its own profiles, object types, keys, encryption settings, and retention configuration. You must create a domain before you can create object types or ingest data. All object types and keys you define are scoped to that domain.

Profile

A *profile* contains all the information known about a specific customer or contact. Each profile includes a single standard profile object and any number of additional profile objects.

Standard profile object

A *standard profile object* is a predefined object that every profile contains. It holds standard fields such as `FirstName`, `LastName`, `PhoneNumber`, `EmailAddress`, `ShippingAddress`, and custom `Attributes`. Because the format is fixed, applications can read profile data the same way regardless of the original source (for example, Salesforce, ServiceNow, or Marketo).

Standard object

A *standard object* is a predefined record with a fixed schema that Customer Profiles maintains alongside (or as part of) a profile. The standard profile object is one example; other standard objects represent business entities like assets, orders, cases, loyalty memberships, and travel records. Field `Target` values write into a standard object—for example, `_asset.SerialNumber` or `_case.Reason`. For more information, see Reference for standard objects in Customer Profiles.

Profile object

A *profile object* is a single unit of source data attached to a profile—for example, a phone call, a support ticket, or a click-stream record. A profile object can be up to 250 KB and can be any structured JSON document. Profile objects are what you ingest with PutProfileObject.

- Every profile object has a type, such as an Connect Customer contact record, a ServiceNow user, or a Marketo lead.
- The type refers to an object type mapping.
- The object type mapping defines how that object is ingested into Customer Profiles.
- A profile object is identified by its `UNIQUE` key. Re-ingesting an object with the same `UNIQUE` value replaces the previous profile object wholesale.

Object type mapping

An *object type mapping* tells Customer Profiles how to ingest a specific type of data: how source values populate the standard profile object and standard objects, and which fields are indexed and used to assign objects to a profile. For more information, see Field definitions in Customer Profiles object type mappings and Key definitions in Customer Profiles object type mappings.

Field

A *field* defines a single piece of data extracted from a source object. Each field specifies a **source** (where to read the value), an optional **target** (where to write it in the standard profile object), and a **content type** (how to normalize it for search and matching). For more information, see Field definitions in Customer Profiles object type mappings.

Key

A *key* is a named combination of one or more fields used to find profiles or objects. Keys are global to a domain, so the same key name in two object type mappings refers to the same logical identifier. Keys drive profile matching during ingestion and power lookups with the SearchProfiles API. For more information, see Key definitions in Customer Profiles object type mappings.

Standard identifier

A *standard identifier* is a tag applied to a key that defines its role during ingestion—for example, `UNIQUE` (identifies the object instance), `PROFILE` (used to match a profile), or `LOOKUP_ONLY` (used to match but not stored). For the full list and combination rules, see Standard identifiers in Customer Profiles.

Content type

A *content type* tells Customer Profiles how to normalize a field value so searches and matches work across formats. Supported values are `STRING`, `NUMBER`, `PHONE_NUMBER`, `EMAIL_ADDRESS`, and `NAME`. For example, a `PHONE_NUMBER` field is normalized so `+12065550100` matches `(206) 555-0100`.

Inferred profile

An *inferred profile* is a profile that Customer Profiles creates automatically when an ingested object can't be matched to any existing profile. Its standard profile object starts mostly empty—only fields Customer Profiles can populate from the ingested object (such as phone or email) are filled in. For more information, see Profile matching and inferred profiles in Customer Profiles.

Mapping template

A *mapping template* is a predefined object type mapping that ships with Customer Profiles for well-known source objects, such as Connect Customer contact records, Salesforce accounts, ServiceNow users, and Marketo leads. Templates let you ingest data from these sources without defining fields or keys yourself. For the complete list, use the ListProfileObjectTypeTemplates API. For more information, see Mapping templates and implicit object types in Customer Profiles.

Create an object type mapping in Connect Customer Customer Profiles

An object type mapping tells Customer Profiles how to ingest a specific type of data from a source application—such as Salesforce, Zendesk, or Amazon S3—into a unified standard profile object. You can then display that data (for example, customer address and email) to your agents using the Connect Customer agent workspace.

There are two ways to create an object type mapping:

- **Connect Customer console**: a no-code experience. See Create an object type mapping in the Connect Customer console.
- **Customer Profiles API**: use PutProfileObjectType. For the JSON model, see Field definitions in Customer Profiles object type mappings and Key definitions in Customer Profiles object type mappings.

The topics in this section describe how to create a mapping in the console, generate one with generative AI, and update and validate a mapping over time.

Topics

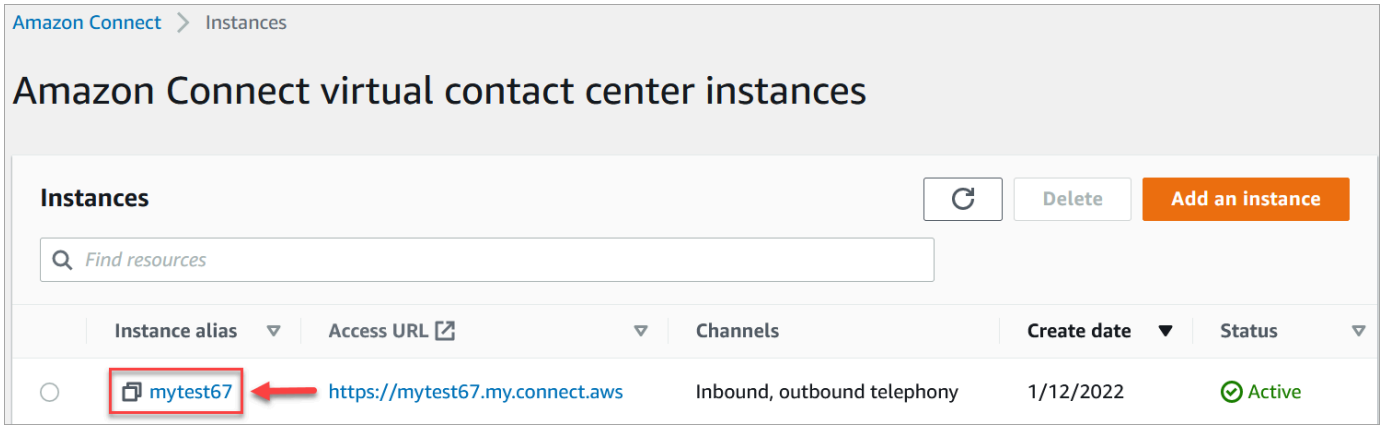
- Create an object type mapping in the Connect Customer console
- Generate a mapping with generative AI in Customer Profiles
- Update and validate an object type mapping in Customer Profiles

Create an object type mapping in the Connect Customer console

The console provides a no-code experience for mapping data from your own and third-party applications with Amazon S3, Salesforce, ServiceNow, Zendesk, and Marketo.

Step 1: Set up data mapping

1. Open the Connect Customer console at https://console.aws.amazon.com/connect/.
2. On the instances page, choose the instance alias. The instance alias is also your **instance name**, which appears in your Connect Customer URL. The following image shows the **Connect Customer virtual contact center instances** page, with a box around the instance alias.



3. In the navigation pane, choose **Customer profiles**, **Data mappings**.
4. Choose **Create data mapping**.
5. On the **Set up data mapping** page, in the **Description** section, add a name that helps you identify the source or purpose of this mapping. This becomes the object type's metadata.
6. In the **Data source** section:
   a. Choose where the data is coming from, such as Salesforce or Zendesk. Connect Customer automatically selects the available destinations based on the predefined template.
   b. Choose the source object used to build your unified profile.
   c. In the **Mapping destination** section, choose the data you want to use to build your unified profile. This information can be shown to your flows and agents to personalize contact interactions.
   d. In the **Additional options** section, choose whether to opt out of creating new profiles and how long to retain data.

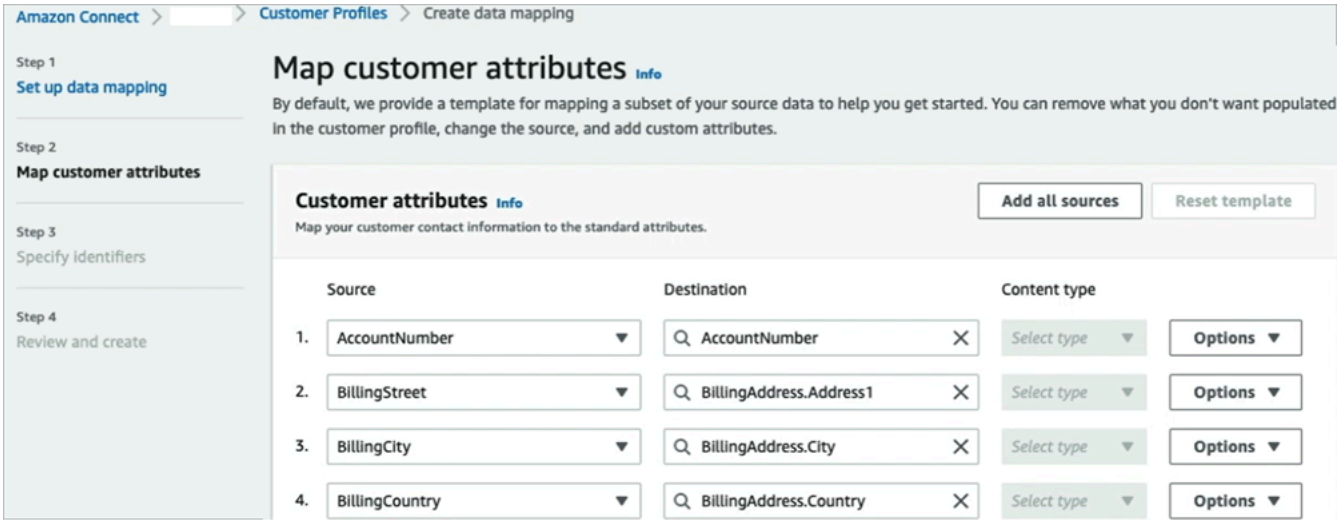
> **Note**
>
> By default, the domain retention period is 366 days. If a profile receives no writes for that period, it expires. Reads don't reset the timer—only write operations (such as ingesting a new profile object or calling UpdateProfile) do.
> To change the retention period, use the UpdateDomain API. To retain expired profiles for long-term storage, enable the Data store feature on the domain.

7. If you chose a source other than S3, in the **Establish a connection** section, choose an existing Amazon AppFlow or Amazon EventBridge connection, or create a new one.
8. Choose **Next**.

Step 2: Map attributes

On the **Map *type* attributes** page, the field mappings table is prefilled from the predefined template based on your mapping destination (for example, customer, product, case, or order attributes). You can change a mapping by choosing an attribute (such as `AccountNumber`) and selecting a different destination, or by entering a custom attribute.

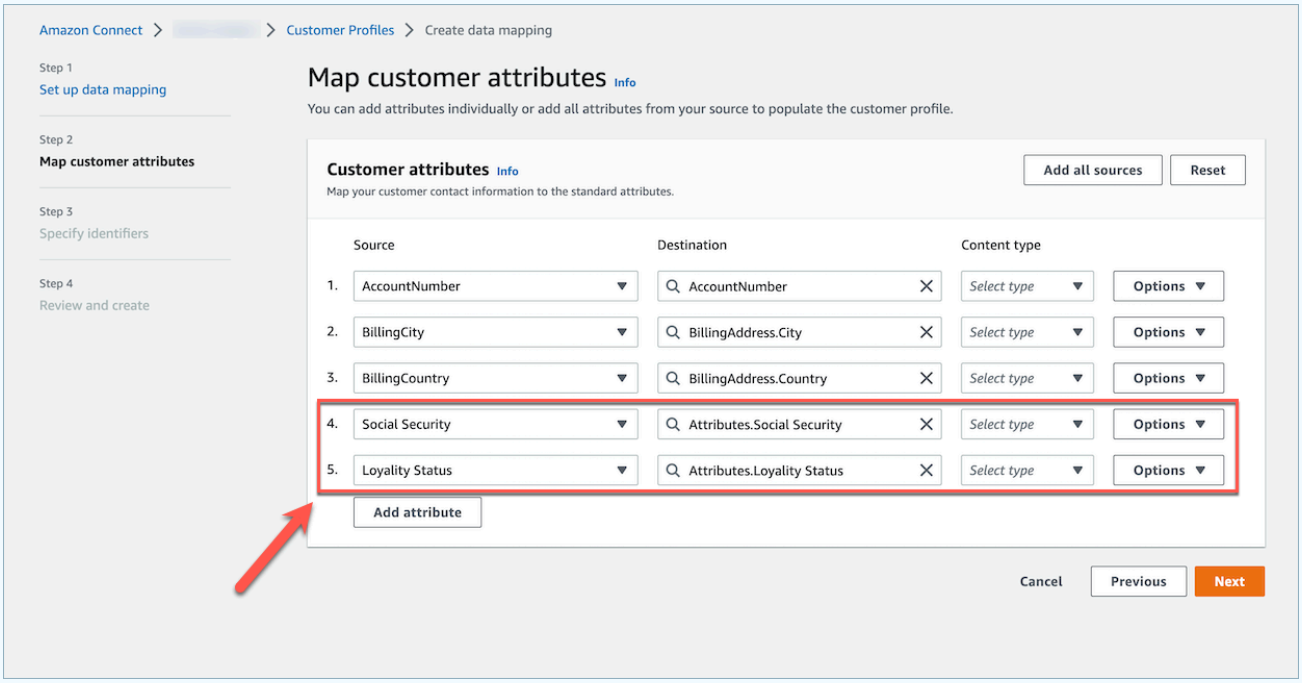
The following image shows an example of the page filled with customer attributes from the template.



You can remove what you don't want populated in the profile, change the source, and add custom attributes. This mapping uses your data source to populate profile contact information, such as a phone number, using attributes from the standard profile template.

Tip

- Custom attributes always have the prefix `Attributes.` added to the destination so Customer Profiles recognizes them as custom.



- Agents view custom attributes in the Connect Customer agent workspace under the **Additional Information** tab. Custom attribute names support the following format: `/^Attributes\.[a-zA-Z0-9]+(?:[ _\-]+[a-zA-Z0-9]+)*$/`
- All ingested custom attributes are displayed to agents. If you don't want certain information shown, don't ingest it as a custom attribute.

Step 3: Specify identifiers

On the **Specify identifiers** page, complete the following sections. Depending on the data you're mapping, not all of these appear.

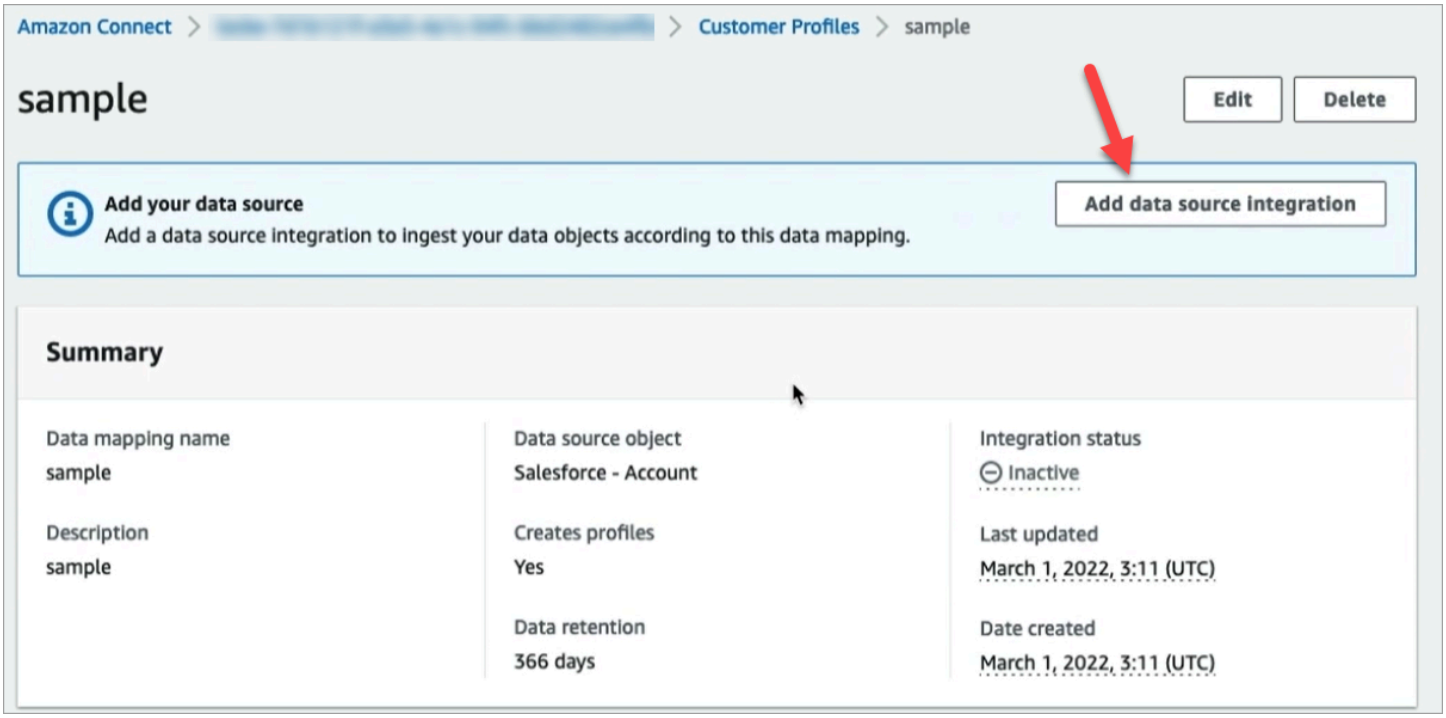
> **Note**
>
> The names `_profileId`, `_orderId`, `_caseId`, and `_assetId` are reserved for internal use. If you use these names as identifiers, they must be declared as `LOOKUP_ONLY`, which means Customer Profiles doesn't save them for matching or searching. To make these keys usable for searching and matching, rename them. For more information, see Standard identifiers in Customer Profiles.

- **Unique identifier**: Required. Also known as the unique key. Customer Profiles uses it to distinguish this object from other source objects and to index it for search and updates. There can be only one.
- **Customer identifier**: At least one is required. Also known as the profile key. Customer Profiles uses it to associate the object with an existing profile or to create a new one. You can have multiple.
- **Product identifier**: Required when mapping product data. Also known as the asset key.
- **Case identifier**: Required when mapping case data. Also known as the case key.
- **Order identifier**: Required when mapping order data. Also known as the order key.
- **Additional search attributes (optional)**: Other attributes you want to index for search. By default, all identifiers are indexed.
- **Data object timestamp**: Used to resolve profile conflicts when Identity Resolution is enabled for consolidating similar profiles.

> **Tip**
>
> If your search attributes mostly contain the same value, ingestion can be slower. Create search attributes that are unique in your source objects.

Step 4: Review and create

Review your mapping, then create it. After the mapping is created, choose **Add data source integration** to start ingesting data against this object type.



For what to do when you need to change a mapping later, see Update and validate an object type mapping in Customer Profiles.

Generate a mapping with generative AI in Customer Profiles

With the generative AI-powered data mapping capability in Connect Customer Customer Profiles, you can reduce the time needed to create unified profiles and deliver more personalized customer experiences.

When you add customer data from any of the more than 70 available no-code data connectors—such as Adobe Analytics, Salesforce, or Amazon S3—Customer Profiles analyzes the source data and automatically determines how to organize and combine data from disparate sources into unified profiles. You can review and complete the setup before ingestion begins.

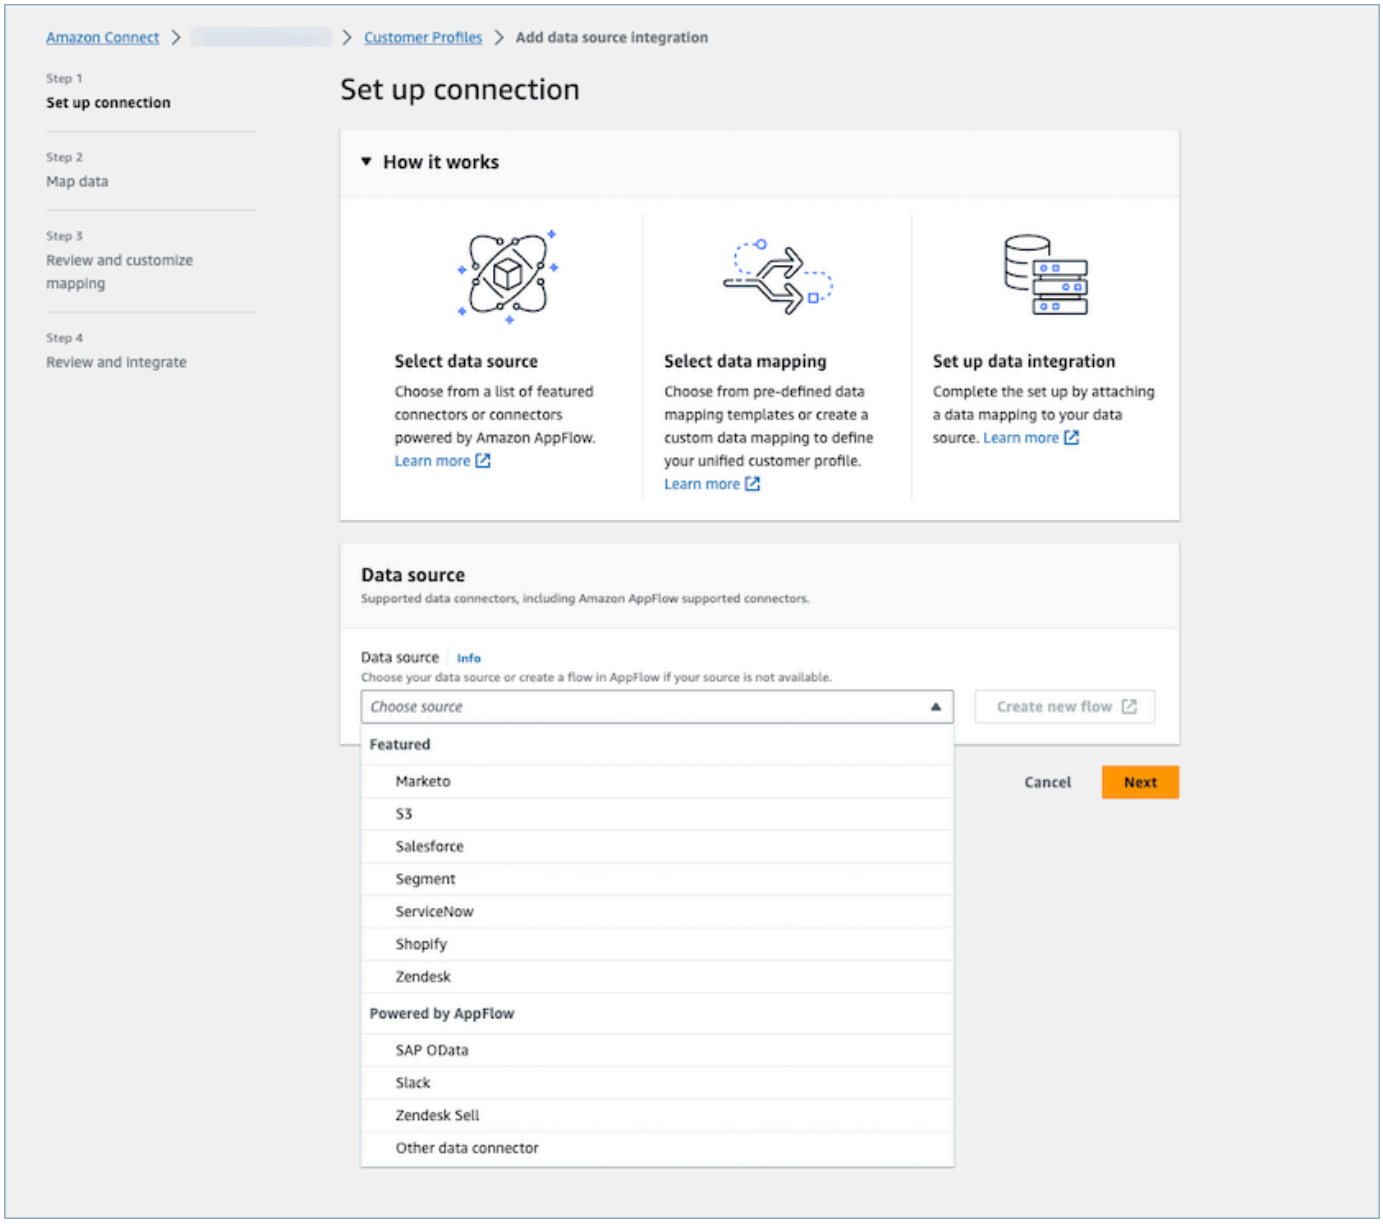
Generative AI powered customer data mapping is available in the following regions:

- US East (N. Virginia)
- US West (Oregon)
- Africa (Cape Town)
- Asia Pacific (Singapore)
- Asia Pacific (Sydney)

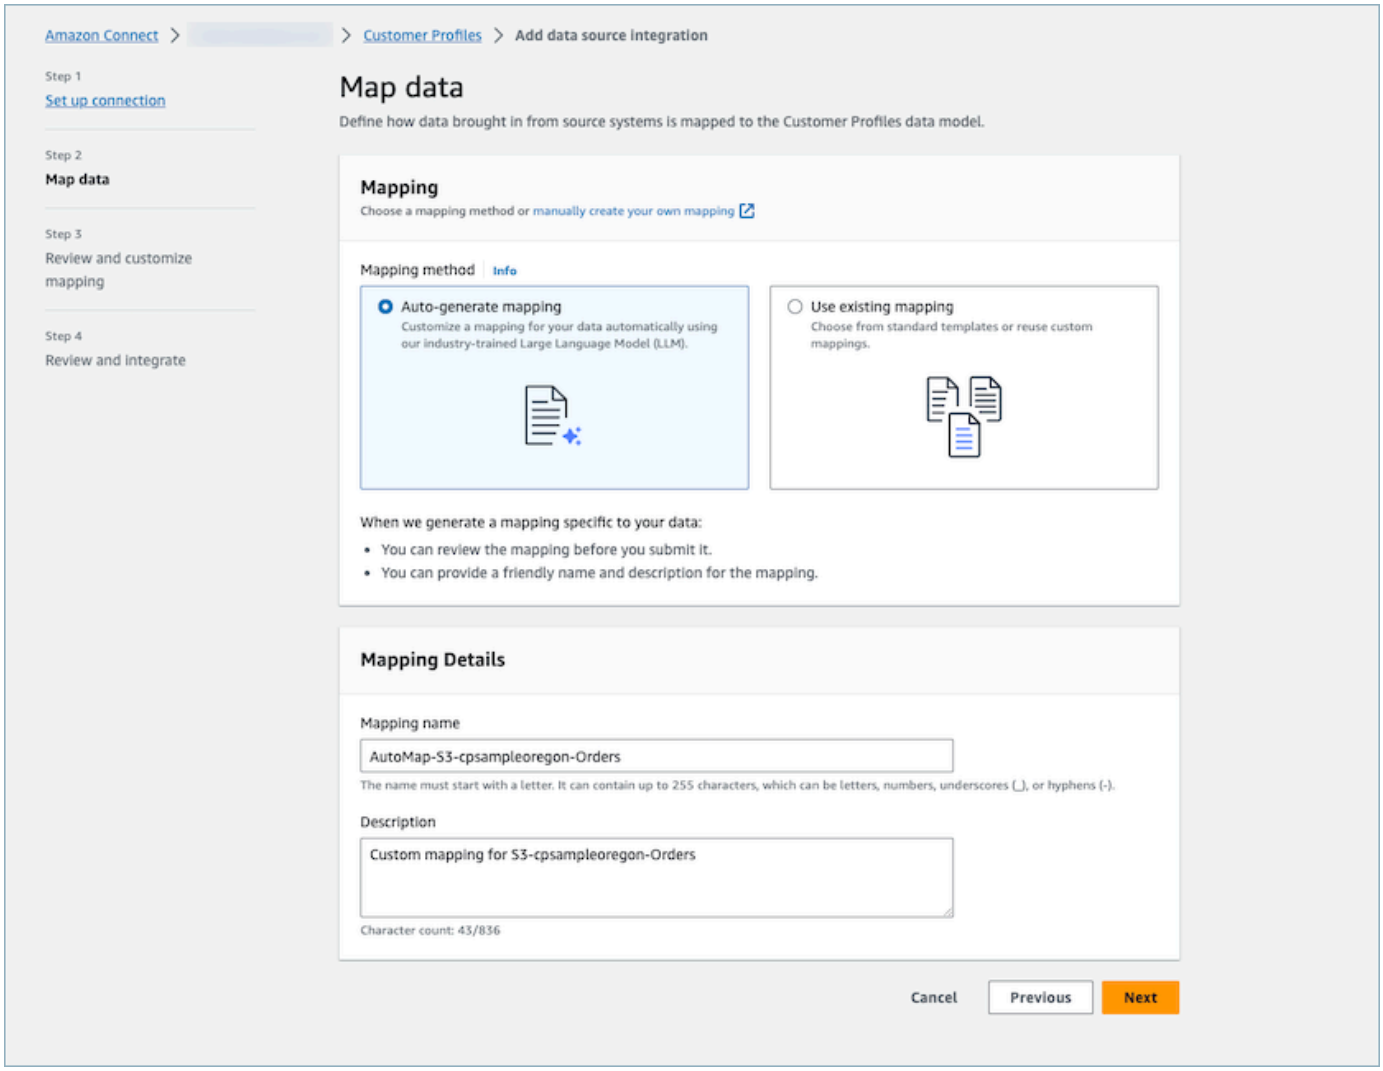
- Asia Pacific (Tokyo)
- Asia Pacific (Seoul)
- Canada (Central)
- Europe (Frankfurt)
- Europe (London)

Set up generative AI-powered data mapping

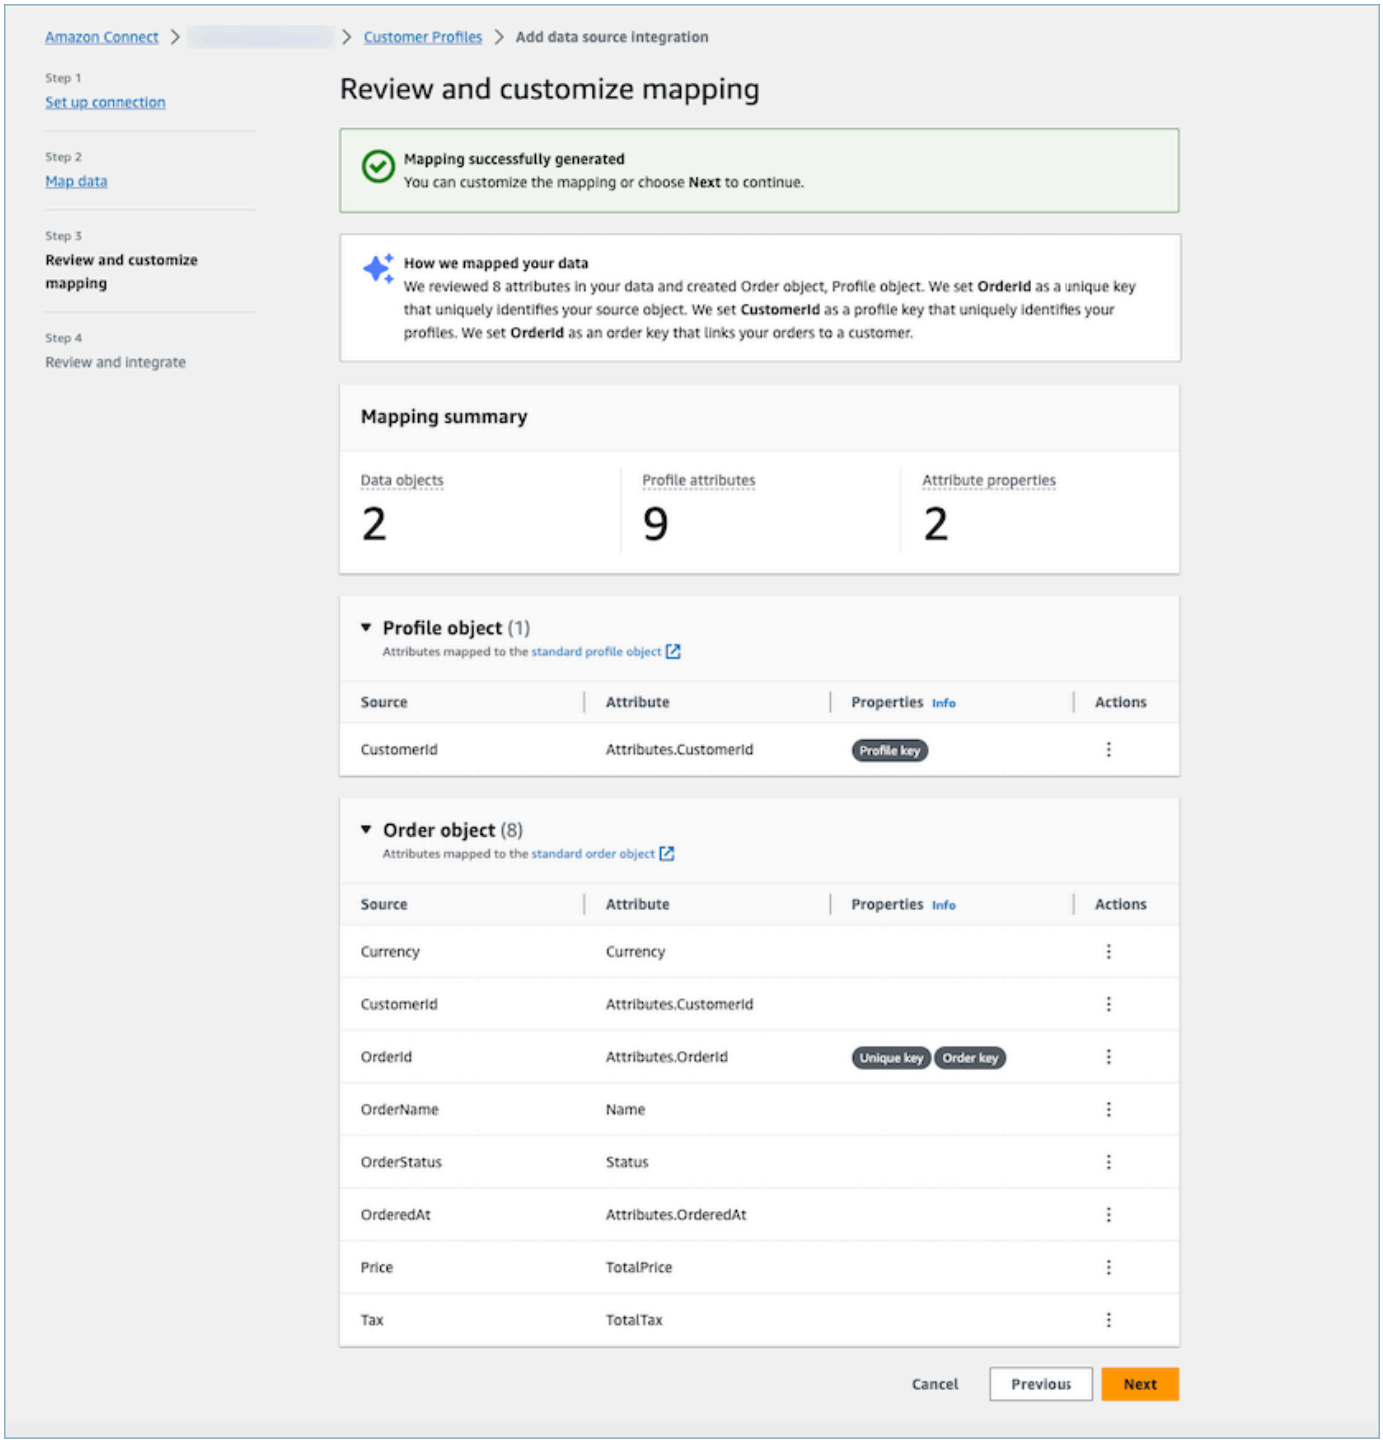
1. Open the Connect Customer Customer Profiles console.
2. On the **Data source integrations** tab, choose **Add data source integration**.
3. Set up the connection. Select the data source from the drop-down list of supported connectors.



4. Map data. Choose to auto-generate the data mapping, select an existing mapping template, or create one from scratch.



5. Review the mapping summary. The auto-generated summary shows all customer attributes. Make edits to ingestion keys and confirm before starting data ingestion. For details on fields and keys, see Field definitions in Customer Profiles object type mappings and Key definitions in Customer Profiles object type mappings.



How it works

Generation runs in four phases:

1. Customer Profiles fetches source attributes and, if available, sample data from your data source, then determines the most appropriate target object type. For an Amazon S3 source, the first CSV

file found in the selected bucket and prefix is used as sample data. For other sources, attributes are fetched through AppFlow.

2. A large language model (LLM) processes each custom attribute and maps it to a standard customer profile attribute.
3. The LLM selects suitable attributes to serve as keys, such as customer identifiers.
4. A timestamp format detector parses timestamps to maintain the correct chronological order of records.

> **Note**
>
> Generative AI produces a starting point that you review and confirm before any data is ingested. Always check the suggested keys—especially the unique and profile keys—against your understanding of the source data. If generation can't produce a valid mapping, fall back to manual mapping in the console.

For errors and warnings you might see during generation, see Troubleshoot object type mappings in Customer Profiles.

Update and validate an object type mapping in Customer Profiles

This topic explains how object type mappings change over time and how Connect Customer Customer Profiles validates them, so you can update a mapping with confidence and avoid surprises in already-ingested data.

Upsert semantics

Object type creation uses upsert semantics: creating an object type whose name already exists updates the existing definition rather than failing. The same PutProfileObjectType API (and the console's data-mapping editor) is used for both creating and updating.

What happens to existing data when you update

> **Important**
>
> Updating a mapping doesn't automatically reprocess data that was previously ingested. A new or changed mapping applies only to objects ingested after the update.

Keep these behaviors in mind when updating:

- **Retention**: Changing `ExpirationDays` only affects newly ingested data. Existing objects keep the retention they were ingested with.
- **Tags**: Tags can't be changed through the update path. Use TagResource and UntagResource instead.
- **Encryption key**: After Data store is enabled on the domain, the encryption key for an existing object type can't be changed.
- **Unused keys**: If you remove a key reference and no other object type in the domain still references that key, Customer Profiles cleans up the unused domain key.
- **Key consistency**: If a key name already exists in the domain, the updated definition's field content types must match the existing definition.

Test a mapping before a full integration

To validate your mapping against real data safely, we recommend the following:

1. Create the object type mapping. Successful creation confirms the mapping is structurally valid.
2. Ingest a small batch of representative source objects with PutProfileObject.
3. Use SearchProfiles to confirm the objects landed on the expected profiles and that the standard profile fields were populated as intended.
4. Adjust the mapping and repeat before pointing a full integration at it.

Object type mapping rules in Connect Customer Customer Profiles

The topics in this section describe the rules and syntax for each part of an object type mapping: the field definitions that extract values from your source data, the key definitions and standard identifiers that match objects to profiles, complete examples that put the pieces together, and a reference for the standard objects that mappings populate.

Topics

- Field definitions in Customer Profiles object type mappings
- Key definitions in Customer Profiles object type mappings
- Standard identifiers in Customer Profiles
- Examples of object type mappings in Connect Customer Customer Profiles

- Reference for standard objects in Customer Profiles

Field definitions in Customer Profiles object type mappings

An object type mapping has two parts: field definitions and key definitions. This topic covers field definitions. For keys, see Key definitions in Customer Profiles object type mappings.

A field defines a single piece of data extracted from a source object. Each field specifies a source, an optional target, and a content type:

```
"Fields": {
    "{fieldName}": {
        "Source": "{source}",
        "Target": "{target}",
        "ContentType": "{contentType}"
    }, ...
}, ...
```

> **Tip**
>
> To learn how to build a mapping end to end, see this blog post: Unify and organize customer information with Connect Customer Customer Profiles with the pre-built Amazon S3 connector.

Source

The `Source` tells Customer Profiles where to read the field's value from the incoming object. Customer Profiles parses the source object as `_source`, so all source paths must be prefaced by this name. Only the `_source` object is supported.

Most fields use a simple JSON accessor:

```
"FirstName": {
    "Source": "_source.FirstName",
    "Target": "_profile.FirstName",
    "ContentType": "STRING"
}
```

Nested paths work the same way—for example, `_source.Address.City`. JSON accessors cover the majority of mapping use cases.

Advanced: Handlebars expressions

The `Source` field also accepts Handlebars expressions, written between double curly braces. Use Handlebars when you need to:

- Combine multiple source fields into one value (for example, building a key from email and timestamp).
- Insert a constant or apply conditional logic.
- Iterate over an array in the source.

Supported expressions:

- **Variable interpolation**: `{{_source.FirstName}}`
- **Nested paths**: `{{_source.Address.City}}`
- **String concatenation**: `{{_source.FirstName}} {{_source.LastName}}`
- **Conditional rendering**: `{{#if _source.MiddleName}}...{{/if}}`
- **Iteration**: `{{#each _source.items}}...{{/each}}`
- **Inverse conditional**: `{{#unless _source.OptOut}}...{{/unless}}`
- **Context switching**: `{{#with _source.Address}}...{{/with}}`
- **`removeExtraSpace` block helper**: collapses extra whitespace when some inputs might be missing. For example, `{{#removeExtraSpace}}{{_source.FirstName}} {{_source.MiddleName}} {{_source.LastName}}{{/removeExtraSpace}}` produces a clean full name even when `MiddleName` is empty.

> **Note**
>
> A `Source` with invalid Handlebars syntax is rejected when the object type is created. If a source path doesn't exist in an incoming object at ingestion time, the field's value is treated as empty. If every field that makes up a `UNIQUE` or `PROFILE` key is empty, the object is rejected. For more information, see Troubleshoot object type mappings in Customer Profiles.

Target

The `Target` specifies which **standard object** the field's value writes to (for example, `_profile.FirstName` or `_asset.SerialNumber`). Standard objects are predefined records with fixed schemas, so applications built on Customer Profiles can read your data without needing to know its original format. For more information, see Reference for standard objects in Customer Profiles.

Fields targeting a standard object don't replace that standard object wholesale—each ingestion updates only the fields it carries. Many profile objects (across one or more object types) can contribute to the same standard object over time. The profile object itself, however, is identified by its `UNIQUE` key and is replaced wholesale on re-ingestion.

`Target` is optional. You might define fields solely for use inside a key. The format is always a JSON accessor.

Supported target object types

- `_profile` (the standard profile object)
- `_asset`, `_case`, `_order`, `_communicationRecord`
- `_airPreference`, `_hotelPreference`, `_airBooking`, `_airSegment`, `_hotelReservation`, `_hotelStayRevenue`
- `_loyalty`, `_loyaltyTransaction`, `_loyaltyPromotion`
- `_device`, `_webAnalytics`

Common _profile targets

- `_profile.FirstName`, `_profile.LastName`
- `_profile.PhoneNumber`, `_profile.EmailAddress`, `_profile.PersonalEmailAddress`
- `_profile.AccountNumber`
- `_profile.ShippingAddress.Address1`, `_profile.ShippingAddress.PostalCode`, `_profile.ShippingAddress.City` (the `MailingAddress` block follows the same pattern)
- `_profile.Gender` or `_profile.GenderString` (mutually exclusive)
- `_profile.PartyType` or `_profile.PartyTypeString` (mutually exclusive)
- `_profile.SourceLastUpdatedTimestamp`

- `_profile.Attributes.{customName}` for custom attributes

Targets that are not allowed

The following targets are reserved for system use and can't be specified as a field target:

- Any standard object ID, such as `_profile.ProfileId`, `_asset.AssetId`, `_case.CaseId`, `_order.OrderId`, `_communicationRecord.CommunicationRecordId`, and the equivalent ID field on every other standard object type.
- `_profile.ImportIds`
- `_profile.FoundByItems[]`

> **Note**
>
> You can't map fields to both `_profile.PartyType` and `_profile.PartyTypeString`, or to both `_profile.Gender` and `_profile.GenderString`. Choose one of each pair.

ContentType

The supported values are `STRING`, `NUMBER`, `PHONE_NUMBER`, `EMAIL_ADDRESS`, and `NAME`. If no `ContentType` is specified, `STRING` is assumed.

`ContentType` determines how the value is normalized for indexing and matching. For example, when `ContentType` is `PHONE_NUMBER`, agents can search in any format—`+12065550100` matches `(206) 555-0100`. When `ContentType` is `EMAIL_ADDRESS`, matches are case-insensitive.

A `ContentType` on its own doesn't write anything to the standard profile—only a `Target` does. The one exception is inferred profile creation, where `EMAIL_ADDRESS` and `PHONE_NUMBER` values populate the new profile automatically. For more information, see Profile matching and inferred profiles in Customer Profiles.

Field naming and structural rules

- Field names must start with a letter and contain only letters, digits, underscores, dots, or hyphens.
- `Tags` and `tags` can't be used as field names.

- An object type can define up to 250 fields. For more information, see Quotas and data limits in Customer Profiles.
- If any field targets `_profile.SourceLastUpdatedTimestamp`, you must also provide `SourceLastUpdatedTimestampFormat`—either the literal `EpochMilli` or a valid `SimpleDateFormat` pattern. Only that exact target requires the format; targeting another standard object's `SourceLastUpdatedTimestamp` does not.

Key definitions in Customer Profiles object type mappings

A key contains one or more fields that together form an identifier you can use to search for objects (or the profiles they belong to) with the SearchProfiles API. A key can also be defined to uniquely identify a profile or the object itself. For field definitions, see Field definitions in Customer Profiles object type mappings.

```
"Keys": {
    "{keyName}": [{
        "StandardIdentifiers": [...],
        "FieldNames": [ "{fieldName}", ...]
    }], ...
}, ...
```

How keys are used

Key definitions are used in two ways:

- **During ingestion**: Customer Profiles uses keys to decide which profile an object attaches to, or whether to create a new profile. For more information, see How object type mapping works in Customer Profiles.
- **After ingestion**: you can use keys with the SearchProfiles API to find a profile by value.

Key names are global to a domain

If you have two keys with the same name in two different object type mappings:

- They share the same namespace.
- They can link profiles together across object types. If they match between objects, Customer Profiles places the two objects in the same profile.

The rule for naming keys: use the **same key name** across object types only when matching values mean the objects belong to the same profile. Use **different key names** when matching values are coincidental.

Two examples:

- **Same name.** A phone number on a Salesforce contact and the same phone number on a ServiceNow user identify the same person, so name both keys _phone. Customer Profiles places both objects on the same profile.
- **Different names.** A Salesforce internal record ID and a Marketo internal record ID happen to be numbers, but a match is coincidental—the records aren't related. Give them different key names (for example, `salesforceId` and `marketoId`) so Customer Profiles doesn't merge unrelated profiles.

Multiple definitions for one key name

The value of a key is an array of definitions, so the same key name can have more than one entry, each with its own `FieldNames` and `StandardIdentifiers`. Multiple definitions are useful when you want the same logical key to be populated from different field combinations or behave differently in different scenarios.

> **Note**
>
> Each entry in a key's array counts toward your account's per-object-type key limit. For more information, see Quotas and data limits in Customer Profiles.

Default search keys

Default search keys, such as _phone and `_email`, are predefined by the Standard Profile, Standard Asset, Standard Order, and Standard Case object templates. You can use them as a key name with the SearchProfiles API to find a profile.

Key naming and structural rules

- Key names must start with a letter (same character set as field names) *or* start with an underscore for predefined system keys.
- Underscore-prefixed key names must already be defined as a domain key (for example, _phone, `_email`).

- `Tags` and `tags` can't be used as key names.
- Each key must reference at least one field, and every referenced field must be defined in the same object type.
- If a key name already exists in the domain, the new definition's field content types must match the existing definition.
- Each object type must have exactly one key with a `UNIQUE` identifier and at least one key with a `PROFILE` identifier. For more information, see Standard identifiers in Customer Profiles.

Standard identifiers in Customer Profiles

Standard identifiers are tags applied to a key that describe its role during ingestion. They tell Customer Profiles how each key participates in matching an object to a profile and whether the key value is stored for future use. You set standard identifiers in the `StandardIdentifiers` array of a key definition. For more information, see Key definitions in Customer Profiles object type mappings.

Standard identifiers reference

Identifier	Purpose
`UNIQUE`	Identifies the specific object instance. Exactly one `UNIQUE` identifier is required per object type. When a new object arrives with the same `UNIQUE` value, it replaces the existing one.
`PROFILE`	Used to look up the profile the object belongs to. At least one `PROFILE` identifier is required. The key is stored so it can also be used for future matching and for `SearchProfiles` queries.
`SECONDARY`	A fallback profile-matching key. `SECONDARY` is always used in combination with `PROFILE`—the key's standard identifiers must include both. Secondary keys are only consulted when no primary `PROFILE` key produces an unambiguous match. The key is always stored.

Identifier	Purpose
LOOKUP_ONLY	Used only to match a profile during this ingestion. The key value is not stored afterward, so it can't be used for future matches or searches. Can't be combined with UNIQUE.
NEW_ONLY	The key is stored only when a new profile is created during this ingestion. If the object matches an existing profile, the key behaves like LOOKUP_ONLY . Can't be combined with UNIQUE.
ASSET, ORDER, CASE	Associates the object with a standard asset, order, or case record.
AIR_PREFERENCE , HOTEL_PREFERENCE , AIR_BOOKING , AIR_SEGMENT , HOTEL_RESERVATION , HOTEL_STAY_REVENUE	Associates the object with the corresponding travel record.
LOYALTY, LOYALTY_TRANSACTION , LOYALTY_PROMOTION	Associates the object with a loyalty record, transaction, or promotion.
DEVICE	Associates the object with a device record.
WEB_ANALYTICS	Associates the object with a web analytics event.
CONTACT	Associates the object with a standard contact record. During ingestion, Customer Profiles looks for a contact record that has this key. If one is found, the object is assigned to it. If more than one is found, the match is rejected.

PROFILE, SECONDARY, and LOOKUP_ONLY compared

All three identify the profile an object belongs to. They differ in when they're evaluated during matching and whether the key value is stored afterward. SECONDARY is not used on its own—a secondary key lists both PROFILE and SECONDARY in its standard identifiers:

Aspect	PROFILE	SECONDARY	LOOKUP_ONLY
Required?	Yes—at least one per object type	No	No
When it's used for matching	In the primary matching pass	Only as a fallback when primary PROFILE keys don't match	In the primary matching pass, alongside PROFILE keys
Stored after ingestion ?	Yes	Yes	No
Available for future lookups and SearchProfiles ?	Yes	Yes	No
Best for	Durable identifiers that reliably locate the profile, such as a customer ID	Lower-priority identifiers that you still want saved for future use	Transient identifiers you don't want permanently associated

NEW_ONLY behavior

NEW_ONLY scopes a key so it's only attached to profiles this ingestion creates:

- If the object matches an **existing** profile, the key is used for matching only and is not stored on that profile (same as LOOKUP_ONLY).
- If the object causes a **new** profile to be created, the key is stored on the new profile (same as PROFILE).

Use NEW_ONLY when you want a value to help create and identify a new profile, but you don't want it added to an existing profile—where it could accidentally cause unrelated profiles to merge.

Combination rules

- UNIQUE can't be combined with LOOKUP_ONLY or NEW_ONLY.

- If any key combines `PROFILE` with `LOOKUP_ONLY` or `NEW_ONLY`, at least one other key must use `PROFILE` on its own (without `LOOKUP_ONLY` or `NEW_ONLY`). This guarantees an ingested object can always be persistently associated with a profile. The `_profileId` key is exempt from this requirement.
- Standard object identifiers (`ASSET`, `ORDER`, and so on) can be combined with `PROFILE` and `UNIQUE` as needed.
- If your fields target a standard object type—for example, `_asset.SerialNumber`—at least one key must carry that object type's standard identifier (`ASSET`).
- Reserved keys such as `_profileId`, `_orderId`, `_caseId`, and `_assetId` must be declared `LOOKUP_ONLY`.

Required identifiers per object type

- Exactly one key with a `UNIQUE` identifier.
- At least one key with a `PROFILE` identifier.
- If fields target a standard object type, at least one key with that object type's standard identifier.

Examples of object type mappings in Connect Customer Customer Profiles

This topic builds a mapping from the ground up. Each example builds on the one before it.

Example	What it adds
1. The smallest valid mapping	The two required keys: `UNIQUE` and `PROFILE`
2. Populate the standard profile	`Target`, `ContentType` , search-only keys
3. Populate a standard object	Standard object identifiers and targets (`ASSET`, `_asset.*`)
4. Link two object types together	Shared key names, one key serving two roles

The shape of a mapping

Every mapping is a set of `Fields` and a set of `Keys`. Fields pull values out of the incoming object. Keys combine fields into identifiers that Customer Profiles uses to match and search.

```
{
    "Fields": {
        "{fieldName}": {                    <-- your name for this value
            "Source": "{source}",           <-- where to read it from the incoming
 object
            "Target": "{target}",           <-- optional: where to write it on a
 standard object
            "ContentType": "{contentType}"  <-- optional: how to normalize it (default
 STRING)
        }
    },
    "Keys": {
        "{keyName}": [                      <-- an array, so one key name can have
 several definitions
            {
                "StandardIdentifiers": [...],  <-- optional: the key's role during
 ingestion
                "FieldNames": ["{fieldName}"]  <-- one or more fields defined above
            }
        ]
    }
}
```

Note

Fields and keys are separate namespaces
A field name is a local label used only inside this mapping. A key name is global to the domain and shared with every other object type that uses the same name. The examples below use different names for the two so the distinction stays visible.

How to build a mapping

Work through these five questions in order. The answers become the mapping.

1. **What makes one incoming record distinct from the next?** That value becomes your `UNIQUE` key. Every object type needs exactly one. Re-ingesting a record with the same `UNIQUE` value replaces the previous one.
2. **What ties the record to a person?** A customer ID, email, phone, or account number. That becomes a `PROFILE` key. Every object type needs at least one.

3. **Which values do you want to appear on the customer's profile?** Give each one a field with a `Target` on the standard profile object, such as `_profile.FirstName`.
4. **Does the record also describe an asset, order, case, or similar record?** Those are other **standard objects**—predefined records with fixed schemas. If your record describes one, target it (`_asset.*`) and add its standard identifier (`ASSET`) to a key.
5. **Which other values do you want to be searchable?** Add a key for each, with no standard identifiers.

> **Note**
>
> **Profile objects and standard objects behave differently**
> The record you ingest is a *profile object*. It's identified by its `UNIQUE` key and is replaced wholesale when the same `UNIQUE` value arrives again. A `Target` writes into a *standard object* (the standard profile, an asset, an order). Standard objects are never replaced wholesale—they accumulate field values from many profile objects over time. For more information, see Reference for standard objects in Customer Profiles.

> **Note**
>
> **Every key is searchable**
> Matching is only half of what a key does. Each key is also indexed for the SearchProfiles API, so you can find a profile after ingestion by passing a key name and a value. Because key names are global to the domain, searching one name finds profiles across every object type that defines it. Only stored keys stay searchable—see Standard identifiers in Customer Profiles to control when keys are stored.

> **Tip**
>
> **Choose distinctive key values**
> Choose key values distinctive enough to identify a profile: a customer ID, an email address, an order number, a serial number. Low-cardinality values such as gender, state, country, status, or loyalty tier make poor keys—avoid them.

Example 1: The smallest valid mapping

A mapping needs one `UNIQUE` key and one `PROFILE` key. Nothing else is required. A single key can carry both roles.

Incoming object:

```
{
  "customerId": "C-10045",
  "signupDate": "2025-01-14"
}
```

Mapping:

```
{
    "Fields": {
        "customerId": {
            "Source": "_source.customerId"
        }
    },
    "Keys": {
        "crmCustomerId": [
            {
                "StandardIdentifiers": ["PROFILE", "UNIQUE"],
                "FieldNames": ["customerId"]
            }
        ]
    }
}
```

What happens at ingestion:

- Customer Profiles looks for a profile whose `crmCustomerId` key equals `C-10045`. If it finds exactly one, the record attaches to it. If it finds none and `AllowProfileCreation = true`, a new inferred profile is created.
- The whole incoming record is stored as a profile object, including `signupDate`—storage doesn't require a field definition. Only the values you want indexed or written to a standard object need fields.
- Nothing appears on the standard profile, because no field has a `Target`. Agents looking at the profile would see an empty record.

Example 2 addresses that last point.

Example 2: Populate the standard profile

Adding a `Target` to a field writes its value onto the standard profile, where agents and downstream applications can read it.

Incoming object:

```
{
  "customerId": "C-10045",
  "email": "john@example.com",
  "phone": "+12065550100",
  "firstName": "John",
  "lastName": "Doe",
  "address": {
    "street": "123 Main St",
    "city": "Seattle",
    "zip": "98101"
  }
}
```

Mapping:

```
{
    "Fields": {
        "customerId": {
            "Source": "_source.customerId",
            "Target": "_profile.AccountNumber"
        },
        "emailAddress": {
            "Source": "_source.email",
            "Target": "_profile.EmailAddress",
            "ContentType": "EMAIL_ADDRESS"
        },
        "phoneNumber": {
            "Source": "_source.phone",
            "Target": "_profile.PhoneNumber",
            "ContentType": "PHONE_NUMBER"
        },
        "firstName": {
            "Source": "_source.firstName",
            "Target": "_profile.FirstName",
```

```
            "ContentType": "NAME"
        },
        "lastName": {
            "Source": "_source.lastName",
            "Target": "_profile.LastName",
            "ContentType": "NAME"
        },
        "fullName": {
            "Source": "{{#removeExtraSpace}}{{_source.firstName}} {{_source.lastName}}
{{/removeExtraSpace}}",
            "ContentType": "NAME"
        },
        "mailingAddress.address1": {
            "Source": "_source.address.street",
            "Target": "_profile.MailingAddress.Address1"
        },
        "mailingAddress.city": {
            "Source": "_source.address.city",
            "Target": "_profile.MailingAddress.City"
        },
        "mailingAddress.postalCode": {
            "Source": "_source.address.zip",
            "Target": "_profile.MailingAddress.PostalCode"
        }
    },
    "Keys": {
        "crmCustomerId": [
            {
                "StandardIdentifiers": ["PROFILE", "UNIQUE"],
                "FieldNames": ["customerId"]
            }
        ],
        "_email": [
            {
                "FieldNames": ["emailAddress"]
            }
        ],
        "_phone": [
            {
                "FieldNames": ["phoneNumber"]
            }
        ],
        "_fullName": [
            {
```

```
                "FieldNames": ["fullName"]
            }
        ]
    }
}
```

What's new here:

- **`Target`**: each targeted field writes to the standard profile. Untargeted fields (`fullName`) still exist for use in keys.
- **`ContentType`**: normalizes the value before it's indexed and matched. `EMAIL_ADDRESS` and `NAME` are both case-insensitive, and `NAME` also collapses repeated spaces, so `John  SMITH` matches `john  smith`. `PHONE_NUMBER` ignores formatting, so `+1 (206) 555-0150` matches `2065550150`. Set it on every email, phone, name, and numeric field you index. Omit it and the value is treated as `STRING` and matched exactly as written.
- **Search-only keys**: `_email`, _phone, and `_fullName` have no `StandardIdentifiers`. They're indexed for `SearchProfiles` but take no part in matching this record to a profile. Only `crmCustomerId` does that.
- **Dotted field names**: `mailingAddress.city` mirrors the target path. This is a readability convention, not a requirement; field names allow letters, digits, underscores, dots, and hyphens.
- **Handlebars**: `fullName` combines two source values. `removeExtraSpace` collapses the gap if one part is missing. Most fields need only a plain accessor like `_source.email`; reach for Handlebars only when you're combining or transforming values. For more information, see Field definitions in Customer Profiles object type mappings.

Tip

Naming your keys

- Use the predefined domain keys as-is when the value means what they mean: `_email`, _phone, `_fullName`, `_account`.
- Give keys you invent a plain name with no leading underscore, such as `crmCustomerId`.
- `_profileId`, `_orderId`, `_caseId`, and `_assetId` are reserved. If you use them, they must be `LOOKUP_ONLY`, which means they aren't stored. Pick a different name if you want the value searchable.

Tip

Custom values

Every `Target` must name a field that actually exists on the standard object. For a value that does not map to a standard field, map it to a custom attribute instead: give it any name you like under `Attributes`, such as `_profile.Attributes.LoyaltyTier`. Other standard objects work the same way, as in `_asset.Attributes.InstallerName`. Check the standard object definition for the exact field names—see Reference for standard objects in Customer Profiles.

Example 3: Populate a standard object

When a record describes an asset, order, case, loyalty membership, or travel booking, you can route values into that standard object as well as the standard profile. This example ingests product registrations.

Incoming object:

```
{
  "customerEmail": "jane@example.com",
  "serialNumber": "SN-987654",
  "productName": "Examplecorp AC 2200",
  "sku": "AC-2200",
  "purchaseDate": "2025-03-12",
  "status": "ACTIVE",
  "price": 449.00
}
```

Mapping:

```
{
    "Fields": {
        "emailAddress": {
            "Source": "_source.customerEmail",
            "Target": "_profile.PersonalEmailAddress",
            "ContentType": "EMAIL_ADDRESS"
        },
        "assetName": {
            "Source": "_source.productName",
            "Target": "_asset.AssetName"
```

```
        },
        "serialNumber": {
            "Source": "_source.serialNumber",
            "Target": "_asset.SerialNumber"
        },
        "productSKU": {
            "Source": "_source.sku",
            "Target": "_asset.ProductSKU"
        },
        "purchaseDate": {
            "Source": "_source.purchaseDate",
            "Target": "_asset.PurchaseDate"
        },
        "status": {
            "Source": "_source.status",
            "Target": "_asset.Status"
        },
        "price": {
            "Source": "_source.price",
            "Target": "_asset.Price",
            "ContentType": "NUMBER"
        }
    },
    "Keys": {
        "_email": [
            {
                "StandardIdentifiers": ["PROFILE"],
                "FieldNames": ["emailAddress"]
            }
        ],
        "productSerialNumber": [
            {
                "StandardIdentifiers": ["ASSET", "UNIQUE"],
                "FieldNames": ["serialNumber"]
            }
        ]
    }
}
```

What's new here:

- **Two destinations.** One field targets `_profile.*`, the rest target `_asset.*`. A single mapping can write to the profile and to other standard objects at the same time.

- **The pairing rule.** Because fields target `_asset.*`, at least one key must carry the `ASSET` identifier. Miss this and the mapping is rejected. The rule holds for every standard object.
- **What ASSET does.** It tells Customer Profiles to look up the asset record whose `productSerialNumber` equals this value. One match, and the record attaches to that asset. More than one, and the ingestion is rejected as ambiguous. None, and a new asset record can be created.
- **Two identifiers on one key.** `productSerialNumber` is both `ASSET` (which asset) and `UNIQUE` (which registration record). Re-registering the same serial number replaces the registration profile object and updates the same asset.
- **Assets accumulate.** Another object type—warranty claims, service history—can target `_asset.*` too. Its values land alongside these on the same asset record.

Every standard object follows this pattern. Swap the identifier and the target prefix:

To populate	Add this identifier to a key	Target fields at
An asset	`ASSET`	`_asset.*`
An order	`ORDER`	`_order.*`
A case	`CASE`	`_case.*`
A device	`DEVICE`	`_device.*`
A loyalty membership	`LOYALTY`	`_loyalty.*`
An air booking	`AIR_BOOKING`	`_airBooking.*`

For the full list of standard objects and their identifiers, see Reference for standard objects in Customer Profiles.

Example 4: Link two object types together

Key names are global to the domain. Two object types that use the same key name for the same real-world identifier are linked—matching values put their data on the same profile and the same standard object. This example ingests service tickets that reference the assets registered in Example 3.

Incoming object:

```
{
  "ticketId": "SR-55021",
  "customerEmail": "jane@example.com",
  "assetSerialNumber": "SN-987654",
  "subject": "Unit not cooling",
  "description": "Customer reports the unit runs but does not cool.",
  "state": "Open",
  "openedAt": "2025-06-02T14:05:00.000Z"
}
```

Mapping:

```
{
    "Fields": {
        "emailAddress": {
            "Source": "_source.customerEmail",
            "ContentType": "EMAIL_ADDRESS"
        },
        "assetSerialNumber": {
            "Source": "_source.assetSerialNumber",
            "Target": "_case.Attributes.SerialNumber"
        },
        "ticketId": {
            "Source": "_source.ticketId"
        },
        "title": {
            "Source": "_source.subject",
            "Target": "_case.Title"
        },
        "summary": {
            "Source": "_source.description",
            "Target": "_case.Summary"
        },
        "status": {
            "Source": "_source.state",
            "Target": "_case.Status"
        },
        "createdDate": {
            "Source": "_source.openedAt",
            "Target": "_case.CreatedDate"
        }
```

```
    },
    "Keys": {
        "_email": [
            {
                "StandardIdentifiers": ["PROFILE"],
                "FieldNames": ["emailAddress"]
            }
        ],
        "productSerialNumber": [
            {
                "StandardIdentifiers": ["ASSET"],
                "FieldNames": ["assetSerialNumber"]
            }
        ],
        "serviceTicketId": [
            {
                "StandardIdentifiers": ["CASE", "UNIQUE"],
                "FieldNames": ["ticketId"]
            }
        ]
    }
}
```

What's new here:

- **A shared key name links the two object types.** `productSerialNumber` is the same key name Example 3 used. When a ticket arrives with `SN-987654`, it attaches to the asset that the registration created. Had this mapping called the key `ticketSerialNumber`, the two would never connect.
- **An identifier without a target.** This key carries `ASSET` but no field targets `_asset.*`. The pairing rule runs one way only: targeting a standard object requires its identifier, but carrying the identifier doesn't require targeting. Use it this way to associate a record with an existing entity without writing to it.
- **Three standard objects, three roles.** `_email` finds the profile, `productSerialNumber` finds the asset, and `serviceTicketId` both identifies the case and identifies this profile object.
- **Content types must agree.** `assetSerialNumber` has no `ContentType`, so it's `STRING`—the same as the field behind `productSerialNumber` in Example 3. A key name reused with a different content type is rejected.
- **One field can do both jobs.** `assetSerialNumber` feeds the `productSerialNumber` key and writes to `_case.Attributes.SerialNumber`. A field carrying a `Target` can still be referenced

by a key, so you don't need a second field for that. You would need one only if the same value had to reach two standard objects, since a field has exactly one `Target`.

Important

Share key names deliberately

A key name is a domain-wide index: two objects with the same key name and the same value land on the same profile, even when they come from different object types.

So before reusing a name, ask whether a shared value really means a shared identity. An email address on a Salesforce contact and the same address on a ServiceNow user belong to one person, so use `_email` for both. But a Salesforce record ID of `12345` and a Marketo record ID of `12345` are unrelated records that happen to share a number—give those distinct names such as `salesforceContactId` and `marketoLeadId`, or you collapse two unrelated customers into one profile. For more information, see Key definitions in Customer Profiles object type mappings.

Before you submit

Check your mapping against both lists. The first group is rejected when you create the object type. The second group is accepted, so nothing tells you it's wrong—the cost shows up later as poor matching.

Rules the mapping must satisfy

Rule	Why
Exactly one key carries `UNIQUE`	It identifies the profile object instance. If no single value is distinct, list several fields in `FieldNames` so their combination is unique.
At least one key carries `PROFILE`	Without it, an ingested object has no way to reach a profile.
At least one `PROFILE` key has neither `LOOKUP_ONLY` nor `NEW_ONLY`	Guarantees an object can always be durably associated with a profile. Waived when `AllowProfileCreation = false`, and the `_profileId` key is exempt.

Rule	Why
`UNIQUE` is not combined with `LOOKUP_ONLY` or `NEW_ONLY`	A key that identifies the object instance has to be stored, and those two identifiers prevent storage.
Every standard object you target has its identifier on a key	Targeting `_asset.*` requires an `ASSET` key, `_case.*` requires `CASE`, and so on. The reverse isn't required.
Every `Target` names a real field on the standard object	Check the standard object definition rather than guessing from the source field name. Values with no standard field go under `Attributes` .
No `Target` is a system-managed ID	`_profile.ProfileId` , `_asset.AssetId` , `_case.CaseId` , and the equivalent ID on every other standard object are assigned by Customer Profiles. Put your source's own ID in `Attributes` .
Not both `Gender` and `GenderString` , or both `PartyType` and `PartyTypeString`	Each pair is mutually exclusive. Choose one of each.
Every `FieldNames` entry names a field defined in this mapping	Keys can only reference fields from their own object type.
A reused key name's field content types match the existing definition	Key names are domain-wide, so the same name must normalize values the same way everywhere it's used.
250 fields or fewer	Per-object-type limit. See Quotas and data limits in Customer Profiles.

Choices that are accepted but cause problems

Choice	What it costs
An indexed email, phone, name, or number with no `ContentType`	The value is treated as `STRING` and matched exactly as written, so the same phone number or address in another format won't match.
A `PROFILE` key on a low-cardinality value	A value shared by many profiles matches ambiguously, gets discarded, and tends to produce inferred profiles instead.

Creating the object type successfully confirms it's structurally valid. To confirm it does what you intended, ingest a few representative records and check the results with `SearchProfiles` before pointing a full integration at it. For more information, see Update and validate an object type mapping in Customer Profiles. For error messages and the symptoms of a mapping that's already ingesting, see Troubleshoot object type mappings in Customer Profiles.

Reference for standard objects in Customer Profiles

Connect Customer Customer Profiles defines a set of **standard objects** that represent common business entities—profiles, orders, cases, loyalty records, travel records, and others. Each standard object is a structured record with a fixed schema that downstream applications (such as the Connect Customer agent workspace) can read without knowing the original format of your data.

This topic describes each standard object, its object type name, the standard identifier you use to associate ingested data with it, and how matching works at ingestion time. The topics in this section provide the full definition of each standard object and the object type mappings from external applications to it. For the identifiers themselves, see Standard identifiers in Customer Profiles. For the field syntax used to populate them, see Field definitions in Customer Profiles object type mappings.

Profile objects compared with standard objects

Profile objects and standard objects sound similar but behave differently:

- A **profile object** is the raw record you ingest with PutProfileObject. Each profile object is identified by its `UNIQUE` key. Re-ingesting an object with the same `UNIQUE` value **replaces the previous profile object wholesale**—the new record's contents fully overwrite the old one.

- A **standard object** is a structured record with a fixed schema (the standard profile, an asset, an order, a loyalty membership, and so on). Standard objects are **not** replaced wholesale by ingestion. Instead, each ingested profile object contributes only the fields its mapping targets at that standard object. Multiple object types can write to the same standard object over time, so a single asset record can accumulate fields from registration data, warranty data, and service-history data—each ingested as a separate profile object type.

> **Note**
>
> **Standard profile objects can't be ingested directly**
> You can't call `PutProfileObject` with `_profile` or any other standard object type name. To create or update a profile directly, use CreateProfile or UpdateProfile. To populate any other standard object, ingest a custom object type whose fields target it (for example, `_asset.SerialNumber`) and whose keys carry the matching standard identifier (for example, `ASSET`).

How fields and keys work with standard objects

A field's `Target` places the field's value into a standard object. For example, `"Target": "_asset.SerialNumber"` stores the field on the asset record associated with the ingested object.

A key's standard identifier (such as `ASSET`, `ORDER`, or `LOYALTY`) tells Customer Profiles which standard object that key looks up. At ingestion, Customer Profiles uses the key value to find the matching record:

- If exactly one record is found, the object is associated with it.
- If more than one record is found, the match is ambiguous and is rejected.
- If no record is found, a new record can be created (depending on the object type).

> **Note**
>
> **Required identifiers when targeting a standard object**
> If any field targets a standard object type—for example, `_asset.SerialNumber`—at least one key must carry that object type's standard identifier (in this case, `ASSET`). For more information, see Standard identifiers in Customer Profiles.

For the complete list of templates that ingest into standard objects, call ListProfileObjectTypeTemplates.

System-managed ID fields

Every standard object has an ID field that Customer Profiles owns and assigns. These ID fields can't be set with a field `Target`:

- `_profile.ProfileId`
- `_asset.AssetId`, `_case.CaseId`, `_order.OrderId`
- `_communicationRecord.CommunicationRecordId`
- `_airPreference.PreferenceId`, `_hotelPreference.PreferenceId`
- `_airBooking.BookingId`, `_airSegment.SegmentId`
- `_hotelReservation.ReservationId`, `_hotelStayRevenue.StayRevenueId`
- `_loyalty.LoyaltyId`, `_loyaltyTransaction.TransactionId`, `_loyaltyPromotion.PromotionId`
- `_device.DeviceId`, `_webAnalytics.EventId`

Profile

Object type name	`_profile`
Standard identifier	`PROFILE`
ID field	`_profile.ProfileId` (system-managed)
Represents	The unified customer profile—the central record that other standard objects attach to.

Most mappings populate the standard profile. Common targets include `FirstName`, `LastName`, `EmailAddress`, `PhoneNumber`, `AccountNumber`, `ShippingAddress.*`, and custom values under `_profile.Attributes.{name}`. For more information, see Field definitions in Customer Profiles object type mappings.

Matching: A key marked `PROFILE` looks up the profile the object belongs to. If no profile matches and `AllowProfileCreation = true`, an inferred profile is created. For more information, see Profile matching and inferred profiles in Customer Profiles.

Customer engagement records

Asset

Object type name	`_asset`
Standard identifier	`ASSET`
ID field	`_asset.AssetId` (system-managed)
Represents	A product the customer owns or has purchased—for example, an appliance, a subscription, or a vehicle.

Use an asset record when an ingested object describes something the customer owns and you want agents and downstream systems to see that asset on the customer's profile. Typical targets are values like a serial number, model, purchase date, or status, mapped under `_asset.{field}`.

Matching: A key marked `ASSET` looks up the asset record. If exactly one asset matches the key value, the ingested object is associated with that asset. Multiple matches reject the ingestion.

Order

Object type name	`_order`
Standard identifier	`ORDER`
ID field	`_order.OrderId` (system-managed)
Represents	A purchase or order the customer placed.

Use an order record for purchase data—order number, line items, totals, status, dates—so the order appears on the customer's profile in agent-facing tools.

Matching: A key marked `ORDER` looks up the order record by the key's value (for example, an order number).

Case

Object type name	`_case`
Standard identifier	`CASE`
ID field	`_case.CaseId` (system-managed)
Represents	A support case opened on behalf of a customer.

Use a case record for ticketing or support-case data—case number, subject, status, severity, opened/closed timestamps. Cases let agents see existing case context when a customer contacts you.

Matching: A key marked CASE looks up the case record by the key's value.

Communication record

Object type name	`_communicationRecord`
Standard identifier	—
ID field	`_communicationRecord.CommunicationRecordId` (system-managed)
Represents	A communication event with a profile—email opens, clicks, message receipts, and similar events.

Communication record targets follow a special pattern: `_communicationRecord.Events.{eventType}.Attributes.{attribute}`. For example, `_communicationRecord.Events.EmailOpen.Attributes.Subject` records an email-open event with a subject attribute.

Communication records are populated through marketing-tool templates (such as Marketo) rather than by attaching a generic key identifier.

Travel records

Travel records form a related set covering preferences, bookings, segments, reservations, and stays. Each has its own standard identifier and ID field.

Object type	Identifier	ID field	Represents
`_airPreference`	`AIR_PREFERENCE`	`PreferenceId`	A traveler's preferences for air travel (seat, meal, cabin, frequent-flyer numbers).
`_hotelPreference`	`HOTEL_PREFERENCE`	`PreferenceId`	A traveler's preferences for hotel stays (room type, floor, smoking preference).
`_airBooking`	`AIR_BOOKING`	`BookingId`	A complete air booking (passenger name record, or PNR), including ticket numbers and passenger information.
`_airSegment`	`AIR_SEGMENT`	`SegmentId`	A single flight segment within a booking (origin, destination, departure, arrival).
`_hotelReservation`	`HOTEL_RESERVATION`	`ReservationId`	A hotel reservation (property, dates, room, rate).
`_hotelStayRevenue`	`HOTEL_STAY_REVENUE`	`StayRevenueId`	Revenue and charges associated with a completed hotel stay.

Matching: Each travel identifier behaves the same way as `ASSET` and `ORDER`—the key value is used to look up exactly one record of that type. Multiple matches reject the ingestion.

Loyalty records

Object type	Identifier	ID field	Represents
`_loyalty`	`LOYALTY`	`LoyaltyId`	A customer's loyalty program membership (program name, tier, points balance).
`_loyaltyTransaction`	`LOYALTY_TRANSACTION`	`TransactionId`	A points-earning or points-redeeming event on a loyalty membership.
`_loyaltyPromotion`	`LOYALTY_PROMOTION`	`PromotionId`	A promotion or campaign tied to a loyalty program.

Matching: A loyalty identifier looks up its record by the key's value. Use `LOYALTY` for membership-level data, `LOYALTY_TRANSACTION` for individual point events, and `LOYALTY_PROMOTION` for promotion definitions.

Other standard objects

Device

Object type name	`_device`
Standard identifier	`DEVICE`
ID field	`_device.DeviceId` (system-managed)
Represents	A device associated with a profile—mobile phone, app install, browser fingerprint, or IoT device.

Matching: A key marked `DEVICE` looks up the device record by the key's value (for example, a device ID or advertising identifier).

Web analytics

Object type name	`_webAnalytics`
Standard identifier	`WEB_ANALYTICS`
ID field	`_webAnalytics.EventId` (system-managed)
Represents	A web-analytics event such as a page view, click, or conversion.

Matching: A key marked `WEB_ANALYTICS` looks up the event record by the key's value.

Identifier compatibility at a glance

Standard object identifiers can be combined with `PROFILE` and `UNIQUE` as needed on the same key. They can't replace `UNIQUE` or `PROFILE`, which remain required on every object type.

- Every object type still needs exactly one `UNIQUE` key and at least one `PROFILE` key.
- If fields target a standard object type, at least one key must also carry that object type's identifier.
- Reserved key names `_profileId`, `_orderId`, `_caseId`, and `_assetId` must be declared `LOOKUP_ONLY`. For more information, see Standard identifiers in Customer Profiles.

Amazon AppFlow access requirements in Customer Profiles

Use the following Amazon AppFlow access requirements to create and delete the Zendesk, Marketo, Salesforce, and ServiceNow integrations with Connect Customer Customer Profiles:

- appflow:CreateFlow
- appflow:DeleteFlow

Amazon AppIntegrations access requirements in Customer Profiles

Use the following Amazon AppIntegrations access requirements to create and delete Segment and Shopify integrations with Connect Customer Customer Profiles:

- app-integrations:GetEventIntegration
- app-integrations:ListEventIntegrationAssociations
- app-integrations:CreateEventIntegrationAssociation
- app-integrations:DeleteEventIntegrationAssociation

Amazon EventBridge access requirements in Customer Profiles

Use the following Amazon EventBridge access requirements to create and delete Segment and Shopify integrations with Connect Customer Customer Profiles:

- `events:ListTargetsByRule`
- `events:PutRule`
- `events:PutTargets`
- `events:DeleteRule`
- `events:RemoveTargets`

Standard profile definition in the Connect Customer Customer Profiles

The following table lists all the fields in the Customer Profiles standard profile object.

Standard profile field	Data type	Description
ProfileId	String	The unique identifier of a customer profile.
AccountNumber	String	A unique account number that you have given to the customer.

Standard profile field	Data type	Description
AdditionalInformation	String	Any additional information relevant to the customer's profile.
PartyType	String	The type of profile used to describe the customer. Valid values: INDIVIDUAL | BUSINESS | OTHER
BusinessName	String	The name of the customer's business.
FirstName	String	The customer's first name.
MiddleName	String	The customer's middle name.
LastName	String	The customer's last name.
BirthDate	String	The customer's birth date.
Gender	String	The gender with which the customer identifies.
PhoneNumber	String	The customer's phone number, which has not been specified as a mobile, home, or business number.
MobilePhoneNumber	String	The customer's mobile phone number.
HomePhoneNumber	String	The customer's home phone number.
BusinessPhoneNumber	String	The customer's business phone number.

Standard profile field	Data type	Description
EmailAddress	String	The customer’s email address, which has not been specified as a personal or business address.
PersonalEmailAddress	String	The customer’s personal email address.
BusinessEmailAddress	String	The customer’s business email address.
Address	Address	A generic address associated with the customer that is not mailing, shipping, or billing.
ShippingAddress	Address	The customer's shipping address.
MailingAddress	Address	The customer's mailing address.
BillingAddress	Address	The customer's billing address.
Attributes	String-to-string map	Key-value pair of attributes of a customer profile.
ProfileType	String	The type of the profile. Valid values: PROFILE | ACCOUNT_PROFILE
EngagementPreferences	EngagementPreferences	The customer or account’s engagement preferences.

The standard profile objects are indexed by the keys in the following table.

Standard index name	Standard profile field
_phone	PhoneNumber, MobilePhoneNumber, HomePhoneNumber, or BusinessPhoneNumber
_email	EmailAddress, PersonalEmailAddress, or BusinessEmailAddress
_account	AccountNumber
_profileId	ProfileId
_fullName	"FirstName MiddleName LastName"

For example, you can use _phone as a key name with the SearchProfiles API to find a profile whose PhoneNumber, MobilePhoneNumber, HomePhoneNumber, or BusinessPhoneNumber attribute matches with the search value.

Address data type

Standard profile field	Data type	Description
Address1	String	The first line of a customer address.
Address2	String	The second line of a customer address.
Address3	String	The third line of a customer address.
Address4	String	The fourth line of a customer address.
City	String	The city in which the customer lives.

Standard profile field	Data type	Description
Country	String	The country in which the customer lives.
County	String	The county in which the customer lives.
PostalCode	String	The postal code of the customer address.
Province	String	The province in which the customer lives.
State	String	The state in which the customer lives.

EngagementPreferences data type

Standard profile field	Data type	Description
Email	Array of ContactPreference objects	A list of email-related contact preferences.
Phone	Array of ContactPreference objects	A list of phone-related contact preferences.

ContactPreference data type

Standard profile field	Data type	Description
KeyName	String	A searchable, unique identifie r of a customer profile.
KeyValue	String	The key value used to look up profile based off the keyName.

Standard profile field	Data type	Description
ProfileId	String	The unique identifier of a customer profile.
ContactType	String	The contact type used for engagement. Valid Values: PhoneNumber | MobilePhoneNumber | HomePhoneNumber | BusinessPhoneNumber | EmailAddress | PersonalEmailAddress | BusinessEmailAddress

Mapping Salesforce objects to the standard profile in Connect Customer Customer Profiles

This topic lists which fields in Salesforce objects map to fields in the standard profile object in Customer Profiles.

Salesforce-Account object

Following is a list of all the fields in a Salesforce-Account object. The fields in your Salesforce-Account object might vary depending on the configuration of your Salesforce instance.

- Id
- IsDeleted
- MasterRecordId
- Name
- Type
- ParentId
- BillingStreet
- BillingCity
- BillingState
- BillingPostalCode

Mapping a Salesforce-Account object to a standard profile

A subset of the fields in the Salesforce-Account object map to the standard profile object in Customer Profiles.

The following table lists which fields can be mapped from the Salesforce-Account object to the standard profile. (The table includes the mapping for a Salesforce instance that has been configured to include Person fields.)

Salesforce-Account source field	Standard profile target field
Id	Attributes.sfdcAccountId
Name	BusinessName
Phone	PhoneNumber
BillingStreet	BillingAddress.Address1
BillingCity	BillingAddress.City
BillingState	BillingAddress.State
BillingCountry	BillingAddress.Country
BillingPostalCode	BillingAddress.PostalCode
ShippingStreet	ShippingAddress.Address1
ShippingCity	ShippingAddress.City
ShippingState	ShippingAddress.State
ShippingCountry	ShippingAddress.Country
ShippingPostalCode	ShippingAddress.PostalCode
IsPersonAccount	PartyType

Salesforce-Account source field	Standard profile target field
PersonMobilePhone	MobilePhoneNumber
PersonHomePhone	HomePhoneNumber
PersonEmail	PersonalEmailAddress
PersonMailingAddress.Street	MailingAddress.Address1
PersonMailingAddress.City	MailingAddress.City
PersonMailingAddress.State	MailingAddress.State
PersonMailingAddress.Country	MailingAddress.Country
PersonMailingAddress.PostalCode	MailingAddress.PostalCode
PersonBirthDate	BirthDate
PersonOtherStreet	Address.Address1
PersonOtherCity	Address.City
PersonOtherState	Address.State
PersonOtherCountry	Address.Country
PersonOtherPostalCode	Address.PostalCode
FirstName	FirstName
LastName	LastName
MiddleName	MiddleName
AccountNumber	AccountNumber

The Salesforce-Account customer data from the Salesforce object is associated with an Connect Customer customer profile using the indexes in the following table.

Standard Index Name	Salesforce-Account source field
_salesforceAccountId	Id

For example, you can use `_salesforceAccountId` as a key name with the SearchProfiles API to find a profile. You can find the Salesforce-Account objects associated with a specific profile by using the ListProfileObjects API with the `ProfileId` and `ObjectTypeName` set to `Salesforce-Account`.

Salesforce-Contact object

Following is a list of all the fields in a Salesforce-Contact object.

- Id
- IsDeleted
- MasterRecordId
- AccountId
- LastName
- FirstName
- Salutation
- Name
- OtherStreet
- OtherCity
- OtherState
- OtherPostalCode
- OtherCountry
- OtherLatitude
- OtherLongitude
- OtherGeocodeAccuracy
- OtherAddress.city
- OtherAddress.country

Mapping a Salesforce-Contact object to a standard profile

A subset of the fields in the Salesforce-Contact object map to the standard profile object in Customer Profiles. The following table lists which fields can be mapped from the Salesforce-Contact object to the standard profile object.

Salesforce-Contact source field	Standard profile target field
Id	Attributes.sfdcContactId

Salesforce-Contact source field	Standard profile target field
AccountId	Attributes.sfdcAccountId
LastName	LastName
FirstName	FirstName
MiddleName	MiddleName
OtherStreet	Address.Address1
OtherCity	Address.City
OtherState	Address.State
OtherCountry	Address.Country
OtherPostalCode	Address.PostalCode
MailingStreet	MailingAddress.Address1
MailingCity	MailingAddress.City
MailingState	MailingAddress.State
MailingCountry	MailingAddress.Country
MailingPostalCode	MailingAddress.PostalCode
Phone	PhoneNumber
HomePhone	HomePhoneNumber
MobilePhone	MobilePhoneNumber
Email	EmailAddress
Birthdate	BirthDate

The Salesforce-Contact customer data from a Salesforce object is associated with an Connect Customer customer profile using the indexes in the following table.

Standard Index Name	Salesforce-Contact source field
_salesforceContactId	Id
_salesforceAccountId	AccountId

For example, you can use `_salesforceAccountId` and `_salesforceContactId` as a key name with the SearchProfiles API to find a profile. You can find the Salesforce-Contact objects associated with a specific profile by using the ListProfileObjects API with the `ProfileId` and `ObjectTypeName` set to `Salesforce-Contact`.

Mapping Zendesk objects to the standard profile in Connect Customer Customer Profiles

This topic lists which fields in Zendesk objects map to fields in the standard profile in Customer Profiles.

Zendesk-users object

Following is a list of all the fields in a Zendesk-users object.

- id
- url
- external_id
- email
- active
- chat_only
- customer_role_id
- role_type
- details
- last_login_at
- locale
- locale_id
- moderator

- notes
- only_private_comments
- default_group_id
- phone
- shared_phone_number
- photo
- restricted_agent
- role
- shared
- tags
- signature
- suspended
- ticket_restriction
- time_zone
- two_factor_auth_enabled
- user_fields
- verified
- report_csv
- created_at
- updated_at

Mapping Zendesk users to a standard profile

A subset of the fields in the Zendesk-users object map to the standard profile in Customer Profiles. The following table lists which fields can be mapped from the Zendesk-users object to the standard profile.

Zendesk-users source field	Standard profile target field
id	Attributes.ZendeskUserId
external_id	Attributes.ZendeskExternalId

Zendesk-users source field	Standard profile target field
email	EmailAddress
phone	PhoneNumber

The Zendesk-users customer data from the Zendesk object is associated with a Connect Customer customer profile using the following indexes.

Standard Index Name	Zendesk-user source field
_zendeskUserId	Id
_zendeskExternalId	external_id

For example, you can use `_zendeskUserId` and `_zendeskExternalId` as a key name with the SearchProfiles API to find an Connect Customer customer profile. You can find the Zendesk-users objects associated with a specific customer profile by using the ListProfileObjects API with the `ProfileId` and `ObjectTypeName` set to `Zendesk-users`.

Mapping Marketo objects to the standard profile in Connect Customer Customer Profiles

This topic lists which fields in Marketo objects map to fields in the standard profile object in Customer Profiles.

Marketo-leads object

Following is a list of all the fields in a Marketo-leads object

- id
- firstName
- lastName
- middleName
- email
- phone
- mobilePhone
- billingStreet

- billingCity
- billingState
- billingCountry
- billingPostalCode
- address
- city
- state
- country
- postalcode
- gender
- dateOfBirth

Mapping Marketo-leads to a standard profile

A subset of fields in the Marketo-leads object map to the standard profile.

Marketo-leads source field	Standard profile target field
id	Attributes.MarketoLeadId
sfdcAccountId	Attributes.sfdcAccountId
sfdcContactId	Attributes.sfdcContactId
firstName	FirstName
lastName	LastName
middleName	MiddleName
email	EmailAddress
phone	PhoneNumber
mobilePhone	MobilePhoneNumber
mobilePhone	MobilePhoneNumber

Marketo-leads source field	Standard profile target field
billingStreet	BillingAddress.Address1
billingCity	BillingAddress.City
billingState	BillingAddress.State
billingCountry	BillingAddress.Country
billingPostalCode	BillingAddress.PostalCode
address	Address.Address1
city	Address.City
state	Address.State
country	Address.Country
postalcode	Address.PostalCode
gender	Gender
dateOfBirth	BirthDate

The Marketo-leads customer data from Marketo is associated with an Connect Customer customer profile using the indexes in the following table.

Standard Index Name	Marketo-leads source field
_marketoLeadId	id
_salesforceAccountId	sfdcAccountId
_salesforceContactId	sfdcContactId

For example, you can use `_marketoLeadId`, `_salesforceAccountId`, and `_salesforceContactId` as a key name with the SearchProfiles API to find an Connect Customer

customer profile. You can find the Marketo-leads objects associated with a specific customer profile by using the ListProfileObjects API with the `ProfileId` and `ObjectTypeName` set to `Marketo-leads`.

Mapping ServiceNow objects to the standard profile object in Connect Customer Customer Profiles

This topic lists which fields in ServiceNow objects map to fields in the standard profile object in Connect Customer Customer Profiles.

Servicenow-sys_user object

Following is a list of all the fields in a Servicenow-sys_user object

- sys_id
- active
- building
- calendar_integration
- city
- company
- cost_center
- country
- date_format
- default_perspective
- department
- edu_status
- email
- employee_number
- enable_multifactor_authn
- failed_attempts
- first_name
- gender
- home_phone
- internal_integration_user
- introduction

- last_login
- last_login_device
- last_login_time
- last_name
- last_password
- ldap_server
- location
- locked_out
- manager
- middle_name
- mobile_phone
- name
- notification
- password_needs_reset
- phone
- photo
- preferred_language
- roles
- schedule
- source
- state
- street
- sys_class_name
- sys_created_by
- sys_created_on
- sys_domain.link
- sys_domain.value
- sys_domain_path
- sys_id
- sys_mod_count

- sys_updated_by
- sys_udpated_on
- time_format
- time_zone
- title
- user_name
- user_password
- web_service_access_only
- zip

Mapping Servicenow-sys_users to a standard profile object

A subset of the fields in the Servicenow-sys_users object map to the standard profile object in Customer Profiles.

The following table lists which fields can be mapped from the Servicenow-sys_users object to the standard profile.

Servicenow-sys_users source field	Customer profiles target field
sys_id	Attributes.ServiceNowSystemId
first_name	FirstName
last_name	LastName
middle_name	MiddleName
gender	Gender
email	EmailAddress
phone	PhoneNumber
home_phone	HomePhoneNumber
mobile_phone	MobilePhoneNumber

Servicenow-sys_users source field	Customer profiles target field
street	Address.Address1
city	Address.City
state	Address.State
country	Address.Country
zip	Address.PostalCode

The Servicenow-sys_user customer data from Servicenow object is associated with an Connect Customer customer profile using the indexes in the following table.

Standard Index Name	Servicenow-sys_user source field
_serviceNowSystemId	sys_id

For example, you can use `_serviceNowSystemId` and `_serviceNowIncidentId` as a key name with the SearchProfiles API to find an Connect Customer customer profile. You can find the Servicenow-sys_user objects associated with a specific profile by using the ListProfileObjects API with the `ProfileId` and `ObjectTypeName` set to `Servicenow-sys_user`.

Mapping Segment objects to the standard profile object in Connect Customer Customer Profiles

This topic lists which fields in Segment objects map to fields in the standard profile object in Connect Customer Customer Profiles.

Segment-Identify object

Following is a list of all the fields in a Segment-Identify object.

- userId
- common fields - see Spec: Common Fields in the Segment documentation
- Segment reserved traits - see Traits in the Segment documentation
- traits.address.street

- traits.address.city
- traits.address.state
- traits.address.postalCode
- traits.address.country
- traits.age
- traits.avatar
- traits.birthday
- traits.company.name
- traits.company.id
- traits.company.industry
- traits.company.employee_count
- traits.company.plan
- traits.createdAt
- traits.description
- traits.email
- traits.firstName
- traits.gender
- traits.id
- traits.lastName
- traits.name
- traits.phone
- traits.title
- traits.username
- traits.website

Mapping a Segment-Identify to a standard profile object

A subset of the fields in the Segment-Identify object map to the standard profile object in Customer Profiles.

The following table lists which fields can be mapped from the Segment-Identify object to the standard profile.

Segment-Identify source field	Standard profile target field
	Standard profile target field
userId	Attributes.SegmentUserId
traits.company.name	BusinessName
traits.firstName	FirstName
traits.lastName	LastName
traits.birthday	BirthDate
traits.gender	Gender
traits.phone	PhoneNumber
traits.email	EmailAddress
traits.address.street	Address.Address1
traits.address.city	Address.City
traits.address.state	Address.State
traits.address.country	Address.Country
traits.address.postalCode	Address.PostalCode

Example

The following example shows how to map a source field to a target field.

```
"segmentUserId": {
    "Source": "_source.detail.event.detail.userId",
    "Target": "_profile.Attributes.SegmentUserId"
}
```

The Segment-Identify customer data from the Segment object is associated with an Connect Customer customer profile using the following index.

Standard Index Name	Segment-Identify source field
_segmentUserId	userId

For example, you can use `_segmentUserId` as a key name with the SearchProfiles API to find an Connect Customer customer profile. You can find the Segment-Identify objects associated with a specific profile by using the ListProfileObjects API with the `ProfileId` and `ObjectTypeName` set to `Segment-Identify`.

Mapping Shopify objects to the standard profile object in Connect Customer Customer Profiles

This topic lists which fields in Shopify objects map to fields in the standard profile object in Connect Customer Customer Profiles.

Shopify-Customer object

Following is a list of all the fields in a Shopify-Customer object.

- accepts_marketing
- accepts_marketing_updated_at
- addresses
- currency
- created_at
- default_address.address1
- default_address.address2
- default_address.city
- default_address.company
- default_address.country
- default_address.country_code
- default_address.country_name
- default_address.customer_id
- default_address.default
- default_address.first_name
- default_address.id

- default_address.last_name
- default_address.name
- default_address.phone
- default_address.province
- default_address.province_code
- default_address.zip
- email
- first_name
- id
- last_name
- last_order_id
- last_order_name
- metafield.key
- metafield.value
- metafield.namespace
- metafield.value_type
- marketing_opt_in_level
- multipass_identifier
- note
- orders_count
- phone
- sms_marketing_consent.state
- sms_marketing_consent.opt_in_level
- sms_marketing_consent.consent_updated_at
- sms_marketing_consent.consent_collected_from
- state
- tags
- tax_exempt
- tax_exemptions
- total_spent

- updated_at
- verified_email

Mapping a Shopify-Customer object to a standard profile

A subset of the fields in the Shopify-Customer object map to the standard profile object in Customer Profiles.

The following table lists which fields can be mapped from the Shopify-Customer object to the standard profile.

Shopify-Customer source field	Standard profile target field
id	Attributes.ShopifyCustomerId
email	EmailAddress
first_name	FirstName
last_name	LastName
note	AdditionalInformation
phone	PhoneNumber
default_address.address1	Address.Address1
default_address.address2	Address.Address2
default_address.city	Address.City
default_address.province	Address.Province
default_address.country	Address.Country
default_address.zip	Address.PostalCode

Example

The following example shows how to map a source field to a target field.

```
"shopifyCustomerId": {
    "Source": "_source.detail.event.detail.payload.id",
    "Target": "_profile.Attributes.ShopifyCustomerId"
}
```

The Shopify-Customer customer data from the Shopify object is associated with an Connect Customer customer profile using the following index.

Standard Index Name	Shopify-Customer source field
_shopifyCustomerId	id

For example, you can use `_shopifyCustomerId` as a key name with the SearchProfiles API to find an Connect Customer customer profile. You can find the Shopify-Customer objects associated with a specific profile by using the ListProfileObjects API with the `ProfileId` and `ObjectTypeName` set to `Shopify-Customer`.

Object type mapping for the standard order in Connect Customer Customer Profiles

The topics in this section provide the standard order definition, and the object type mapping from external applications to the standard order.

Topics

- Amazon AppIntegrations access requirements
- Amazon EventBridge access requirements
- Customer Profiles standard order object fields
- Mapping Shopify objects to the standard order in Connect Customer Customer Profiles

Amazon AppIntegrations access requirements

Use the following Amazon AppIntegrations access requirements to create and delete Shopify integrations with Connect Customer Customer Profiles:

- app-integrations:GetEventIntegration
- app-integrations:ListEventIntegrationAssociations
- app-integrations:CreateEventIntegrationAssociation

- app-integrations:DeleteEventIntegrationAssociation

Amazon EventBridge access requirements

Use the following Amazon EventBridge access requirements to create and delete Shopify integrations with Connect Customer Customer Profiles:

- `events:ListTargetsByRule`
- `events:PutRule`
- `events:PutTargets`
- `events:DeleteRule`
- `events:RemoveTargets`

Customer Profiles standard order object fields

The following table lists all the fields in the Customer Profiles standard order object.

Standard order field	Data type	Description
OrderId	String	The unique identifier of a standard order.
CustomerEmail	String	The customer's email address.
CustomerPhone	String	The customer's phone number.
CreatedDate	String	The order's date created.
UpdatedDate	String	The order's date updated.
ProcessedDate	String	The order's date processed.
ClosedDate	String	The order's date closed.
CancelledDate	String	The order's date cancelled.
CancelReason	String	The order's cancel reason.

Standard order field	Data type	Description
Name	String	The order's name.
AdditionalInformation	String	Any additional information relevant to the order.
Gateway	String	The order's payment gateway.
Status	String	The order's status.
StatusCode	String	The order's status code. Valid values: DRAFT | ACTIVATED
StatusUrl	String	The order's status URL.
CreditCardNumber	String	The customer's credit card last four digits.
CreditCardCompany	String	The customer's credit card company.
FulfillmentStatus	String	The order's fulfillment status.
TotalPrice	String	The order's total price.
TotalTax	String	The order's total tax.
TotalDiscounts	String	The order's total discounts.
TotalItemsPrice	String	The order's total items price.
TotalShippingPrice	String	The order's total shipping price.
TotalTipReceived	String	The order's total tip received.
Currency	String	The order's currency.
TotalWeight	String	The order's total weight.

Standard order field	Data type	Description
BillingAddress	OrderAddress	The customer's billing address.
ShippingAddress	OrderAddress	The customer's shipping address.
OrderItems	OrderItem list	The order's items.
Attributes	String-to-string map	Key-value pair of attributes of a standard order.

The standard order objects are indexed by the keys in the following table.

Standard index name	Standard order field
_orderId	OrderId

For example, you can use `_orderId` as a key name with the SearchProfiles API to find a profile that has an order whose OrderId matches with the search value. You can find the standard order objects associated with a specific profile by using the ListProfileObjects API with the `ProfileId` and `ObjectTypeName` set to `_order`.

OrderAddress data type

Standard order field	Data type	Description
Name	String	The name associated with an order address.
Address1	String	The first line of an order address.
Address2	String	The second line of an order address.

Standard order field	Data type	Description
Address3	String	The third line of an order address.
Address4	String	The fourth line of an order address.
City	String	The city of an order address.
County	String	The county of an order address.
State	String	The state of an order address.
Province	String	The province of an order address.
Country	String	The country of an order address.
PostalCode	String	The postal code of an order address.

OrderItem data type

Standard order field	Data type	Description
Title	String	The title of an order item.
Price	String	The price of an order item.
Quantity	String	The quantity of an order item.

Mapping Shopify objects to the standard order in Connect Customer Customer Profiles

This topic lists which fields in Shopify objects map to fields in the standard order object in Customer Profiles.

Shopify-DraftOrder object

For a list of all the fields in a Shopify-DraftOrder object see The DraftOrder object in the Shopify documentation.

Mapping a Shopify-DraftOrder object to a standard order

A subset of the fields in the Shopify-DraftOrder object map to the standard order object in Customer Profiles.

The following table lists which fields can be mapped from the Shopify-DraftOrder object to the standard order.

The `StatusCode` is `ACTIVATED` if `order_status_url` exists in the source. Otherwise, the `StatusCode` is `DRAFT`.

Shopify-DraftOrder source field	Standard order target field
id	Attributes.ShopifyOrderId
customer.id	Attributes.ShopifyCustomerId
note	AdditionalInformation
email	CustomerEmail
currency	Currency
created_at	CreatedDate
updated_at	UpdatedDate
name	Name
status	Status
order_status_url	StatusCode
billing_address.address1	BillingAddress.Address1
billing_address.address2	BillingAddress.Address2

Shopify-DraftOrder source field	Standard order target field
billing_address.city	BillingAddress.City
billing_address.zip	BillingAddress.PostalCode
billing_address.province	BillingAddress.Province
billing_address.country	BillingAddress.Country
billing_address.name	BillingAddress.Name
shipping_address.address1	ShippingAddress.Address1
shipping_address.address2	ShippingAddress.Address2
shipping_address.city	ShippingAddress.City
shipping_address.zip	ShippingAddress.PostalCode
shipping_address.province	ShippingAddress.Province
shipping_address.country	ShippingAddress.Country
shipping_address.name	ShippingAddress.Name
invoice_url	StatusUrl
total_price	TotalPrice
total_tax	TotalTax
line_items[].title	OrderItems[].Title
line_items[].price	OrderItems[].Price
line_items[].quantity	OrderItems[].Quantity

Example

The following example shows how to map a source field to a target field.

```
"shopifyOrderId": {
    "Source": "_source.detail.event.detail.payload.id",
    "Target": "_order.Attributes.ShopifyOrderId"
}
```

The Shopify-DraftOrder customer data from the Shopify object is associated with an Connect Customer standard order using the following index.

Standard Index Name	Shopify-DraftOrder source field
_shopifyOrderId	id

For example, you can use `_shopifyOrderId` as an `ObjectFilter.KeyName` with the the ListProfileObjects API to find a standard order. You can find the Shopify-DraftOrder objects associated with a specific profile by using the ListProfileObjects API with the `ProfileId` and `ObjectTypeName` set to `Shopify-DraftOrder`.

Shopify-Order object

For a list of all the fields in a Shopify-Order object see The Order object in the Shopify documentation.

Mapping a Shopify-Order object to a standard order

A subset of the fields in the Shopify-Order object map to the standard order object in Customer Profiles.

The following table lists which fields can be mapped from the Shopify-Order object to the standard order.

The `StatusCode` is `ACTIVATED` if `order_status_url` exists in the source. Otherwise, the `StatusCode` is `DRAFT`.

Shopify-Order source field	Standard order target field
id	Attributes.ShopifyOrderId
customer.id	Attributes.ShopifyCustomerId

Shopify-Order source field	Standard order target field
cancelled_at	CancelledDate
cancel_reason	CancelReason
closed_at	ClosedDate
created_at	CreatedDate
currency	Currency
email	CustomerEmail
financial_status	Status
order_status_url	StatusCode
fulfillment_status	FulfillmentStatus
gateway	Gateway
name	Name
note	AdditionalInformation
order_status_url	StatusUrl
phone	CustomerPhone
processed_at	ProcessedDate
total_discounts	TotalDiscounts
total_line_items_price	TotalItemsPrice
total_price	TotalPrice
total_shipping_price_set.shop_money.amount	TotalShippingPrice
total_tax	TotalTax

Shopify-Order source field	Standard order target field
total_tip_received	TotalTipReceived
total_weight	TotalWeight
updated_at	UpdatedDate
billing_address.address1	BillingAddress.Address1
billing_address.address2	BillingAddress.Address2
billing_address.city	BillingAddress.City
billing_address.zip	BillingAddress.PostalCode
billing_address.province	BillingAddress.Province
billing_address.country	BillingAddress.Country
billing_address.name	BillingAddress.Name
payment_details.credit_card_number	CreditCardNumber
payment_details.credit_card_company	CreditCardCompany
shipping_address.address1	ShippingAddress.Address1
shipping_address.address2	ShippingAddress.Address2
shipping_address.city	ShippingAddress.City
shipping_address.zip	ShippingAddress.PostalCode
shipping_address.province	ShippingAddress.Province
shipping_address.country	ShippingAddress.Country
shipping_address.name	ShippingAddress.Name
line_items[].title	OrderItems[].Title

Shopify-Order source field	Standard order target field
line_items[].price	OrderItems[].Price
line_items[].quantity	OrderItems[].Quantity

Example

The following example shows how to map a source field to a target field.

```
"shopifyOrderId": {
    "Source": "_source.detail.event.detail.payload.id",
    "Target": "_order.Attributes.ShopifyOrderId"
}
```

The Shopify-Order customer data from the Shopify object is associated with an Connect Customer standard order using the following index.

Standard Index Name	Shopify-Order source field
_shopifyOrderId	id

For example, you can use `_shopifyOrderId` as an `ObjectFilter.KeyName` with the the ListProfileObjects API to find a standard order. You can find the Shopify-Order objects associated with a specific profile by using the ListProfileObjects API with the `ProfileId` and `ObjectTypeName` set to `Shopify-Order`.

Object type mapping for the standard communication record

The topics in this section provide the standard communication record definition, and the object type mapping from campaign events to the standard communication record.

Topics

- Customer Profiles standard communication record object fields
- Mapping Campaign objects to the standard communication record in Amazon Connect Customer Profiles

Customer Profiles standard communication record object fields

The following table lists all the fields in the Customer Profiles standard communication record object.

Standard communicationRecord field	Data type	Description
CommunicationRecordId	String	The unique identifier of a standard communication record.
Channel	String	The method used to contact your contact center. For example: VOICE, CHAT, EMAIL
ConnectInstanceArn	String	The ARN of the AWS Connect instance.
CreatedDate	String	The timestamp indicating when the communication record was created.
UpdatedDate	String	The timestamp indicating when the communication record was last updated.
LastEventType	String	The event type of the last event ingested for this communication.
Campaign	Campaign	Details about the campaign associated with this communication.
Endpoint	Endpoint	Information about the endpoint used for this communication.

Standard communicationRecord field	Data type	Description
Events	Map<String, Event>	A map of events where the key is the event type such as email delivered, opened or clicked. This tracks the last event of each unique event type that occurred during this communication.
Attributes	Map<String, String>	Key-value pair of attributes of a standard communication record.

The standard communication record objects are indexed by the keys in the following table.

Standard index name	Standard communication record field
_communicationRecordId	CommunicationRecordId

For example, you can use `_communicationRecordId` as a key name with the SearchProfiles API to find a profile that has a communication record whose `CommunicationRecordId` matches with the search value. You can find the standard `communicationRecord` objects associated with a specific profile by using the ListProfileObjects API with the `ProfileId` and `ObjectTypeName` set to `_communicationRecord`.

Campaign data type

Field	Data type	Description
CampaignId	String	The unique ID for the outbound campaign.
CampaignName	String	The name of the outbound campaign.

Field	Data type	Description
CampaignRunId	String	The unique ID for a specific run of the campaign.
CampaignActivityId	String	The unique ID of the activity within the campaign.
SegmentArn	String	The ARN of a segment of users.

Endpoint data type

Field	Data type	Description
EndpointAddress	String	The address of the endpoint (for example, email address, phone number).
EndpointType	String	The type of the endpoint such as default email or business email.

Event data type

Field	Data type	Description
UpdatedDate	String	The timestamp indicating when the communication event occurred.
EventId	String	The unique identifier for each communication event.
EventType	String	The specific communication event type.

Field	Data type	Description
Attributes	Map<String, String>	Key-value pair of attributes specific to the event type.

Mapping Campaign objects to the standard communication record in Amazon Connect Customer Profiles

This topic lists which fields in Campaign objects map to fields in the standard communication record object in Customer Profiles.

Campaign-Email object

For a list of all the fields in a Campaign-Email object see the Email object in the Amazon SES documentation.

Mapping a Campaign-Email object to a standard communication record

A subset of the fields in the Campaign-Email object map to the standard communication record object in Customer Profiles.

The following table lists which fields can be mapped from the Campaign-Email object to the standard communication record.

Campaign-Email source field	Standard communication record target field
campaign_event_id	Attributes.LastCampaignEventId
outbound_request_id	Attributes.OutboundCampaignRequestId
campaign_message_id	Attributes.CampaignMessageId
channel.name	Channel
channel.subtype	Attributes.ChannelSubType
endpoint_address	Endpoint.EndpointAddress
endpoint_type	Endpoint.EndpointType

Campaign-Email source field	Standard communication record target field
instance_arn	ConnectInstanceArn
campaign_name	Campaign.CampaignName
campaign_id	Campaign.CampaignId
campaign_run_id	Campaign.CampaignRunId
campaign_activity_id	Campaign.CampaignActivityId
segment_arn	Campaign.SegmentArn
outbound_request_creation_timestamp	CreatedDate
campaign_event_timestamp	UpdatedDate
campaign_event_type	LastEventType
campaign_event_timestamp	Events.{{campaign_event_type}}.UpdatedDate
campaign_event_id	Events.{{campaign_event_type}}.EventId
campaign_event_type	Events.{{campaign_event_type}}.EventType
email.bounce.bounceType	Events.Bounce.Attributes.BounceType
email.bounce.bounceSubType	Events.Bounce.Attributes.BounceSubType
email.choose.link	Events.Choose.Attributes.Link
email.choose.ipAddress	Events.Choose.Attributes.IpAddress
email.open.ipAddress	Events.Open.Attributes.IpAddress
email.reject.reason	Events.Reject.Attributes.Reason
email.renderingFailure.templateName	Events.RenderingFailure.Attributes.TemplateName

Campaign-Email source field	Standard communication record target field
email.renderingFailure.errorMessage	Events.RenderingFailure.Attributes.ErrorMessage
email.deliveryDelay.delayType	Events.DeliveryDelay.Attributes.DelayType
email.complaint.complaintFeedbackType	Events.Complaint.Attributes.ComplaintFeedbackType
email.complaint.complaintSubType	Events.Complaint.Attributes.ComplaintSubType
email.mail.commonHeaders.subject	Attributes.Subject

Campaign-SMS object

For a list of all the fields in a Campaign-SMS object see The SMS object in the AWS End User Messaging SMS documentation.

Mapping a Campaign-SMS object to a standard communication record

A subset of the fields in the Campaign-SMS object map to the standard communication record object in Customer Profiles.

The following table lists which fields can be mapped from the Campaign-SMS object to the standard communication record.

Campaign-SMS source field	Standard communication record target field
campaign_event_id	Attributes.LastCampaignEventId
outbound_request_id	Attributes.OutboundCampaignRequestId
campaign_message_id	Attributes.CampaignMessageId
channel.name	Channel
channel.subtype	Attributes.ChannelSubType

Campaign-SMS source field	Standard communication record target field
endpoint_address	Endpoint.EndpointAddress
endpoint_type	Endpoint.EndpointType
instance_arn	ConnectInstanceArn
campaign_name	Campaign.CampaignName
campaign.campaign_id	Campaign.CampaignId
campaign.campaign_run_id	Campaign.CampaignRunId
campaign_activity_id	Campaign.CampaignActivityId
segment_arn	Campaign.SegmentArn
outbound_request_creation_timestamp	CreatedDate
campaign_event_timestamp	UpdatedDate
campaign_event_type	LastEventType
campaign_event_timestamp	Events.{{campaign_event_type}}.UpdatedDate
campaign_event_id	Events.{{campaign_event_type}}.EventId
campaign_event_type	Events.{{campaign_event_type}}.EventType
sms.messageType	Events.{{campaign_event_type}}.Attributes.MessageType
sms.messageStatus	Events.{{campaign_event_type}}.Attributes.MessageStatus
sms.messageStatusDescription	Events.{{campaign_event_type}}.Attributes.MessageStatusDescription
sms.totalMessagePrice	Events.{{campaign_event_type}}.Attributes.TotalMessagePrice

Campaign-SMS source field	Standard communication record target field
sms.totalCarrierFee	Events.{{campaign_event_type}}.Attributes.TotalCarrierFee
sms.isoCountryCode	Events.{{campaign_event_type}}.Attributes.IsoCountryCode

Campaign-Telephony object

For a list of all the fields in a Campaign-Telephony object, see the Voice object in the AWS End User Messaging SMS documentation.

Mapping a Campaign-Telephony object to a standard communication record

A subset of the fields in the Campaign-Telephony object map to the standard communication record object in Customer Profiles.

The following table lists which fields can be mapped from the Campaign-Telephony object to the standard communication record.

Campaign-Telephony source field	Standard communication record target field
campaign_event_id	Attributes.LastCampaignEventId
outbound_request_id	Attributes.OutboundCampaignRequestId
campaign_message_id	Attributes.CampaignMessageId
channel.name	Channel
channel.subtype	Attributes.ChannelSubType
endpoint.endpoint_address	Endpoint.EndpointAddress
endpoint.endpoint_type	Endpoint.EndpointType
instance_arn	ConnectInstanceArn
campaign.campaign_name	Campaign.CampaignName

Campaign-Telephony source field	Standard communication record target field
campaign.campaign_id	Campaign.CampaignId
campaign.campaign_run_id	Campaign.CampaignRunId
campaign.campaign_activity_id	Campaign.CampaignActivityId
campaign.segment_arn	Campaign.SegmentArn
outbound_request_creation_timestamp	CreatedDate
campaign_event_timestamp	UpdatedDate
campaign_event_type	LastEventType
campaign_event_timestamp	Events.{{campaign_event_type}}.UpdatedDate
campaign_event_id	Events.{{campaign_event_type}}.EventId
campaign_event_type	Events.{{campaign_event_type}}.EventType
voice.agentInfo.connectedToAgentTimestamp	Events.{{campaign_event_type}}.Attributes.ConnectedToAgentTimestamp
voice.customerVoiceActivity.greetingEndTimestamp	Events.{{campaign_event_type}}.Attributes.GreetingEndTimestamp
voice.answeringMachineDetectionStatus	Events.{{campaign_event_type}}.Attributes.AnsweringMachineDetectionStatus
campaign_event_timestamp	SourceLastUpdatedTimestamp

Campaign-WhatsApp object

Mapping a Campaign-WhatsApp object to a standard communication record

A subset of the fields in the Campaign-WhatsApp object map to the standard communication record object in Customer Profiles.

The following table lists which fields can be mapped from the Campaign-WhatsApp object to the standard communication record.

Campaign-WhatsApp source field	Standard communication record target field
campaign_event_id	Attributes.LastCampaignEventId
engagement.outbound_request_id	Attributes.OutboundCampaignRequestId
campaign_message_id	Attributes.CampaignMessageId
engagement.channel.name	Channel
engagement.channel.subtype	Attributes.ChannelSubType
engagement.endpoint.endpoint_address	Endpoint.EndpointAddress
engagement.endpoint.endpoint_type	Endpoint.EndpointType
instance_arn	ConnectInstanceArn
campaign.campaign_name	Campaign.CampaignName
campaign.campaign_id	Campaign.CampaignId
campaign.campaign_run_id	Campaign.CampaignRunId
campaign.campaign_activity_id	Campaign.CampaignActivityId
campaign.segment_arn	Campaign.SegmentArn
engagement.outbound_request_creation _timestamp	CreatedDate
campaign_event_timestamp	UpdatedDate
campaign_event_type	LastEventType
campaign_event_timestamp	Events.{{campaign_event_type}}.UpdatedDate
campaign_event_id	Events.{{campaign_event_type}}.EventId

Campaign-WhatsApp source field	Standard communication record target field
campaign_event_type	Events.{{campaign_event_type}}.EventType
engagement.engagement_details.whatsapp.errors[].code	Events.{{campaign_event_type}}.Errors[].Code
engagement.engagement_details.whatsapp.errors[].message	Events.{{campaign_event_type}}.Errors[].Message
campaign_event_timestamp	SourceLastUpdatedTimestamp

Campaign-WebNotification object

Mapping a Campaign-WebNotification object to a standard communication record

A subset of the fields in the Campaign-WebNotification object map to the standard communication record object in Customer Profiles.

The following table lists which fields can be mapped from the Campaign-WebNotification object to the standard communication record.

Campaign-WebNotification source field	Standard communication record target field
campaign_event_id	Attributes.LastCampaignEventId
engagement.outbound_request_id	Attributes.OutboundCampaignRequestId
campaign_message_id	Attributes.CampaignMessageId
engagement.channel.name	Channel
engagement.channel.subtype	Attributes.ChannelSubType
engagement.endpoint.endpoint_address	Endpoint.EndpointAddress
engagement.endpoint.endpoint_type	Endpoint.EndpointType
instance_arn	ConnectInstanceArn

Campaign-WebNotification source field	Standard communication record target field
campaign.campaign_name	Campaign.CampaignName
campaign.campaign_id	Campaign.CampaignId
campaign.campaign_run_id	Campaign.CampaignRunId
campaign.campaign_activity_id	Campaign.CampaignActivityId
campaign.segment_arn	Campaign.SegmentArn
engagement.outbound_request_creation_timestamp	CreatedDate
campaign_event_timestamp	UpdatedDate
campaign_event_type	LastEventType
campaign_event_timestamp	Events.{{campaign_event_type}}.UpdatedDate
campaign_event_id	Events.{{campaign_event_type}}.EventId
campaign_event_type	Events.{{campaign_event_type}}.EventType
engagement.engagement_details.webNotification.eventType	Events.{{campaign_event_type}}.Attributes.WebNotificationEventType
engagement.engagement_details.webNotification.notificationType	Events.{{campaign_event_type}}.Attributes.NotificationType
engagement.engagement_details.webNotification.deviceType	Events.{{campaign_event_type}}.Attributes.DeviceType
engagement.engagement_details.webNotification.deviceModel	Events.{{campaign_event_type}}.Attributes.DeviceModel
engagement.engagement_details.webNotification.browserName	Events.{{campaign_event_type}}.Attributes.BrowserName
campaign_event_timestamp	SourceLastUpdatedTimestamp

Campaign-Orchestration object

Mapping a Campaign-Orchestration object to a standard communication record

A subset of the fields in the Campaign-Orchestration object map to the standard communication record object in Customer Profiles.

The following table lists which fields can be mapped from the Campaign-Orchestration object to the standard communication record.

Campaign-Orchestration source field	Standard communication record target field
campaign_event_id	Attributes.LastCampaignEventId
channel.name	Channel
channel.subtype	Attributes.ChannelSubType
instance_arn	ConnectInstanceArn
campaign.campaign_name	Campaign.CampaignName
campaign.campaign_id	Campaign.CampaignId
campaign.campaign_run_id	Campaign.CampaignRunId
campaign.campaign_activity_id	Campaign.CampaignActivityId
campaign.segment_arn	Campaign.SegmentArn
campaign_event_timestamp	UpdatedDate
campaign_event_type	LastEventType
campaign_event_timestamp	Events.{{campaign_event_type}}.UpdatedDate
campaign_event_id	Events.{{campaign_event_type}}.EventId
campaign_event_type	Events.{{campaign_event_type}}.EventType
campaign_event_timestamp	SourceLastUpdatedTimestamp

Example

The following example shows how to map a source field to a target field:

```
"channel": {
    "source": "_source.engagement.channel.name",
    "target": "_communicationRecord.Channel"
}
```

Object type mapping for the standard asset in Customer Profiles

The topics in this section provide the standard asset definition, and the object type mapping from external applications to the standard asset.

Topics

- Amazon AppFlow access requirements in Customer Profiles
- Standard asset definition in Connect Customer Customer Profiles
- Mapping Salesforce objects to the standard asset in Customer Profiles

Amazon AppFlow access requirements in Customer Profiles

Use the following Amazon AppFlow access requirements to create and delete Salesforce integrations with Connect Customer Customer Profiles:

- `appflow:CreateFlow`
- `appflow:DeleteFlow`

Standard asset definition in Connect Customer Customer Profiles

The following table lists all the fields in the Customer Profiles standard asset object.

Standard asset field	Data type	Description
AssetId	String	The unique identifier of a standard asset.
AssetName	String	The asset's name.

Standard asset field	Data type	Description
SerialNumber	String	The asset's serial number.
ModelNumber	String	The asset's model number.
ModelName	String	The asset's model name.
ProductSKU	String	The asset's stock keeping unit.
PurchaseDate	String	The asset's purchase date.
UsageEndDate	String	The asset's usage end date.
Status	String	The asset's status.
Price	String	The asset's price.
Quantity	String	The asset's quantity.
Description	String	The asset's description.
AdditionalInformation	String	Any additional information relevant to the asset.
DataSource	String	The asset's data source.
Attributes	String-to-string map	Key-value pair of attributes of a standard asset.

The standard asset objects are indexed by the keys in the following table.

Standard index name	Standard asset field
_assetId	AssetId
_assetName	AssetName
_serialNumber	SerialNumber

For example, you can use `_assetName` as a key name with the SearchProfiles API to find a profile that has an asset whose AssetName matches with the search value. You can find the standard asset objects associated with a specific profile by using the ListProfileObjects API with the `ProfileId` and `ObjectTypeName` set to `_asset`.

Mapping Salesforce objects to the standard asset in Customer Profiles

This topic lists which fields in Salesforce objects map to fields in the standard asset object in Customer Profiles.

Salesforce-Asset object

Following is a list of all the fields in a Salesforce-Asset object.

- Id
- ContactId
- AccountId
- ParentId
- RootAssetId
- Product2Id
- ProductCode
- IsCompetitorProduct
- CreatedDate
- CreatedById
- LastModifiedDate
- LastModifiedById
- SystemModstamp
- IsDeleted
- Name
- SerialNumber
- InstallDate
- PurchaseDate
- UsageEndDate
- LifecycleStartDate

- LifecycleEndDate
- Status
- Price
- Quantity
- Description
- OwnerId
- AssetProvidedById
- AssetServiceById
- IsInternal
- AssetLevel
- StockKeepingUnit
- HasLifecycleManagement
- CurrentMrr
- CurrentLifecycleEndDate
- CurrentQuantity
- CurrentAmount
- LastViewedDate
- LastReferencedDate

Mapping a Salesforce-Asset object to a standard asset

A subset of the fields in the Salesforce-Asset object map to the standard asset object in Customer Profiles.

The following table lists which fields can be mapped from the Salesforce-Asset object to the standard asset.

Saleforce-Asset source field	Standard asset target field
Id	Attributes.sfdcAssetId
ContactId	Attributes.sfdcContactId
AccountId	Attributes.sfdcAccountId

Saleforce-Asset source field	Standard asset target field
SerialNumber	SerialNumber
StockKeepingUnit	ProductSKU
UsageEndDate	UsageEndDate
Status	Status
Price	Price
Quantity	Quantity
Description	Description

The Salesforce-Asset customer data from the Salesforce object is associated with an Connect Customer standard asset using the indexes in the following table.

Standard Index Name	Salesforce-Asset source field
_salesforceAssetId	Id
_salesforceContactId	ContactId
_salesforceAccountId	AccountId

For example, you can use `_salesforceAssetId` and `_salesforceAccountId` as an `ObjectFilter.KeyName` with the ListProfileObjects API to find a standard asset. You can find the Salesforce-Asset objects associated with a specific profile by using the ListProfileObjects API with the `ProfileId` and `ObjectTypeName` set to `Salesforce-Asset`.

Object type mapping for the standard case in Customer Profiles

The topics in this section provide the standard case definition, and the object type mapping from external applications to the standard case.

Topics

- Amazon AppFlow access requirements in Customer Profiles

- Customer Profiles standard case object fields
- Mapping Zendesk objects to the standard case in Connect Customer Customer Profiles
- Mapping ServiceNow objects to the standard case in Connect Customer Customer Profiles

Amazon AppFlow access requirements in Customer Profiles

Use the following Amazon AppFlow access requirements to create and delete Zendesk and ServiceNow integrations with Connect Customer Customer Profiles:

- `appflow:CreateFlow`
- `appflow:DeleteFlow`

Customer Profiles standard case object fields

The following table lists all the fields in the Customer Profiles standard case object.

Standard case field	Data type	Description
CaseId	String	The unique identifier of a standard case.
Title	String	The case's title
Summary	String	The case's summary.
Status	String	The case's status.
Reason	String	The case's reason.
CreatedBy	String	The case's creator.
CreatedDate	String	The case's date created.
UpdatedDate	String	The case's date updated.
ClosedDate	String	The case's date closed.
AdditionalInformation	String	Any additional information relevant to the case.

Standard case field	Data type	Description
DataSource	String	The case's data source.
Attributes	String-to-string map	Key-value pair of attributes of a standard case.

The standard case objects are indexed by the keys in the following table.

Standard index name	Standard case field
_caseId	CaseId

For example, you can use `_caseId` as a key name with the SearchProfiles API to find a profile that has a case whose CaseId matches with the search value. You can find the standard case objects associated with a specific profile by using the ListProfileObjects API with the `ProfileId` and `ObjectTypeName` set to `_case`.

Mapping Zendesk objects to the standard case in Connect Customer Customer Profiles

This topic lists which fields in Zendesk objects map to fields in the standard case in Customer Profiles.

Zendesk-tickets object

Following is a list of all the fields in a Zendesk-tickets object.

- id
- url
- type
- subject
- raw_subject
- description
- priority
- status
- recipient

- requester_id
- submitter_id
- assignee_id
- organization_id
- group_id
- collaborator_ids
- email_cc_ids
- follower_ids
- forum_topic_id
- problem_id
- has_incidents
- due_at
- tags
- via.channel
- custom_fields
- satisfaction_rating
- sharing_agreement_ids
- followup_ids
- ticket_form_id
- brand_id
- allow_channelback
- allow_attachments
- is_public
- created_at
- updated_at

Mapping Zendesk-tickets object to a standard case

A subset of the fields in the Zendesk-tickets object map to the standard case in Customer Profiles. The following table lists which fields can be mapped from the Zendesk-tickets object to the standard case.

Zendesk-tickets source field	Standard case target field
requester_id	Attributes.ZendeskUserId
id	Attributes.ZendeskTicketId
subject	Title
description	Summary
status	Status
requester_id	CreatedBy
created_at	CreatedDate
updated_at	UpdatedDate

The Zendesk-tickets customer data from the Zendesk object is associated with a Connect Customer standard case using the following indexes.

Standard Index Name	Zendesk-tickets source field
_zendeskUserId	requester_id
_zendeskTicketId	id

For example, you can use `_zendeskUserId` and `_zendeskTicketId` as an `ObjectFilter.KeyName` with the ListProfileObjects API to find a standard case. You can find the Zendesk-tickets objects associated with a specific profile by using the ListProfileObjects API with the `ProfileId` and `ObjectTypeName` set to `Zendesk-tickets`.

Mapping ServiceNow objects to the standard case in Connect Customer Customer Profiles

This topic lists which fields in ServiceNow objects map to fields in the standard case in Connect Customer Customer Profiles.

Servicenow-task object

Following is list of all the fields in a Servicenow-task object.

- sys_id
- active
- activity_due
- additional_assignee_list
- approval
- approval_history
- approval_set
- assigned_to
- assignment_group
- business_duration
- business_service
- calendar_duration
- closed_at
- closed_by
- cmdb_ci.display_value
- cmdb_ci.link
- comments
- comments_and_work_notes
- company
- contact_type
- contract
- correlation_display
- active
- correlation_id
- delivery_plan
- delivery_task
- description
- due_date

- escalation
- expected_start
- follow_up
- group_list
- impact
- knowledge
- location
- made_sla
- number
- opened_at
- opened_by.display_value
- order
- parent
- priority
- reassignment_count
- service_offering
- short_description
- sla_due
- state
- sys_class_name
- sys_created_by
- sys_created_on
- active
- sys_domain.global
- sys_domain.link
- sys_domain_path
- sys_mod_count
- sys_updated_by
- sys_updated_on
- time_worked

- upon_approval
- upon_reject
- urgency
- user_input
- watch_list
- work_end
- work_notes
- work_notes_list
- work_start

Mapping Servicenow-task to a standard case

A subset of the fields in the Servicenow-task object map to the standard case in Customer Profiles.

The following table lists which fields can be mapped from the Servicenow-task object to the standard case.

Servicenow-task source field	Standard case target field
sys_id	Attributes.ServiceNowTaskId
opened_by.link	Attributes.ServiceNowSystemUserId
short_description	Title
description	Summary
status	Status
sys_created_by	CreatedBy
sys_created_on	CreatedDate
sys_updated_on	UpdatedDate

The Servicenow-task customer data from Servicenow is associated with an Connect Customer standard case using the indexes in the following table.

Standard Index Name	Servicenow-task source field
_serviceNowTaskId	sys_id
_serviceNowSystemId	open_by.link

For example, you can use `_serviceNowTaskId` and `_serviceNowSystemId` as an `ObjectFilter.KeyName` with the ListProfileObjects API to find a standard case. You can find the Servicenow-task objects associated with a specific profile by using the ListProfileObjects API with the `ProfileId` and `ObjectTypeName` set to `Servicenow-task`.

Servicenow-incident object

Following is a list of all the fields in a Servicenow-incident object.

- sys_id
- business_stc
- calendar_stc
- caller_id.link
- caller_id.value
- category
- caused_by
- child_incidents
- close_code
- hold_reason
- incident_state
- notify
- parent_incident
- problem_id
- reopened_by
- reopened_time
- reopen_count

- resolved_at
- resolved_by.link
- resolved_by.value
- rfc
- severity
- subcategory

Mapping Servicenow-incident to a standard case

A subset of the fields in the Servicenow-incident object map to the standard case in Customer Profiles.

The following table lists which fields can be mapped from the Servicenow-incident object to the standard case.

Servicenow-Incident source field	Standard case target field
sys_id	Attributes_ServiceNowIncidentId
caller_id.link	Attributes_ServiceNowSystemUserId
incident_status	Status
caller_id.link	CreatedBy
resolved_at	ClosedDate
category	Reason

The Servicenow-incident customer data from the Servicenow object is associated with an Connect Customer standard case using the indexes in the following table.

Standard Index Name	Servicenow source field
_serviceNowIncidentId	sys_id
_serviceNowSystemId	caller_id.link

For example, you can use `_serviceNowIncidentId` and `_serviceNowSystemId` as a ObjectFilter.KeyName with the ListProfileObjects API to find a standard case. You can find the Servicenow-incident objects associated with a specific profile by using the ListProfileObjects API with the `ProfileId` and `ObjectTypeName` set to `Servicenow-incident`.

Object type mapping for the standard air preference

The topics in this section provide the standard air preference definition.

Topics

- Customer Profiles standard air preference object fields

Customer Profiles standard air preference object fields

The following table lists all the fields in the Customer Profiles standard air preference object.

Air preference

Standard airPreference field	Data type	Description
PreferenceId	String	The unique identifier of a standard air preference
Name	String	The name of the preference
CreatedDate	String	The date when the preference was created
CreatedBy	String	The identifier of the creator
UpdatedDate	String	The date of last update
UpdatedBy	String	The identifier of the person who last updated
StartDate	String	The preference start date
EndDate	String	The preference end date
Status	String	The current status of the preference

Standard airPreference field	Data type	Description
ReferenceId	String	The id to the object referenced
ReferenceType	String	The type of object referenced
TravelType	String	The type of travel (for example, direct flights)
Transfer	String	The preferred type of transfer
ArrivalAirport	String	The preferred arrival airport
ArrivalTerminal	String	The preferred arrival airport terminal
DepartureAirport	String	The preferred departure airport
DepartureTerminal	String	The preferred departure airport terminal
HomeAirport	String	The home airport
CheckInChannel	String	The mode of checkin
CheckInChannelDevice	String	The device used for checkin
Language	Language	Details on preferred languages for communication
Seat	Seat	Detail on seat selection
Journey	Journey	Trip preferences
Accessibility	Accessibility	Details on accessibility requests
Insurance	Insurance	Details on insurance

Standard airPreference field	Data type	Description
Interest	Interest	Details on interests
Loyalty	Loyalty	Details on loyalty
Dining	Dining	Dining preferences
MediaEntertainment	MediaEntertainment	Media and entertainment preferences
PaymentForm	PaymentForm	Payment method preferences
PetInfo	PetInfo	Pet details
SpecialRequest	SpecialRequest	Special Request details
TicketDistribution	TicketDistribution	Ticket Distribution preferenc es
Marketing	Marketing	Marketing preferences
Medical	Medical	Preferences on medical
Baggage	Baggage	Preferences on baggage
ContactDetail	ContactDetail	Details about contact in preference
ContactDetailAddress	ContactDetailAddress	Address for the contact detail
ContactDetailCommunication	ContactDetailCommunication	Preferences on communica tion
Attributes	Map<String, String>	Key-value pair of attributes of an air preference

The standard air preference objects are indexed by the keys in the following table.

Standard Index Fields

Standard index name	Standard preference record field
_airPreferenceId	PreferenceId
_airReferenceId	ReferenceId

For example, you can use `_airPreferenceId` as a key name with the SearchProfiles API to find a profile that has an air preference whose PreferenceId matches with the search value. You can find the standard airPreference objects associated with a specific profile by using the ListProfileObjects API with the `ProfileId` and `ObjectTypeName` set to `_airPreference`.

ContactDetail data type

Standard airPreference field	Data type	Description
Type	String	The type of contact (for example, personal, emergency)
PreferenceLevel	String	Priority level of this contact
PhoneNumber	String	Phone number
Relationship	String	The relationship to the profile
EmailAddress	String	Email address
EmailLanguage	String	Preferred language for contact detail email communication
PhoneLanguage	String	Preferred language for contact detail phone communication

ContactDetailAddress data type

Standard airPreference field	Data type	Description
Type	String	The type of address for the contact
Address1	String	The first line of a contact address.
Address2	String	The second line of a contact address.
Address3	String	The third line of a contact address.
Address4	String	The fourth line of a contact address.
City	String	The city of a contact address.
Country	String	The country of a contact address.
County	String	The county of a contact address.
PostalCode	String	The postal of a contact address.
Province	String	The province of a contact address.
State	String	The state of a contact address.

ContactDetailCommunication data type

Standard airPreference field	Data type	Description
Method	String	Communication method (for example, SMS, Email)
PreferenceLevel	String	Level of preference for communication method

Language data type

Standard airPreference field	Data type	Description
PhoneLanguage	String	Preferred language for phone communication
EmailLanguage	String	Preferred language for email communication
InPersonLanguage	String	Preferred language for in person communication
PreferenceLevel	String	Language preference level

Seat data type

Standard airPreference field	Data type	Description
PreferenceLevel	String	Priority of seat preferences
Direction	String	The Preferred seat direction (for example, front, back)
Location	String	The Preferred seat location (for example, window, aisle)
Position	String	The Seat position (for example, left, right)

Standard airPreference field	Data type	Description
Row	String	The desired seat row
ClassOfService	String	The travel class (for example, Economy, Business)
NeighborFree	String	Preference for a seat without neighbors
Infant	String	Preference for infant seat
ExtraSeat	String	Preference for extra seat

Journey data type

Standard airPreference field	Data type	Description
MaxConnections	String	The maximum allowed connections
PreferredAirline	String	Preferred airline
UpgradeAuction	String	Opt-in for upgrade auctions
FlightTime	String	Preferred Flight time
FlightMaxDuration	String	Preferred maximum travel duration

Accessibility data type

Standard airPreference field	Data type	Description
Wheelchair	String	Wheelchair accessibility info
Bathroom	String	Bathroom accessibility info
Assistance	String	Assistance infomation

Standard airPreference field	Data type	Description
DisabilityType	String	Information on disability
SupportAnimal	String	Support animal information
ProximityToFacilities	String	Needs proximity to facilities

Insurance data type

Standard airPreference field	Data type	Description
Name	String	Insurance provider or plan name
PreferenceLevel	String	Level of preference for insurance

Interest data type

Standard airPreference field	Data type	Description
Name	String	Specific area of interest
PreferenceLevel	String	Priority of this interest

Loyalty data type

Standard airPreference field	Data type	Description
Name	String	Name of loyalty program
MembershipId	String	Membership ID in the loyalty program
PreferenceLevel	String	Loyalty program preference level

Dining data type

Standard airPreference field	Data type	Description
MealType	String	Preferred type of meal
FavoriteCuisine	String	Favorite cuisine types
Beverage	String	Preferred beverages
DietaryRestriction	String	Dietary restrictions
AllergyInfo	String	Details on allergies
PreferenceLevel	String	Dining preference level

Media and entertainment data type

Standard airPreference field	Data type	Description
Name	String	Name of preferred entertain ment
PreferenceLevel	String	Preference level for media/ entertainment

PaymentForm data type

Standard airPreference field	Data type	Description
Name	String	Name of payment method
Type	String	Type of payment (for example, credit card, PayPal)
PreferenceLevel	String	Payment method preference level
UsageContext	String	Where the payment method is used

PetInfo data type

Standard airPreference field	Data type	Description
Type	String	Type of pet
PreferenceLevel	String	Preference level regarding pets

SpecialRequest data type

Standard airPreference field	Data type	Description
Type	String	Type of special request
Name	String	Name or description of request
PreferenceLevel	String	Priority level of the request

TicketDistribution data type

Standard airPreference field	Data type	Description
PreferenceLevel	String	Level of preference for ticket distribution
Method	String	Ticket delivery method (for example, email, physical)
TicketTime	String	Preferred time for ticket delivery

Marketing data type

Standard airPreference field	Data type	Description
ChannelType	String	Type of marketing channel (for example, SMS, Email)
OptIn	String	Opt-in status for marketing
Frequency	String	Frequency of marketing communications
StartDate	String	Start date of marketing preference
EndDate	String	End date of marketing preference

Medical data type

Standard airPreference field	Data type	Description
Oxygen	String	(Airline supplied, passenger owned, concentrator, etc)
MedicalEquipment	String	Details on medical equipment (for example, CPAP machine, oxygen concentrator).
Assistance	String	Specifies whether the traveler needs general medical assistance during travel (for example, in-flight support, help with medication).
Stretcher	String	If the traveler requires a stretcher during flight, typically used for medical transport cases.

Standard airPreference field	Data type	Description
WheelChair	String	Wheelchair details (non-spil lable, wet cell, immobile, RampNeeded, stairsAss istance, airline provided, etc)

Baggage data type

Standard airPreference field	Data type	Description
Animal	String	Indicates if the traveler is traveling with a service animal or pet, and includes relevant specifications or restrictions. (inHold, Cabin)
BaggageType	String	Specifies the preferred type of baggage handling (for example, carry-on only, checked baggage, oversized).
Assistance	String	Indicates whether the traveler requires assistance with carrying or managing their baggage, such as airport porter services or curbside luggage help.
PreferenceLevel	String	Level of preference for Baggage fields

Object type mapping for the standard hotel preference

The topics in this section provide the standard hotel preference definition.

Topics

- Customer Profiles standard hotel preference object fields

Customer Profiles standard hotel preference object fields

The following table lists all the fields in the Customer Profiles standard hotel preference object.

Hotel Preference

Standard hotelPreference field	Data type	Description
PreferenceId	String	Unique identifier of a standard hotel preference
Name	String	The name of the preference
CreatedDate	String	The date the preference was created
CreatedBy	String	The identifier of the creator
UpdatedDate	String	The date of last update
UpdatedBy	String	The identifier of the person who last updated
StartDate	String	The preference start date
EndDate	String	The preference end date
Status	String	The current status of the preference
Smoking	String	Smoking preference
CleaningTime	String	Time of cleaning
CheckInType	String	Type of check-in
CheckOutType	String	Type of check-out

Standard hotelPreference field	Data type	Description
ReferenceId	String	The id to the object referenced
ReferenceType	String	The type of object referenced
Location	Location	Preferences on hotel room location
Bedding	Bedding	Bedding preferences
Tour	Tour	Tour preferences
ContactDetail	ContactDetail	Details about contact in preference
ContactDetailAddress	ContactDetailAddress	Address for the contact detail
ContactDetailCommunication	ContactDetailCommunication	Preferences on communication
Language	Language	Language preferences
CarRental	CarRental	Car rental preferences
Accessibility	Accessibility	Accessibility preferences
Interest	Interest	Interest details
Loyalty	Loyalty	Loyalty preferences
Dining	Dining	Dining preferences
MediaEntertainment	MediaEntertainment	Media and entertainment preferences
PaymentForm	PaymentForm	Payment form preferences
PetInfo	PetInfo	Pet info preferences

Standard hotelPreference field	Data type	Description
SpecialRequest	SpecialRequest	Details on special requests
Marketing	Marketing	Marketing preferences
Medical	Medical	Medical preferences
Baggage	Baggage	Baggage preferences
Attributes	Map<String, String>	Key-value pair of attributes of a hotel preference

The standard hotel preference objects are indexed by the keys in the following table.

Standard Index Fields

Standard index name	Standard preference record field
_hotelPreferenceId	PreferenceId
_hotelReferenceId	ReferenceId

For example, you can use `_hotelPreferenceId` as a key name with the SearchProfiles API to find a profile that has a hotel preference whose PreferenceId matches with the search value. You can find the standard hotelPreference objects associated with a specific profile by using the ListProfileObjects API with the `ProfileId` and `ObjectTypeName` set to `_hotelPreference`.

ContactDetail data type

Standard airPreference field	Data type	Description
Type	String	The type of contact (for example, personal, emergency)
PreferenceLevel	String	Priority level of this contact

Standard airPreference field	Data type	Description
PhoneNumber	String	Phone number
Relationship	String	The relationship to the profile
EmailAddress	String	Email address
EmailLanguage	String	Preferred language for contact detail email communication
PhoneLanguage	String	Preferred language for contact detail phone communication

ContactDetailAddress data type

Standard airPreference field	Data type	Description
Type	String	The type of address for the contact
Address1	String	The first line of a contact address.
Address2	String	The second line of a contact address.
Address3	String	The third line of a contact address.
Address4	String	The fourth line of a contact address.
City	String	The city of a contact address.
Country	String	The country of a contact address.

Standard airPreference field	Data type	Description
County	String	The county of a contact address.
PostalCode	String	The postal code of a contact address.
Province	String	The province of a contact address.
State	String	The state of a contact address.

ContactDetailCommunication data type

Standard hotelPreference field	Type	Description
Method	String	Method of communication
PreferenceLevel	String	Preference level for communication method
Frequency	String	Frequency of communication

Language data type

Standard hotelPreference field	Type	Description
PhoneLanguage	String	Preferred phone language
EmailLanguage	String	Preferred email language

CarRental data type

Standard hotelPreference field	Type	Description
Vendor	String	Preferred car rental vendor
VehicleType	String	Preferred vehicle type
PreferenceLevel	String	Preference level for car rental

Location data type

Standard hotelPreference field	Type	Description
PreferredFloor	String	Preference for room floor
ElevatorProximity	String	Preference for proximity to elevators
QuietZone	String	Preference for quiet zone
LobbyProximity	String	Preference for proximity to the lobby
View	String	Desired view from the room
RoomType	String	Preferred room type
PreferenceLevel	String	Level of preference for location

Bedding data type

Standard hotelPreference field	Type	Description
BedType	String	Preferred bed type

Standard hotelPreference field	Type	Description
MattressType	String	Preferred mattress type
PillowType	String	Preferred pillow type
NumberOfPillows	String	Number of pillows preferred
BeddingMaterial	String	Material of the bedding
Allergy	String	Allergy-related bedding preferences

Tour data type

Standard hotelPreference field	Type	Description
City	String	Preferred cities for tours
Cultural	String	Cultural tour interests
Adventure	String	Adventure tour interests
Nightlife	String	Nightlife tour interests
GuideLanguage	String	Preferred language for the tour guide
StartTime	String	Preferred start time for tours
GroupSize	String	Preferred group size for tours
PreferenceLevel	String	Importance of the tour preferences

Accessibility data types

Standard airPreference field	Data type	Description
Wheelchair	String	Wheelchair accessibility info
Bathroom	String	Bathroom accessibility info
Assistance	String	Assistance infomation
DisabilityType	String	Information on disability
SupportAnimal	String	Support animal information
ProximityToFacilities	String	Needs proximity to facilities

Interest data type

Standard hotelPreference field	Type	Description
NameOfInterest	String	Name of the interest
PreferenceLevel	String	Preference level for the interest

Loyalty data type

Standard hotelPreference field	Type	Description
LoyaltyName	String	Name of the loyalty program
MembershipId	String	Loyalty membership ID
PreferenceLevel	String	Loyalty preference level
PriorityServices	String	Priority services preference

Dining data type

Standard hotelPreference field	Type	Description
MealType	String	Preferred meal types
FavoriteCuisine	String	Favorite cuisine preferences
Beverage	String	Beverage preferences
DietaryRestriction	String	Dietary restrictions
AllergyInfo	String	Allergy information
PreferenceLevel	String	Dining preference level

MediaEntertainment data type

Standard hotelPreference field	Type	Description
Name	String	Name of preferred media or entertainment
PreferenceLevel	String	Preference level for media or entertainment

PaymentForm data type

Standard hotelPreference field	Type	Description
Name	String	Name associated with the payment method
Type	String	Type of payment method

Standard hotelPreference field	Type	Description
PreferenceLevel	String	Payment method preference level
UsageContext	String	Context in which payment form is used

PetInfo data type

Standard hotelPreference field	Type	Description
Type	String	Type of pet
PreferenceLevel	String	preference level for pet

Special Request data type

Standard hotelPreference field	Type	Description
Type	String	Type of special request
Name	String	Name of the special request
PreferenceLevel	String	Preference level of the request

Marketing data type

Standard hotelPreference field	Type	Description
ChannelType	String	Type of marketing channel (for example, SMS, Email)

Standard hotelPreference field	Type	Description
OptIn	String	Opt-in status for marketing
Frequency	String	Frequency of marketing communications
StartDate	String	Start date of marketing preference
EndDate	String	End date of marketing preference

Medical data type

Standard hotelPreference field	Type	Description
Oxygen	String	Oxygen supply preferences
MedicalEquipment	String	Details on medical equipment
Assistance	String	Type of medical assistance required
Stretcher	String	Stretcher guest requirement
WheelChair	String	Wheelchair type and assistanc e needed

Baggage data type

Standard hotelPreference field	Type	Description
Bicycle	String	Bicycle baggage needs
BaggageType	String	Baggage details (e.g bulky)

Standard hotelPreference field	Type	Description
Courier	String	Courier-related baggage preference
Fragile	String	Fragile item preferences
Preference Level	String	Baggage preference level

Object type mapping for the standard air booking

The topics in this section provide the standard air booking definition.

Topics

- Customer Profiles standard air booking object fields

Customer Profiles standard air booking object fields

The following table lists all the fields in the Customer Profiles standard air booking object.

AirBooking

Standard airBooking field	Type	Description
BookingId	String	The unique identifier of the standard air booking
ContextId	String	The context-specific identifier for tracing reservation source
PreferenceRef	String	The identifier referencing the Preference object for the booking
BookingName	String	The name associated with the booking

Standard airBooking field	Type	Description
PassengerIndex	String	Index for the passenger within the booking
TravellerId	String	Unique identifier for traveler associated with the booking
GroupBooking	String	Indicates if the booking is for a group
NumberOfPassengers	String	Total number of passengers in the booking
NumberOfAdults	String	Total number of adults in the booking
NumberOfChildren	String	Total number of children in the booking
ProcessedDate	String	Date the booking was processed
CreatedDate	String	Date the booking was created
CreatedBy	String	Identity of the creator
UpdatedDate	String	Last update date
UpdatedBy	String	Identifier of who last updated the booking
Status	String	Current booking status
PriorityStatus	String	Priority tier of the booking
ReservationStatus	String	Reservation status of the booking

Standard airBooking field	Type	Description
MarketingCode	String	Code representing marketing source or campaign
MarketingName	String	Marketing campaign name
TravelAgent	String	Travel agent associated with the booking
TravelAgency	String	Name of corporate travel agency
TravelCorpNumber	String	Corporate customer number
Booker	String	Indicates if the person is the one who made the booking
AdditionalInformation	String	Additional freeform info
Email	String	Contact email for travel day updates
PhoneNumber	String	Contact phone for travel day updates
CancelledDate	String	Date of booking cancellation (if applicable)
Diplomat	String	Indicates diplomatic status
Child	String	Indicates if the passenger is a child
Disabled	String	Indicates disability status
Oxygen	String	Indicates need for oxygen support

Standard airBooking field	Type	Description
PetOnly	String	Booking is only for transport ing pet
CancellationCharge	String	Cancellation charge if applicable. 0 would mean no charge
Refundable	String	Details on booking refund
Inventory	Inventory	Inventory details for booking
Loyalty	Loyalty	Loyalty details for booking
Channel	Channel	Channel details for booking
Payment	Payment	Payment details for booking
BillingAddress	Address	Billing address details for booking
Price	Price	Booking price details
PaymentStatus	PaymentStatus	Payment status of booking
Attributes	Map<String, String>	Custom or extension attributes

Standard Index Fields

Standard index name	Standard preference record field
_airBookingId	BookingId
_airPreferenceRef	PreferenceRef

Loyalty data type

Standard airBooking field	Type	Description
ProgramName	String	Name of the loyalty program
MembershipId	String	Loyalty program membership number
Tier	String	Loyalty membership tier level

Channel data type

Standard airBooking field	Type	Description
CreationChannelId	String	ID of the channel used to create the booking
LastUpdatedChannelId	String	ID of the channel used to update the booking
Method	String	Method used through the channel (for example, web, app, phone)

Payment data type

Standard airBooking field	Type	Description
Type	String	Payment method type (for example, card, voucher)
CreditCardToken	String	Tokenized card for secure reference
CreditCardType	String	Type of credit card used
CreditCardExpiration	String	Expiry date of the card

Standard airBooking field	Type	Description
Cvv	String	CVV number
NameOnCreditCard	String	Cardholder name
RoutingNumber	String	Bank routing number (if applicable)
AccountNumber	String	Bank account number (if applicable)
VoucherId	String	Voucher used for payment
DiscountCode	String	Promotional discount code applied
DiscountPercent	String	Percent of discount applied to payment

Billing Address data type

Standard airPreference field	Data type	Description
Address1	String	The first line of a customer address.
Address2	String	The second line of a customer address.
Address3	String	The third line of a customer address.
Address4	String	The fourth line of a customer address.
City	String	The city of the customer address.

Standard airPreference field	Data type	Description
Country	String	The country of the customer address.
County	String	The county of the customer address.
PostalCode	String	The postal code of the customer address.
Province	String	The province of the customer address.
State	String	The state of the customer address.

Price data type

Standard airBooking field	Type	Description
TotalPrice	String	Total Price of the booking
BasePrice	String	Base price of the booking
TravellerPrice	String	Price paid per traveler
DiscountAmount	String	Discount applied to base fare
Currency	String	Currency in which payment was made

Payment Status data type

Standard airBooking field	Type	Description
PaidAt	String	Timestamp when payment was completed

Standard airBooking field	Type	Description
AwaitingPayment	String	Indicates payment is pending
RequiredBy	String	Payment due date

Inventory data type

Standard airBooking field	Type	Description
Seats	String	Total number of seats in booking

Object type mapping for the standard air segment

The topics in this section provide the standard air segment definition.

Topics

- Customer Profiles standard air segment object fields

Customer Profiles standard air segment object fields

The following table lists all the fields in the Customer Profiles standard air segment object.

Air Segment

Standard airSegment Field	Type	Description
SegmentId	String	Unique identifier of the standard air segment
BookingRef	String	Booking reference identifier
SegmentName	String	Name/description of the segment
PassengerIndex	String	Index number of the passenger

Standard airSegment Field	Type	Description
SegmentIndex	String	Index number of the segment
SeatSelection	String	Seat selection detail
NumberOfPassengers	String	Total number of passengers
NumberOfLegs	String	Number of flight legs
Tier	String	Passenger tier/status level
Origin	String	Departure airport code
OriginCountryCode	String	Country code of departure
Dest	String	Destination airport code
DestCountryCode	String	Country code of destination
ProcessedDate	String	Date when the segment was processed
CreatedDate	String	Date when the record was created
CreatedBy	String	User who created the record
UpdatedDate	String	Date when the record was last updated
UpdatedBy	String	User who last updated the record
Status	String	Current status of the segment
FlightNumber	String	Flight number
Carrier	String	Operating carrier code
CarrierType	String	Type of carrier

Standard airSegment Field	Type	Description
IsInternational	String	Indicates if flight is internati onal
IsEticket	String	Indicates if electronic ticket
IsArmed	String	Indicates if armed passenger
LapInfant	String	Lap infant details
Pet	String	Indicates if traveling with pet
PrisonerOrGuard	String	Indicates prisoner or guard status
Child	String	Indicates if passenger is a child
Married	String	Indicates if segments are married
CheckinEligible	String	Indicates check-in eligibility
InEligibleReason	String	Reason if not eligible for check-in
UnEscortedMinor	String	Indicates unaccompanied minor status
PremiumAccess	String	Indicates premium access purchase
MissingData	String	Indicates missing data
CurrentClassOfService	String	Current service class
BookedClassOfService	String	Originally booked service class
CodeShare	String	Indicates codeshare flight

Standard airSegment Field	Type	Description
ReverseCodeShare	String	Indicates reverse codeshare
MarketCarrierCode	String	Marketing carrier code
OpCarrierCode	String	Operating carrier code
InConnection	String	Incoming connection detail
OutConnection	String	Outgoing connection detail
MilesToEarn	String	Miles to be earned
Duration	String	Duration of the flight
DurationTimeUnit	String	Time unit for duration
Distance	String	Distance of the flight
DistanceUnit	String	Unit for distance measureme nt
SellType	String	Indicates if this is a forced sell
GoShow	String	Indicates if this is a go show
Incapacitated	String	Indicates if passenger is incapacitated
Upgraded	String	Indicates if flight was upgraded
Downgraded	String	Indicates if flight was downgraded
BaggageInsurance	String	baggage insurance
MaxAllowedBaggage	String	Maximum allowed bags
BaggageQuantity	String	Number of bags

Standard airSegment Field	Type	Description
BaggageFee	String	Total Baggage Fee
Arrival	Port	Arrival details for Segment
Departure	Port	Departure details for Segment
Seat	Seat	Seat detail
Priority	Priority	Priority detail
Doc	Doc	Accompanying document information for travel
Baggage	Baggage List	Baggage detail
Pets	Pet List	Pet details
OtherServices	OtherService List	Other services detail
Attributes	Map<String, String>	Additional attributes

Standard Index Fields

Standard index name	Standard preference record field
_airSegmentId	SegmentId
_airBookingRef	BookingRef

Baggage data type

Standard airSegment Field	Type	Description
Id	String	Baggage identifier
TagNumber	String	Baggage tag number

Standard airSegment Field	Type	Description
DepartureDate	String	Departure date
BaggageType	String	Type of baggage
Weight	String	Weight of baggage
Length	String	Length of baggage
Width	String	Width of baggage
Height	String	Height of baggage
PriorityBagDrop	String	Priority bag drop service
PriorityBagReturn	String	Priority bag return service
HandsFreeBaggage	String	Hands-free baggage service
Fee	String	Baggage fee
IsGateBag	String	Indicates gate check baggage
IsHeavy	String	Indicates heavy baggage

Seat data type

Standard airSegment Field	Type	Description
SeatNumber	String	Seat number
SeatZone	String	Zone of the seat
SeatType	String	Type of seat
Price	String	Seat price
NeighborFree	String	Indicates if neighboring seat is free

Standard airSegment Field	Type	Description
UpgradeAuction	String	Indicates auction upgrade availability
Available	String	Indicates seat availability
ExtraSeat	String	Indicates extra seat
AdditionalInformation	String	Extra seat information

Port data type

Standard airSegment Field	Type	Description
Location	String	Location name
Code	String	Airport code
Terminal	String	Airport terminal
Country	String	Airport country
Date	String	Date
Time	String	Time
EstimatedTime	String	Estimated time
ScheduledTime	String	Scheduled time

Priority data type

Standard airSegment Field	Type	Description
TransactionId	String	Transaction identifier
PriorityServiceType	String	Type of priority service
LoungeAccess	String	Indicates lounge access

Standard airSegment Field	Type	Description
Price	String	Priority service price
AdditionalInformation	String	Extra priority information

Pet data type

Standard airSegment Field	Type	Description
Species	String	Pet species
Breed	String	Pet breed
Weight	String	Pet weight
WeightUnit	String	Weight unit of measurement
TransportType	String	Type of pet transport

OtherService data type

Standard airSegment Field	Type	Description
ServiceType	String	Type of service
Description	String	Service description
Price	String	Service price

Doc data type

Standard airSegment Field	Type	Description
DocType	String	Type of document
DocTypeNeeded	String	Indicates if document is required

Standard airSegment Field	Type	Description
Nationality	String	Nationality on document
DateOfBirth	String	Date of birth
AppId	String	Application identifier
AgentId	String	Agent identifier
VerifiedDateTime	String	Document verification time

Object type mapping for the standard hotel reservation

The topics in this section provide the standard hotel reservation definition.

Topics

- Customer Profiles standard hotel reservation object fields

Customer Profiles standard hotel reservation object fields

The following table lists all the fields in the Customer Profiles standard hotel reservation object.

Hotel Reservation

Standard hotelReservation field	Type	Description
ReservationId	String	Unique identifier of the stanndard hotel reservation
ConfirmationNumber	String	Confirmation number provided by the hotel or booking engine
PreferenceRef	String	The identifier referencing the Preference object for the reservation

Standard hotelReservation field	Type	Description
Status	String	Current status of the reservation (for example, confirmed, cancelled)
TripType	String	Purpose or nature of the trip (for example, leisure, business)
BrandCode	String	Code representing the hotel brand
HotelCode	String	Code identifying the specific hotel
PhoneNumber	String	Contact phone number for the reservation
EmailAddress	String	Contact email address for the reservation
GroupId	String	ID linking the reservation to a group booking
ContextId	String	Context-specific identifier for tracing reservation source
ProcessedDate	String	Timestamp when the reservation was processed
CreatedDate	String	Timestamp when the reservation was created
CreatedBy	String	Identifier of the user/system that created the reservation

Standard hotelReservation field	Type	Description
UpdatedDate	String	Timestamp when the reservation was last updated
UpdatedBy	String	Identifier of the user/system that updated the reservation
AgentId	String	ID of the agent handling the booking
Reserver	String	Denotes if the profile is the reserver
SameDayRate	String	Indicates if the booking was made for the same day
Refundable	String	Indicates if the booking is refundable
CancellationCharge	String	Cancellation charge if applicable. 0 would mean no charge
TransactionId	String	Unique identifier of transacti on
AmountPerNight	String	Amount charged per night for room
AdditionalNote	String	Special notes or instructions
NumberOfNights	String	Number of nights in reservati on
NumberOfGuests	String	Number of total guests in reservation
TotalAmountBeforeTax	String	Total cost before tax

Standard hotelReservation field	Type	Description
TotalAmountAfterTax	String	Total cost after tax
Checkout	CheckOut	Checkout details
Loyalty	Loyalty	Loyalty details
Room	Room	Room details
CheckIn	CheckIn	Check-in details
Payment	Payment	Payment details
Currency	Currency	Currency details
Cancellation	Cancellation	Cancellation details
Channel	Channel	Channel details
RatePlan	RatePlan	Rate plan details
Guests	Guests	Guest details
Services	Service List	List of services
Attributes	Map<String, String>	Additional attributes

Standard Index Fields

Standard index name	Standard preference record field
_hotelReservationId	ReservationId
_hotelPreferenceRef	preferenceRef

Checkout data type

Standard hotelReservation field	Type	Description
Early	String	Early checkout is scheduled or requested
Late	String	Late checkout is scheduled or requested
Self	String	Self checkout is scheduled or requested
Date	String	Checkout date of reservation

Loyalty data type

Standard hotelReservation field	Type	Description
ProgramName	String	Name of the loyalty program
MembershipId	String	Member's ID in the loyalty program
Tier	String	Loyalty tier or level

Room data type

Standard hotelReservation field	Type	Description
TypeCode	String	Code for room type/category
TypeName	String	Name of room type
TypeDesc	String	Description of room type

Standard hotelReservation field	Type	Description
Number	String	Assigned room number
Capacity	String	Maximum capacity of the room
AccessibilityType	String	Accessibility features
SmokingAllowed	String	Indicates if smoking is allowed in the room

CheckIn data type

Standard hotelReservation field	Type	Description
Date	String	Check-in date of reservation
DigitalKey	String	Indicates if a digital room key was issued
Early	String	Indicates if early check-in was requested
Late	String	Indicates if late check-in was requested
RoomKeys	String	Number of room keys issued
UserSelectedRoom	String	True if guest selected their own room

Payment data type

Standard hotelReservation field	Type	Description
Type	String	Payment method type (for example, credit, debit, voucher)
CreditCardToken	String	Tokenized credit card number
CreditCardType	String	Type of credit card (for example, Visa, Amex)
CreditCardExpiration	String	Credit card expiration date
Cvv	String	Card verification value
NameOnCreditCard	String	Name printed on the credit card
RoutingNumber	String	Bank routing number
AccountNumber	String	Bank account number
VoucherId	String	Voucher identifier if used
DiscountCode	String	Applied discount code
DiscountPercent	String	Percentage discount applied

Currency data type

Standard hotelReservation field	Type	Description
Code	String	ISO code for the currency (for example, USD)

Standard hotelReservation field	Type	Description
Name	String	Full name of the currency (for example, US Dollar)
Symbol	String	Symbol of the currency (for example, $)

Cancellation data type

Standard hotelReservation field	Type	Description
Reason	String	Reason for cancellation
Comment	String	Additional cancellation notes

Channel data type

Standard hotelReservation field	Type	Description
CreationChannelId	String	ID for the channel through which the reservation was made
LastUpdatedChannelId	String	ID for the channel that last updated the reservation
Method	String	Method used for booking (for example, web, mobile app)

RatePlan data type

Standard hotelReservation field	Type	Description
Code	String	Code Identifier of the rate plan booked
Name	String	Name of the rate plan booked
Description	String	Description of the rate plan

Service data type

Standard hotelReservation field	Type	Description
ServiceType	String	Type of service (for example, spa, breakfast)
Description	String	Description of the service
Cost	String	Cost of the service

Guest data type

Standard hotelReservation field	Type	Description
Adults	String	Number of adult guests
Children	String	Number of child guests

Object type mapping for the standard loyalty

The topics in this section provide the standard loyalty definition.

Topics

- Customer Profiles standard loyalty object fields

Customer Profiles standard loyalty object fields

The following table lists all the fields in the Customer Profiles standard loyalty object.

Loyalty

Standard loyalty field	Type	Description
LoyaltyId	String	Unique identifier of the standard loyalty
ProgramId	String	Identifier for the loyalty program
MembershipId	String	Alternate identifier within the program
ProgramName	String	Name of the loyalty program
Group	String	Group or category of the loyalty program
Channel	String	Channel through which the loyalty program is accessed
CreatedDate	String	Date the loyalty account was created
EnrollmentDate	String	Date the customer enrolled in the program
CreatedBy	String	User or system that created the loyalty account
UpdatedDate	String	Date the loyalty account was last updated
LastUpdatedBy	String	User or system that last updated the loyalty account

Standard loyalty field	Type	Description
UpgradeDate	String	Date when the tier was last upgraded
RenewalDate	String	Date of loyalty membership renewal
AdditionalInformation	String	Any additional information
EmailAddress	String	Customer's email address
EmailAddressVerified	String	Flag indicating if email is verified
PhoneNumber	String	Customer's phone number
PhoneNumberVerified	String	Flag indicating if phone number is verified
Status	String	Current status of the loyalty account
Tier	Tier	Tier details
Points	Points	Points details
PointExpirations	PointExpiration List	Point expiration details
Payment	Payment	Payment details
PaymentInformation	PaymentInformation	Payment Information details
BillingAddress	Loyalty Address	Address details
Attributes	Map<String, String>	Additional attributes not otherwise covered

Standard Index Fields

Standard index name	Standard preference record field
_loyaltyId	LoyaltyId
_loyaltyMembershipId	membershipId

Loyalty Address data type

Standard airPreference field	Data type	Description
Address1	String	The first line of a customer address.
Address2	String	The second line of a customer address.
Address3	String	The third line of a customer address.
Address4	String	The fourth line of a customer address.
City	String	The city in which the customer lives.
Country	String	The country in which the customer lives.
County	String	The county in which the customer lives.
PostalCode	String	The postal code of the customer address.
Province	String	The province in which the customer lives.

Standard airPreference field	Data type	Description
State	String	The state in which the customer lives.

Tier data type

Standard loyalty field	Type	Description
CurrentTier	String	Customer's current loyalty tier
NextTier	String	Next possible tier for the customer
PointsToNextTier	String	Points needed to reach the next tier

Points data type

Standard loyalty field	Type	Description
Points.Unit	String	Unit of measurement for points
Points.Lifetime	String	Total lifetime points earned
Points.Balance	String	Current points balance
Points.Redeemed	String	Total points redeemed

PointExpiration data type

Standard loyalty field	Type	Description
Points	String	Points expiring
Date	String	Expiration date for points

Payment data type

Standard loyalty field	Type	Description
Type	String	Type of payment
CreditCardToken	String	Tokenized credit card reference
CreditCardType	String	Type of credit card (for example, Visa)
CreditCardExpiration	String	Expiration date of the credit card
Cvv	String	Card verification value
NameOnCreditCard	String	Name on the card
RoutingNumber	String	Bank routing number
AccountNumber	String	Bank account number
VoucherId	String	Voucher identifier

PaymentInformation data type

Standard loyalty field	Type	Description
Schedule	String	Schedule of payments
LastPaymentDate	String	Date of last payment
NextPaymentDate	String	Date of next payment
NextBillAmount	String	Amount for the next bill
CurrencyCode	String	Currency code (for example, USD)
CurrencyName	String	Full name of the currency

Standard loyalty field	Type	Description
CurrencySymbol	String	Currency symbol (for example, $)

Object type mapping for the standard loyalty transaction

The topics in this section provide the standard loyalty transaction definition.

Topics

- Customer Profiles standard loyalty transaction object fields

Customer Profiles standard loyalty transaction object fields

The following table lists all the fields in the Customer Profiles standard loyalty transaction object.

Loyalty Transaction

Standard loyaltyTransaction field	Type	Description
TransactionId	String	Unique identifier of the standard loyalty transaction.
TransactionName	String	Name or label of the transacti on.
TransactionType	String	Type of transaction (for example, earn, redeem, adjust).
ProgramRef	String	Reference to the associated loyalty program.
MembershipRef	String	Reference to the loyalty membership used in the transaction.

Standard loyaltyTransaction field	Type	Description
PromotionRef	String	Reference to a promotion that influenced this transacti on.
CreatedDate	String	Date the transaction was created.
TransactionDate	String	Date the transaction occurred.
Industry	String	Industry associated with the transaction (for example, airline, hotel).
Location	String	Location where the transacti on occurred.
CreatedBy	String	Identifier for who created the transaction.
UpdatedDate	String	Last date the transaction was updated.
UpdatedBy	String	Identifier of who last updated the transaction.
Status	String	Current status of the transacti on.
AccrualType	String	Method of accrual (manual, automated).
Category	String	Category of the transaction (for example, flight, hotel stay).

Standard loyaltyTransaction field	Type	Description
Channel	String	Channel where the transacti on was initiated (for example, online, in-store).
ProductId	String	Identifier of the product or service tied to the transacti on.
Amount	String	Amount spent or transacted in the transaction.
OriginValue	String	Original value before any conversion or offset.
OriginValueCurrency	String	Currency of the original transaction value.
OriginValueOffset	String	Adjustment to the original value for promotions, refunds.
PointsEarned	String	Total points earned from this transaction.
PointOffset	String	Points adjusted (for example, bonuses, penalties).
QualifyingPointsEarned	String	Points that count toward tier qualification.
TierBefore	String	Customer tier before the transaction.
TierAfter	String	Customer tier after the transaction.

Standard loyaltyTransaction field	Type	Description
Brand	String	Brand associated with the transaction.
Description	String	Narrative description of the transaction.
AdditionalInformation	String	Freeform additional informati on related to the transaction.
PaymentMethod	String	Payment method used (for example, card, voucher).
PointTransfer	PointTransfer	Point transfer details
Attributes	Map<String, String>	Additional attributes.

Standard Index Fields

Standard index name	Standard preference record field
_loyaltyTransactionId	TransactionId

PointTransfer data type

Standard loyaltyTransaction field	Type	Description
TransferId	String	Identifier for the transfer transaction.
SourceProgramId	String	ID of the source loyalty program.
DestinationProgramId	String	ID of the destination loyalty program.

Standard loyaltyTransaction field	Type	Description
SourceMembershipId	String	Membership ID in the source program.
DestinationMembershipId	String	Membership ID in the destination program.
PointsTransferred	String	Points deducted from the source program.
PointsReceived	String	Points credited to the destination program.

Object type mapping for the standard loyalty promotion

The topics in this section provide the standard loyalty promotion definition.

Topics

- Customer Profiles standard loyalty promotion object fields

Customer Profiles standard loyalty promotion object fields

The following table lists all the fields in the Customer Profiles standard loyalty promotion object.

Loyalty Promotion

Standard loyaltyPromotion field	Type	Description
PromotionId	String	Unique identifier of the standard loyalty promotion.
PromotionName	String	Display name of the promotion.

Standard loyaltyPromotion field	Type	Description
PromotionType	String	The type or category of promotion (for example, bonus, tier boost, voucher).
ProgramType	String	Indicates the type of loyalty program the promotion is tied to.
ProgramRef	String	Reference ID to the related loyalty program.
PartnerId	String	Reference ID of a partner organization involved in the promotion.
PartnerNumber	String	An identifier or number related to the partner.
Tier	String	Tier level targeted or impacted by the promotion.
StartDate	String	When the promotion becomes active.
EnrolledDate	String	Date the user enrolled in the promotion.
EndDate	String	When the promotion ends.
Amount	String	Associated monetary or point value with the promotion.
Period	String	Time period of the promotion (for example, weekly, monthly, campaign-based).

Standard loyaltyPromotion field	Type	Description
Status	String	Current status of the promotion (for example, active, expired, completed).
CreatedDate	String	Date the promotion record was created.
CreatedBy	String	User or system that created the promotion record.
UpdatedDate	String	Last date the promotion record was updated.
UpdatedBy	String	User or system that last updated the promotion.
CampaignRef	String	External reference to a broader campaign this promotion belongs to.
AdditionalInformation	String	Miscellaneous notes or marketing copy about the promotion.
TriggerLimit	TriggerLimit	Trigger limit details
Usage	Usage	Usage details
Rules	Rules	Promotion rule details
Incentive	Incentive	Promotion incentive details
Attributes	Map<String, String>	Additional metadata or program-specific values.

Standard Index Fields

Standard index name	Standard preference record field
_loyaltyPromotionId	PromotionId

Rules data type

Standard loyaltyPromotion field	Type	Description
Name	String	Rule name within the promotion rules.
Description	String	Rule description within the promotion rules.

Incentive data type

Standard loyaltyPromotion field	Type	Description
Type	String	The type of incentive (for example, bonusPoints, voucher, tierUpgrade).
Value	String	Value of the incentive, such as point amount or voucher value.
Unit	String	The unit for the incentive value (for example, points, %, USD).

TriggerLimit data type

Standard loyaltyPromotion field	Type	Description
Times	String	Number of times a promotion can be triggered.
Interval	String	Interval for trigger limit.

Usage data type

Standard loyaltyPromotion field	Type	Description
UsageProgressPercent	String	Progress percentage of the promotion usage.
UsageCompleted	String	Number of completed usages.
UsageTarget	String	Target number of usages.

Object type mapping for the standard contact

The topics in this section provide the standard contact definition.

Topics

- Customer Profiles standard contact object fields

Customer Profiles standard contact object fields

The standard contact object stores a customer's contact methods—phone numbers and email addresses—with history retained. Each version of a contact method is stored as a separate record, so a changed phone number doesn't overwrite the previous one. Register the built-in template with `PutProfileObjectType` using the template ID `_contact`, or create a custom object type whose fields target `_contact.*` and whose key carries the `CONTACT`, `PROFILE`, and `UNIQUE` standard identifiers.

The following table lists all the fields in the Customer Profiles standard contact object. All fields are of type `String`.

Contact

Standard contact field	Type	Description
Contact	String	The contact value itself: a phone number or an email address. Part of the unique key.
ChannelType	String	The kind of contact method, for example Home, Business, Mobile, or Land. Part of the unique key.
Type	String	The purpose or context of the contact method, for example Profile, Booking, Subscription, or Payment. Part of the unique key.
EffectiveDate	String	The date this version of the contact method became effective. Part of the unique key. This value is compared as text and is never parsed, so use one format for every record—ISO 8601 (`YYYY-MM-DD`) is recommended. A new `EffectiveDate` creates a new record instead of overwriting the previous one.
ChannelCode	String	The channel of the contact value, for example Phone or Email.
PhoneCountryCode	String	Dialing country code for phone contacts, for example 1 or 44. Empty for email contacts.
IsVerified	String	Whether the contact method has been verified. Stored and returned as text, not a JSON boolean: send the string `true` or `false` and compare it as a string on read. Other values are stored as sent and are not normalized.

Standard contact field	Type	Description
OptIn	String	Whether the customer has opted in to communication on this contact method. Stored and returned as text, not a JSON boolean, following the same rule as `IsVerified` .
LastUpdated	String	Timestamp of the last update in the source system.
OrganizationId	String	Identifier of the organization or business unit that owns the contact record.

Standard Index Fields

Standard index name	Standard contact record fields
_contactId	Contact, ChannelType, Type, EffectiveDate

The `_contactId` key carries the `CONTACT`, `PROFILE`, and `UNIQUE` standard identifiers. All four key fields (Contact, ChannelType, Type, and EffectiveDate) are required on every `_contact` object; an object missing any of them is rejected. By default, a profile can hold up to 250 `_contact` objects.

To read contact data, use `ListProfileObjects` with `ObjectTypeName` `_contact` to return the full contact history of a profile, `SearchProfiles` with `KeyName` `_contactId` to find the profile that owns a contact record, or `GetProfile`, which reports `_contactId` in `FoundByItems`.

Object type mapping for the standard web analytics

The topics in this section provide the standard web analytics definition, and the object type mapping from clickstream events to the standard web analytics, order, and device objects.

Topics

- Customer Profiles standard web analytics object fields
- Mapping WebAnalytics-Clickstream objects to standard objects

Customer Profiles standard web analytics object fields

WebAnalytics Standard Object Schema

Field	Type	Description
Event Attributes		
EventId	String	Unique identifier for a web analytics event.
EventType	String	Type of the web analytics event, such as page views, form submissions, button selections, search bar interactions, app error prompts, cart interactions, purchases, and scrolls.
EventTimestamp	Number	Epoch millisecond timestamp of the event.
EventDuration	Number	EventDuration represents the amount of time a user spent during a particular interaction, measured in seconds. Common use cases include: Time spent viewing a product, Length of a browsing session on a particular page, Time spent on a feature.
EventValue	Number	EventValue is a numerical attribute that represents the value or importance of an interaction event. Common use cases include: Purchase amount for transaction events, Rating values for product ratings, Percentage completion for video views.
Session Attributes		
Session.Id	String	Unique identifier for the session.
Session.StartTimestamp	Number	Epoch millisecond indicating the start timestamp of the session.
Page/Screen Attributes		

Field	Type	Description
Page.Title	String	Title of a Web App/Screen Name for a mobile app.
Page.Location	String	URL of a Web page. For mobile, it could be deep link or route to the screen.
Page.Referrer	String	Previous screen/page.
Page.Category	String	Logical grouping of a screen/page. Might be useful to group nested URLs/app locations.
HTML/DOM Elements		
Element.Id	String	HTML Element Id
Element.Type	String	Element Type - Button, Anchor Links, Etc.
Element.Classes	String	CSS Styling Classes of the Element
Element.Text	String	Element text (Useful for buttons, input fields placeholders, etc).
Element.AltText	String	AltText of a HTML element (generally used for images).
Element.Source	String	Source of an video, image.
Form		
Form.Id	String	Unique Identifier for an input form
Form.Name	String	Name of the Form
Form.Length	String	Number of input fields in a form.
Form.ValidationErrors	Number	Number of validation errors in the form.
Form.FieldsCompleted	Number	Number of fields completed.

Field	Type	Description
Form.FieldsRequired	Number	Number of fields required.
Search		
Search.Query	String	Query string used in the input
Search.TotalMatchingResults	Number	Total number of search results.
Search.ResultsPerPage	Number	Number of results shown per page.
Search.CurrentResultsPage	Number	Current results page that the user is viewing.
Search.FilterExpression	String	Any additional filter expressions used.
Search.SortCriteria	String	Criteria for sorting the search result. For example - Relevance, Price.
Search.SortOrder	String	Sort order for Search results - Ascending/ Descending.
Item/Item List		
Item	Item	Focused item in an event, indicating, the item added to a cart, item viewed.
ItemsList	List<Item>	Focused list of items in an event, indicating, items purchased, items in a cart, item search results.
Item Impressions		
AdditionalItemImpressions	List<Item>	Additional Item impressions list

Field	Type	Description
Cart		
Cart.Id	String	Unique identifier for a cart.
Cart.ItemsCount	Number	Number of items in the cart.
Cart.Currency	String	Currency for cart value.
Cart.Value	Number	Monetary value of items in the cart.
Order Information		
OrderId	String	Unique identifier for a order. We will only store the order identifier here, other informati on related to the order will be stored in the standard order object.
Device		
DeviceId	String	Unique identifier of the user's device.
Scroll Attributes		
Scroll.DepthPercen tage	String	Vertical Scroll depth percentage. This helps understand how far a users scroll through a web page.
Scroll.PositionX	Number	Horizontal Scroll position in pixels from the left.
Scroll.PositionY	Number	Vertical Scroll position in pixels from the top.
Error		
Error.Description	String	A short description of the error.
Error.Type	String	User Input Error/Server Error.
User		

Field	Type	Description
User.Id	String	Unique identifier of the user
User.AnonymousId	String	Anonymous UserId. This would be a uniqueId assigned to a user when they are not logged in.
User.IsReturning	String	A Boolean value indicating if a user is revisitin g.
User.IsLoggedIn	String	A Boolean value indicating if a user is logged in.
Activity Location		
Location.Country	String	User activity country.
Location.State	String	User activity state.
Location.Province	String	User activity province.
Location.County	String	User activity county.
Location.City	String	User activity city.
Location.Latitude	String	User activity location coordinates
Location.Longitude	String	User activity location coordinates
Application Attributes		
Application.Name	String	The name of the application.
Application.Version	String	If the device is Mobile, we can capture the Application Version here. User could also consider using this for population A/B testing or experimentation attributes.
Application.Enviro nment	String	Application environments, like - Beta, Gamma, Prod.

Field	Type	Description
Custom Attributes		
Attributes	Map<String, String>	Any custom attributes or metadata to add to the event.

WebAnalytics Item Object Schema

Field	Type	Description
Id	String	Unique Identifier for the item.
Title	String	Title of the Item.
Category	String	Category of the item.
Value	String	Monetary value of the item.
Currency	String	Currency of the item.
Quantity	Number	Quantity of the item.
ImpressionType	String	String identifying the impression type for an event. For example - Featured, Sponsored, Top picks.
ImpressionId	String	A string identifier for uniquely identifying an impression.

Device Standard Object Schema

Field	Type	Description
DeviceId	String	A unique identifier for the device.
Type	String	Type of device (for example, desktop, mobile)

Field	Type	Description
Model	String	Device model, like - Macbook Pro/Air, IPhone 16.
Manufacturer	String	Manufacturer of the device.
OperatingSystem	String	Indicates Windows, MacOs, IOS, Android.
OperatingSystemVersion	String	OS Version
ScreenWidth	Number	Width of the Screen ViewPort
ScreenHeight	Number	Height of the Screen ViewPort
Browser	String	Name of the Browser the user is interacting with.
BrowserVersion	String	Version of the Browser
Locale	String	Device or App locale.
Attributes	Map<String, String>	Any Custom Attributes for a Device.

Mapping WebAnalytics-Clickstream objects to standard objects

The WebAnalytics-Clickstream mapping template defines how clickstream event data is ingested into Customer Profiles. It maps source fields to the standard web analytics object, the standard order object, and the standard device object.

Mapping to the standard web analytics object

The following table lists which fields are mapped from the WebAnalytics-Clickstream source to the standard web analytics object.

WebAnalytics-Clickstream source field	Standard web analytics target field
EventId	Attributes.ClickstreamEventId

WebAnalytics-Clickstream source field	Standard web analytics target field
Session.Id	Session.Id
Session.StartTimestamp	Session.StartTimestamp
Browser.Id	Browser.Id
User.Id	User.Id
User.AnonymousId	User.AnonymousId
User.IsReturning	User.IsReturning
User.IsLoggedIn	User.IsLoggedIn
OrderId	OrderId
DeviceId	DeviceId
EventType	EventType
EventTimestamp	EventTimestamp
EventDuration	EventDuration
EventValue	EventValue
Page.Title	Page.Title
Page.Location	Page.Location
Page.Referrer	Page.Referrer
Page.Category	Page.Category
Element.Id	Element.Id
Element.Type	Element.Type
Element.Classes	Element.Classes

WebAnalytics-Clickstream source field	Standard web analytics target field
Element.Text	Element.Text
Element.AltText	Element.AltText
Element.Source	Element.Source
Search.Query	Search.Query
Search.TotalMatchingResults	Search.TotalMatchingResults
Search.ResultsPerPage	Search.ResultsPerPage
Search.CurrentResultsPage	Search.CurrentResultsPage
Search.FilterExpression	Search.FilterExpression
Search.SortCriteria	Search.SortCriteria
Search.SortOrder	Search.SortOrder
Item.Id	Item.Id
Item.Title	Item.Title
Item.Category	Item.Category
Item.Value	Item.Value
Item.Currency	Item.Currency
Item.Quantity	Item.Quantity
Item.ImpressionId	Item.ImpressionId
Item.ImpressionType	Item.ImpressionType
ItemsList[].Id	ItemsList[].Id
ItemsList[].Title	ItemsList[].Title

WebAnalytics-Clickstream source field	Standard web analytics target field
ItemsList[].Category	ItemsList[].Category
ItemsList[].Value	ItemsList[].Value
ItemsList[].Currency	ItemsList[].Currency
ItemsList[].Quantity	ItemsList[].Quantity
ItemsList[].ImpressionType	ItemsList[].ImpressionType
ItemsList[].ImpressionId	ItemsList[].ImpressionId
AdditionalItemImpressions[].Title	AdditionalItemImpressions[].Title
AdditionalItemImpressions[].Id	AdditionalItemImpressions[].Id
AdditionalItemImpressions[].Category	AdditionalItemImpressions[].Category
AdditionalItemImpressions[].Value	AdditionalItemImpressions[].Value
AdditionalItemImpressions[].Currency	AdditionalItemImpressions[].Currency
Cart.Id	Cart.Id
Cart.Value	Cart.Value
Cart.Currency	Cart.Currency
Form.Id	Form.Id
Form.Name	Form.Name
Form.Length	Form.Length
Form.ValidationErrors	Form.ValidationErrors
Form.FieldsCompleted	Form.FieldsCompleted
Form.FieldsRequired	Form.FieldsRequired

WebAnalytics-Clickstream source field	Standard web analytics target field
Scroll.DepthPercentage	Scroll.DepthPercentage
Scroll.PositionX	Scroll.PositionX
Scroll.PositionY	Scroll.PositionY
Error.Description	Error.Description
Error.Type	Error.Type
Location.Country	Location.Country
Location.State	Location.State
Location.Province	Location.Province
Location.City	Location.City
Location.County	Location.County
Location.Latitude	Location.Latitude
Location.Longitude	Location.Longitude
Application.Name	Application.Name
Application.Version	Application.Version
Application.Environment	Application.Environment

Mapping to the standard order object

The following table lists which fields are mapped from the WebAnalytics-Clickstream source to the standard order object.

WebAnalytics-Clickstream source field	Standard order target field
OrderId	Attributes.WebAnalyticsOrderId

WebAnalytics-Clickstream source field	Standard order target field
Session.Id	Attributes.WebSessionId
Order.Value	TotalPrice
Order.Currency	Currency
Order.Discounts	TotalDiscounts
Order.ShippingMethod	Attributes.ShippingMethod
Order.ShipmentTrackingId	Attributes.ShipmentTrackingId
Order.ShippingAddress	ShippingAddress.Address1
Order.PaymentMethod	Gateway
ItemsList[].Title	OrderItems[].Title
ItemsList[].Price	OrderItems[].Price
ItemsList[].Quantity	OrderItems[].Quantity

Mapping to the standard device object

The following table lists which fields are mapped from the WebAnalytics-Clickstream source to the standard device object.

WebAnalytics-Clickstream source field	Standard device target field
DeviceId	Attributes.WebAnalyticsDeviceId
Session.Id	Attributes.WebSessionId
Device.Type	Type
Device.OperatingSystem	OperatingSystem
Device.OSVersion	OperatingSystemVersion

WebAnalytics-Clickstream source field	Standard device target field
Device.ScreenWidth	ScreenWidth
Device.ScreenHeight	ScreenHeight
Device.Browser	Browser
Device.BrowserVersion	BrowserVersion
Device.Locale	Locale
Device.Model	Model
Device.Manufacturer	Manufacturer

WebAnalytics-Clickstream keys

The WebAnalytics-Clickstream data is associated with profiles using the following indexes.

Standard index name	WebAnalytics-Clickstream source field	Standard identifiers
_webAnalyticsClickstreamEventId	EventId	WEB_ANALYTICS, UNIQUE
_webAnalyticsUserId	User.Id	PROFILE
_webAnalyticsAnonymousUserId	User.AnonymousId	PROFILE
_webAnalyticsOrderId	OrderId	ORDER
_webAnalyticsDeviceId	DeviceId	DEVICE

For example, you can use `_webAnalyticsUserId` or `_webAnalyticsAnonymousUserId` as a key name with the SearchProfiles API to find a profile associated with web analytics clickstream events. You can find the WebAnalytics-Clickstream objects associated with a specific

profile by using the ListProfileObjects API with the `ProfileId` and `ObjectTypeName` set to `WebAnalytics-Clickstream`.

Object type mapping for Item Catalog

Field	Type	Description
Id	String	Unique Identifier for the Item in the Catalog.
Name	String	Name of the Item
Code	String	Catalog item's code
Type	String	Catalog item's type
Category	String	Category of the item in the Catalog
Description	String	Item description
AdditionalInformation	String	Any additional information relevant to the item.
ImageLink	String	Link to the image of the Item
Link	String	Item URL
Price	String	Price of the Item
CreatedAt	Long	Epoch timestamp for which the Item was created
UpdatedAt	Long	Epoch timestamp for which the Item was updated
Attributes	Map<String, String>	Additional Item Attributes

> **Note**
>
> You can only delete domain object type through APIs. You can delete item catalog integration after all recommenders have been deleted first. This prevents data dependency issues.
>
> **Steps to delete:**
>
> 1. Delete all existing recommenders in your domain
> 2. Navigate to the item catalog integration.
> 3. Select the delete option.

Object type mapping for the standard hotel stay revenue

The topics in this section provide the standard hotel stay revenue definition.

Topics

- Customer Profiles standard hotel stay revenue object fields

Customer Profiles standard hotel stay revenue object fields

The following table lists all the fields in the Customer Profiles standard hotel stay revenue object.

Hotel Stay Revenue

Standard hotelStayRevenue field	Type	Description
StayRevenueId	String	The unique identifier of the standard hotel stay revenue.
CurrencyCode	String	ISO code for the currency (for example, USD)
CurrencyName	String	Full name of the currency (for example, US Dollar)
CurrencySymbol	String	Symbol of the currency (for example, $)

Standard hotelStayRevenue field	Type	Description
ReservationId	String	Unique identifier for the hotel reservation
GuestId	String	Unique identifier for the guest
LastUpdatedOn	String	Timestamp of the last update to the stay record
CreatedOn	String	Timestamp of when the stay record was created
LastUpdatedBy	String	Identifier of the user/system that last updated the stay record
CreatedBy	String	Identifier of the user/system that created the stay record
StartDate	String	Start date of the hotel stay
HotelCode	String	Code identifying the specific hotel
Type	String	Type of revenue (for example, room rate, incidentals, taxes)
Description	String	Description of the revenue item
Amount	String	Amount of the revenue item
ProcessedDate	String	Date the revenue was processed
Status	String	Status of the revenue item

Standard hotelStayRevenue field	Type	Description
Attributes	Map<String, String>	Additional metadata or program-specific values.

Standard Index Fields

Standard index name	Standard preference record field
_hotelStayRevenueId	StayRevenueId

How mappings create and update profiles in Connect Customer Customer Profiles

The topics in this section describe how Customer Profiles matches ingested objects to profiles, when it creates inferred profiles, and how mapping templates and contact record templates control that behavior.

Topics

- Profile matching and inferred profiles in Customer Profiles
- Mapping templates and implicit object types in Customer Profiles
- Contact record templates in Connect Customer Customer Profiles

Profile matching and inferred profiles in Customer Profiles

This topic explains how Connect Customer Customer Profiles decides which profile an ingested object belongs to, when it creates a new profile, and how it protects manually entered data. For the end-to-end ingestion flow, see How object type mapping works in Customer Profiles.

How a profile is matched

An ingested object is validated and queued, and profile matching happens shortly afterward. Matching follows this order:

1. Customer Profiles evaluates each primary `PROFILE` key:

- If exactly one profile matches, the object is attached to that profile.
- If more than one profile matches, the match is ambiguous—that key is discarded and the next is tried.
- If no profile matches, the next key is tried.

2. If no primary `PROFILE` key produces an unambiguous match, Customer Profiles repeats the process with any secondary keys (keys whose standard identifiers include both `PROFILE` and `SECONDARY`).
3. If no key produces a single match, the outcome depends on `AllowProfileCreation` (see Controlling profile creation with AllowProfileCreation).

> **Note**
>
> An ambiguous match—a key value that points to more than one profile—is never used to attach an object. This prevents a shared value, such as a common email address, from silently merging unrelated profiles.

Controlling profile creation with AllowProfileCreation

`AllowProfileCreation` is a property of the object type that controls what happens when no profile matches:

- **`true`**: a new inferred profile is created and the object is attached to it.
- **`false`**: the object is rejected and sent to the domain dead-letter queue. Use this when you only want to enrich profiles that already exist, for example because they're created through a separate provisioning flow.

When you create an object type from a template, the template's `AllowProfileCreation` value is used and can't be overridden on the request.

Inferred profiles

An inferred profile is a profile that Customer Profiles creates automatically when an ingested object can't be matched to any existing profile. Because the source object usually doesn't carry a full customer record, the standard profile object on an inferred profile starts mostly empty.

What gets populated on an inferred profile

When an inferred profile is created, the standard profile object is initialized from the fields in the object type mapping. Fields that define a `Target` are populated as usual. Two fields are also populated automatically, even when the field defines no `Target`:

- A field with `ContentType` of `EMAIL_ADDRESS` populates `_profile.EmailAddress`.
- A field with `ContentType` of `PHONE_NUMBER` populates `_profile.PhoneNumber`.

> **Note**
>
> This automatic population happens only when an inferred profile is created, and it writes to the standard profile fields `_profile.EmailAddress` and `_profile.PhoneNumber`—not to the `_email` and _phone search keys. When an object matches an existing profile, a `ContentType` on its own writes nothing; only fields with a `Target` update the standard profile.

Avoiding unwanted inferred profiles

With inferred profiles, you can keep ingesting data even when the customer isn't already known, but they can accumulate when source data is sparse. To control this:

- Set `AllowProfileCreation = false` if you only want to enrich existing profiles.
- For contact records, choose a template that suppresses inferred profile creation. For more information, see Contact record templates in Connect Customer Customer Profiles.
- Use `SECONDARY` and `NEW_ONLY` identifiers thoughtfully so a single weak signal (such as an email shared by many profiles) doesn't force a new profile. For more information, see Standard identifiers in Customer Profiles.

Merging behavior and source priority

When an object matches an existing profile, its `Target` fields update the standard profile object. When multiple object types map to the same standard field—for example, both a Salesforce and a Marketo mapping populate `_profile.EmailAddress`—`SourcePriority` determines which value wins. `SourcePriority` is an integer where 1 is the highest priority—object types with lower values take precedence. An object type without a `SourcePriority` defaults to the lowest priority.

Manual updates are protected by default

> **Note**
>
> By default, an ingested object that matches an existing profile doesn't overwrite fields populated manually through the UpdateProfile API or the Connect Customer agent workspace. This protects intentional changes from being silently replaced by automated ingestion. Use `SourcePriority` when you do want a trusted ingestion source to take precedence over manual updates.

For example, suppose an agent creates a profile with `FirstName` set to `John`. Later, an object that maps to `_profile.FirstName` is ingested and matched to that profile. If the ingesting object type has no `SourcePriority` configured, the `FirstName` value remains `John`—the ingested value is stored on the profile object but doesn't replace the manually set standard field. If you configure `SourcePriority` to rank that object type above manual updates, the ingested value replaces `John` instead.

Mapping templates and implicit object types in Customer Profiles

With mapping templates, you can ingest data from well-known sources without writing field and key definitions yourself. With implicit object types, you can use a template by name without explicitly creating it first. This topic explains both and how they interact with explicit object types.

Mapping templates

A mapping template is a predefined object type mapping included with Connect Customer Customer Profiles. Templates exist for standard object types (such as `_asset`, `_case`, `_order`, `_communicationRecord`, `_loyalty`, and several travel records), for contact records (`CTR`, `CTR-NoInferred`, `CTR-AutoAssociateOnly`), and for third-party sources such as Salesforce, ServiceNow, Marketo, and Zendesk.

For the complete, current list, use the ListProfileObjectTypeTemplates API.

> **Note**
>
> When you create an object type from a template, you can't also specify `Fields` or `Keys`—the template provides them. For non-standard object types, you can still set `ExpirationDays` and `EncryptionKey`.

Implicit object types

You can use any object type whose name matches a template ID (as returned by ListProfileObjectTypeTemplates) without explicitly defining it. The object type uses the template's definition exactly. This is called an implicit object type.

Replacing an implicit object type with an explicit one

If you create an explicit object type whose name was previously implicit, your explicit definition replaces the template definition entirely—you can't partially override a template. Keep these behaviors in mind:

- Subsequent ingestions follow the explicit definition.
- The object type's `createdAt` timestamp is set to the time you created the explicit definition.
- Already-ingested data is not reprocessed automatically. Existing objects retain the field values they were ingested with. For more information, see Update and validate an object type mapping in Customer Profiles.

Contact record templates in Connect Customer Customer Profiles

A contact record is a profile object that captures contact trace record (CTR) data from contacts, such as phone calls or chats. Connect Customer Customer Profiles uses contact records to document and analyze your interactions with customers.

The Connect Customer integration automatically ingests contact records and provides the contact event's identifier as the `_ctrContactId` key. Ingestion happens after the contact ends, and you can't view the profile association during the live interaction—it appears only after the contact record has been processed.

> **Note**
>
> **Assign a contact record to a specific profile**
> You don't have to rely on automatic matching to choose the profile. Call AddProfileKey on the profile you want, with `KeyName` set to `_ctrContactId` and the contact's ID as the value. When the contact record is ingested after the contact ends, its `_ctrContactId` key matches the profile you chose, and the record is associated there instead of falling back to _phone or creating an inferred profile. Add the key during the contact, while it's still in

progress, so it's in place before ingestion. This works with all three templates, because each one evaluates `_ctrContactId` first.

When a contact event occurs, one of three default templates determines how the event is handled. Each template defines specific rules for matching and profile creation, so you can tailor processing to your business needs.

Topics

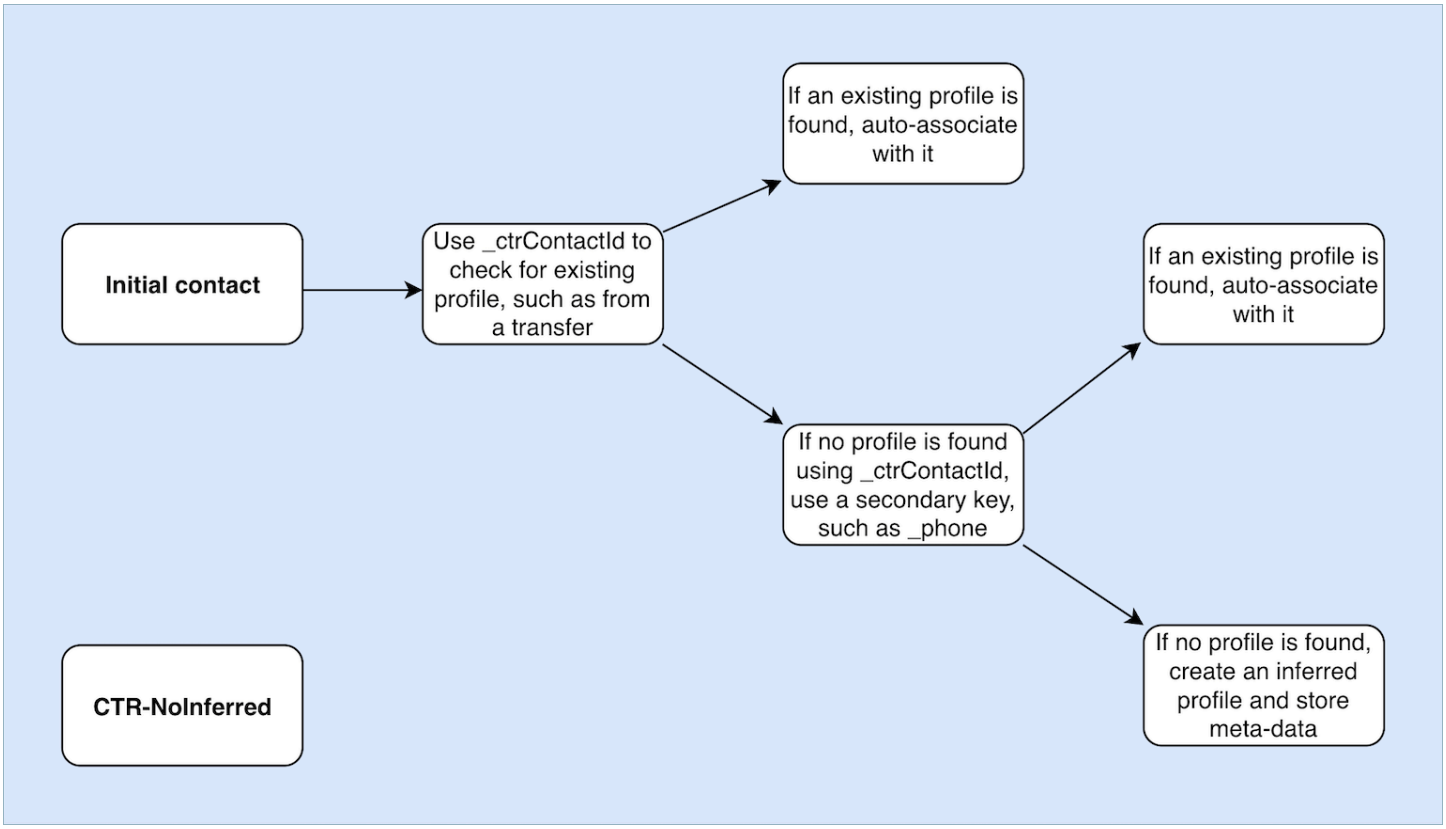
- Create inferred profiles and auto-associate profiles (CTR-NoInferred)
- Auto-associate profiles only (CTR-AutoAssociateOnly)
- Create inferred profiles only (CTR)
- Update the contact record type (console)
- Update the contact record type (AWS CLI)
- Automatically add names from email contacts to a profile

Create inferred profiles and auto-associate profiles (CTR-NoInferred)

With the CTR-NoInferred template, when a contact event such as a phone call occurs, Customer Profiles first uses the `_ctrContactId` key to search for an existing profile. If a match is found, the contact event is auto-associated with that profile. If not, Customer Profiles searches using the secondary _phone key to locate a profile by the caller's phone number, and auto-associates if a match is found.

If neither `_ctrContactId` nor _phone finds an existing profile, Customer Profiles creates a new inferred profile and populates it with the contact event metadata.

The CTR-NoInferred behavior is useful for reducing duplicate profiles.

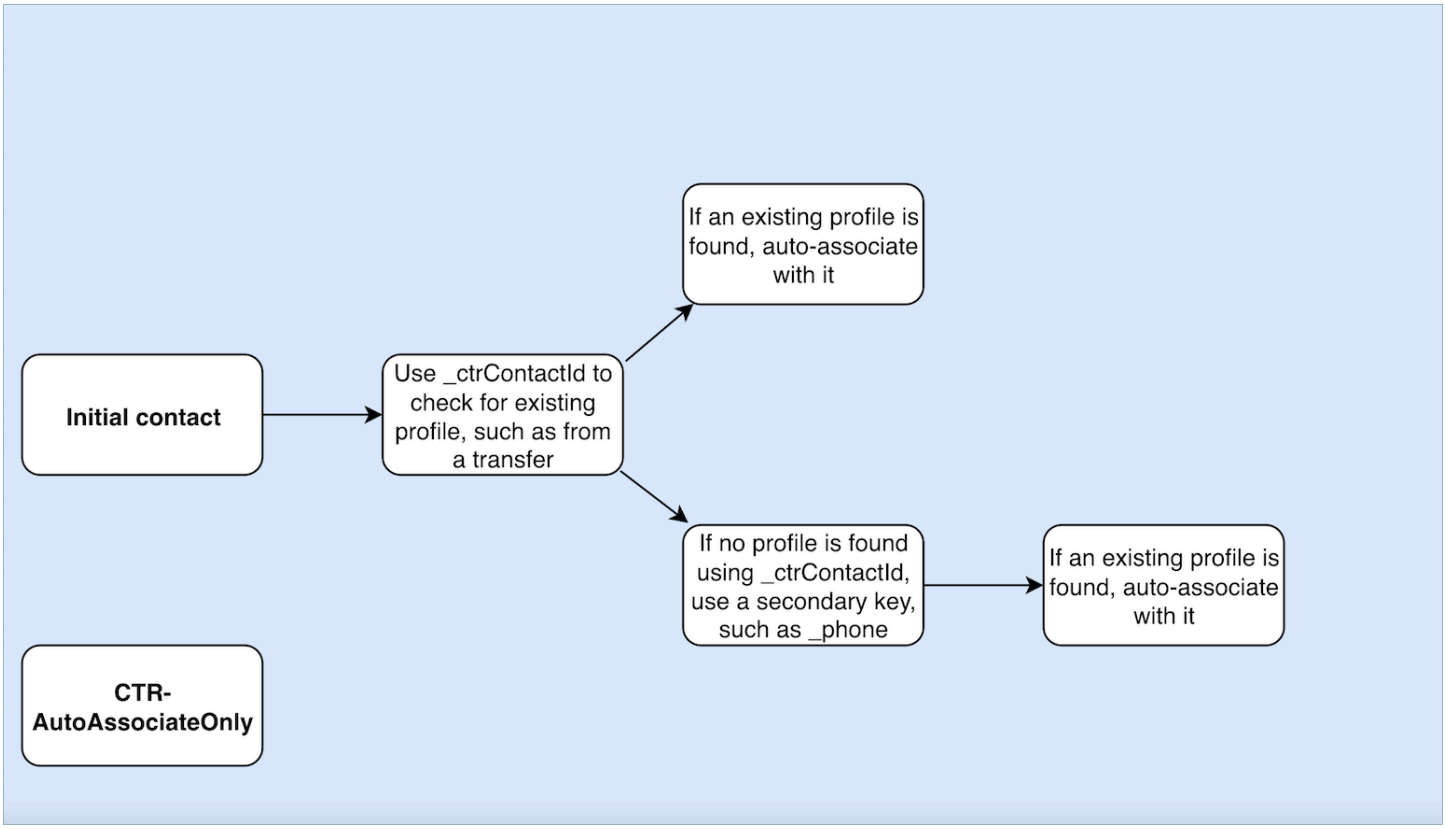


Auto-associate profiles only (CTR-AutoAssociateOnly)

CTR-AutoAssociateOnly works like CTR-NoInferred with one important distinction: it doesn't create an inferred profile when no existing profile can be found for auto-association.

It uses `_ctrContactId` first and falls back to _phone. If a match is found, the contact event is auto-associated. If no match is found, no inferred profile is created.

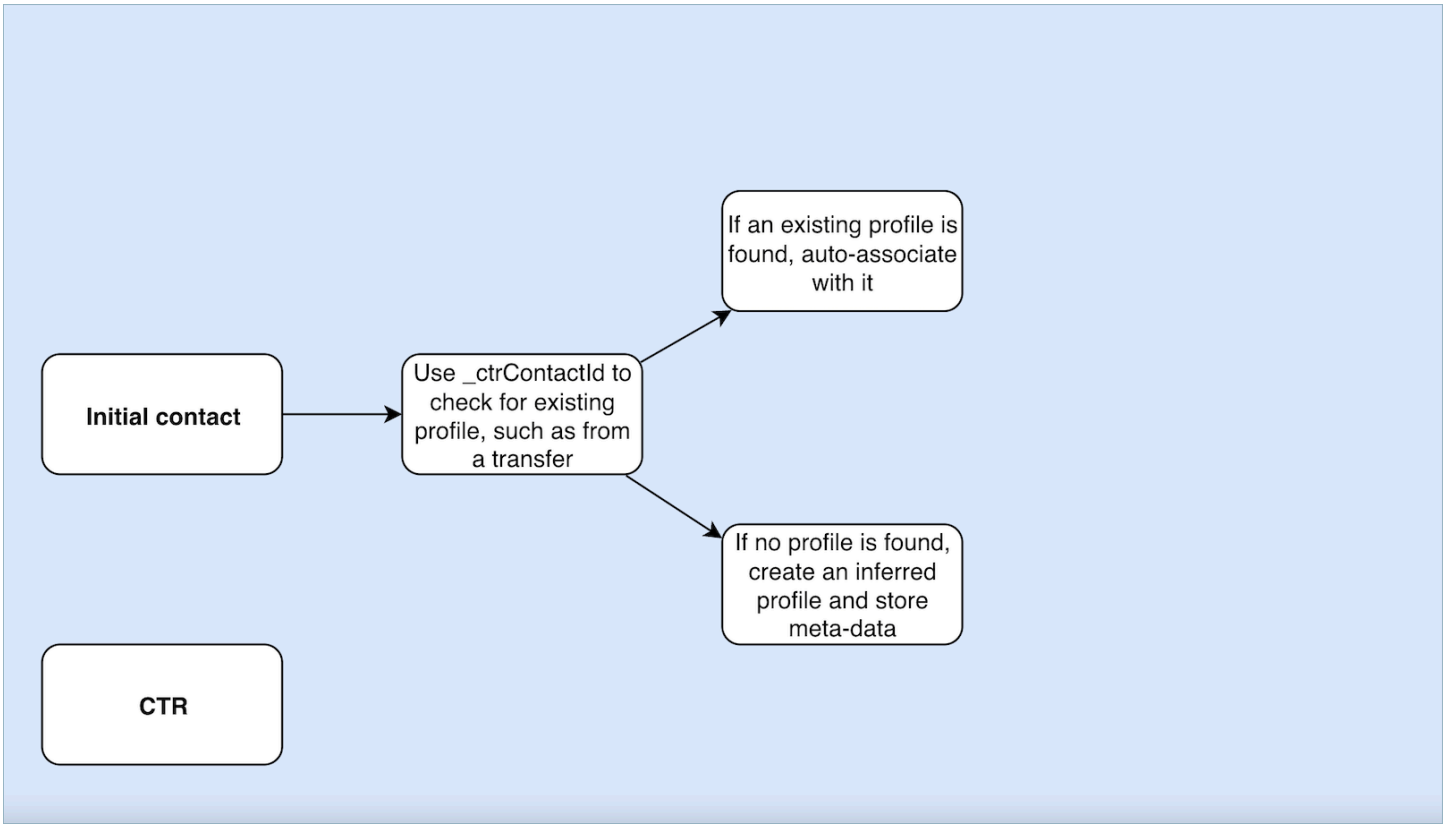
Use CTR-AutoAssociateOnly when you want automatic association with existing profiles while maintaining strict control over profile creation.



Create inferred profiles only (CTR)

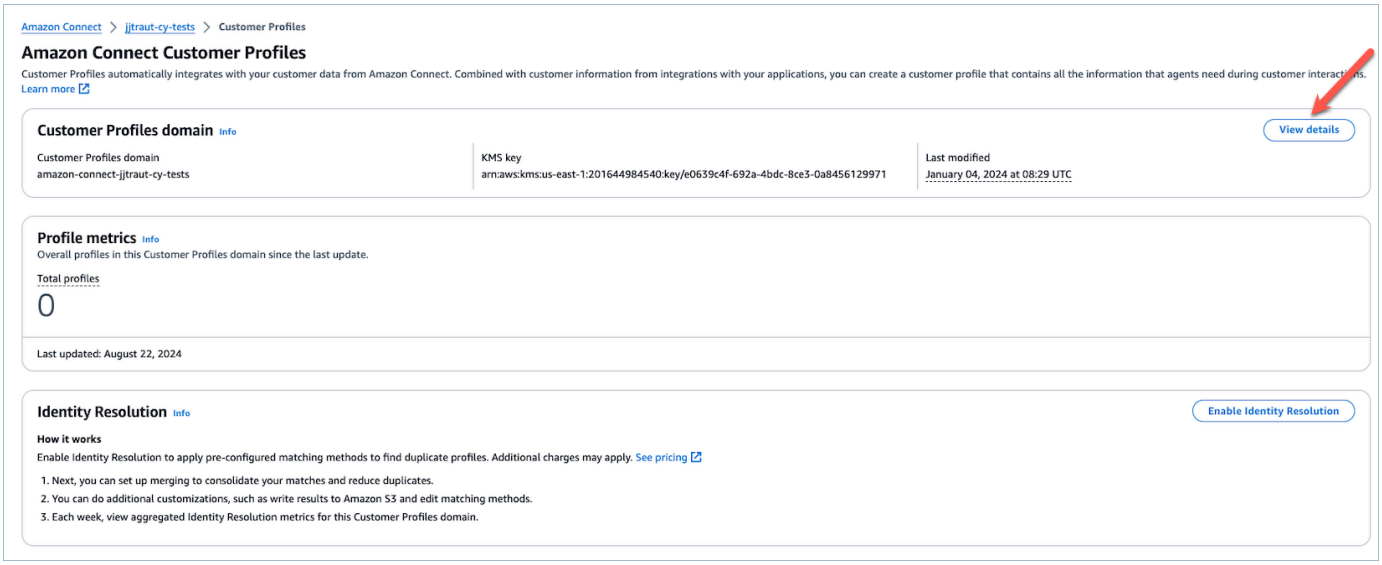
The CTR template relies solely on the `_ctrContactId` key. If a match is found, the contact event is associated with that profile. If not, the template creates an inferred profile and populates it with the contact event metadata.

Because this template doesn't fall back to _phone for matching, it can create many inferred profiles, which might lead to duplicate profiles. We recommend CTR-NoInferred instead.

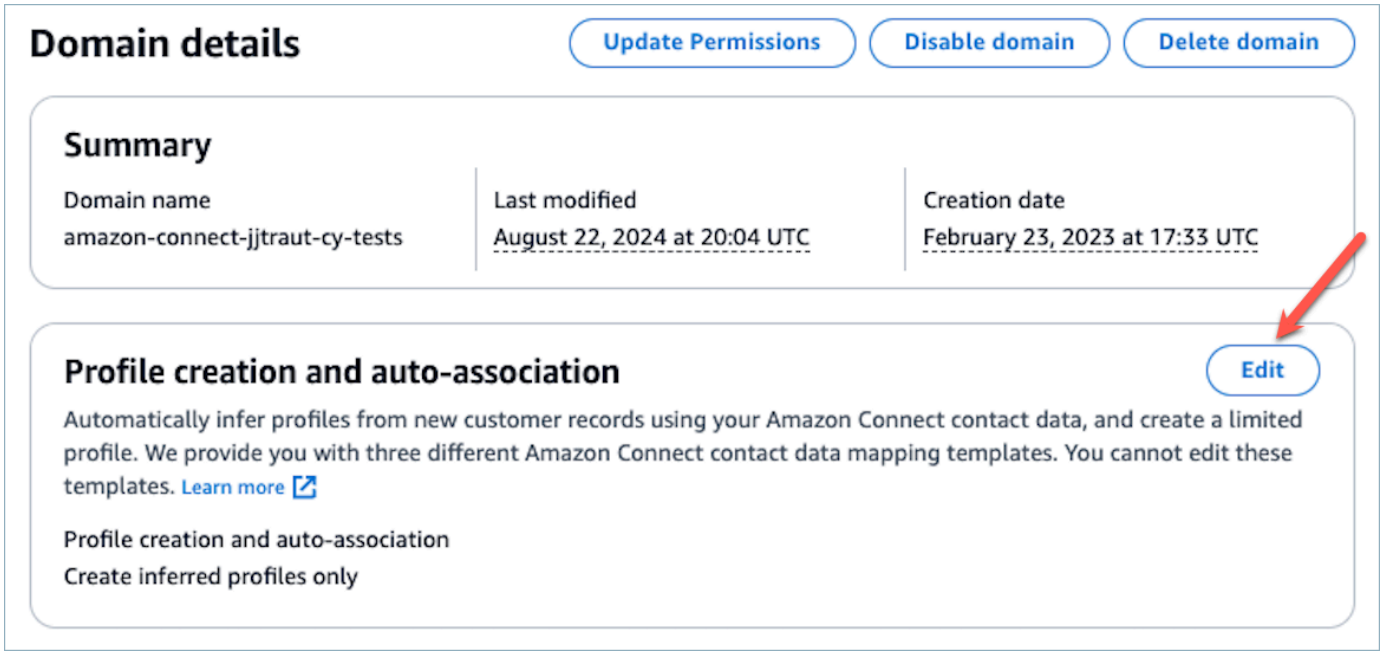


Update the contact record type (console)

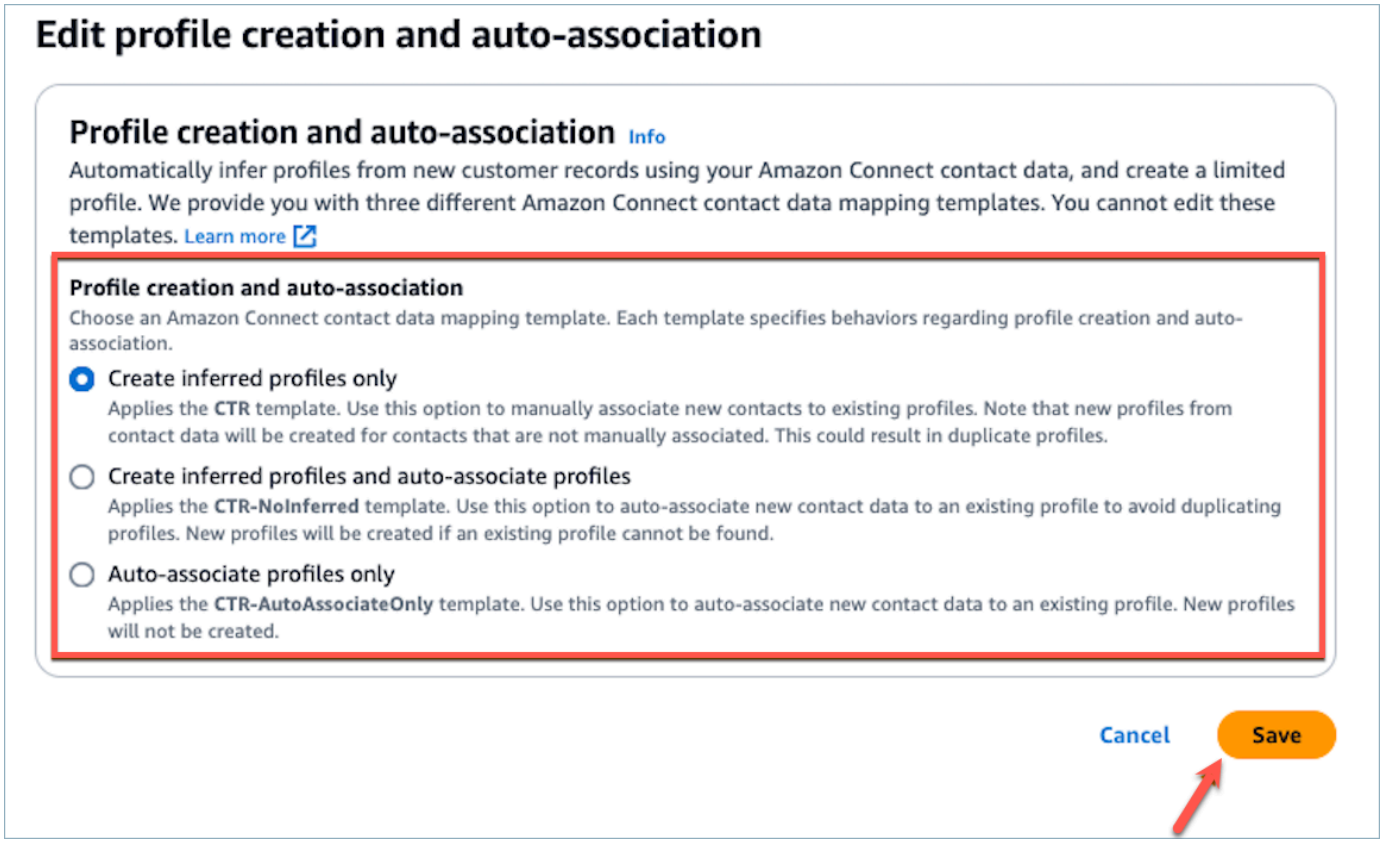
1. In the Connect Customer Customer Profiles console, choose **View details** in the **Customer Profiles domain** section.



2. On the **Domain details** page, choose **Edit** in the **Profile creation and auto-association** section.



3. Select the contact-record behavior you want and choose **Save**.



Update the contact record type (AWS CLI)

- CTR-NoInferred:

```
aws customer-profiles put-profile-object-type --domain-name {domain} --object-type-name CTR --description "Creates inferred profiles and auto-associates profiles" --template-id CTR-NoInferred
```

- CTR-AutoAssociateOnly:

```
aws customer-profiles put-profile-object-type --domain-name {domain} --object-type-name CTR --description "Auto-associate with profiles only" --template-id CTR-AutoAssociateOnly
```

- CTR:

```
aws customer-profiles put-profile-object-type --domain-name {domain} --object-type-name CTR --description "Creates inferred profiles only" --template-id CTR
```

For information on using the API, see PutProfileObjectType.

Automatically add names from email contacts to a profile

You can set up a flow to populate a name from an email contact to the customer's profile. Use the Customer profiles block, configured to use the Update profile action.

Quotas and troubleshooting for object type mapping in Connect Customer Customer Profiles

The topics in this section describe the limits that apply to object type mappings and how to troubleshoot common issues with mapping creation, ingestion, and generative AI mapping.

Topics

- Quotas and data limits in Customer Profiles
- Troubleshoot object type mappings in Customer Profiles

Quotas and data limits in Customer Profiles

With Connect Customer Customer Profiles, you can customize data onboarding by setting ingestion limits on the various types of customer data you use to build a unified profile. Setting limits across mappings helps you prioritize which sources get capacity on each profile. The default maximum across all mappings per profile is 1000 objects.

> **Note**
>
> Data limits are estimates and might vary slightly, with a possible deviation of a few units in either direction during periods of high ingestion on a single profile.

Object count compared with retention

Customer Profiles enforces two independent limits on ingested data. They serve different purposes and can both apply to the same object.

Limit	What it controls	Where it's set
`MaxProfileObjectCount`	The maximum number of objects of a given type that can be attached to a single profile. The sum across all object types in the domain can't exceed the per-profile object limit (default 1000).	Per object type, when it's created or updated.
`ExpirationDays`	The number of days an individual object is retained before it expires and is deleted. Must be greater than zero and within your account's expiration limit.	Per object type. Recorded on each object at ingestion time—changes apply only to newly ingested data.

Use `MaxProfileObjectCount` to allocate capacity across object types. Use `ExpirationDays` to manage how long historical data remains available. For example, if you ingest both contact records and web analytics events, you can give web analytics a smaller cap so a high-volume source can't consume the entire per-profile budget on its own.

A per-object-type limit does more than cap how many objects of a type are stored. It also determines how Connect Customer chooses which objects to remove when a profile reaches its total object limit. For more information, see How data limits control object eviction.

How data limits control object eviction

Each profile can store a limited total number of objects across all object types (1000 by default; you can request a limit increase, see Connect Customer service quotas). When a profile reaches this total limit, Connect Customer removes (evicts) an existing object to make room. The per-object-type limits you set determine which object is evicted:

1. Connect Customer first looks for object types that have exceeded their configured limit. It evicts the oldest object of the object type that is furthest over its limit (the largest overage). This continues, one object per ingestion. Eviction stops when that object type is back within its limit, or when another object type becomes the one furthest over its limit.
2. If no object type is over its limit, Connect Customer falls back to *self-eviction*. The incoming object evicts the oldest object of its own object type. The total object count for the profile stays the same, and no other object type is reduced.

Important

An object type that has no limit set is never considered to be over its limit. As a result, its objects can only be removed through self-eviction. A high-volume object type with no limit can therefore occupy a large share of the profile budget indefinitely. This leaves less room for other object types to grow. To reclaim that space for your business-critical object types, set a limit on the high-volume object type, such as clickstream or web analytics data.

Note

Eviction affects only the objects that count toward a profile's object limit. It does not delete the underlying ingested data from the data store. If you have enabled the data store (see Data store), the data store still retains evicted objects. To delete data from the data store, use the `DeleteProfile` API, or delete the object types or the Customer Profiles domain.

Default limits for standard object types

Standard object types (object type templates) provided by Customer Profiles can include a built-in default limit. This limit helps prevent high-volume data from consuming the entire profile budget. Connect Customer applies this default limit automatically during eviction when you have not set your own `MaxProfileObjectCount` for that object type. You do not need to configure anything.

- **Your own limit takes priority.** If you have set a limit for the object type, Connect Customer uses that value instead of the default. When you clear your limit, the object type falls back to the default limit if it has one. For how to set or clear a limit, see Configure data limits in the console and Clear data limits in the console.
- **Defaults are managed by Connect Customer.** Connect Customer applies these default limits automatically—you do not set them. To use a different limit for an object type, set your own limit for that object type.
- **Effective date for existing domains.** A default limit can have an effective date so that domains that already accumulated objects before the default existed are not affected. When a default limit has an effective date, it applies only to domains created after that date. Domains created on or before that date keep their existing behavior unless you set your own limit. Connect Customer manages this effective date—you do not configure it.

The following object types include a default limit.

Object type	Default limit	Applies to	Rationale
`_webAnalytics`	250	Domains created after September 1, 2026	Retains roughly the last 10 sessions of activity, which gives predictive insights a baseline of data for predictio n performance.
`WebAnalytics-Clickstream`	100	All domains	Retains roughly the last 4 sessions of activity, which supports basic event triggers and calculated attributes.

> **Note**
>
> A per-object-type limit (including these defaults) is not an additional storage budget. It does not add to the total per-profile object limit. It only controls whether objects of that type are selected as eviction candidates when a profile reaches its total limit. When every object type is within its limit, Connect Customer uses self-eviction. In that case, a per-object-type limit does not, by itself, increase or reduce the total number of objects a profile can store. The per-profile object limit, which is a service quota, always controls this total. For more information, see Connect Customer service quotas.

To retain more history for these object types (for example, for high-interaction applications), set a higher `MaxProfileObjectCount` on the object type. If necessary, request an increase to your total per-profile object limit (see Connect Customer service quotas).

Object type structure limits

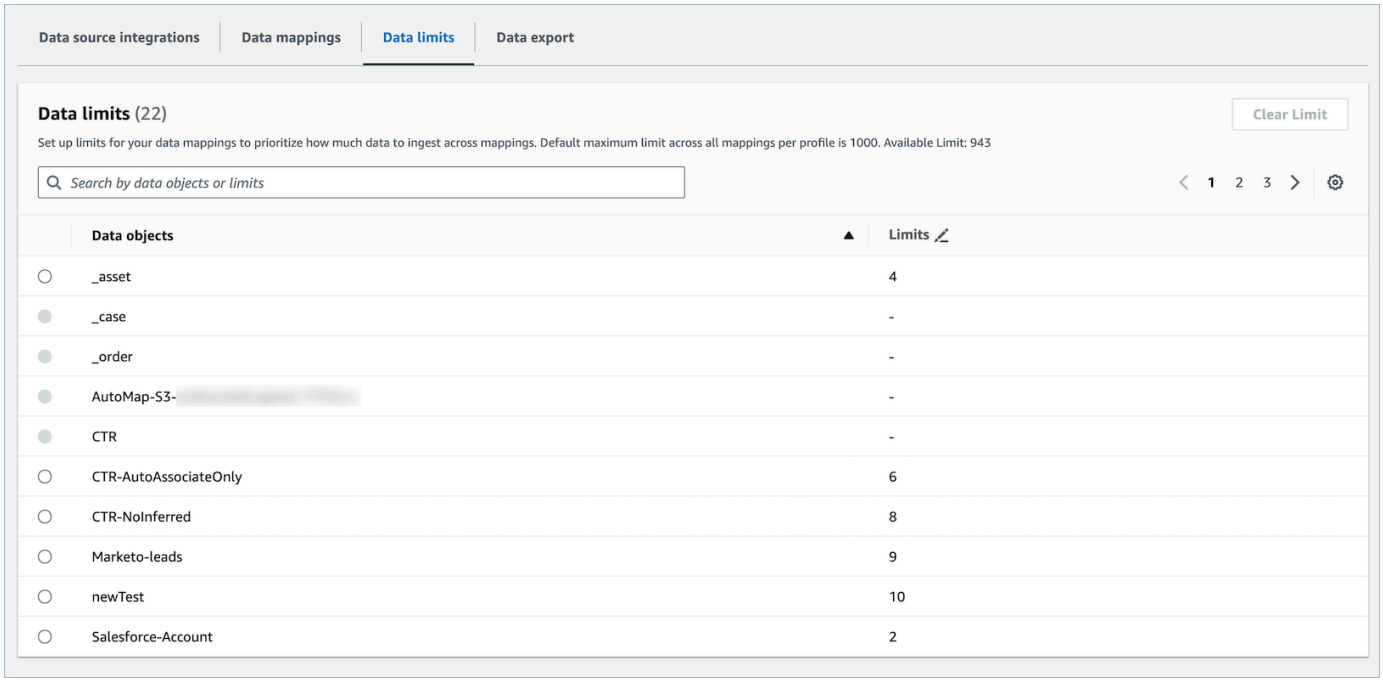
The following limits apply to the structure of an object type itself.

Limit	Value
Maximum size of a single profile object	250 KB
Maximum number of fields per object type	250
Maximum number of object types per domain	Account-specific.

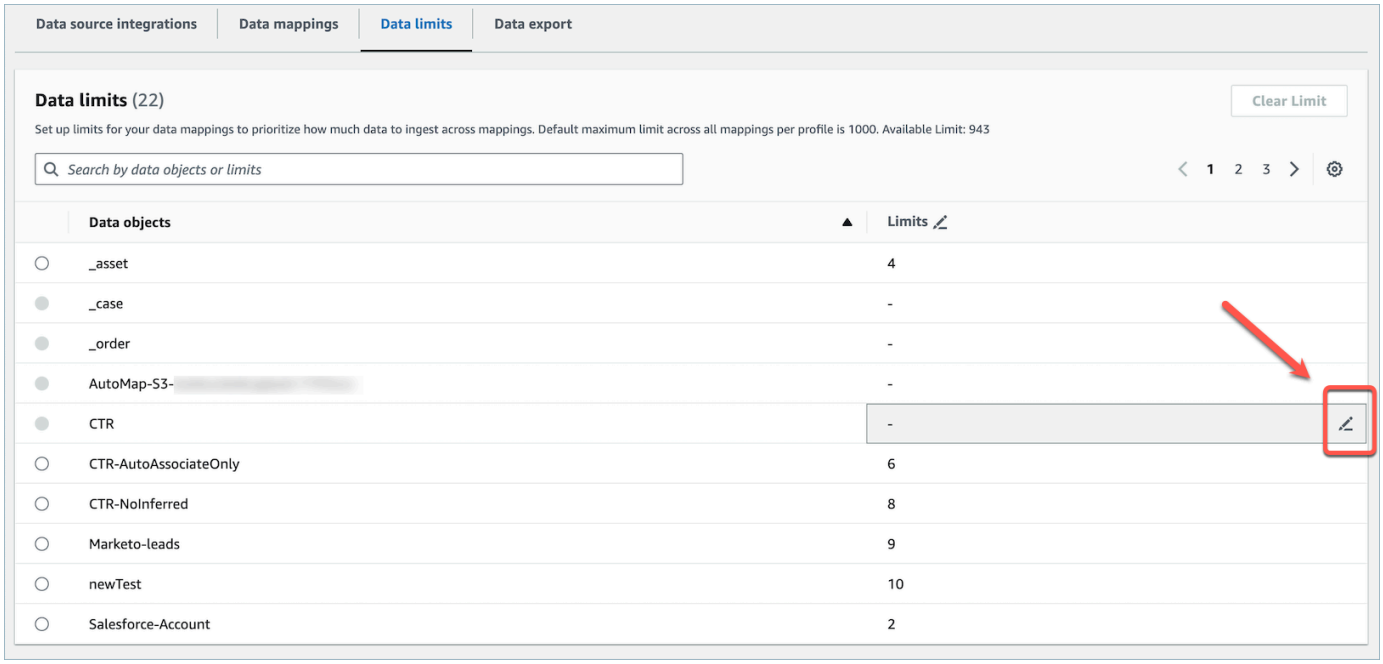
Configure data limits in the console

You can set a limit for a data object in the Connect Customer admin website, as described in the following steps. You can also set it programmatically by using the `PutProfileObjectType` API. A limit that you set takes priority over any default that Connect Customer manages for that object type.

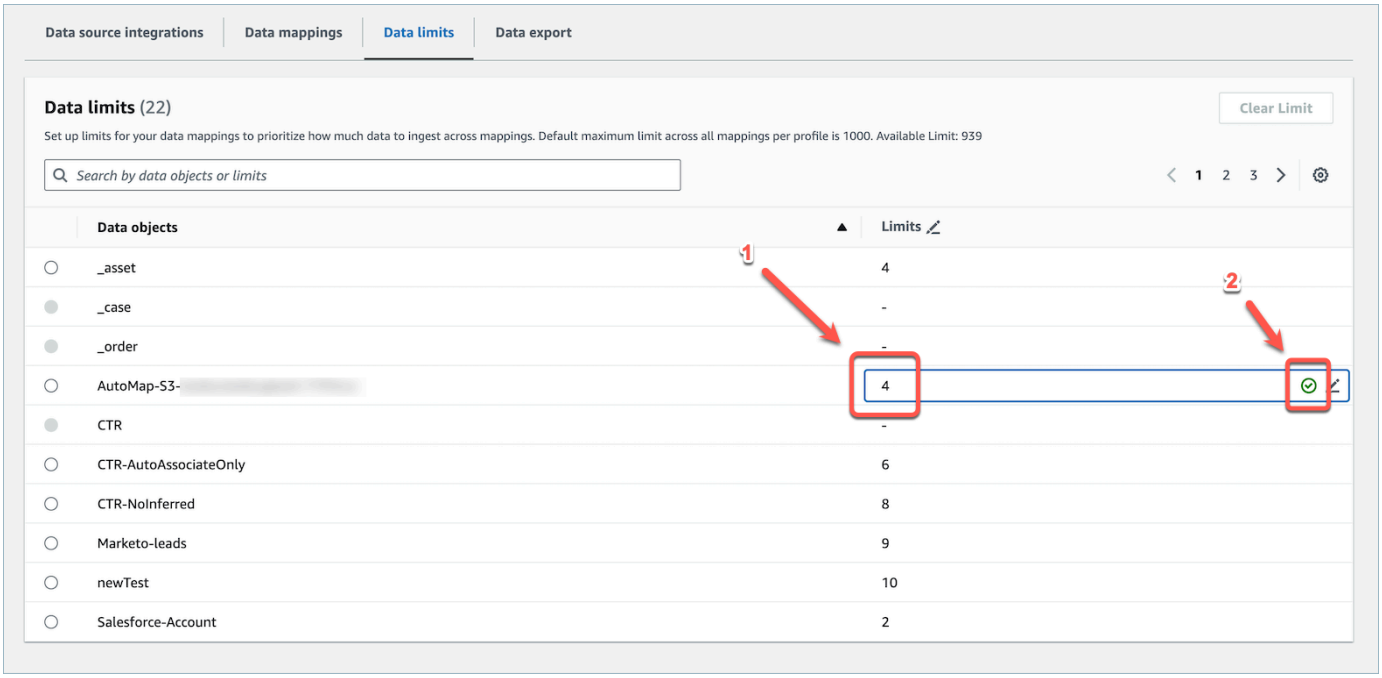
1. Open the Connect Customer Customer Profiles console.
2. Choose the **Data limits** tab to configure limits for data objects.



3. Hover over the data object's limit and choose the edit icon.

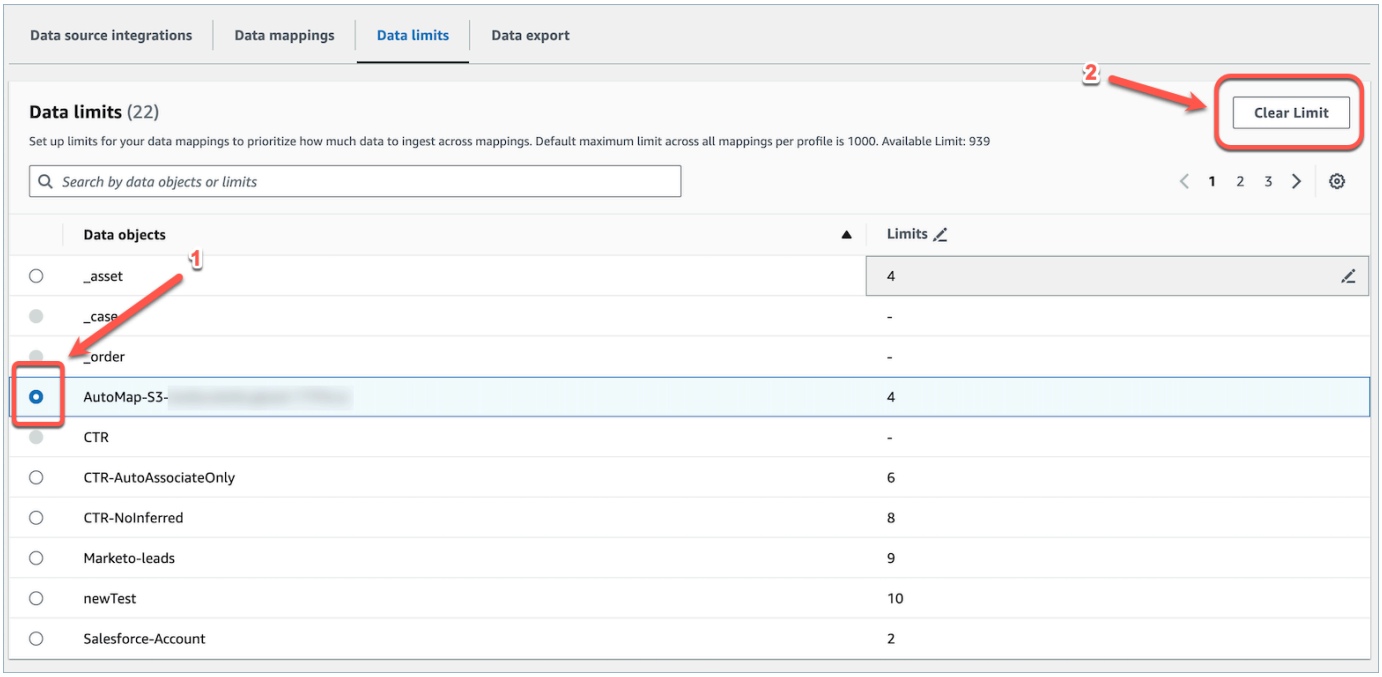


4. Enter the limit and choose the check-mark icon to save or update it.

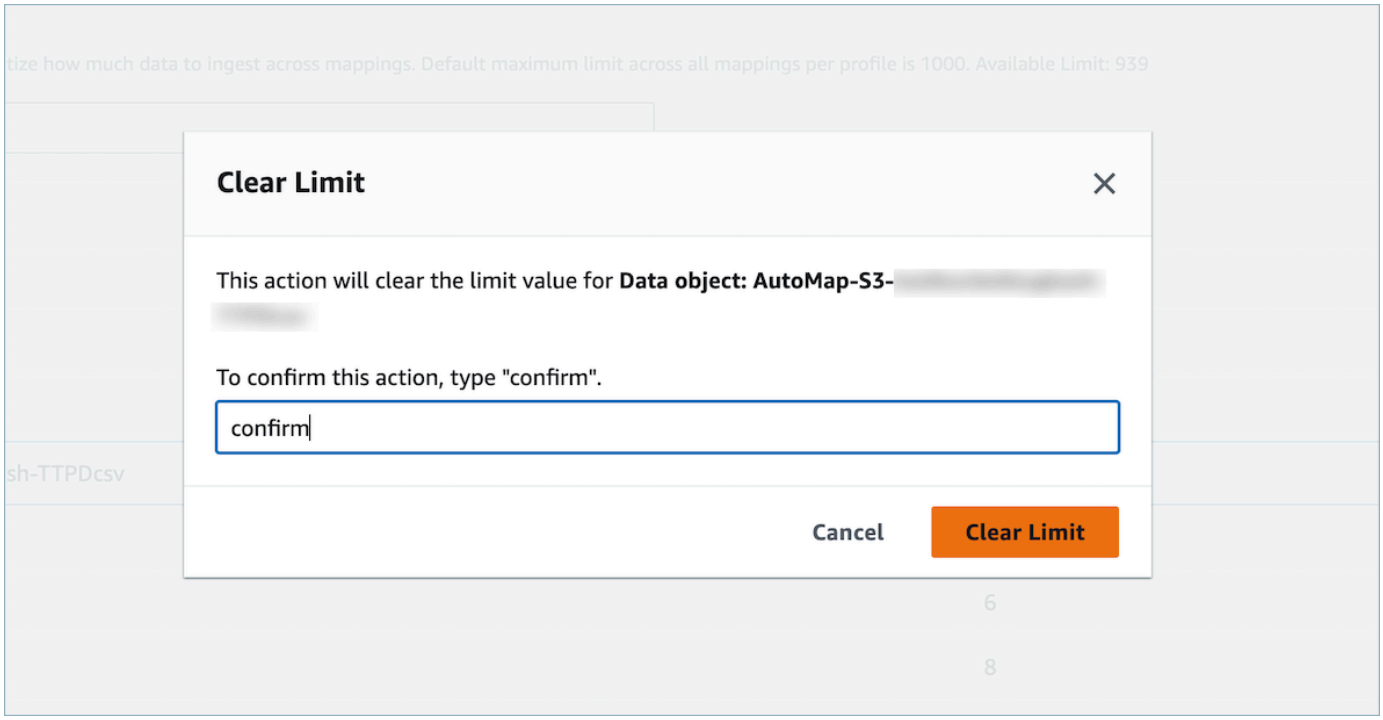


Clear data limits in the console

1. Select the radio button for the data object whose limit you want to clear, then choose **Clear limit**.



2. Enter *confirm* to clear the limit value of the selected data object.



Troubleshoot object type mappings in Customer Profiles

This topic covers common issues when creating mappings, ingesting objects, and generating mappings with AI.

Mapping creation and validation errors

Connect Customer Customer Profiles validates a mapping when you create or update it and rejects an invalid one before any data is ingested. The error message names the specific problem—a missing or wrongly combined identifier, an unsupported target, a name that breaks the character rules, or a quota you've reached.

For the rules a mapping has to satisfy, and for the choices that are accepted but quietly degrade matching, see Before you submit. For the syntax behind each part of a mapping, see Field definitions in Customer Profiles object type mappings, Key definitions in Customer Profiles object type mappings, Standard identifiers in Customer Profiles, and Reference for standard objects in Customer Profiles.

Object ingestion errors

Symptom	Likely cause and fix
Object rejected as invalid	The submitted object isn't valid JSON, or it can't be parsed against the object type's fields. Verify the request body is well-formed JSON matching the field `Source` paths.
Missing unique or profile key	Every field that makes up the `UNIQUE` key, or every `PROFILE` key, resolved to empty for this object. Ensure the source data contains the values those keys depend on. See Field definitions in Customer Profiles object type mappings.
Standard object type rejected at ingestion	`PutProfileObject` can't be called with a standard object type name (such as `_profile`, `_asset`, or `_order`). Standard objects aren't ingested directly—they're populated as a result of ingesting a custom object type whose fields target them. To create or update a profile directly, use `CreateProfile` or `UpdateProfile` . See Reference for standard objects in Customer Profiles.

An object wasn't associated with the expected profile

If an ingested object landed on the wrong profile or created a new one unexpectedly, check the following:

- **Ambiguous match**: If a `PROFILE` key value matched more than one profile, Customer Profiles discards that key. Make sure the key you rely on for matching is unique enough to identify a single profile. See Profile matching and inferred profiles in Customer Profiles.
- **Normalization mismatch**: Matching uses the field's `ContentType`. A phone or email that isn't tagged with the right content type might not match a value stored in another format. See Field definitions in Customer Profiles object type mappings.
- **LOOKUP_ONLY / NEW_ONLY keys**: A key with `LOOKUP_ONLY` is never stored, and `NEW_ONLY` is stored only on newly created profiles. If you expected to match on such a key later, it might not have been saved. See Standard identifiers in Customer Profiles.

- **Ingestion timing**: Ingestion takes a short time to complete. If you searched immediately after ingesting, the association might not have finished yet. See Profile matching and inferred profiles in Customer Profiles.
- **Profile creation disabled**: If `AllowProfileCreation` is `false` and no profile matched, the object was sent to the domain dead-letter queue instead of creating a profile.

You can use SearchProfiles to confirm which key values are associated with which profiles.

Old field values are still on a standard object after ingestion

Standard objects (such as the standard profile, `_asset`, or `_order`) are not replaced wholesale on ingestion—they accumulate field values across many profile objects. Re-ingesting a profile object with the same `UNIQUE` key replaces only that profile object; the standard object keeps every field that was previously written and updates only the fields the new ingestion targets.

If a standard field looks "stale," check:

- **Targeting**: Make sure the field you want to overwrite is actually targeted in the new ingestion's mapping. A field with no `Target` doesn't write to the standard object.
- **SourcePriority**: When several object types target the same standard field, `SourcePriority` decides which value wins. A lower-priority source can't overwrite a higher-priority one. See Merging behavior and source priority.
- **Manual overrides**: By default, values set with UpdateProfile or in the Connect Customer agent workspace aren't overwritten by ingestion. If you need an ingested value to win, configure `SourcePriority` on the object type. See Manual updates are protected by default.
- **Empty source values**: A field whose `Source` resolves to empty is treated as absent—it won't blank out an existing value on the standard object.

To explicitly clear a profile field, use `UpdateProfile`. For more information, see How object type mapping works in Customer Profiles and Reference for standard objects in Customer Profiles.

Generative AI mapping errors

These errors and warnings can appear when generating a mapping with generative AI. For more information, see Generate a mapping with generative AI in Customer Profiles.

Error: Could not parse object string into JSON

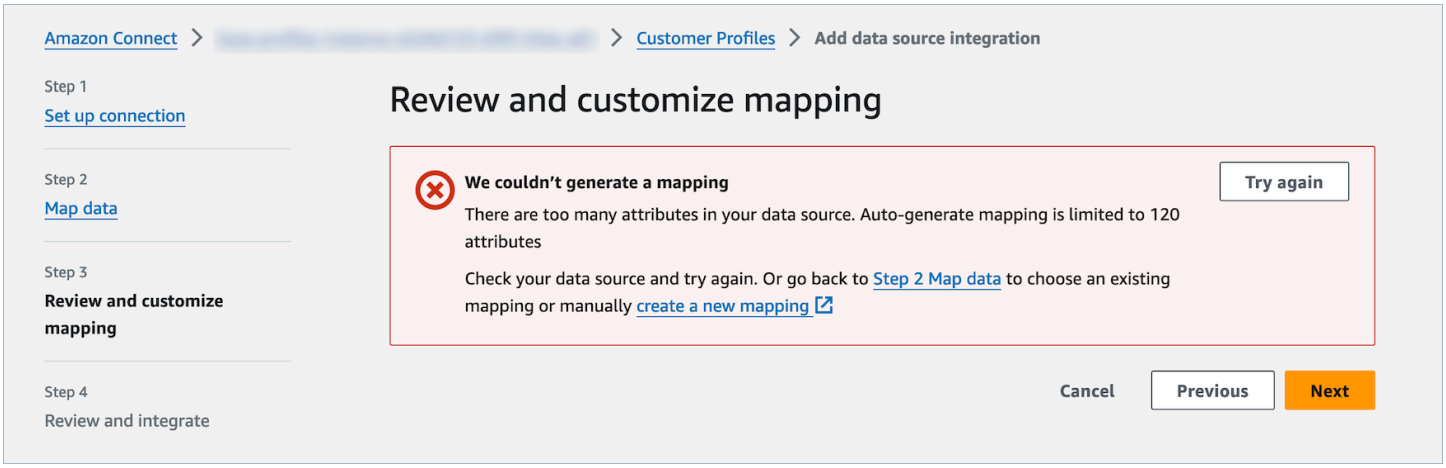
The object string in the request isn't valid JSON. Review it and verify that it's valid JSON.

Error: Value at 'objects' failed to satisfy constraint: Member must have length less than or equal to 5

There are too many objects in the request. Up to five are allowed. Reduce the number of objects to five or fewer.

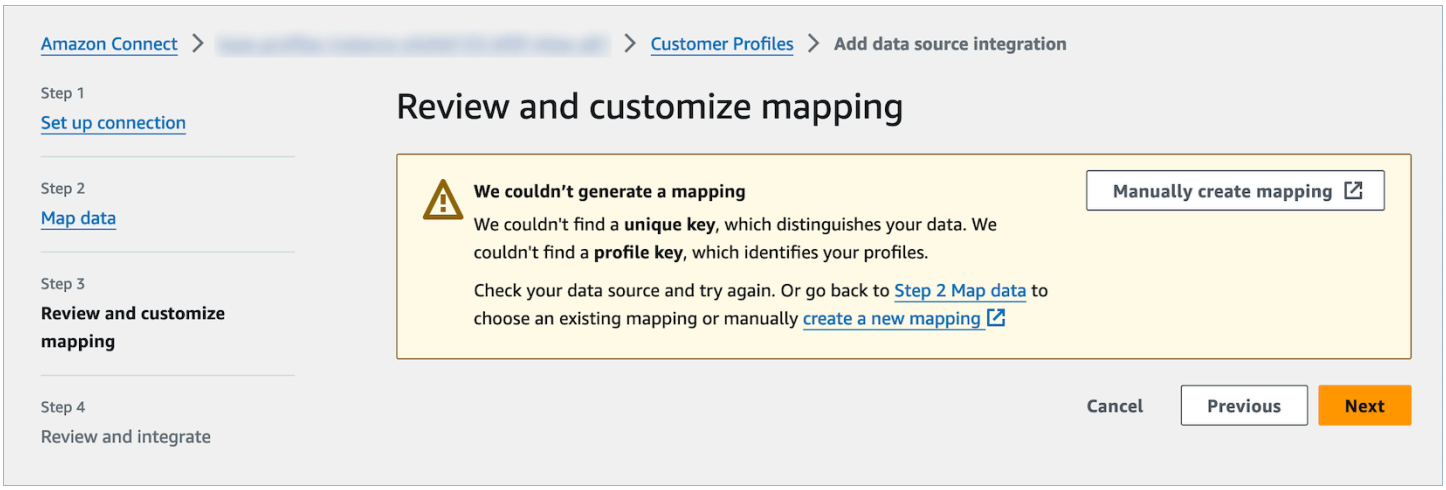
Error: Breached limit of 120 attributes

Up to 120 attributes are allowed in a JSON object, including nested attributes. Remove attributes that don't need to be mapped.



Warning: We couldn't find a unique key, which distinguishes your data. We couldn't find a profile key, which identifies your profiles.

The model couldn't determine a valid object type from the given object. Change the input or use the manual mapping approach. For more information, see Create an object type mapping in the Connect Customer console.



Create and ingest customer data into Customer Profiles

You can define data from any source using Amazon S3 and seamlessly enrich a customer profile without the need for custom or pre-built integrations. For example, say you want to provide agents with relevant purchase history information. You can import purchase transaction data from an internal application into a spreadsheet file on S3 and then link it to a customer profile.

To set this up, you need to define an object type mapping that describes what the custom profile object looks like. This mapping defines how fields from your data can be used to either populate fields in the standard profile or how it can be used to assign the data to a specific profile.

After you create the object type mapping, you can use the PutProfileObject API to upload the custom profile data from your CRM into the custom profile object.

> **Note**
>
> Customer Profiles does not support ingesting data from CSV headers that contain dot notation.

For a list of the required IAM permissions needed for Customer Profiles to access data from the Amazon S3 bucket for data mapping, see `PutProfileObject` in the table in Actions defined by Connect Customer Customer Profiles.

Prerequisite: Configure a dead-letter queue

Before you ingest data from Amazon S3, configure a dead-letter queue (DLQ) for your Customer Profiles domain. Without a DLQ, failed records go unnoticed and you can't diagnose configuration problems.

A DLQ is an Amazon SQS queue where Customer Profiles reports ingestion errors. When you create a domain, you can specify a DLQ. For instructions on specifying a DLQ, see Enable Customer Profiles, and specify a dead-letter queue and KMS key. For an existing domain, use the UpdateDomain operation to add or change the DLQ.

Customer Profile ingestion

Ingesting account-based profiles

1. Upload data files to S3. Ingestion for profiles referenced in account-profiles and the account-profiles itself should happen separately.
2. The new file used for account-profile ingestion should include new attributes: profile type and engagement preferences for email and phone.
3. Ingest files from S3 to Customer profile by using AWS console

Sample Profiles (referenced in the following account-based profiles) CSV

FirstName	LastName	PersonalEmailAddress	PhoneNumber	State	CustomerId	ProfileType
Sam	Joe	sam@example.com	1111111111	WA	456	PROFILE
John	Doe	john@example.com	2222222222	IL	789	PROFILE
Sally	Doe	sally@example.com	3333333333	OR	111	PROFILE

Sample account-based profiles CSV

AccountId	ProfileType	PrimaryOwner	SecondaryOwner	EmailEngagementPreferences	PhoneEngagementPreferences
ACC111	ACCOUNT_PROFILE	Sam Joe	John Doe	[{"KeyName":"CustomerId","KeyValue":"456","Co	[{"KeyName":"CustomerId","KeyValue":"456","Co

AccountId	ProfileType	PrimaryOwner	Secondary Owner	EmailEngagementPreferences	PhoneEngagementPreferences
				ntactType":"PersonalEmailAddress"},{"KeyName":"CustomerId","KeyValue":"789","ContactType":"PersonalEmailAddress"}]	ntactType":"PhoneNumber"},{"KeyName":"CustomerId","KeyValue":"789","ContactType":"PhoneNumber"}]
ACC112	ACCOUNT_PROFILE	John Doe	Sally Doe	[{"KeyName":"CustomerId","KeyValue":"111","ContactType":"PersonalEmailAddress"}]	[{"KeyName":"CustomerId","KeyValue":"111","ContactType":"PhoneNumber"}]

Example of engagement preferences with Email:

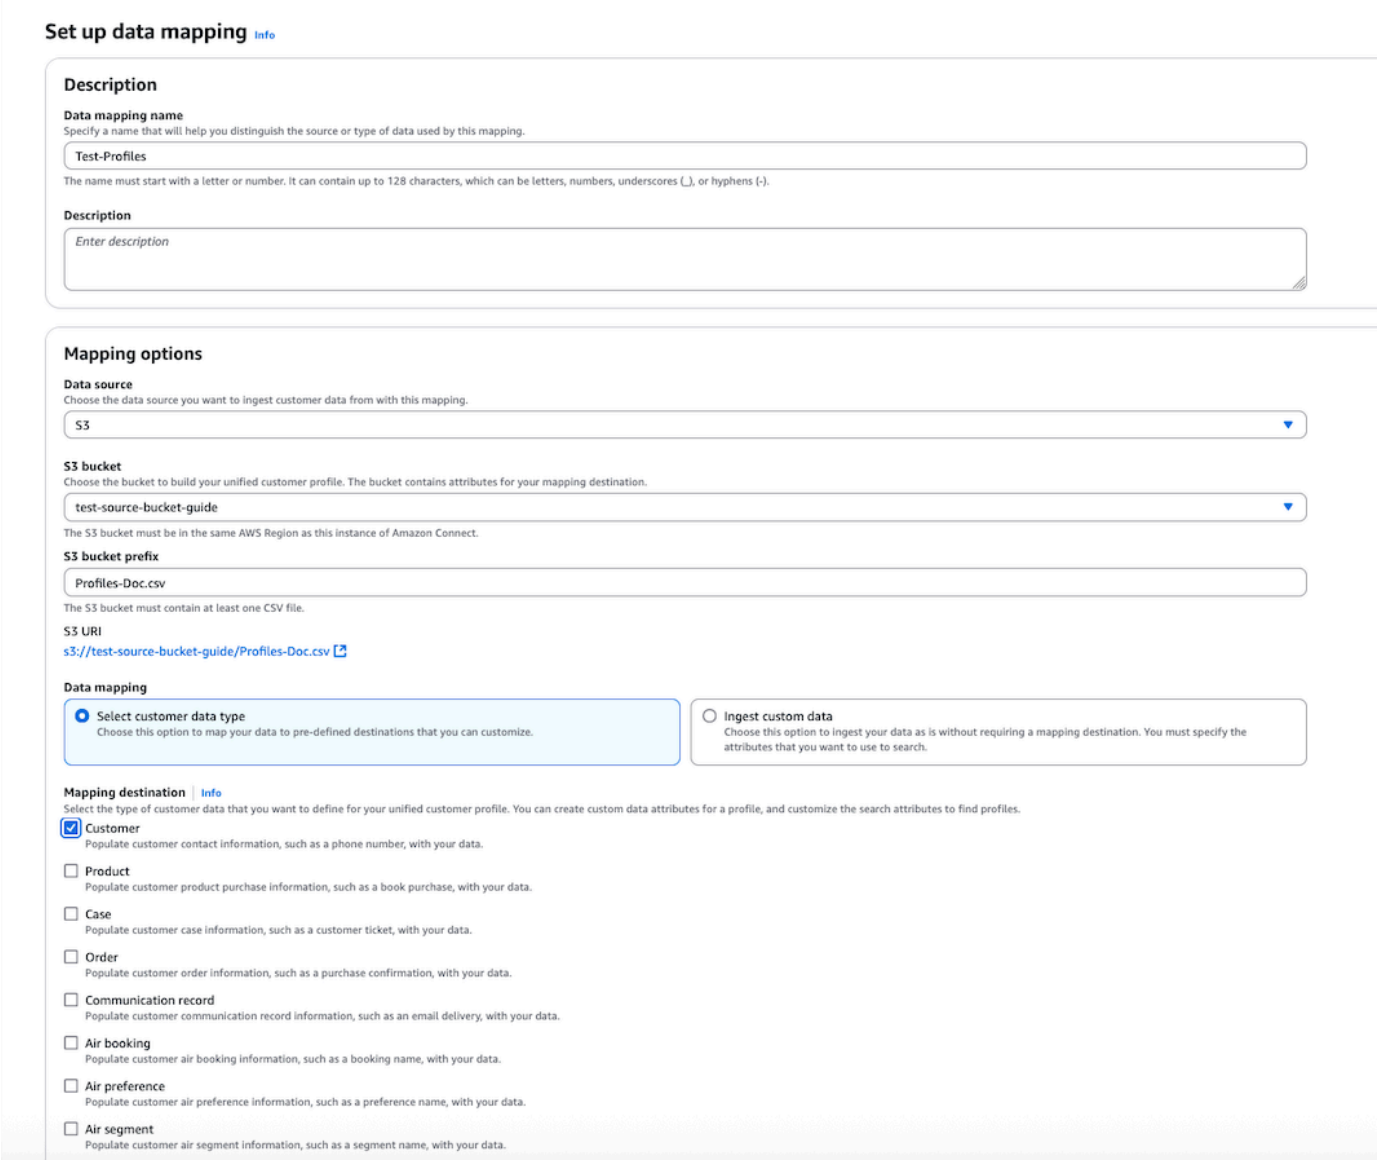
```
[
 {"KeyName": "CustomerId", "KeyValue": "456", "ContactType":
 "PersonalEmailAddress"},
 {"KeyName": "CustomerId", "KeyValue": "789", "ContactType":
 "PersonalEmailAddress"}
]
```

Example of engagement preferences with Phone:

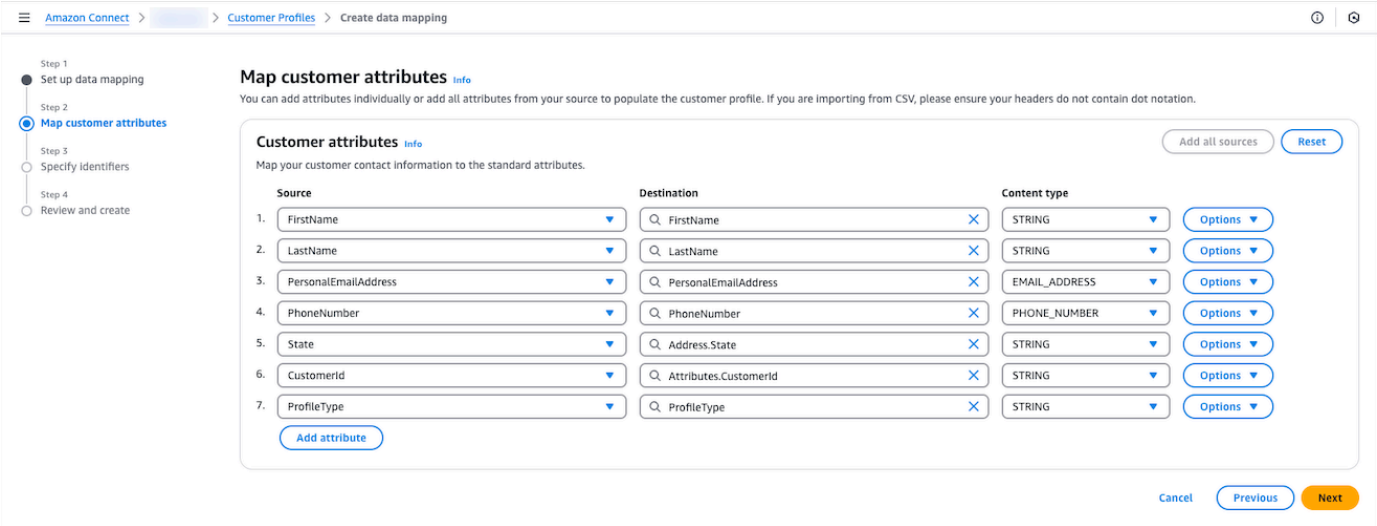
```
[
 {"KeyName": "CustomerId", "KeyValue": "456", "ContactType": "PhoneNumber"},
 {"KeyName": "CustomerId", "KeyValue": "789", "ContactType": "PhoneNumber"}
]
```

> **Note**
>
> For **ProfileType** `PROFILE`, you can ingest and add engagement preferences using the same method.

4. Create two data mappings - one for sub-profiles and one for account-based profiles.



5. Next, map customer profile attributes. Note the destination called `ProfileType`.

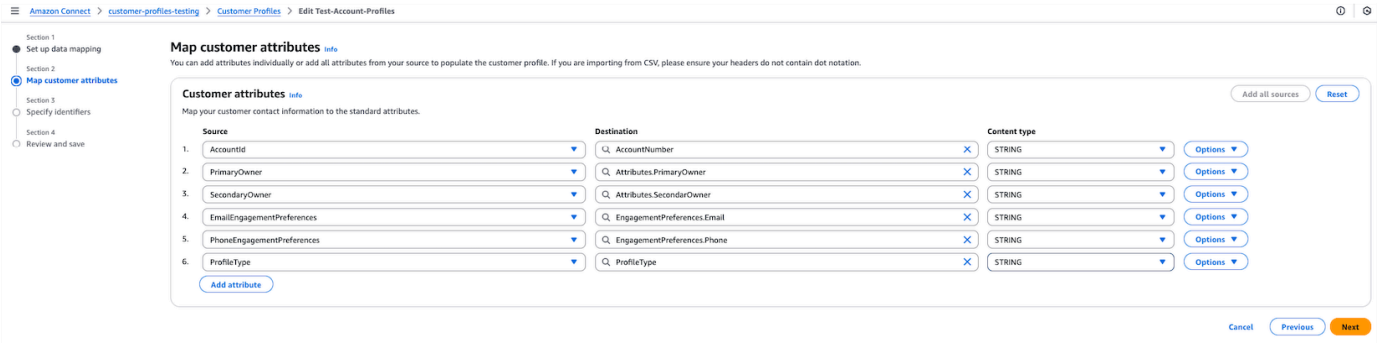


Sample object-type mapping for ingesting profiles referenced in account-based profiles

```
{
    "AllowProfileCreation": true,
    "Description": "Standard Profile Object Type",
    "Fields": {
        "FirstName": {
            "ContentType": "STRING",
            "Source": "_source.FirstName",
            "Target": "_profile.FirstName"
        },
        "LastName": {
            "ContentType": "STRING",
            "Source": "_source.LastName",
            "Target": "_profile.LastName"
        },
        "PhoneNumber": {
            "ContentType": "PHONE_NUMBER",
            "Source": "_source.PhoneNumber",
            "Target": "_profile.PhoneNumber"
        },
        "PersonalEmailAddress": {
            "ContentType": "EMAIL_ADDRESS",
            "Source": "_source.PersonalEmailAddress",
            "Target": "_profile.PersonalEmailAddress"
        },
        "State": {
            "ContentType": "STRING",
```

```
            "Source": "_source.State",
            "Target": "_profile.Address.State"
        },
        "CustomerId": {
            "ContentType": "STRING",
            "Source": "_source.CustomerId",
            "Target": "_profile.Attributes.CustomerId"
        },
        "ProfileType": {
            "ContentType": "STRING",
            "Source": "_source.ProfileType",
            "Target": "_profile.ProfileType"
        }
    },
    "Keys": {
        "CustomerId": [
            {
                "FieldNames": [
                    "CustomerId"
                ],
                "StandardIdentifiers": [
                    "PROFILE",
                    "UNIQUE"
                ]
            }
        ]
    }
}
```

6. Repeat the process to ingest account-based profiles. Note EngagementPreferences.Email and EngagementPreference.Phone.



Sample object-type mapping for ingesting account based profiles

```
{
    "AllowProfileCreation": true,
    "Description": "Account-based profiles Object Type",
    "Fields": {
        "AccountNumber": {
            "ContentType": "STRING",
            "Source": "_source.AccountId",
            "Target": "_profile.AccountNumber"
        },
        "PrimaryOwner": {
            "ContentType": "STRING",
            "Source": "_source.PrimaryOwner",
            "Target": "_profile.Attributes.PrimaryOwner"
        },
        "SecondaryOwner": {
            "ContentType": "STRING",
            "Source": "_source.SecondaryOwner",
            "Target": "_profile.Attributes.SecondaryOwner"
        },
        "ProfileType": {
            "ContentType": "STRING",
            "Source": "_source.ProfileType",
            "Target": "_profile.ProfileType"
        },
        "EmailEngagementPreferences": {
            "ContentType": "STRING",
            "Source": "_source.EmailEngagementPreferences",
            "Target": "_profile.EngagementPreferences.Email"
        },
        "PhoneEngagementPreferences": {
            "ContentType": "STRING",
            "Source": "_source.PhoneEngagementPreferences",
            "Target": "_profile.EngagementPreferences.Phone"
        }
    },
    "Keys": {
        "Account": [
            {
                "FieldNames": [
                    "AccountNumber"
                ],
                "StandardIdentifiers": [
```

```
                    "PROFILE",
                    "UNIQUE"
                ]
            }
        ]
    }
}
```

7. Create two data source integration that will each create a mapping based off the relationship described. For example, accounts/profiles.

> **Note**
>
> - Ingesting account-based profiles should only happen after verifying successful ingestion of profiles referenced in account-based profiles by using the SearchProfiles API or Profile metrics in the Connect Customer Customer Profiles console.
> - Auto-generate mapping doesn't work for ingesting account-based profiles and it's sub-profiles.
> - Email and phone list of contact preferences can either have `KeyName` and `KeyValue` or `ProfileId` to reference child profiles. `KeyName` should be the unique identifier.
> - Updates to sub-profiles doesn't update the engagement preferences in account-based profiles. Updates have to be through ingestion path.

Create a Kinesis Integration with Connect Customer Customer Profiles

The following steps outline the process of streaming objects from an Amazon Kinesis Data Stream into Connect Customer Customer Profiles. First complete the prerequisite, then complete the two integration steps:

1. Configure a dead-letter queue (DLQ) for your domain so that failed events are captured for troubleshooting.
2. Configure an EventBridge Pipe to stream data from your Kinesis Data Stream to an EventBridge bus.

3. Set up a Customer Profiles data integration with your Kinesis Data Stream using your created EventBridge Pipe

Prerequisite: Configure a dead-letter queue

Before you stream data into Customer Profiles, configure a dead-letter queue (DLQ) for your domain. Without a DLQ, failed events go unnoticed and you can't diagnose configuration problems.

A DLQ is an Amazon SQS queue where Customer Profiles reports errors from streamed events. When you create a domain, you can specify a DLQ. For instructions on specifying a DLQ, see Enable Customer Profiles, and specify a dead-letter queue and KMS key. For an existing domain, use the UpdateDomain operation to add or change the DLQ.

Step 1: Stream Data from Kinesis to EventBridge

1. Open the Amazon EventBridge console at https://console.aws.amazon.com/events/
2. In the navigation pane, choose **Event buses**.
3. Choose **Create event bus**.
4. In the **Event bus details** section, provide a descriptive name. For example, `kinesis-to-customer-profiles`.
5. Choose **Create**.
6. Go to your Kinesis Data Stream details page.
7. Select the **EventBridge Pipes** tab and choose **Connect Kinesis Data Stream to Pipe**.
8. Create a name for your EventBridge pipe.
9. Follow the setup wizard until you reach the **Target setup** page.
10. For the target, select the Event Bus created in step 1. For example, `kinesis-to-customer-profiles`.
11. After the **Target** section, expand the **Target Input Transformer** accordion.
12. Set the target input transformer as follows:

```
{
    "data": <$.data>
}
```

13. Choose **Create pipe** to complete the setup.

At this point, you have successfully configured the routing of Kinesis events to EventBridge. Next, we will create an integration with Customer Profiles.

Step 2: Ingest EventBridge Data into Customer Profiles

1. Go to **Customer Profiles** in the Amazon Connect console.
2. Select the **Data source Integrations** tab and choose **Add a data source integration**.
3. Select **Kinesis** from the **Data source** dropdown
4. In the **EventBridge pipe name** dropdown, select the pipe that was created in Step 1 and choose **Next**.
5. On the **Map data** page, select the appropriate object type mapping and choose **Next**.
6. Review your configuration on the **Review and integrate** page and choose **Add data source integration** to complete the setup.

Your Kinesis Data Stream is now integrated with Connect Customer Customer Profiles, and you are now ready to send events from Kinesis to Customer Profiles.

Export your unified customer profile data

Connect Customer Customer Profiles provides real-time data export of unified customer profiles to an Amazon Kinesis Data Stream. You can enable data streaming and automatically receive data for new profiles and updates to existing profiles into your Amazon Kinesis Data Stream.

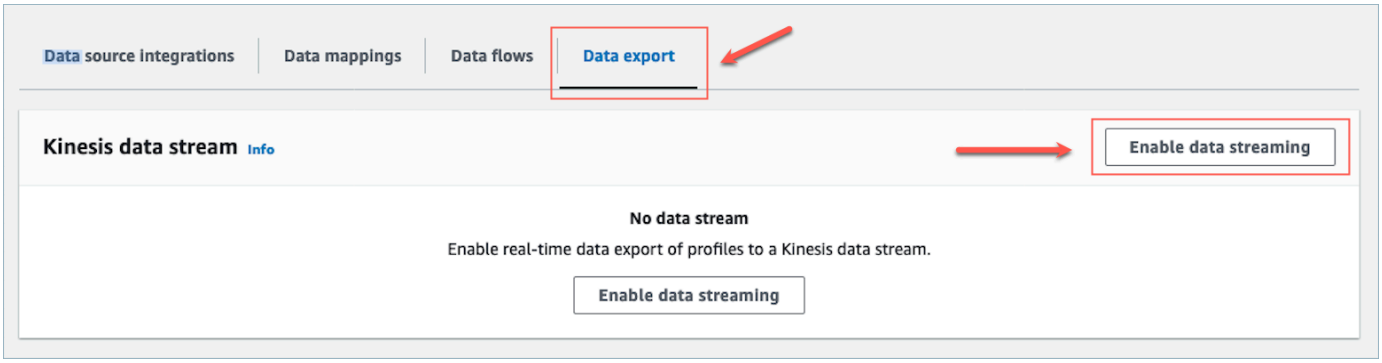
You can keep your source systems data, such as CRMs and marketing automation tools, up-to-date with the latest information from Connect Customer Customer Profiles. For example, when a customer calls your contact center to update their address, an agent can make the change to add the new customer address. The updated profile information is sent to a Kinesis Data Stream in real-time.

To set this up, you need to enable **Data export** in the Customer Profiles console.

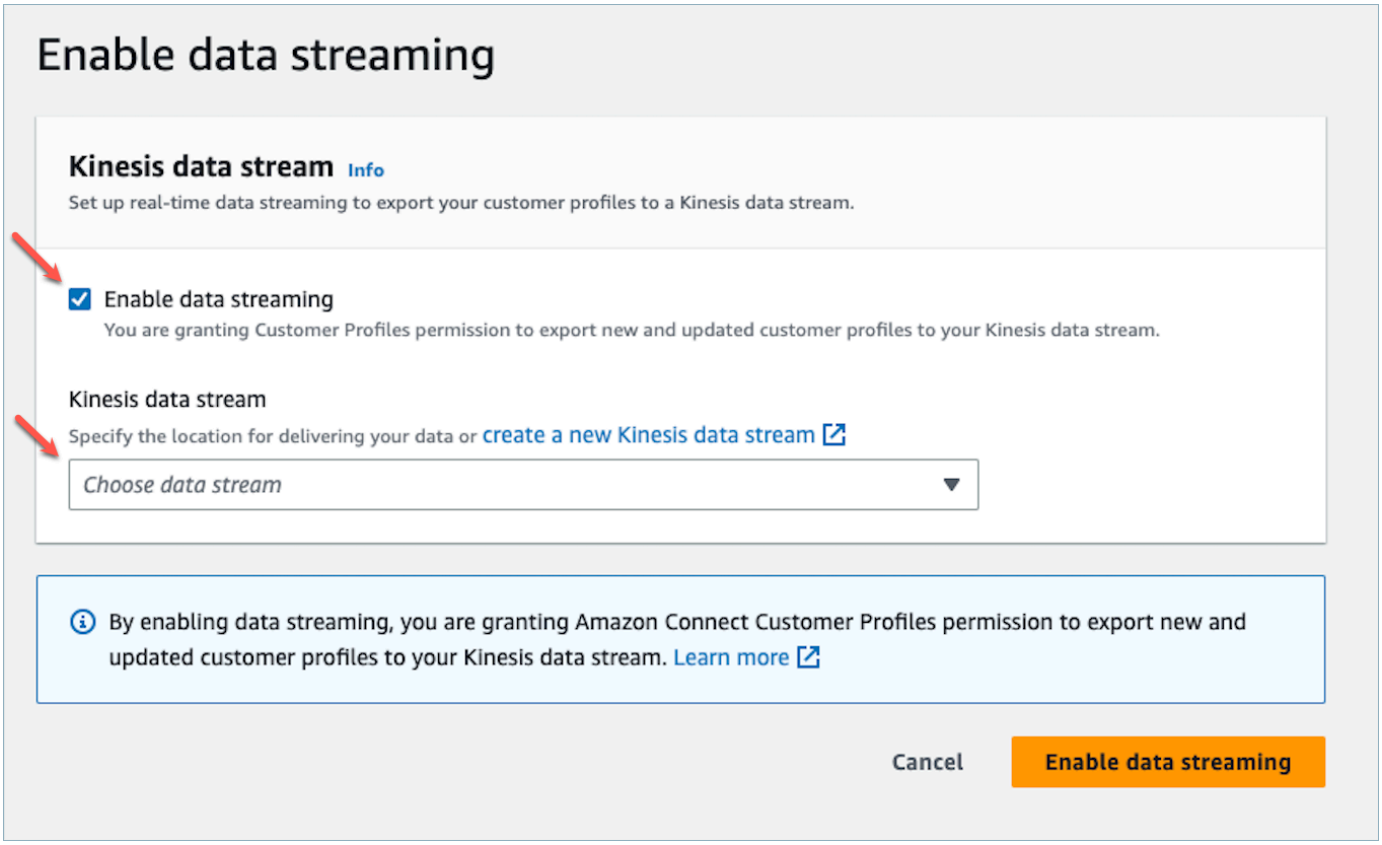
Enable real-time export

To enable data streaming for your domain

1. Open the Connect Customer Customer Profiles console.
2. Select the **Data export** tab and choose **Enable data streaming**



3. Choose **Enable data streaming** and select an existing Kinesis data stream from the drop-down menu, or choose **create a new Kinesis data stream** to open the Kinesis console and create the stream. For more information, see Creating and Managing Streams.

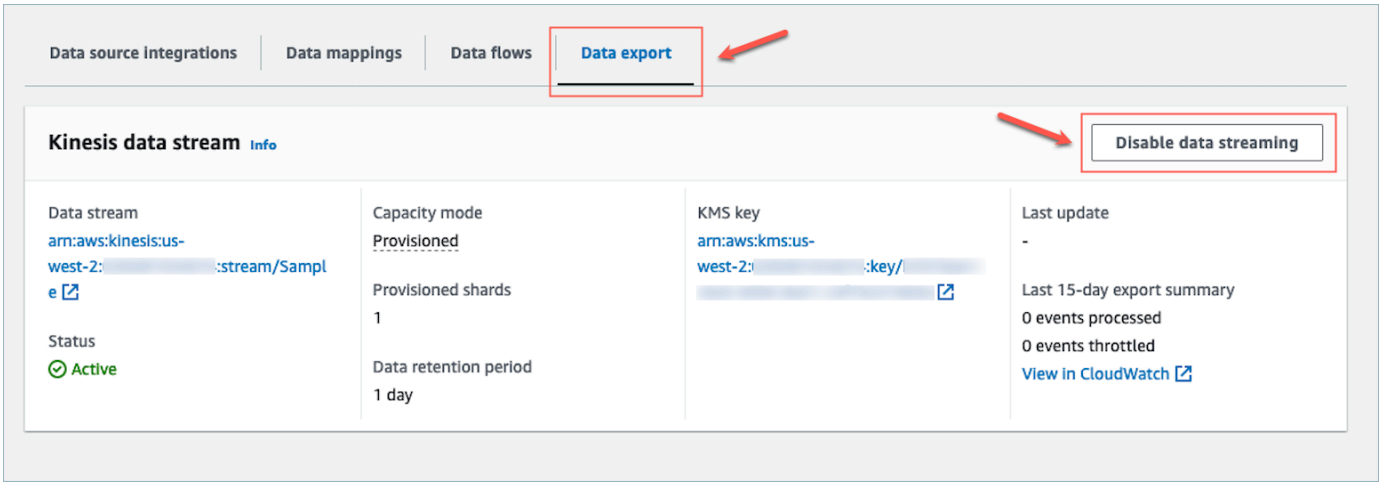


4. Choose the **Enable data streaming** button to save your settings.

Disable real-time export

To disable data streaming for your domain

1. Open the Connect Customer Customer Profiles console.
2. Select the **Data export** tab and choose **Disable data streaming**.



Real-time export Kinesis payload

Sample output event in JSON

```
{
    "SchemaVersion": 0,
    "EventId": "eventId",
    "EventTimestamp": "2020-01-01T00:00:00Z",
    "EventType": "CREATED",
    "DomainName": "domainName",
    "ObjectTypeName": "objectTypeName",
    "AssociatedProfileId": "associatedProfileId",
    "ProfileObjectUniqueKey": "profileObjectUniqueKey",
    "Object": {
        "map": {
            "k1": [
                "a",
                "b",
                "c"
            ]
        }
    },
    "IsMessageRealTime": true
}
```

SchemaVersion

The current version of the schema.

EventId

The unique event ID.

EventTimestamp

Timestamp of the event using the ISO8601 standard.

EventType

The type of event exported.

Values: CREATED, UPDATED, HEALTH_CHECK

- CREATED: The export event was for CreateProfile.
- UPDATED: The export event was for a UpdateProfile.
- HEALTH_CHECK: The export event was for a HealthCheck event to make sure Customer Profiles could successfully `putEvent` in Kinesis Stream.

DomainName

The domain the event belongs to. `/Domain` of the event

ObjectTypeName

Object type of the event

Values: `_profile`, `_asset`, `_order`, `_case`. You can also use predefined template name such as `Salesforce-Account` or a custom defined object name that you can create using the PutProfileObjectType API.

AssociatedProfileId

ID of the Standard Profile that the Object is associated to. It is only present if the object type is not `_profile`

ProfileObjectUniqueKey

The unique identifier of the ProfileObject generated by the service.

Type: String

Object

The Standard Profile or Standard Profile Object itself.

IsMessageRealTime

Flag to inform if the message is real-time or was re-driven.

Sample payload in JSON

```
{
    "SchemaVersion": 0,
    "EventId": "6049bf39-0000-0000-0000-b75656dd51a8",
    "EventTimestamp": "2023-02-24T07:17:05.356Z",
    "EventType": "UPDATED",
    "DomainName": "SampleDomain",
    "ObjectTypeName": "Salesforce-Account",
    "AssociatedProfileId": "5ffcee99ab0000000000b3ae01225e40",
    "ProfileObjectUniqueKey": "cNo77ZI0000000000pCPB7RQcqfeBaRfBwrzW2MMbws=",
    "Object": {
        "Id": "0012v00002kVKVuAAO",
        "IsDeleted": false,
        "Name": "Company A",
        "Phone": "+12065551234",
        "PhotoUrl": "/services/images/photo/0012v00002kVKVuAAO",
        "OwnerId": "0052v00000fmQ7sAAE",

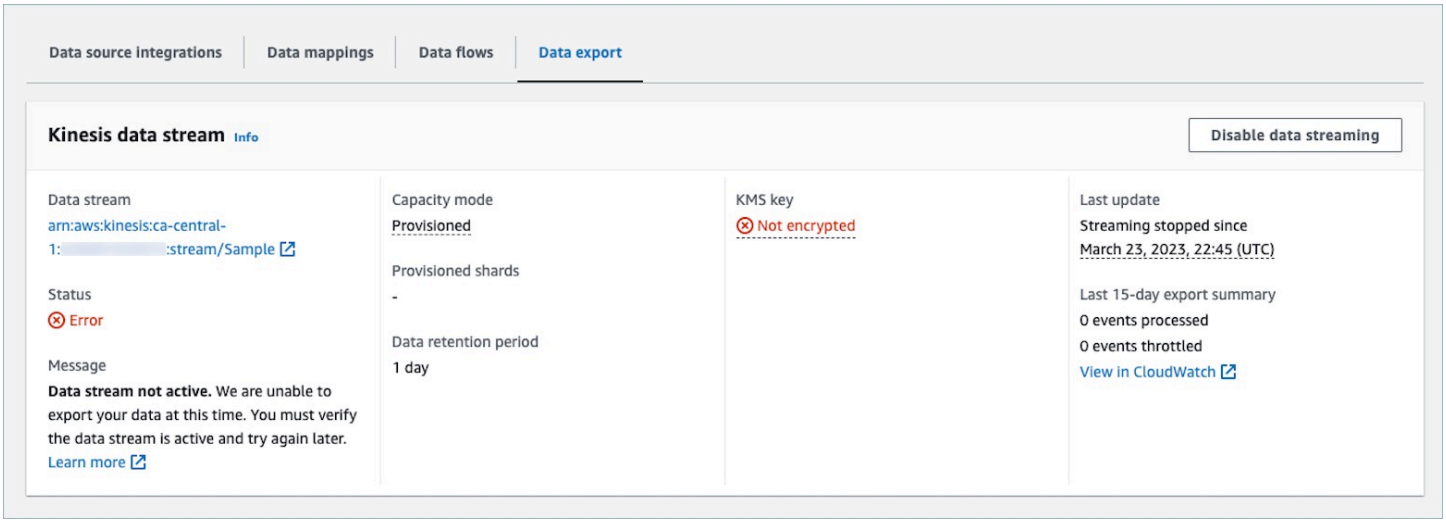
        "LastReferencedDate": "2023-02-23T00:09:49.000+0000",
        "CleanStatus": "Pending"
    },
    "IsMessageRealTime": true
}
```

Troubleshoot real-time event exporting to your Kinesis Data Stream

There might be a delay when first exporting events to your Kinesis Data Stream. This is due to the time it takes to propagate IAM permissions for the service-linked role. When an actual issue occurs, the streaming status can enter an error state.



The following sections display the possible error messages that you might encounter. It also provides the cause and resolution for each issue.

Error: The Kinesis Data Stream is not Active. Please check the configuration and recreate the event stream later

The destination Kinesis Data Stream is not in ACTIVE state. This can happen when your Kinesis Data Stream is being created or being deleted. To resolve the error, make sure your Kinesis Data Stream is in ACTIVE state and re-enable the data streaming setting.

Error: The Kinesis Data Stream does not exist. Please recreate the event stream with valid Kinesis Data Stream destination

The destination Kinesis Data Stream is deleted. To resolve the error, re-enable data streaming with an existing Kinesis Data Stream as the destination.

Error: The Kinesis Data Stream is being throttled. Please consider provision higher Kinesis throughput appropriately

The destination Kinesis Data Stream is being throttled (under-provisioned). To resolve the error, make sure the destination Kinesis Data Stream has enough shard count and then re-enable data streaming.

Error: The KMS key used to encrypt Kinesis Data Stream is being throttled. Please consider increasing the KMS request quota appropriately

The KMS key used by Kinesis Data Stream is being throttled. To resolve the error, re-enable data streaming.

Error: Check the KMS Key configuration of you Kinesis Data Stream

Customer Profiles cannot access the KMS key used by Kinesis Data Stream. This can happen when your KMS key has a key policy that denies access from Customer Profiles service-linked role, or the key is not in Enabled status. To resolve the error, make sure the KMS key policy does not deny access from Customer Profiles service-linked role, and the key is in Enabled status. Re-enable data streaming to resolve the error.

Set up bulk export for all of your unified customer profile data

> **Note**
>
> To complete the steps in this topic, you need to have developer skills, and be experienced with using AWS KMS and Amazon S3.

When Connect Customer Customer Profiles creates a unified customer profile, it enhances, refines, and improves raw data and information into a more accurate profile by combining data from first-party and third-party sources. Customer Profiles also improves the quality of the datasets through the addition of new data. You can use the improved datasets for additional use cases, such as to formulate more informed and targeted marketing, sales, and customer service strategies. For example, you might want to use the unified customer profile to:

- Audit the customer data you have in the entirety of a domain.
- Perform in-house analytics, for example, for sales and marketing reports.
- Export the data into your own tools or third-party products, to personalize ads and target customers.

To use the unified customer profile data for additional use cases, you can bulk export it to Amazon S3. This topic explains how to do that.

Topics

- Step 1: Set up a KMS key and S3 bucket
- Step 2: Create a bulk export job
- Step 3: Check the status of a bulk export job
- Step 4: View the exported data in S3
- Update the bulk export job
- Delete or cancel the bulk export job - not supported

Step 1: Set up a KMS key and S3 bucket

To enable bulk export for your domain, you'll need to setup the following resources:

- A KMS key with a specific resource policy
- A destination S3 bucket with a specific resource policy. Do not configure access control lists (ACLs) on the bucket.

These steps are explained next.

Create a new KMS key or reuse an existing KMS key

To set up a KMS key for bulk export, you must create or reuse an existing KMS key that is in the same AWS Region as the Amazon S3 bucket you plan on configuring as your bulk export destination. You must allow the Connect Customer AppIntegrations service to perform KMS actions for the key.

Add the following statement to your **key policy**.

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Sid": "Enable AppIntegrations access to KMS key",
            "Effect": "Allow",
            "Principal": {
                "AWS": [
                    "arn:aws:iam::111122223333:root"
                ],
```

```
                "Service": [
                    "app-integrations.amazonaws.com"
                ]
            },
            "Action": [
                "kms:Encrypt*",
                "kms:Describe*",
                "kms:Decrypt*",
                "kms:GenerateDataKey*"
            ],
            "Resource": "*"
        }
    ]
}
```

Set up an S3 destination bucket

You must configure a new or existing bucket in the same AWS Region as the KMS key, and configure a resource policy on the S3 bucket.

When configuring the bucket, make sure that you select **Encryption with SSE-KMS** and use the same KMS key from the previous procedure. In addition, do not enable ACLs on the S3 bucket.

Following is an example resource policy.

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Sid": "Allow AppIntegrations to write data to destination bucket",
            "Effect": "Allow",
            "Principal": {
                 "Service": [
                    "app-integrations.amazonaws.com"
                ]
            },
            "Action": [
                "s3:GetObject",
                "s3:ListBucket",
```

```
                "s3:PutObject",
                "s3:PutObjectAcl"
            ],
            "Resource": [
                "arn:aws:s3:::{{amzn-s3-demo-bucket1}}",
                "arn:aws:s3:::{{amzn-s3-demo-bucket2}}/*"
            ],
            "Condition": {
                "StringEquals": {
                    "aws:SourceAccount": "{{AwsAccountId}}"
                },
                "ArnEquals": {
                    "aws:SourceArn": "arn:aws:*-*:{us-east-1}:
{{AwsAccountId}}:data-integration/*"
                }
            }
        }
    ]
}
```

Step 2: Create a bulk export job

To create a bulk export job, you invoke the following Connect Customer AppIntegrations APIs:

1. CreateDataIntegration: This API creates an integration with the data source (for example, Customer Profiles).
2. CreateDataIntegrationAssociation: This API writes data to the destination (for example, an S3 bucket) by using the data source.

Following is more information about how to call these APIs.

Create a data integration

A data integration represents the *data source* of your data. You can call the CreateDataIntegration API or run the create-data-integration CLI command to create a data integration. You must provide a Customer Profiles *object type* and Customer Profiles *domain*.

If you want to export multiple object types, you need to create a separate data integration for each one. For example, if you want to export both `_profile` and `_asset` objects, you need to create two separate data integrations.

> **Note**
>
> Any data that is ingested within the last 30 minutes might not be included in the export.

The following code sample shows how to run the create-data-integration CLI command.

```
aws appintegrations create-data-integration \
--region "us-west-2" \
--name "bulk-export-job-01" \
--description "Data integration for _profile objects" \
--kms-key "arn:aws:kms:us-west-2:123456789012:key/123456789012-1234-1234-123456789012"
 \
--source-uri "AmazonConnect://AppIntegrations" \
--object-configuration '{"CustomerProfiles":{"domainName":["my-domain-
pdx"],"objectType":["_profile"]}}'
```

The following code sample shows how to call the CreateDataIntegration API.

```
{
    "Description": "Data integration for _profile objects",
    "KmsKey": "arn:aws:kms:us-
west-2:123456789012:key/123456789012-1234-1234-123456789012",
    "Name": "unique-data-integration-name-01",
    "SourceURI": "AmazonConnect://AppIntegrations",
    "ObjectConfiguration": {
        "CustomerProfiles": {
            "domainName": [
                "my-domain-pdx"
            ],
            "objectType": [
                "_profile"
            ]
        }
    }
}
```

Create a data integration association

A data integration association represents the destination for where you want to export your data and a time range for choosing which data to export. You can call the

CreateDataIntegrationAssociation API or run the create-data-integration-association CLI command to create a data integration. You configure the time range by using the `StartTime` and `EndTime` properties. This time range corresponds to when objects were last updated in Customer Profiles.

The destination S3 bucket that you specify can be just the bucket name, or it can include an additional folder or S3 prefix where you want the data to be exported.

> **Note**
>
> For the quota for **Concurrent bulk export jobs**, see Connect Customer Customer Profiles service quotas. After a bulk export job completes or fails, it no longer counts towards the concurrency quota.

The following code sample shows how to run the create-data-integration-association CLI command.

```
aws appintegrations create-data-integration-association \
--region "us-west-2" \
--data-integration-identifier "unique-data-integration-name-01" \
--destination-uri "s3://amzn-s3-demo-bucket1" \
--execution-configuration '{"ExecutionMode": "ON_DEMAND", "OnDemandConfiguration":
 {"StartTime":"1715278292014", "EndTime":"1715364692014"}}'
```

The following code sample shows how to call the CreateDataIntegrationAssociation API.

```
{
    "DataIntegrationIdentifier": "arn:aws:app-integrations:us-west-2:123456789012:data-
integration/123456789012-1234-1234-123456789012",
    "DestinationURI": "s3://amzn-s3-demo-bucket1",
    "ExecutionConfiguration": {
        "ExecutionMode": "ON_DEMAND",
        "OnDemandConfiguration": {
            "StartTime": "1713565000004",
            "EndTime": "1713565000005"
        }
    }
}
```

Step 3: Check the status of a bulk export job

To view the status of your bulk export job, you can call the ListDataIntegrationAssociations API, or run the list-data-integration-associations CLI command.

The following code sample shows how to run the list-data-integration-associations CLI command.

```
aws appintegrations list-data-integration-associations \
--region "us-west-2" \
--data-integration-identifier "unique-data-integration-name-01"
```

Step 4: View the exported data in S3

When the data integration association is in `IN_PROGRESS`, you will begin to see data being copied over to your S3 bucket.

The exported data is written using the following path structure:

- {BucketNameAndFolderName}
  - {AwsAccountId}
    - {DomainName}
      - {RequestTimestamp}
        - {lStartTime}-{EndTime}
          - {ObjectTypeName}
            - <filename: uuid>

Following is an example path:

```
amzn-s3-demo-bucket1/123456789012/my-domain-
pdx/20240607T175023/20240101T235959-20240430T235959/
_profile/123456789012-1234-1234-123456789012
```

Update the bulk export job

After the job finishes, you can update the data integration association with a different data pull start time and data pull end time. This creates a new bulk export job. You might want to do this if you performed a bulk export in the past and want to export only data that was updated since the

previous export. For example, if your last bulk export job was three months ago, you can update your data integration association with a time range of 3 months ago to today.

You can call the UpdateDataIntegrationAssociation API, or run the update-data-integration-association CLI command to update the export job.

The following code sample shows how to run the update-data-integration-association CLI command.

```
aws appintegrations update-data-integration-association \
--region "us-west-2" \
--data-integration-identifier "unique-data-integration-name-01" \
--data-integration-association-identifier "arn:aws:app-integrations:us-
west-2:123456789012:data-integration-
association/123456789012-1234-1234-123456789012/123456789012-1234-1234-123456789012" \
--execution-configuration '{"ExecutionMode": "ON_DEMAND", "OnDemandConfiguration":
 {"StartTime":"1715278292014", "EndTime":"1715364692014"}}'
```

Delete or cancel the bulk export job - not supported

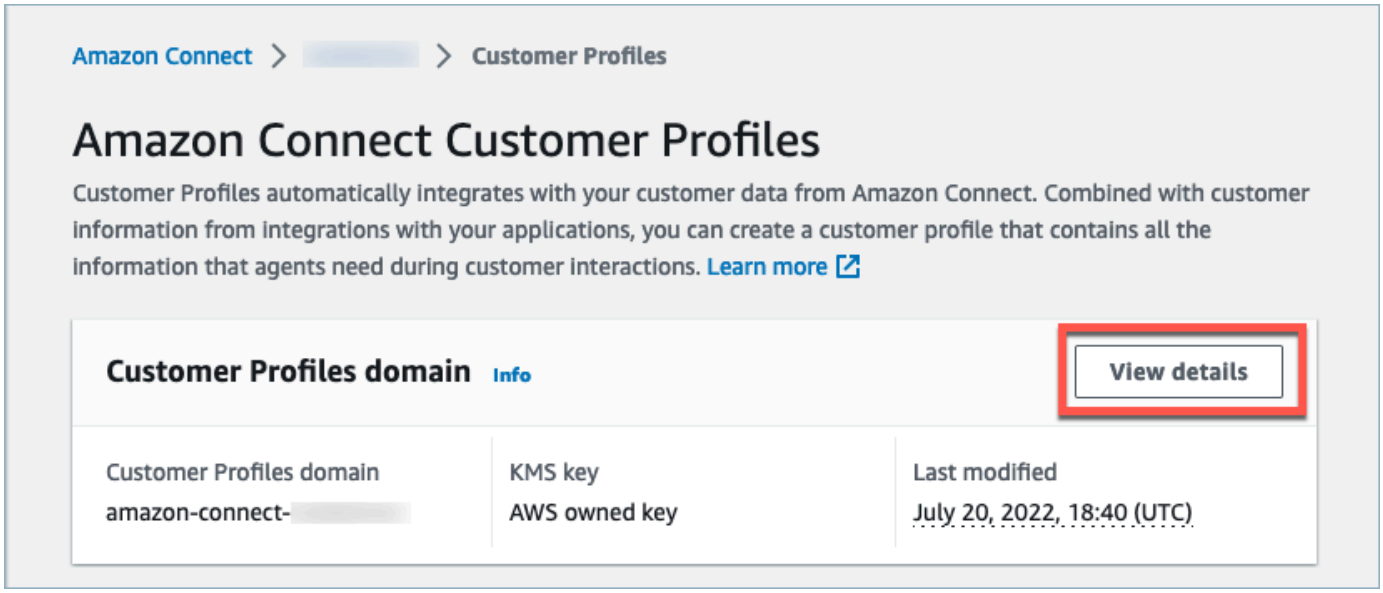
You cannot delete or cancel bulk export. After an export job finishes, it no longer counts toward your export quota.

Delete a Connect Customer Customer Profiles domain

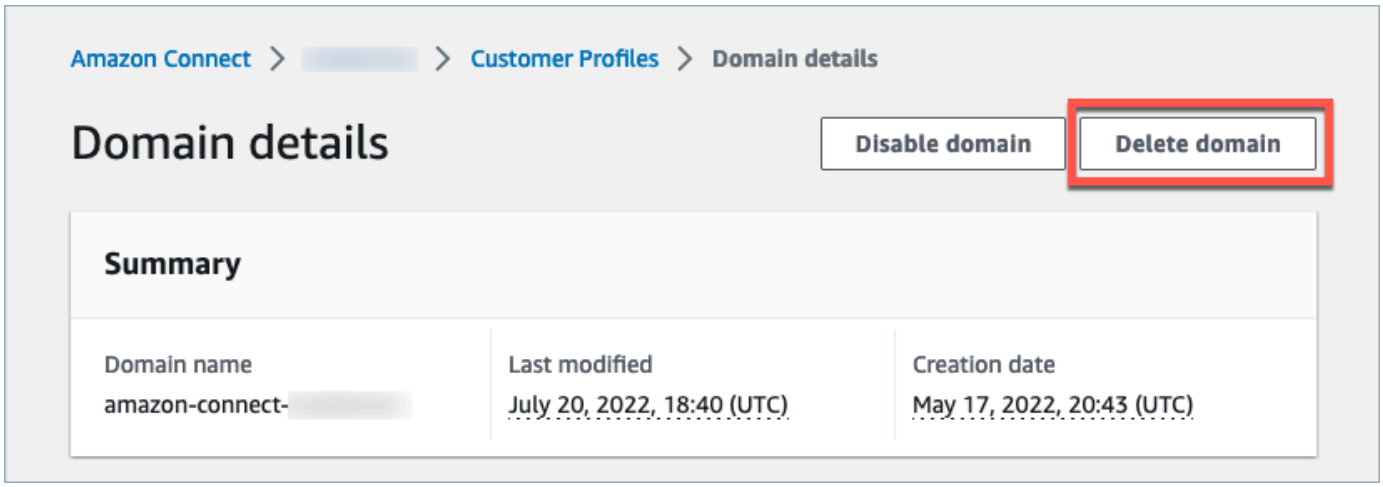
> **Select your instance first**
>
> You must select your Connect Customer instance in the console before the Customer Profiles domain appears in the navigation pane.

Deleting mappings will only delete objects and data associated with that specific mapping. If there are multiple objects associated with a profile, then deleting a specific mapping might not clear the profile data. If you want to delete specific data, you would then delete the mapping, but your profiles might still exist if they contain data from other mappings. This could result in additional charges for the existing profiles. To avoid this from occurring, you can delete your Customer Profiles domain using the Connect Customer console by following these steps.

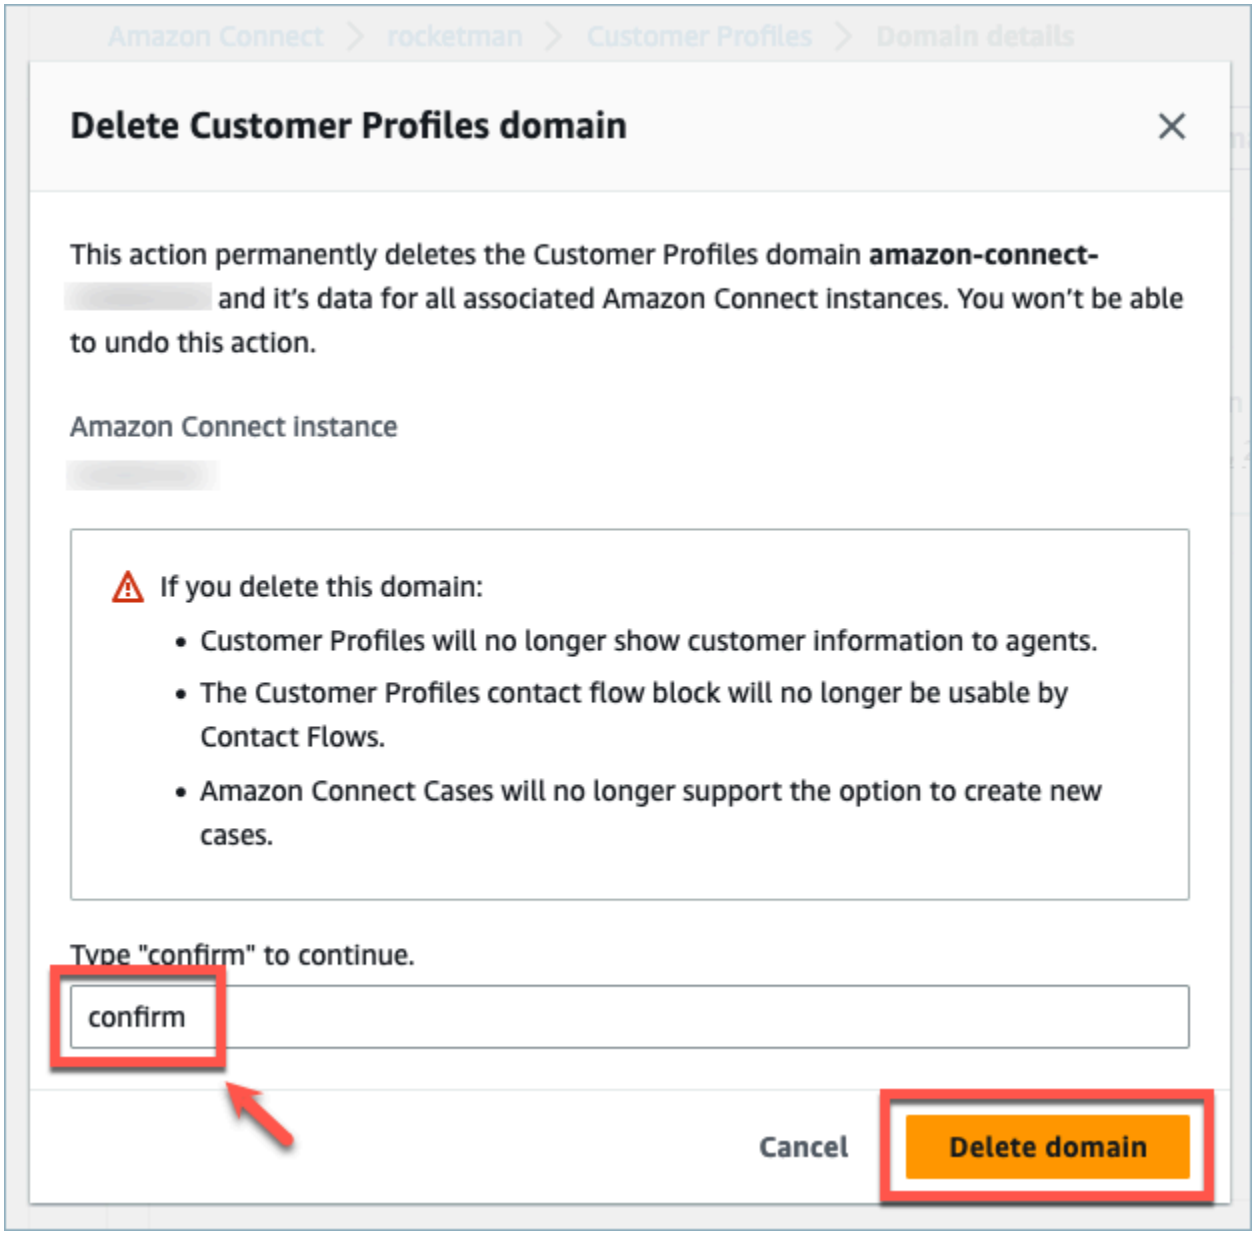
1. Login to the Connect Customer console and select Customer Profiles from the left navigation pane. Choose your Customer Profiles domain and then choose **View details**.



2. Choose **Delete domain**.



3. To delete your domain, enter *confirm* in the box and choose **Delete domain**.



Set up calculated attributes in Connect Customer Customer Profiles

Calculated attributes are values that are derived from other attributes by using formulas. You can use them to identify users' aggregate behaviors.

You can create calculated attributes to define your own business logic to transform your customer profile data into actionable data points. With calculated attributes, you can personalize automated experiences such as interactive voice responses.

By using calculated attributes, you can identify key attributes about your customer's past behaviour. For example:

- The last website visited or last agent spoken to
- Patterns of behaviour, such as preferred channel and frequency of contact
- Customer value, such as new customer and average ticket size

You can use the calculated attributes API to create a new attribute using common aggregation operations such as average, count, minimum, maximum, and sum.

Calculated attributes automatically transform raw data in real-time into actionable data points and metrics. Contact center administrators are able to define and configure calculations based on the raw data available in customer profiles. These calculated attributes make it easier for you to build automated experiences such as Interactive Voice Response (IVR) or chatbots. You can build personalized experiences and help agents understand customer context faster.

For a list of AWS Regions where the calculated attributes APIs are available, see Customer Profiles calculated attributes API availability by Region.

Getting started with calculated attributes in Connect Customer Customer Profiles

Use calculated attributes to define your own business logic to transform your customer profile data into actionable data points to personalize automated experiences, such as interactive voice responses.

By using calculated attributes, you can identify key attributes about your customer’s past behavior, behavior patterns, and customer value.

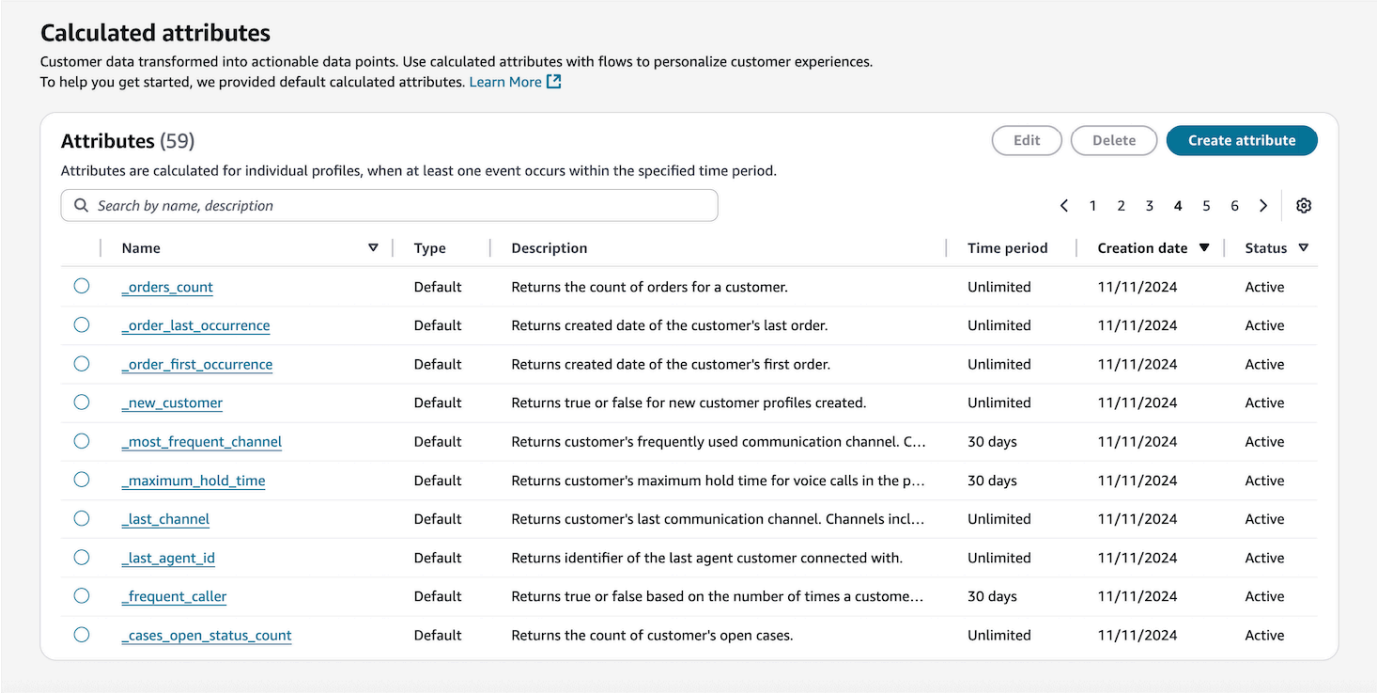
The topics in this section show you how to create, view, edit, and delete Calculated Attributes.

Topics

- Create calculated attributes in Connect Customer
- Set up event filters
- View calculated attributes in Connect Customer
- Edit calculated attributes in Connect Customer
- Delete calculated attributes in Connect Customer

Create calculated attributes in Connect Customer

1. Prerequisites: Make sure you have the necessary security profile permissions. For more information, see Update permissions for calculated attributes in Connect Customer Customer Profiles.
2. In Connect Customer admin website, navigate to **Customer Profiles**, **Calculated attributes**, choose **Create attribute** in the **Calculated attributes** table view.

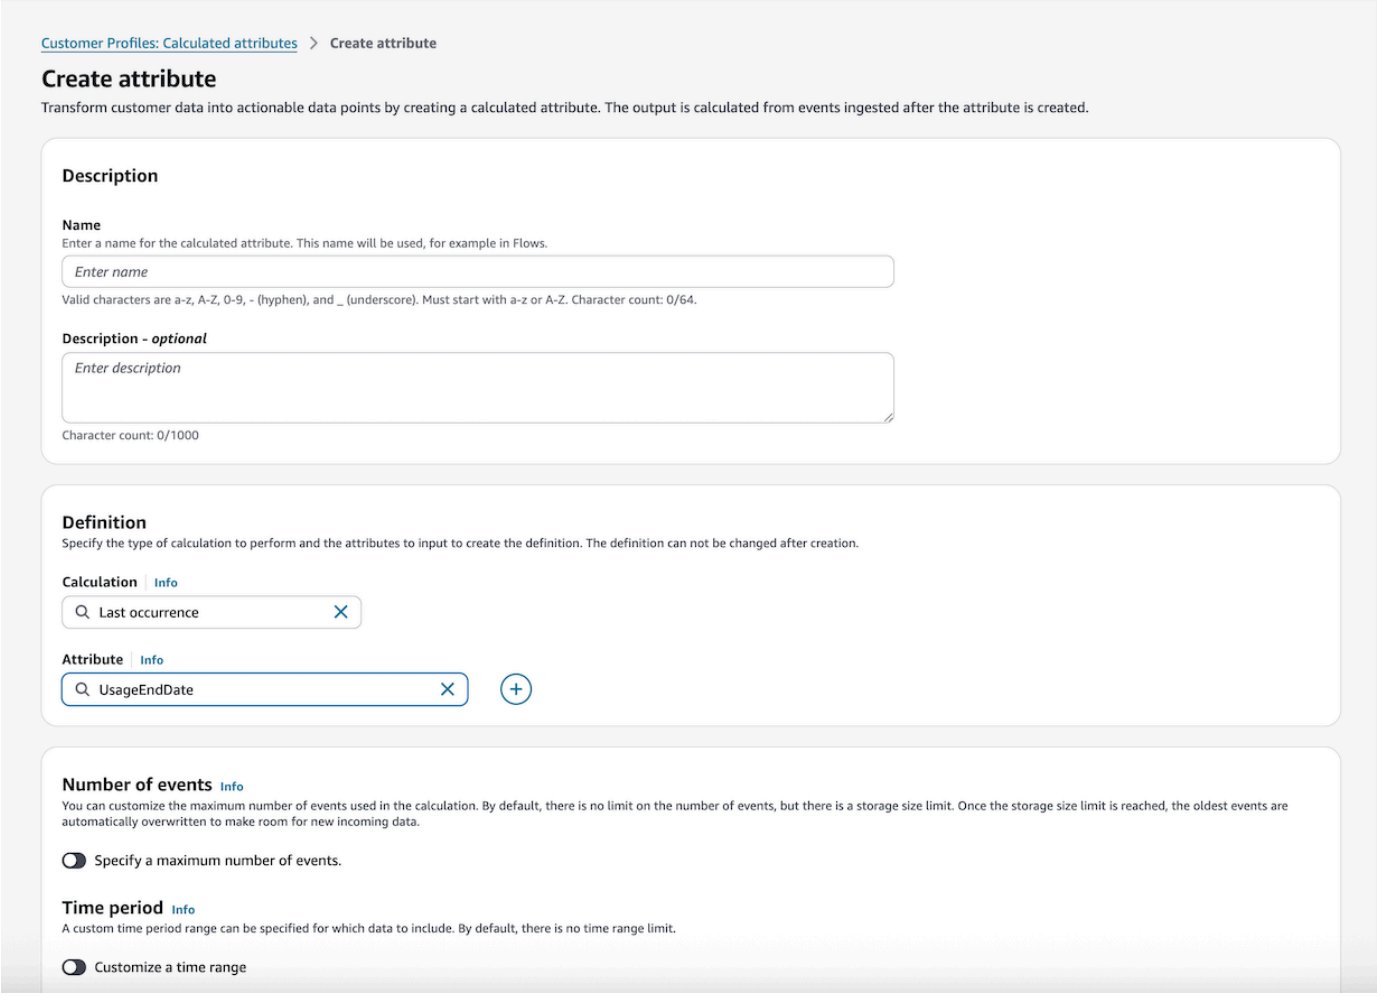


3. To create a calculated attribute, assign a descriptive name, add description (optional) with details about the attribute, and configure the required fields:

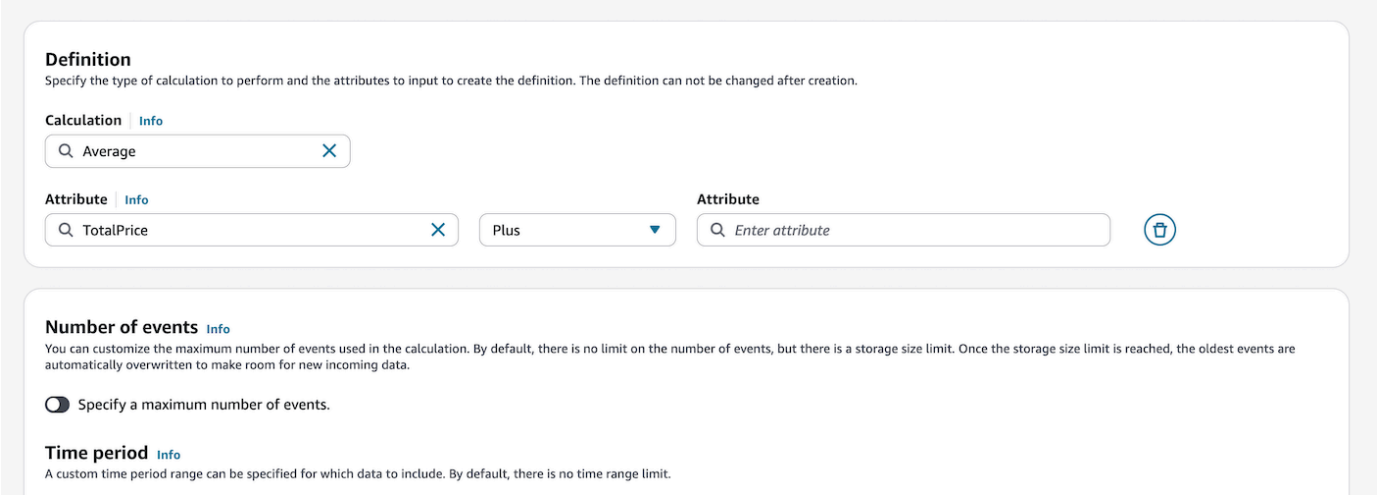
   - **Calculation:** Defines how attributes are computed (average/count/sum/minimum/first occurrence/last occurrence/max occurrence).

- **Attribute:** A data point from your customer profiles data.

> **Note**
>
> If you are selecting an attribute from a standard object type (`_asset`, `_case`, `_order`), the attributes must be in PascalCase. This means that the first letter of each word in the attribute name is capitalized, such as `_case.CreatedBy` or `_order.TotalPrice`.



4. Additionally, you can add another attribute by selecting the *plus* icon. You can choose up to two attributes to calculate and combine them by an operator. Specify an operator such as *plus* or *minus* to combine the attribute values.

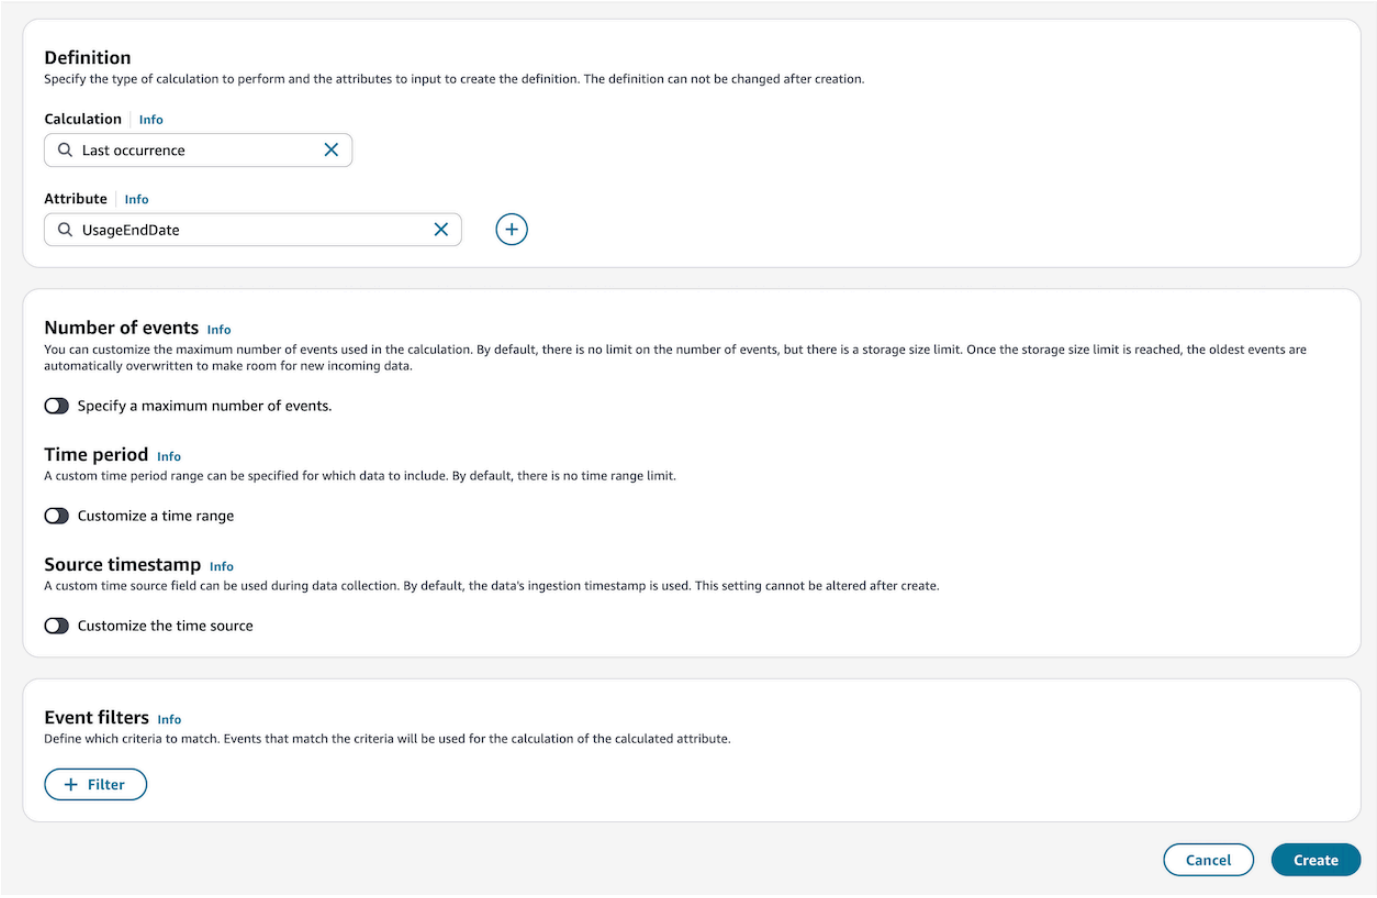


5. After the calculation is selected, you can optionally configure the Number of events, Time period, and Source timestamp. By default, calculated attributes is configured to use unlimited events, an unlimited time period, and a timestamp based on ingestion date.

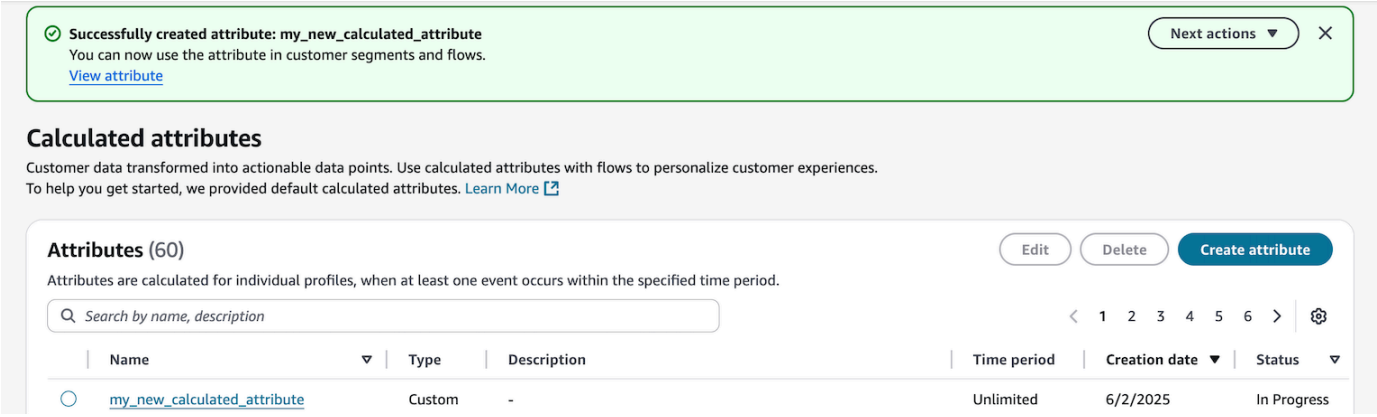
   An output is returned when there is at least one event during the specified time period.

   - **Number of events:** configure limit or use unlimited (default)
   - **Time period:** set specific timeframe or use unlimited (default)
   - **Source timestamp:** choose between a specific timestamp field or ingestion date (default)

   > **Note**
   >
   > While there's no event limit, a data size limit exists where oldest data will be replaced by newer data. Source timestamp cannot be changed after creation.



6. Optionally, you can define criteria to include only relevant events in calculations. See [Set up event filters] for more information.
7. Select **Create** to create the calculated attribute.
8. After a calculated attribute has been created successfully, a banner is displayed on the table view for using the calculated attribute in a segment or flow. You will also be able to view the status of calculated attributes based on the readiness.

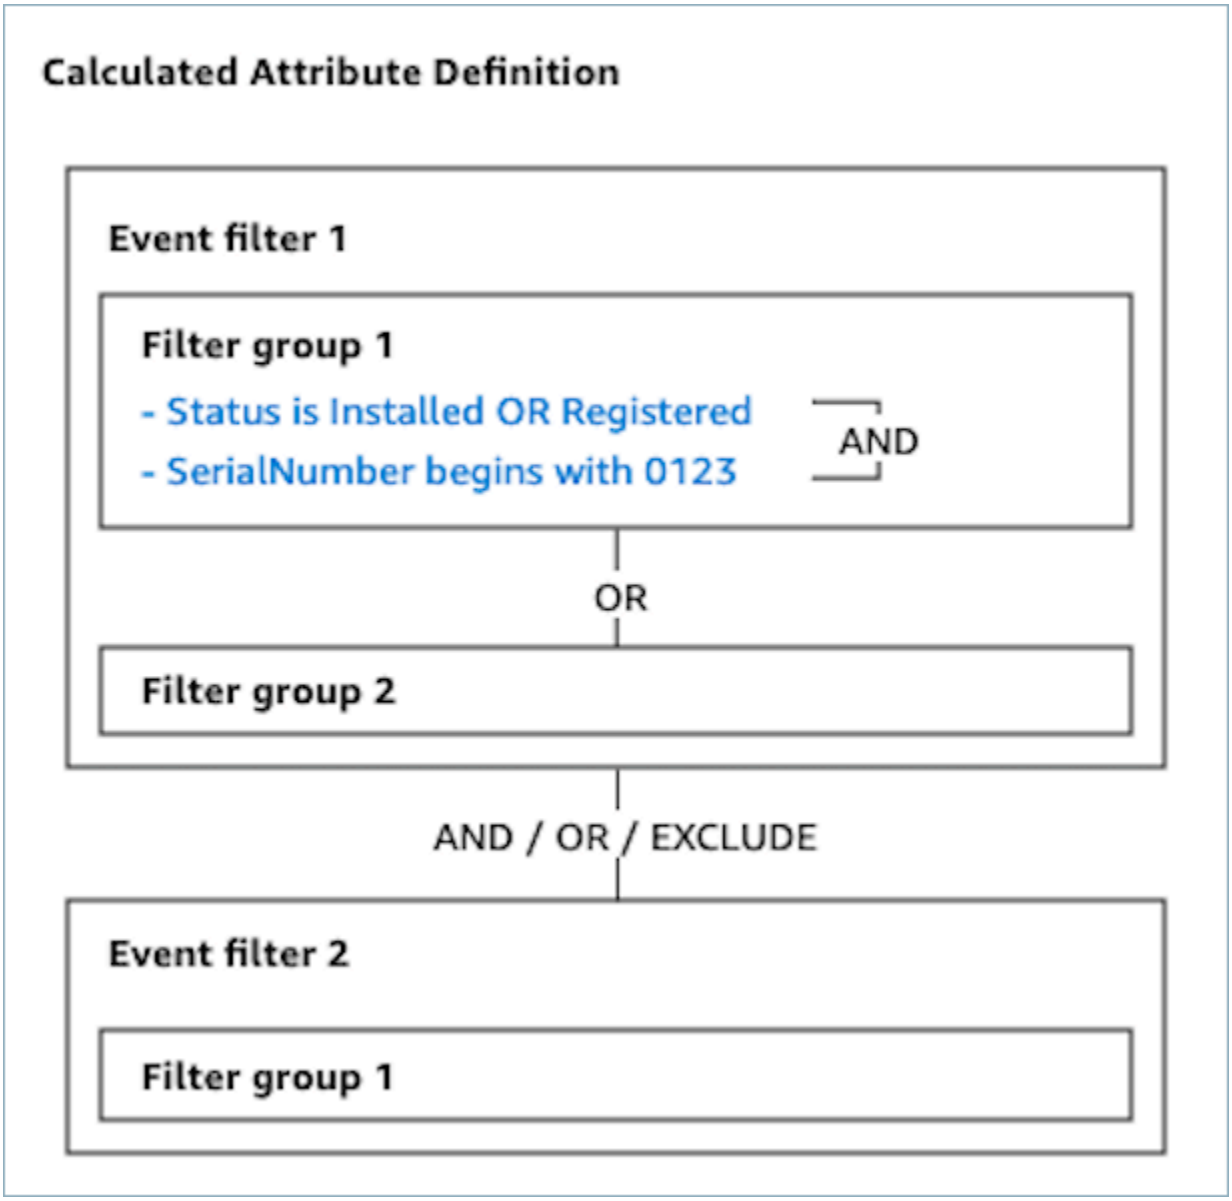


Set up event filters

With event filters, you can filter the profile objects to be used in the calculated attribute. For example, an event filter might filter the customer's standard asset objects so that only the assets with **Status is Installed OR Registered** are included in the calculation.

> **Note**
>
> You cannot edit event filters after creating a calculated attribute definition.

When you create a calculated attribute, you can create one or more event filters. An event filter consists of the following components:



- **Filter groups**: Group of filters that you apply to the profile objects. You can add multiple filter groups which are connected by OR relationships.
- **Filters**: Filters the profile objects that are included in the calculation of the calculated attribute by specifying attributes, operators, and values. You can add as many filters as needed for your use case.
- **Attribute**: The attribute of the object to filter by. You can select attributes from objects stored in the Customer Profiles domain or use the field names defined in the object type definition. for more information about object type mappings, see Object type mapping in Connect Customer Customer Profiles.

> **Note**
>
> - In Connect Customer admin website, the attribute dropdown shows the timestamp of the last time any profile object was saved or updated with the attribute.
> - If there is both an attribute of a profile object and a field of an object type with the same name, the event filter prioritizes the object type field name in its filtering. For example, if a profile object has an attribute named **Status** and there is also an object type field named **Status**, the filter will use the object type field **Status** for filtering.

- **Operator** — The operator determines the relationship of the attribute to a value you enter. For more information, see Filter operators
- **Value** — The value to filter objects with. You can specify multiple values connected by OR relationships. For example, *Asset's Status is Installed or Registered*. Note that values are case-sensitive. For example, *Asset's Status is Installed* returns different results than *Asset's Status is installed*. To view profile objects, use the Connect Customer Customer Profiles ListProfileObjects API.

You can optionally create up to two event filters and create a relationship (AND/OR/EXCLUDE) between them. For more details about the relationship, see Relationship between event filters.

Filter operators

Operators determine the relationship of the attribute to a value you enter. The following table describes the available operators.

Supported type of attribute value	Operator	Description
Number	Greater than	Used for numeric attributes only. This operator filters results that are greater than the number passed. For example, *Asset's Quantity* is greater than 1 .

Supported type of attribute value	Operator	Description
	Greater than or equal	Used for numeric attributes only. This operator filters results that are greater than or equal to the number passed. For example, *Asset's Quantity* is greater than or equal to 1.
	Equals	Used for numeric attributes only. This operator filters the audience by numeric value equality. For example, *Asset's Quantity* equals 1 .
	Less than	Used for numeric attributes only. This operator filters results that are less than the number passed. For example, *Asset's Quantity* is less than 2.
	Less than or equal	Used for numeric attributes only. This operator filters results that are less than or equal to the number passed. For example, *Asset's Quantity* is less than or equal to 2.
String	Is	Filters the object whose attribute matches with the given string. For example, *Ticket's Title* is Refund.

Supported type of attribute value	Operator	Description
	Is not	Filters the object whose attribute does not match with a given string. For example, Ticket's title is not Refund.
	Contains	Use this to filter the object based on a substring within a string. For example, *Ticket's Title* contains Refund.
	Begins with	Filters the object whose attribute begins with the given string. For example, Asset's SerialNumber begins with "1234".
	Ends with	Filters the audience whose attribute ends with the given string. For example, *Asset's SerialNumber* ends with "0000".
Date	Before	Filters the object whose attribute has a date value that is before a specific date. For example, *Asset's UsageEndDate* is before 2024/10/01.
	On	Filters the object whose attribute value matches with a specific date. For example, *Asset's UsageEndDate* is on 2024/10/01.

Supported type of attribute value	Operator	Description
	After	Filters the object whose attribute has a date value that is after a specific date. For example, *Asset's UsageEndDate* is after 2024/10/01.
	Time range is	Filters the object whose attribute has a date value that is between a specific time range. You can either specify the time range in absolute time mode or relative time mode.
		Absolute time mode: allows you to specify an absolute time range. For example, between 2024/10/01 12:00 AM and 2024/10/07 12:00 AM.

Supported type of attribute value	Operator	Description
		Relative time mode: allows you to specify the relative time range of future or past X hours, days, weeks, months, or years. • **Future time direction**: will filter audience whose attribute has a date value that is between now and a specified future time. For example, within the next 2 days. • **Past time direction**: will filter audience whose attribute has a date value that is between a specified past time and now. For example, within the last 2 days.
	Time range is not	Filters the audience whose attribute has a date value that is not between a specific time range. You can either specify the time range in absolute time mode or relative time mode. See the **Time range is** operator in this table for more details.

Note

Calculated attributes in the Connect Customer admin website use the UTC timezone and a default time of 00:00:00 UTC for all time-based filters. You can filter on dates but times are recorded as the same value. If you enter a date of 2024-01-01, the console passes the time as 2024-01-01T00:00:00Z.

Note

By default, event filters are evaluated when a profile object is saved or updated. For instance, if you filter standard asset objects where the `PurchaseDate` is within the last week, the relative time is calculated as *within the last week from the moment the asset object is saved or updated*. This means the filtering results might vary depending on when the object is saved or updated.

Relationship between event filters

Optionally, you can add the second event filter and define a relationship with the first event filter. When you create a calculated attribute in the Connect Customer admin website, you can have a maximum of two event filters per calculated attribute. If you add the second event filter to your calculated attribute, you can choose one of two ways to specify how the two event filters are connected:

- **AND relationship** — If you use the AND relationship to connect two event filters, objects that meets both the first and second event filter, will be included in the calculation.
- **OR relationship** — If you use the OR relationship to connect two event filters, objects that meets either the first or second event filter, will be included in the calculation.
- **EXCLUDE relationship** — If you use the EXCLUDE relationship to connect two event filters, objects that meets the first event filter but does not meet the second event filter, will be included in the calculation.

Next steps

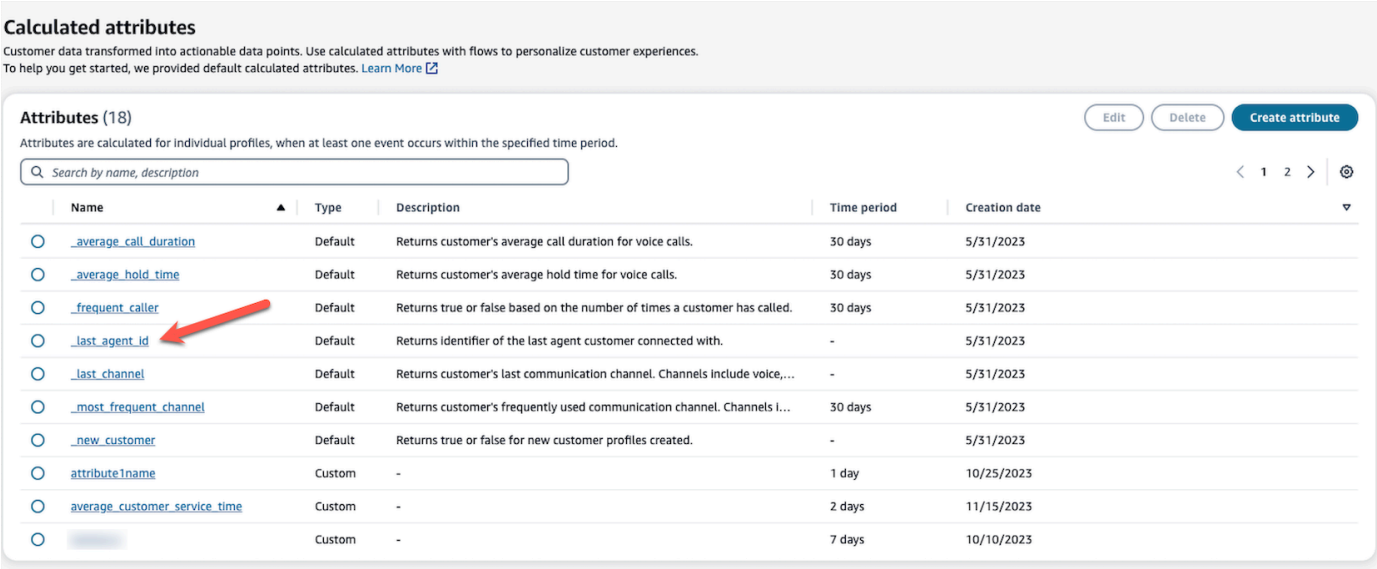
- Use your calculated attribute in your contact center through the Flow editor
- Use your calculated attribute to define a customer segment

- View Calculated Attributes in Amazon Connect
- Edit Calculated Attributes in Amazon Connect
- Delete Calculated Attributes in Amazon Connect

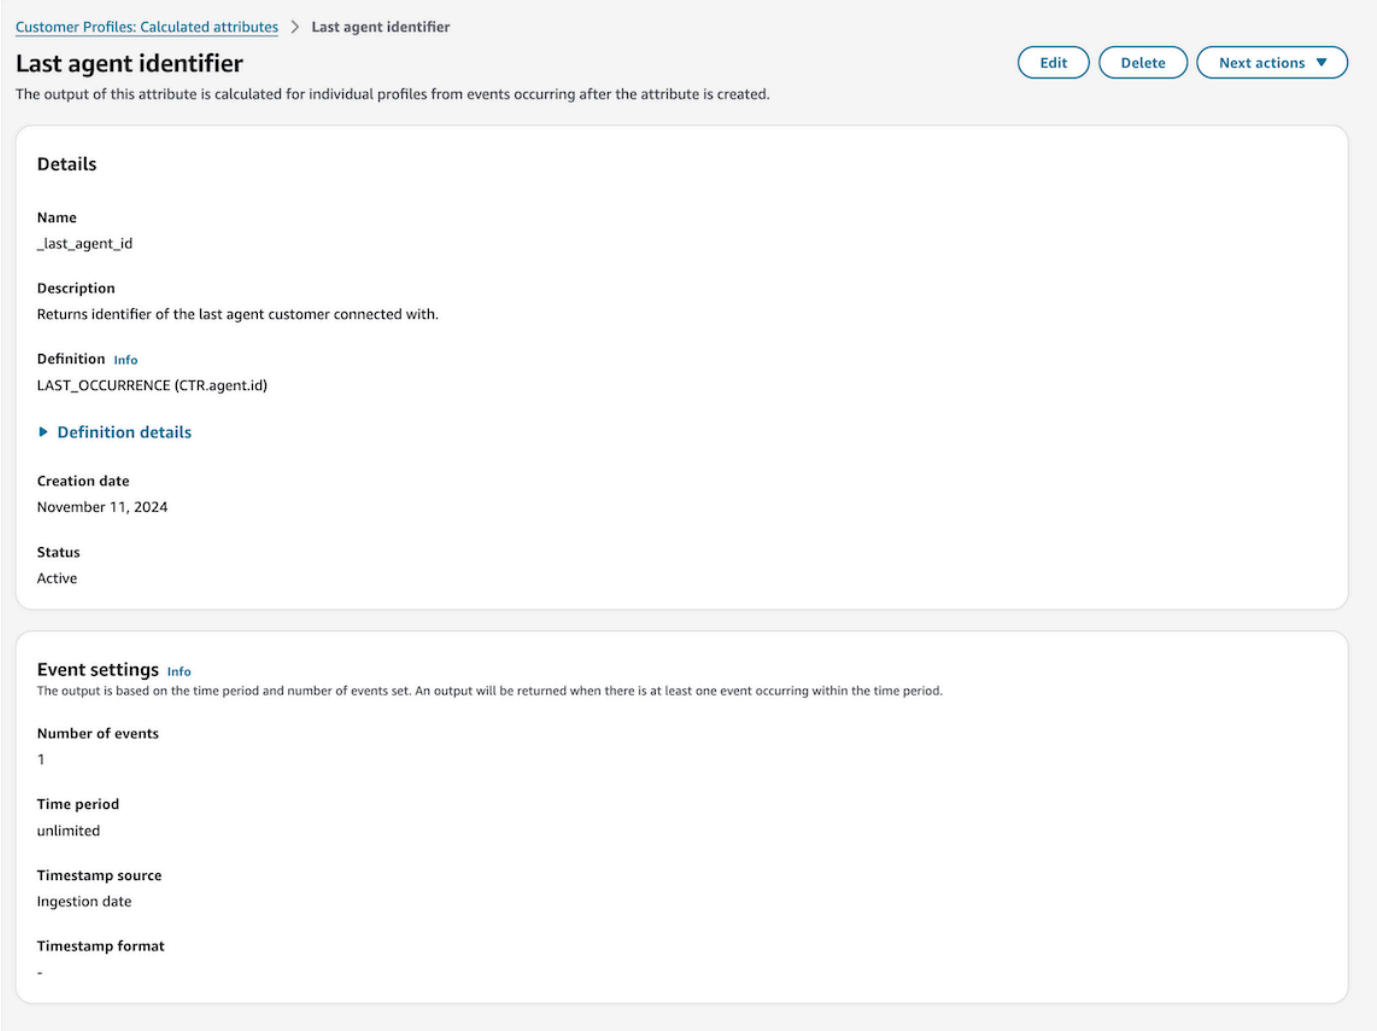
View calculated attributes in Connect Customer

1. Log in to the Connect Customer admin website at https://*instance name*.my.connect.aws/. Use an Admin account, or an account assigned to a security profile that has **Customer Profiles - Calculated Attributes** permission. permission.
2. In Connect Customer, on the left navigation pane, choose **Customer Profiles**, **Calculated attributes**.
3. On the **Calculated attributes** page, choose a calculated attribute from the **Name** column in the table.

   The following image shows an example of calculated attributes listed in the **Name** column.

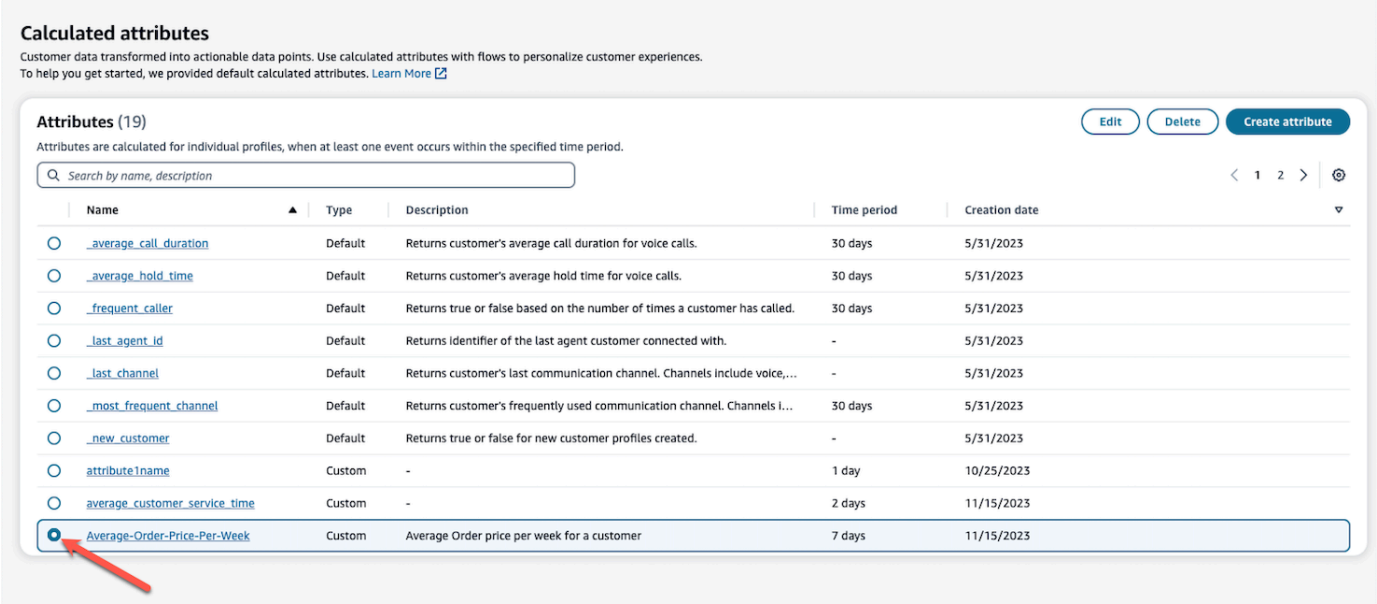


4. You can now view the details of the attribute that you selected. The following image shows a page of details for a calculated attribute.

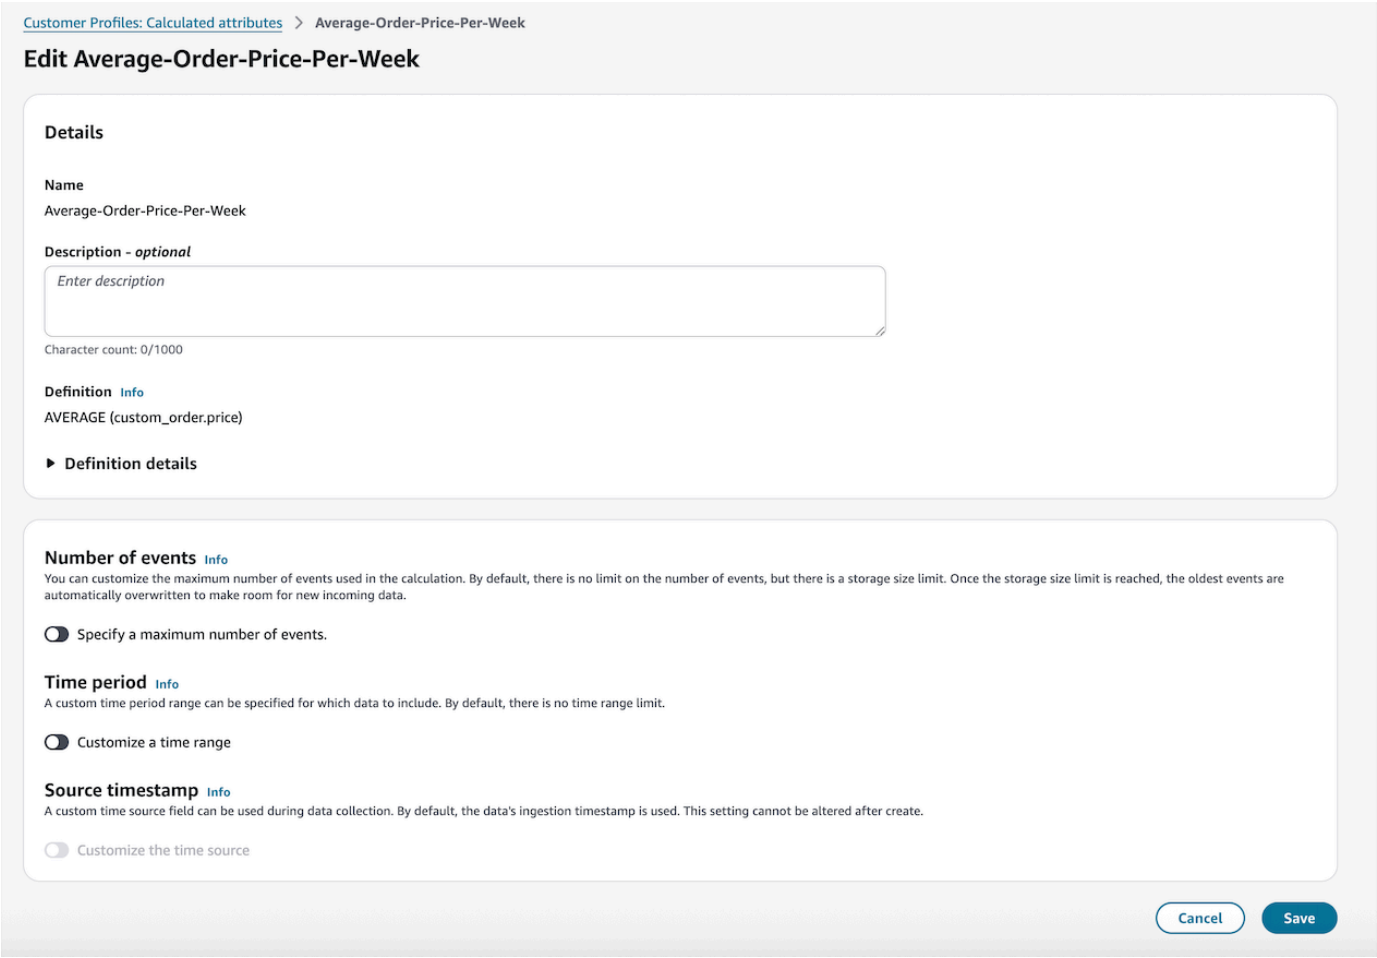


Edit calculated attributes in Connect Customer

1. To edit a calculated attribute, choose an attribute in the table view by selecting the radio button, which enables the **Edit** button. Choose **Edit**.

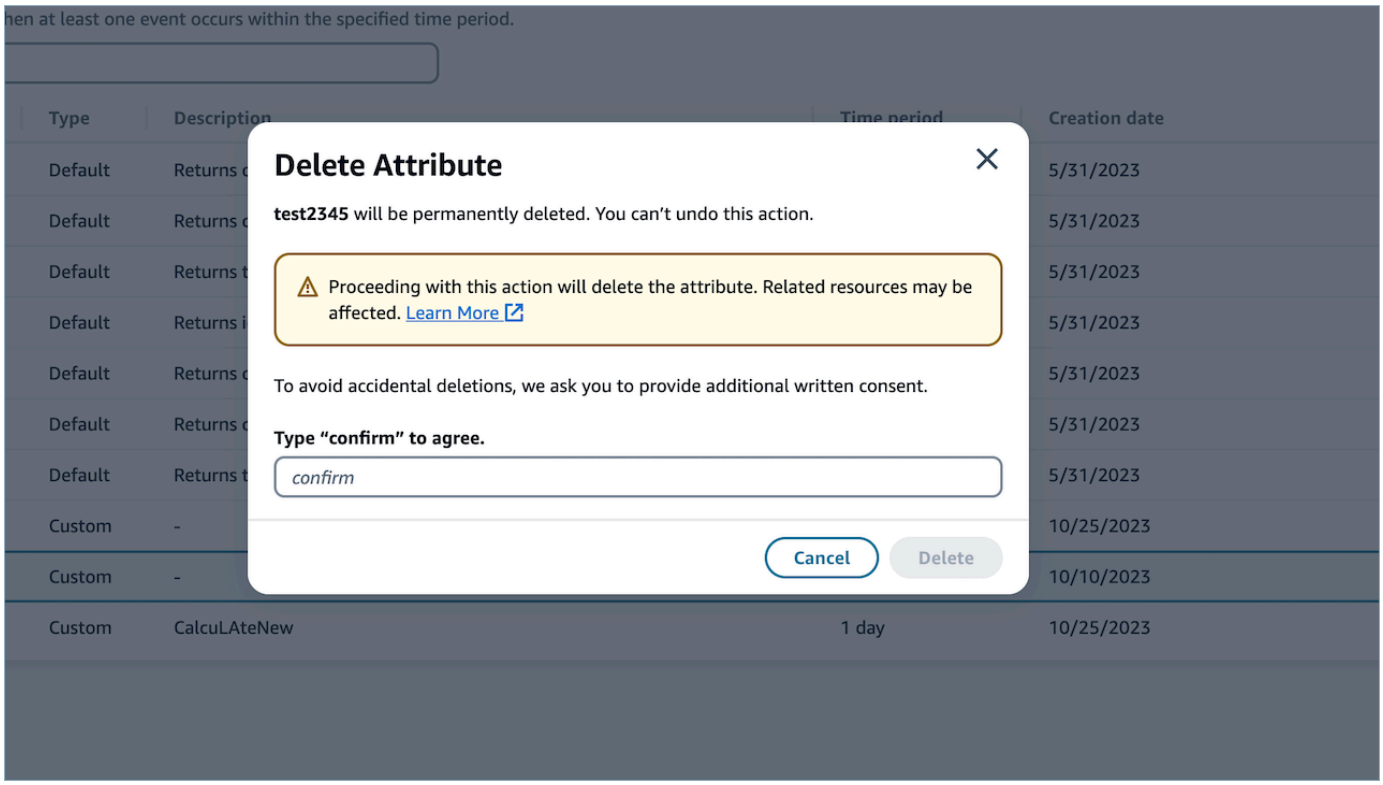


2. You can edit the **Description**, **Number of events**, and **Time period**. When done, choose **Save**.



Delete calculated attributes in Connect Customer

1. To delete a calculated attribute, choose an attribute in the table by selecting the radio button next to the attribute that you would like to delete.
2. Once selected, choose **Delete**.
3. In the **Delete Attribute** pop-up, verify the details and enter *confirm* to enable the **Delete** button.



4. Choose **Delete**.

Connect Customer Customer Profiles calculated attributes APIs

You can use the following Customer Profiles calculated attribute APIs

CreateCalculatedAttributeDefinition

CreateCalculatedAttributeDefinition

Create a new calculated attribute. This requires an existing object type in the domain. You can define attributes that you want to pull from a single source object and the mathematical operations to apply to them in aggregate as well as the time range and object count.

After creation, new object data ingested into Customer Profiles will be included in the calculated attribute, which can be retrieved for a profile using the `GetCalculatedAttributeForProfile` API. To use historical data as well, specify `UseHistoricalData` as true. The `Readiness` and `Status` fields on the API response will provide information regarding the status of including historical data in the calculated attribute.

Defining a calculated attribute makes it available for all profiles within a domain. Each calculated attribute can only reference one ObjectType and at most two fields from that ObjectType.

Request

```
POST /domains/DomainName/calculated-attributes/CalculatedAttributeName
```

```
{
    "CalculatedAttributeName": "string",

Request body

- **CalculatedAttributeName**

The unique (per domain) name of the calculated attribute.

- Type : String
- Length Constraints: Minimum length of 1. Maximum length of 64.
- Pattern: `^[a-zA-Z0-9_-]+$`
- Required: Yes

- **DisplayName**

  The display name of the calculated attribute.

  - Length Constraints: Minimum length of 1. Maximum length of 64.
  - Pattern: `^[a-zA-Z_][a-zA-Z_0-9-\s]*$`
  - Required: No

- **Description**

  The description of the calculated attribute.

  - Type : String
  - Length Constraints: Minimum length of 1. Maximum length of 1000.
  - Required: No

- **UseHistoricalData**

  Whether historical data ingested before the Calculated Attribute was created should be included in calculations.

  - Type : Boolean
  - Required: No

- **AttributeDetails**

  Details of the attributes used in the definition and the mathematical operations involved between the attributes. See the following components:

  - **Attributes**

    A list of attribute items specified in the mathematical expression.

    - **AttributeItem**

      The details of a single attribute item specified in the mathematical expression.

      - Name

    - The name of an attribute defined in a profile object type.
    - Type: String
- **Expression**

  Mathematical expression that is performed on attribute items provided in the attribute list. Each element in the expression should follow the structure of \"{ObjectTypeName.AttributeName}\".
  - Example : `{ObjA.AttributeA} - {ObjA.AttributeB}`
  - Type : String
  - We only support the following mathematical operations: `+ - * /`
  - You cannot make modifications to the Expression once a calculated attribute definition is created
- **Conditions**

  Defines the calculated attribute aggregation criteria and threshold.
  - Type: Conditions object
    - Range
    - ObjectCount
    - Threshold
- **Range**

  The relative time period over which data is included in the aggregation.
  - Type: Range object
    - Value: The length of time of the specified units. `ValueRange` overrides Value.
      - Type: Integer
      - Required: No
    - ValueRange: A structure letting customers specify a relative time window over which over which data is included in the Calculated Attribute. Use positive numbers to indicate that the endpoint is in the past, and negative numbers to indicate it is in the future. ValueRange overrides Value.
      - Type: ValueRange
      - Required: No
    - Start

        - The start time of when to include objects. Use positive numbers to indicate that the startpoint is in the past, and negative numbers to indicate it is in the future.
        - Type: Integer
        - Required: Yes
      - End
        - The end time of when to include objects. Use positive numbers to indicate that the startpoint is in the past, and negative numbers to indicate it is in the future.
        - Type: Integer
        - Required: Yes
    - TimestampSource: An expression specifying the field in your JSON object from which the date should be parsed. The expression should follow the structure of \"{ObjectTypeName.<Location of timestamp field in JSON pointer format>}\". For example, if your object type is MyType and source JSON is `{"generatedAt": {"timestamp": "1737587945945"}}`, then TimestampSource should be `"{MyType.generatedAt.timestamp}"`.
      - Length Constraints: Minimum length of 1. Maximum length of 255.
      - Required: No
    - TimestampFormat: The format the timestamp field in your JSON object is specified. This value should be one of EPOCHMILLI (for Unix epoch timestamps with second/millisecond level precision) or ISO_8601 (following ISO_8601 format with second/millisecond level precision, with an optional offset of Z or in the format HH:MM or HHMM.). For example, if your object type is MyType and source JSON is `{"generatedAt": {"timestamp": "2001-07-04T12:08:56.235-0700"}},` then TimestampFormat should be `"ISO_8601"`.
    - Unit: Unit of time
      - Valid values: Days
      - Required: Yes
    - Required: Yes
    - Initial scope: Max of 366 days
- **ObjectCount**

  The number of profile objects used for the calculated attribute.

  - Type: Number

- Range: 1 through 100
- Required: No

- **Threshold**

  The comparison logic to generate a true/false calculated attribute.

  - Type: Threshold object
    - Value
      - The value of the threshold
      - Type: String
      - Required: No
    - Operator
      - The operator of the threshold
      - Type: ENUM
      - Valid Values:
        - GREATER_THAN
        - LESS_THAN
        - EQUAL_TO
        - NOT_EQUAL_TO
  - Required: No

- **Statistic**

  The aggregation operation to perform for the calculated attribute.

  - Type: ENUM
  - Valid Values:
    - FIRST_OCCURRENCE
    - LAST_OCCURRENCE
    - COUNT
    - SUM
    - MINIMUM
    - MAXIMUM
    - AVERAGE
    - MAX_OCCURRENCE

- RECENT_OCCURRENCES

UpdateCalculatedAttributeDefinition

UpdateCalculatedAttributeDefinition

Update a calculated attribute definition. Updates are limited to display name, description, time range, object count, and threshold. This API supports partial updates, so only the parameters that require updating need to be included.

> **Note**
>
> When updating the Conditions:
>
> - Increasing the date range of a calculated attribute will not trigger inclusion of historical data greater than the current date range.
> - TimestampSource and TimestampFormat cannot be updated after a calculated attribute definition has been created.

Request

```
PUT /domains/DomainName/calculated-attributes/CalculatedAttributeName
```

```
{
    "DisplayName": "string",
    "Description": "string",
    "Conditions": {
        "Range": {
             "Value": "number",
             "Units": "string"
        },
        "ObjectCount": "number",
        "Threshold": {
            "Value": "string",
            "Operator": "EQUAL_TO" | "GREATER_THAN" | "LESS_THAN" | "NOT_EQUAL_TO"
        }
   }
```

```
}
```

Response

```
{
    "CalculatedAttributeName": "string",
    "DisplayName": "string",
    "Description": "string",
    "AttributeDetails": {
       "Attributes": [
           {
               "Name": "string"
           }
           ...
       ],
       "Expression": "string",
    },
    "Statistic": "AVERAGE" | "COUNT" | "SUM" | "FIRST_OCCURRENCE" |
 "LAST_OCCURRENCE" | "MINIMUM" | "MAXIMUM" | "MAX_OCCURRENCE" | "RECENT_OCCURRENCES"
    "Conditions": {
        "Range": {
             "Value": "number",
             "Units": "string"
        },
        "ObjectCount": "number",
        "Threshold": {
            "Value": "string",
            "Operator": "EQUAL_TO" | "GREATER_THAN" | "LESS_THAN" | "NOT_EQUAL_TO"
        }
    },
    "CreatedAt": number,
    "LastUpdatedAt": number,
    "Tags": {}
}
```

Request body

- **DisplayName**

  The display name of the calculated attribute.

- Length Constraints: Minimum length of 1. Maximum length of 64.
- Pattern: `^[a-zA-Z_][a-zA-Z_0-9-\s]*$`
- Required: No

- **Description**

  The description of the calculated attribute.

  - Type : String
  - Length Constraints: Minimum length of 1. Maximum length of 1000.
  - Required: No

- **Conditions**

  Defines the calculated attribute aggregation criteria and threshold.

  - Type: Conditions object
    - Range
    - ObjectCount
    - Threshold

- **Range**

  The relative time period over which data is included in the aggregation.

  - Type: Range object
    - Value: The length of time of the specified units
      - Type: Integer
      - Required: No
    - ValueRange: A structure letting customers specify a relative time window over which over which data is included in the Calculated Attribute. Use positive numbers to indicate that the endpoint is in the past, and negative numbers to indicate it is in the future. ValueRange overrides Value.
      - Type: ValueRange
      - Required: No
        - Start
          - The start time of when to include objects. Use positive numbers to indicate that the startpoint is in the past, and negative numbers to indicate it is in the future.
          - Type: Integer

        - Required: Yes
      - End
        - The end time of when to include objects. Use positive numbers to indicate that the startpoint is in the past, and negative numbers to indicate it is in the future.
        - Type: Integer
        - Required: Yes
    - Unit: Unit of time
      - Valid values: Days
      - Required: Yes
  - Required: Yes
  - Initial scope: Max of 366 days
- **ObjectCount**

  The number of profile objects used for the calculated attribute.
  - Type: Number
  - Range: 1 through 100
  - Required: No
- **Threshold**

  The comparison logic to generate a true/false calculated attribute.
  - Type: Threshold object
    - Value
      - The value of the threshold
      - Type: String
      - Required: No
    - Operator
      - The operator of the threshold
      - Type: ENUM
      - Valid Values:
        - GREATER_THAN
        - LESS_THAN
        - EQUAL_TO

- NOT_EQUAL_TO
- Required: No

GetCalculatedAttributeDefinition

GetCalculatedAttributeDefinition

Retrieve a calculated attribute definition.

Request

```
GET /domains/DomainName/calculated-attributes/CalculatedAttributeName
```

Request Body

```
The request does not have a request body.
```

Response

```
{
"CalculatedAttributeName": "string",
    "DisplayName": "string",
    "Description": "string",
    "AttributeDetails": {
"Attributes": [
          {
"Name": "string"
          }
          ...
       ],
       "Expression": "string",
    },
    "Statistic": "AVERAGE" | "COUNT" | "SUM" | "FIRST_OCCURRENCE" |
 "LAST_OCCURRENCE" | "MINIMUM" | "MAXIMUM" | "MAX_OCCURRENCE" | "RECENT_OCCURRENCES"
"Conditions": {
"Range": {
      "Unit": "string",
      "Value": number
      "ValueRange"
```

```
        {
            "Start": number
            "End": number
        },
      "TimestampFormat": "string",
      "TimestampSource": "string"
    },
        "ObjectCount": "number",
        "Threshold": {
"Value": "string",
            "Operator": "EQUAL_TO" | "GREATER_THAN" | "LESS_THAN" | "NOT_EQUAL_TO"
        }
    },
    "UseHistoricalData" boolean,
  "Status": "PREPARING" | "IN_PROGRESS" | "COMPLETED" | "FAILED",
  "Readiness": {
        "ProgressPercentage": number,
        "Message": "string",
        },
    "CreatedAt": number,
    "LastUpdatedAt": number,
    "Tags": {}
}
```

URI request parameters

- **DomainName**

  The unique name of the domain.

  - Length Constraints: Minimum length of 1. Maximum length of 64.
  - Pattern: `^[a-zA-Z0-9_-]+$`
  - Required: Yes

- **CalculatedAttributeName**

  The unique (per domain) name of the calculated attribute.

  - Type : String
  - Length Constraints: Minimum length of 1. Maximum length of 64.
  - Pattern: `^[a-zA-Z0-9_-]+$`
  - Required: Yes

DeleteCalculatedAttributeDefinition

DeleteCalculatedAttributeDefinition

Delete an existing calculated attribute definition. Note that deleting a default calculated attribute is possible, however once deleted you will be unable to undo that action and will need to recreate it on your own using the `CreateCalculatedAttributeDefinition` API if you want it back.

Request

```
DELETE /domains/DomainName/calculated-attributes/CalculatedAttributeName
```

Request Body

```
The request does not have a request body.
```

Response

```
The response does not have a response body.
```

URI request parameters

- **DomainName**

  The unique name of the domain.

  - Length Constraints: Minimum length of 1. Maximum length of 64.
  - Pattern: `^[a-zA-Z0-9_-]+$`
  - Required: Yes
- **CalculatedAttributeName**

  The unique (per domain) name of the calculated attribute.

  - Type : String
  - Length Constraints: Minimum length of 1. Maximum length of 64.
  - Pattern: `^[a-zA-Z0-9_-]+$`

- Required: Yes

ListCalculatedAttributeDefinitions

ListCalculatedAttributeDefinitions

Retrieve all calculated attribute definitions for a domain.

Request

```
GET /domains/DomainName/calculated-attributes?max-results=MaxResults&next-token=NextToken
```

Request Body

```
The request does not have a request body.
```

Response

```
{
    "Items": [
        {
            "UseHistoricalData": boolean,
            "ReadinessStatus": PREPARING | IN_PROGRESS | COMPLETED | FAILED,
            "CalculatedAttributeName": "string",
            "CreatedAt": number,
            "Description": "string",
            "DisplayName": "string",
            "LastUpdatedAt": number,
            "Tags": {
                "string" : "string"
            }
        }
    ],
    "NextToken": "string"
}
```

URI request parameters

- **DomainName**

  The unique name of the domain.

  - Length Constraints: Minimum length of 1. Maximum length of 64.
  - Pattern: `^[a-zA-Z0-9_-]+$`
  - Required: Yes
- **MaxResults**

  The maximum number of objects returned per page.

  - Valid Range: Minimum value of 1. Maximum value of 100
- **NextToken**

  The pagination token from the previous ListCalculatedAttributeDefinition API call.

  - Length Constraints: Minimum length of 1. Maximum length of 1024

GetCalculatedAttributeForProfile

GetCalculatedAttributeForProfile

Initiates the calculation and retrieves the result of a single calculated attribute for a single profile.

Request

```
GET /domains/DomainName/profile/ProfileId/calculated-
attributes/CalculatedAttributeName
```

Request Body

```
The request does not have a request body.
```

Response

```
{
```

```
"Name": "string",
    "DisplayName": "string",
    "Value": "string",
    "IsDataPartial": "string",
    "LastObjectTimestamp" : number
}
```

URI request parameters

- **DomainName**

  The unique name of the domain.

  - Length Constraints: Minimum length of 1. Maximum length of 64.
  - Pattern: `^[a-zA-Z0-9_-]+$`
  - Required: Yes
- **CalculatedAttributeName**

  The unique (per domain) name of the calculated attribute.

  - Type : String
  - Length Constraints: Minimum length of 1. Maximum length of 64.
  - Pattern: `^[a-zA-Z0-9_-]+$`
  - Required: Yes

ListCalculatedAttributesForProfile

ListCalculatedAttributesForProfile

Initiates the calculation and retrieves the results of all calculated attributes for a single profile.

Request

```
GET /domains/DomainName/profile/ProfileId/calculated-attributes?max-
results=MaxResults&next-token=NextToken
```

Request Body

```
The request does not have a request body.
```

Response

```
{
"Items": [
        {
"CalculatedAttributeName": "string",
            "DisplayName": "string",
            "Value": "string",
            "IsDataPartial" : "string",
            "LastObjectTimestamp" : number
        },
        ...
    ],
    "NextToken": "string"
}
```

URI request parameters

- **DomainName**

  The unique name of the domain.

  - Length Constraints: Minimum length of 1. Maximum length of 64.
  - Pattern: `^[a-zA-Z0-9_-]+$`
  - Required: Yes
- **ProfileId**
  - Pattern: `[a-f0-9]{32}`
  - Required: Yes
- **MaxResults**

  The maximum number of objects returned per page.

  - Valid Range: Minimum value of 1. Maximum value of 100
- **NextToken**

  The pagination token from the previous ListCalculatedAttributeDefinition API call.

  - Length Constraints: Minimum length of 1. Maximum length of 1024

Create a custom Connect Customer Customer Profiles calculated attribute definition

Using the Customer Profiles CreateCalculatedAttributeDefinition API, you can programmatically create your own calculated attribute based on a custom object type.

In this topic we show how to create a calculated attribute using a custom JSON file.

Step 1: Create a JSON file

Create a JSON file with the following contents:

```
{
"DomainName": "your-domain-name",
   "CalculatedAttributeName": "your-calculated-attribute-name",
   "UseHistoricalData": true,
   "DisplayName": "your-display-name",
   "Description": "your-description",
   "AttributeDetails": {
"Attributes": [
         {
            "Name": "your-attribute-name"
         }
       ],
       "Expression": "{your-object-type.your-attribute-name}"
   },
    "Statistic": "your-statistic",
    "Conditions": {
       "Range": {
        "ValueRange"
        {
            "Start": your-range-start
            "End": your-range-end
        },
        "TimestampSource": "{your-object-type.your-timestamp-source}",
        "Unit": "days"
        },
        "ObjectCount":  your-object-count,
        "Threshold": {
           "Value": "your-threshold-value",
           "Operator": "your-threshold-operator"
```

```
        }
    }
}
```

To customize the JSON with your own values, follow these guidelines:

- **Attributes**: This should contain the name of the field from your object type that you want to use for the calculated attribute. Two attributes being referenced in this list are supported.
- **Expression**: Basic math expressions to perform between attributes are supported. If you only have one attribute, this field should be `{ObjectTypeName.AttributeName}`, otherwise if you have a math expression in mind this field should contain both attributes.
- **Statistic**: This is the operation performed when you call one of the calculate APIs that actually performs the aggregation operation. Most are self-explanatory, but we have added explanations for ones that aren't.

  Supported statistics

  - `FIRST_OCCURRENCE` returns the attribute specified in the expression of the earliest ingested object.
  - `LAST_OCCURRENCE` returns the attribute specified in the expression of the latest ingested object.
  - `COUNT` returns the count from the selected data.
  - `SUM` returns the sum from the selected data.
  - `MINIMUM` returns minimum from the selected data.
  - `MAXIMUM` returns maximum from the selected data.
  - `AVERAGE` returns average from the selected data.
  - `MAX_OCCURRENCE` returns the most frequently occurring value specified in the expression.
  - `RECENT_OCCURRENCES` returns a list of recent values for the attribute specified in the expression.
- **Range**:
  - Units: Currently supports only DAYS units.
  - ValueRange: Specify positive numbers in ValueRange's Start or End fields to indicate how many days ago to begin from, and negative numbers to indicate how many days in the future to begin from.
  - TimestampSource: An expression specifying the field in your JSON object from which the date should be parsed. The expression should follow the structure of \"{ObjectTypeName.<Location

of timestamp field in JSON pointer format>}\". For example; if your object type is MyType and source JSON is `{"generatedAt": {"timestamp": "1737587945945"}}`, then TimestampSource should be `"{MyType.generatedAt.timestamp}"`.

- **ObjectCount**: Indicates how many objects the calculated attribute calculation should be based on.
- **Threshold**: If instead of the exact calculated attribute value you instead want to know if it's, for example, greater than a certain value, you can use a threshold.

  The threshold value can be any string, and the following threshold operators are supported.

  - `GREATER_THAN`
  - `LESS_THAN`
  - `EQUAL_TO`
  - `NOT_EQUAL_TO`
- UseHistoricalData: Whether historical data ingested before the Calculated Attribute was created should be included in calculations.

Step 2: Call the CreateCalculatedAttributeDefinition API

After you have created and customized the JSON file with your values, call the CreateCalculatedAttributeDefinition API, as shown in the following example:

```
aws customer-profiles create-calculated-attribute-definition --cli-input-json
 file:///custom_calculated_attribute_cli.json --region region_name
```

You can also use the following endpoint:

```
https://profile.your-region.amazonaws.com/domains/your-domain-name/calculated-
attributes
```

Validate calculated attribute values in Connect Customer Customer Profiles using APIs

There are two APIs, `GetCalculatedAttributeForProfile` and `ListCalculatedAttributesForProfile`, that are at the profile level.

- **GetCalculatedAttributeForProfile** - retrieves a single calculated attribute for a single profile.

- **ListCalculatedAttributesForProfile** - retrieves a list of calculated attributes for a single profile

With a valid profile ID, you should see values for your calculated attributes:

Example response

```
{
    "CalculatedAttributeName": "_average_hold_time",
    "DisplayName": "Average hold time",
    "IsDataPartial": "true",
    "Value": "24144"
}
```

IsDataPartial - This flag means that either the time range (30 days) or object count have not been achieved and therefore the calculated attribute is still being calculated. For example, if you want an average over 30 days, only after 30 days have elapsed will the `IsDataPartial` field be set to false.

Retrieve a list of calculated attributes

Use the AWS CLI

```
aws customer-profiles list-calculated-attributes-for-profile --region your-region --
domain-name your-domain-name --profile-id your-profile-id
```

Use the AWS CLI with a custom JSON file

Create a JSON file with the following contents:

```
{
    "DomainName": "your-domain-name",
    "ProfileId" "some-profile-id"
}
```

```
aws customer-profiles list-calculated-attributes-for-profile --region your-region --
cli-input-json file://list_calculated_attributes_for_profile_cli.json
```

Endpoint:

```
https://profile.your-region.amazonaws.com/domains/your-domain-name/profile/your-profile-id/calculated-attributes/
```

Retrieve a single calculated attribute

Use the AWS CLI:

```
aws customer-profiles get-calculated-attributes-for-profile --region your-region --domain-name your-domain-name --calculated-attribute-name your-calculated-attribute-name --profile-id your-profile-id
```

Use the AWS CLI with a custom JSON file:

Create a JSON file with the following contents:

```
{
    "DomainName": "your-domain-name",
    "CalculatedAttributeName": "your-calculated-attribute-name",
    "ProfileId" "your-profile-id"
}
```

```
aws customer-profiles get-calculated-attributes-for-profile --region your-region --cli-input-json file://list_calculated_attributes_for_profile_cli.json
```

Endpoint:

```
https://profile.your-region.amazonaws.com/domains/your-domain-name/profile/your-profile-id/calculated-attributes/your-calculated-attribute-name
```

Default calculated attributes in Connect Customer Customer Profiles

Default CTR calculated attributes

Connect Customer Customer Profiles provides out-of-the box default attributes based on contact records. The attributes are as follows:

Most frequent channel

```
{
   "CalculatedAttributeName": "_most_frequent_channel",
   "DisplayName": "Most frequent channel",
   "Description": "Returns customer's frequently used communication channel. Channels
 include voice, chat, task.",
   "CreatedAt": null,
   "LastUpdatedAt": null,
   "Statistic": "MAX_OCCURRENCE",
   "Conditions": {
      "Range": {
         "Value": 30,
         "Unit": "DAYS"
       },
       "ObjectCount": null
   },
   "AttributeDetails": {
      "Attributes": [
         {
            "Name": "channel"
         }
      ],
      "Expression": "{CTR.channel}"
   },
   "Tags": {
   }
}
```

Last channel

```
{
   "CalculatedAttributeName": "_last_channel",
   "DisplayName": "Last channel",
   "Description": "Returns customer's last communication channel. Channels include
 voice, chat, task.",
   "CreatedAt": null,
   "LastUpdatedAt": null,
   "Statistic": "LAST_OCCURRENCE",
   "Conditions": {
      "ObjectCount": null
   },
```

```
   "AttributeDetails": {
      "Attributes": [
         {
            "Name": "channel"
         }
       ],
       "Expression": "{CTR.channel}"
   },
   "Tags": {
   }
}
```

Last agent identifier

```
{
   "CalculatedAttributeName": "_last_agent_id",
   "DisplayName": "Last agent identifier",
   "Description": "Returns identifier of the last agent customer connected with.",
   "CreatedAt": null,
   "LastUpdatedAt": null,
   "Statistic": "LAST_OCCURRENCE",
   "Conditions": {
      "ObjectCount": null
   },
   "AttributeDetails": {
      "Attributes": [
         {
            "Name": "agent.id"
         }
      ],
      "Expression": "{CTR.agent.id}"
   },
   "Tags": {
   }
}
```

Frequent caller

```
{
```

```
   "CalculatedAttributeName": "_frequent_caller",
   "DisplayName": "Frequent caller",
   "Description": "Returns true or false based on the number of times a customer has
 called.",
   "CreatedAt": null,
   "LastUpdatedAt": null,
   "Statistic": "COUNT",

Default order calculated attributes

Connect Customer Customer Profiles provides out-of-the box default attributes based on orders. The attributes are as follows:

Count of orders

```
{
    "CalculatedAttributeName": "_orders_count",
    "DisplayName": "Count of orders",
    "Description": "Returns the count of orders for a customer.",
    "AttributeDetails": {
      "Attributes": [
        {
          "Name": "OrderId"
        }
      ],
      "Expression": "{_order.OrderId}"
    },
    "Statistic": "COUNT",
    "Conditions": {
      "Range": null,
      "ObjectCount": null,
      "Threshold":null
    },
    "Launched": false
  }
```

First order created date

```
{
    "CalculatedAttributeName": "_order_first_occurrence",
    "DisplayName": "First order created date",
    "Description": "Returns created date of the customer's first order.",
    "AttributeDetails": {
      "Attributes": [
        {
          "Name": "CreatedDate"
        }
      ],
      "Expression": "{_order.CreatedDate}"
    },
    "Statistic": "FIRST_OCCURRENCE",
    "Conditions": {
      "Range": null,
      "ObjectCount": null,
      "Threshold": null
    },
    "Launched": false
```

```
  }
```

Last order created date

```
{
    "CalculatedAttributeName": "_order_last_occurrence",
    "DisplayName": "Last order created date",
    "Description": "Returns created date of the customer's last order.",
    "AttributeDetails": {
      "Attributes": [
        {
          "Name": "CreatedDate"
        }
      ],
      "Expression": "{_order.CreatedDate}"
    },
    "Statistic": "LAST_OCCURRENCE",
    "Conditions": {
      "Range": null,
      "ObjectCount": null,
      "Threshold": null
    },
    "Launched": false
  }
```

Total price of all orders

```
{
    "CalculatedAttributeName": "_orders_total_price_sum",
    "DisplayName": "Total price of all orders",
    "Description": "Returns sum of total price for all customer's orders.",
    "Statistic": "SUM",
    "AttributeDetails": {
      "Attributes": [
        {
          "Name": "TotalPrice"
        }
      ],
      "Expression": "{_order.TotalPrice}"
    },
    "Conditions": {
```

```
      "Range": null,
      "ObjectCount": null,
      "Threshold":null
    },
    "Launched": false
  }
```

Orders average of total price

```
{
    "CalculatedAttributeName": "_orders_total_price_average",
    "DisplayName": "Orders average of total price",
    "Description": "Returns average of total price for all customer's orders.",
    "AttributeDetails": {
      "Attributes": [
        {
          "Name": "TotalPrice"
        }
      ],
      "Expression": "{_order.TotalPrice}"
    },
    "Statistic": "AVERAGE",
    "Conditions": {
      "Range": null,
      "ObjectCount": null,
      "Threshold": null
    },
    "Launched": false
  }
```

High lifetime value

```
{
    "CalculatedAttributeName": "_lifetime_value_high",
    "DisplayName": "High lifetime value",
    "Description": "Returns true if a customer's total order value exceeds the high
 lifetime value threshold.",
    "AttributeDetails": {
      "Attributes": [
        {
          "Name": "TotalPrice"
```

```
        }
      ],
      "Expression": "{_order.TotalPrice}"
    },
    "Statistic": "SUM",
    "Conditions": {
      "Range": null,
      "ObjectCount": null,
      "Threshold": {
        "Value": 1000,
        "Operator": "GREATER_THAN"
      }
    }
  }
```

Low lifetime value

```
{
    "CalculatedAttributeName": "_lifetime_value_low",
    "DisplayName": "Low lifetime value",
    "Description": "Returns true if a customer's total order value is below the low
 lifetime value threshold.",
    "AttributeDetails": {
      "Attributes": [
        {
          "Name": "TotalPrice"
        }
      ],
      "Expression": "{_order.TotalPrice}"
    },
    "Statistic": "SUM",
    "Conditions": {
      "Range": null,
      "ObjectCount": null,
      "Threshold": {
        "Value": 200,
        "Operator": "LESS_THAN"
      }
    }
  }
```

Error messages and resolutions for Connect Customer Customer Profiles calculated attributes

The following table shows calculated attributes error messages, cause, and resolution for each error.

Error message	Cause	Resolution
Retrieval of a calculated attribute for a profile shows a null value	This is likely due to the calculated attribute not having data. After creation of a calculated attribute, new data must be ingested.	Ingest new data or re-ingest old data through integrations or the `CreateProfile` and `PutProfileObject` APIs.

Set up customer segments in Connect Customer Customer Profiles

A *customer segment* is a group of customer profiles that share certain attributes. For example, a customer segment might contain all of your customers who live in a particular city, or all customers who are frequent callers and whose average spend is more than 500 dollars. With Connect Customer Outbound campaigns, you can send campaigns to a customer segment.

Customer segments are dynamically evaluated based on attributes that you define, and can change over time when the value of the attributes change. For example, if you add new profiles to Customer Profiles domain, or if you modify or delete existing profiles, the number of profiles in that customer segment might increase or decrease. For more information about creating a customer segment, see Build customer segments in Connect Customer.

As a prerequisite to building segments in Connect Customer, your administrator must setup your domain in the AWS Management Console and configure integrations to bring profile, order, asset, or case data into Customer Profiles. For more information, see Enable Customer Profiles for your Connect Customer instance. Enabling data integrations will let continue to generate your dynamic segments based on new data coming to your domain

Customer segments only contain customer profiles in your Connect Customer Customer Profiles domain. Customer Profiles can be ingested from S3 or external applications, or created through the

agent workspace, Contact Flows, or API. For more information about customer profiles, see What is a customer profile in Connect Customer?.

Build customer segments in Connect Customer

Note

Segmentation powered by SQL (Beta) requires Data store to be turned on. Please visit Customer Profiles home page screen and enable Data store from the top blue banner

Note

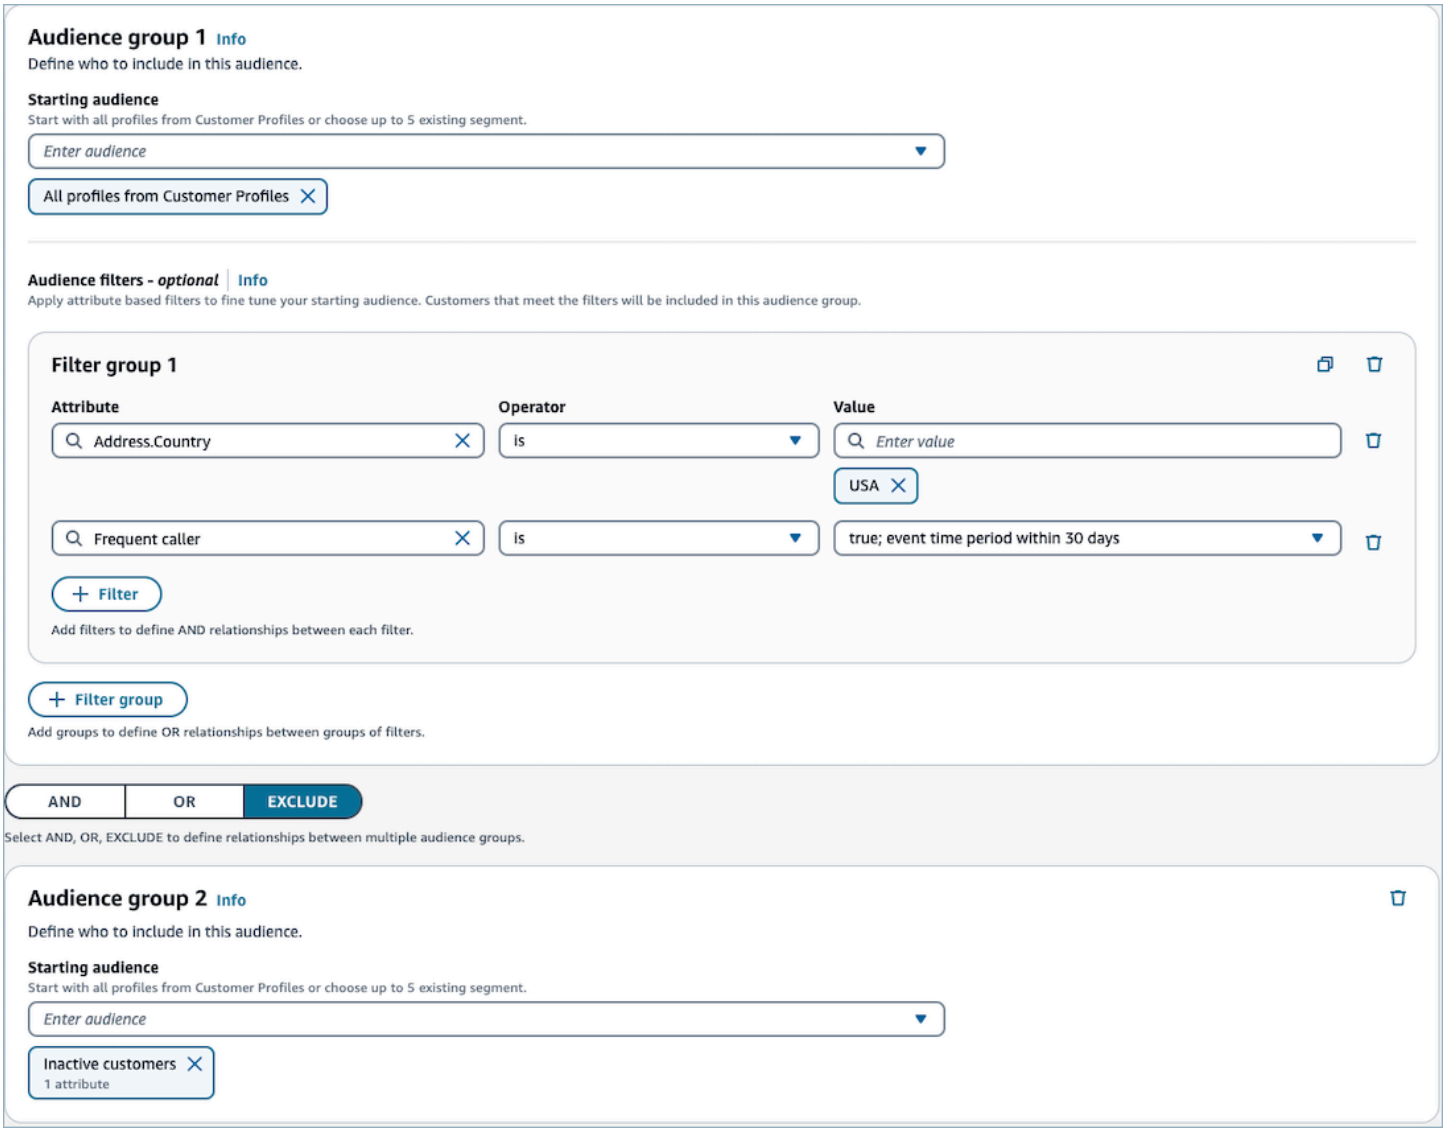
- To navigate to the segmentation builder experience in the Connect Customer admin website, you need security profiles permissions for this feature. For more information, see Assign security profile permissions to manage customer segments.
- Before building segments, we recommend your Customer Profiles domain setup data integrations to populate profiles in your Customer Profiles Domain. For more information on how to configure data integrations with Customer Profiles, see Integrate external applications with Connect Customer Customer Profiles.
- Segments can include events you captured using Calculated Attributes. For more information on how to configure custom Calculated Attributes and review the default Calculated Attributes Customer Profiles offers, see Set up calculated attributes in Connect Customer Customer Profiles.

Connect Customer provides two ways to build customer segments: 1/ Define segments through Spark SQL (Beta; requires Data store to be enabled); 2/ Define segments through audience groups and filters (Classic Segmentation). For both, you can use natural language prompts through Generative AI-powered Segment AI assistant. If you define segments in one of the ways, you move that segment to the other and would have to start again.

Classic segmentation with audience groups and filters

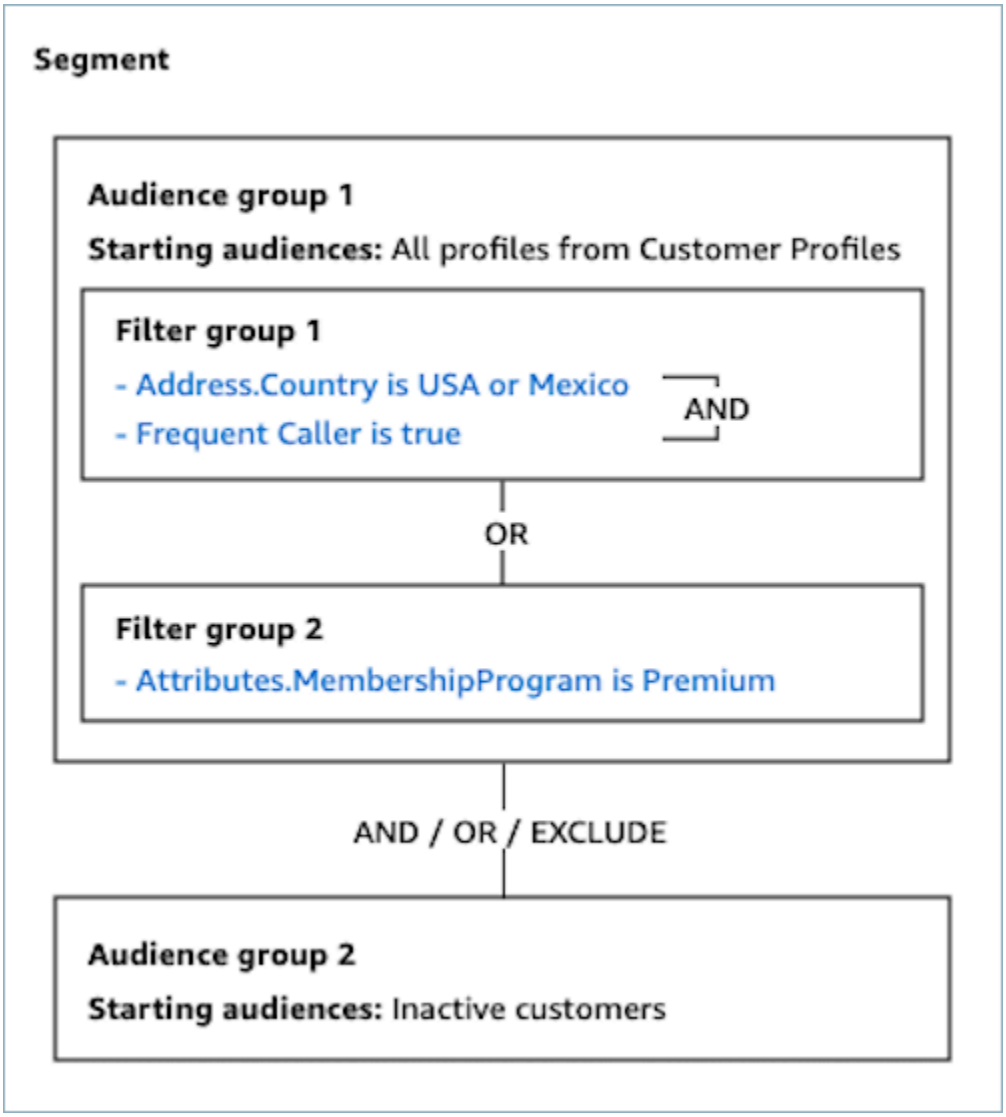
When you create a customer segment, you choose starting audiences and refine that audiences by choosing the filters that define the segment. For example, you could create an audience group, then choose a filter of all customers who live in a specific country and who are frequent callers. Segments are recalculated on demand, such as during campaign execution, contact flow execution, and segment estimate or export. As a result, the size and membership of each segment changes over time.

Additionally, you can create a second audience group, and then create a relationship (AND, OR, or EXCLUDE) between the two audience groups to further narrow down, concatenate, or exclude customers from the first audience group.



Audience groups

When you create a customer segment, you create one or more audience groups. An audience group consists of these components:



- **Starting audiences**: The customer segments that define the initial user population. You can specify up to 5 starting audiences, or all of the profiles in your Customer Profiles domain.
- **Filter groups**: Categories of audience information that you apply on top of the starting audiences. You can add multiple groups of filters which are connected by OR relationships.
- **Filters**: Filters reduce the audience number that belong to the segment. You can add as many filters as you want to tailor the segment to your needs.

A customer segment has to have at least one audience group, but you can optionally create a second audience group, and then create a relationship (AND/OR/EXCLUDE) between the two audience groups. See Step 5: Add the second audience group (optional) for more details about the relationship.

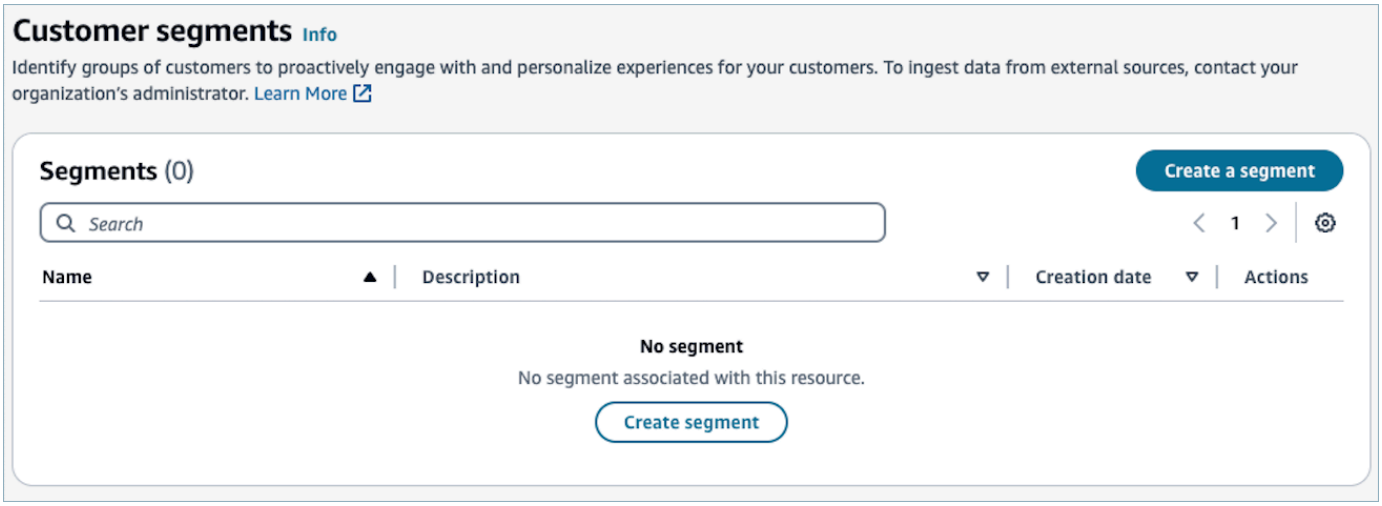
Creating a customer segment

The following steps describe creating and configuring a customer segment:

- Step 1: Build a new segment
- Step 2: Configure name and description
- Step 3: Choose the starting audiences to include in audience group 1
- Step 4: Choose and configure the filter groups (optional)
- Step 5: Add audience group 2 (optional)
- Step 6: Enable Sorting (optional)

Step 1: Build a new segment

1. To create a segment, make sure that you have created security profiles permissions as a prerequisite. For more information, see Assign security profile permissions to manage customer segments. In addition, to best visualize the membership of your segment, we recommend data ingestion before segment creation. To ingest profiles through S3 or external applications, see Create and ingest customer data into Customer Profiles or Integrate external applications with Connect Customer Customer Profiles.
2. Choose **Create a segment** in the Customer segment table view.



Step 2: Specify a name and description

- For **Name**, enter a name for the customer segment to make it easy to recognize later.

> **Note**
>
> The Connect Customer admin website uses the entered name as the `DisplayName` of the segment, and generates an identifier based on it. The generated identifier is used as the `SegmentDefinitionName` when you access the segment by using Customer Profiles APIs.

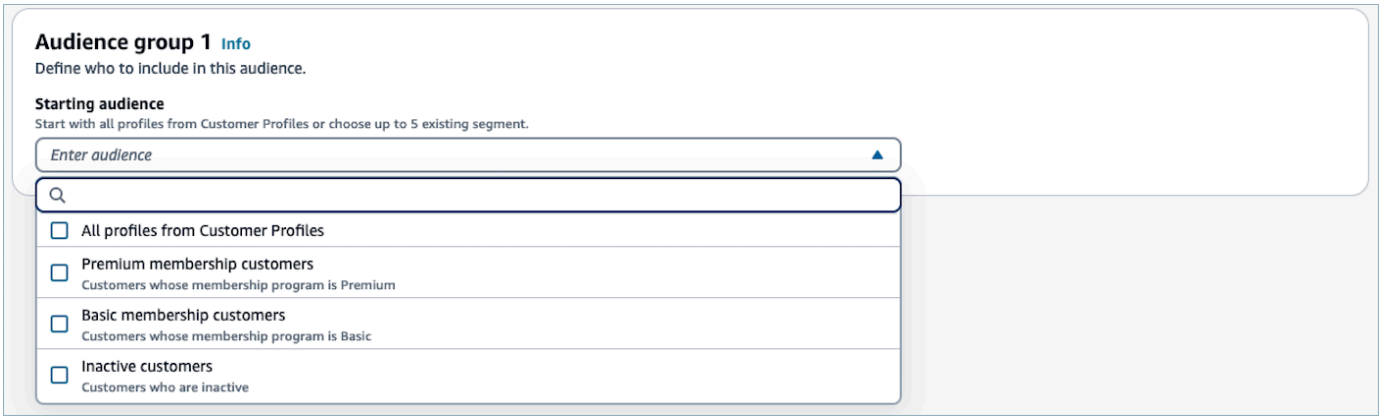
- For **Description**, optionally enter a description for the customer segment.

Step 3: Choose the starting audiences to include in audience group 1

You'll first choose how you want to define the starting audience for the audience group.

1. Under **Audience group 1**, for the **Starting audience** dropdown list, select one or more segments to include in the audience group, or choose **All profiles from Customer Profiles**.

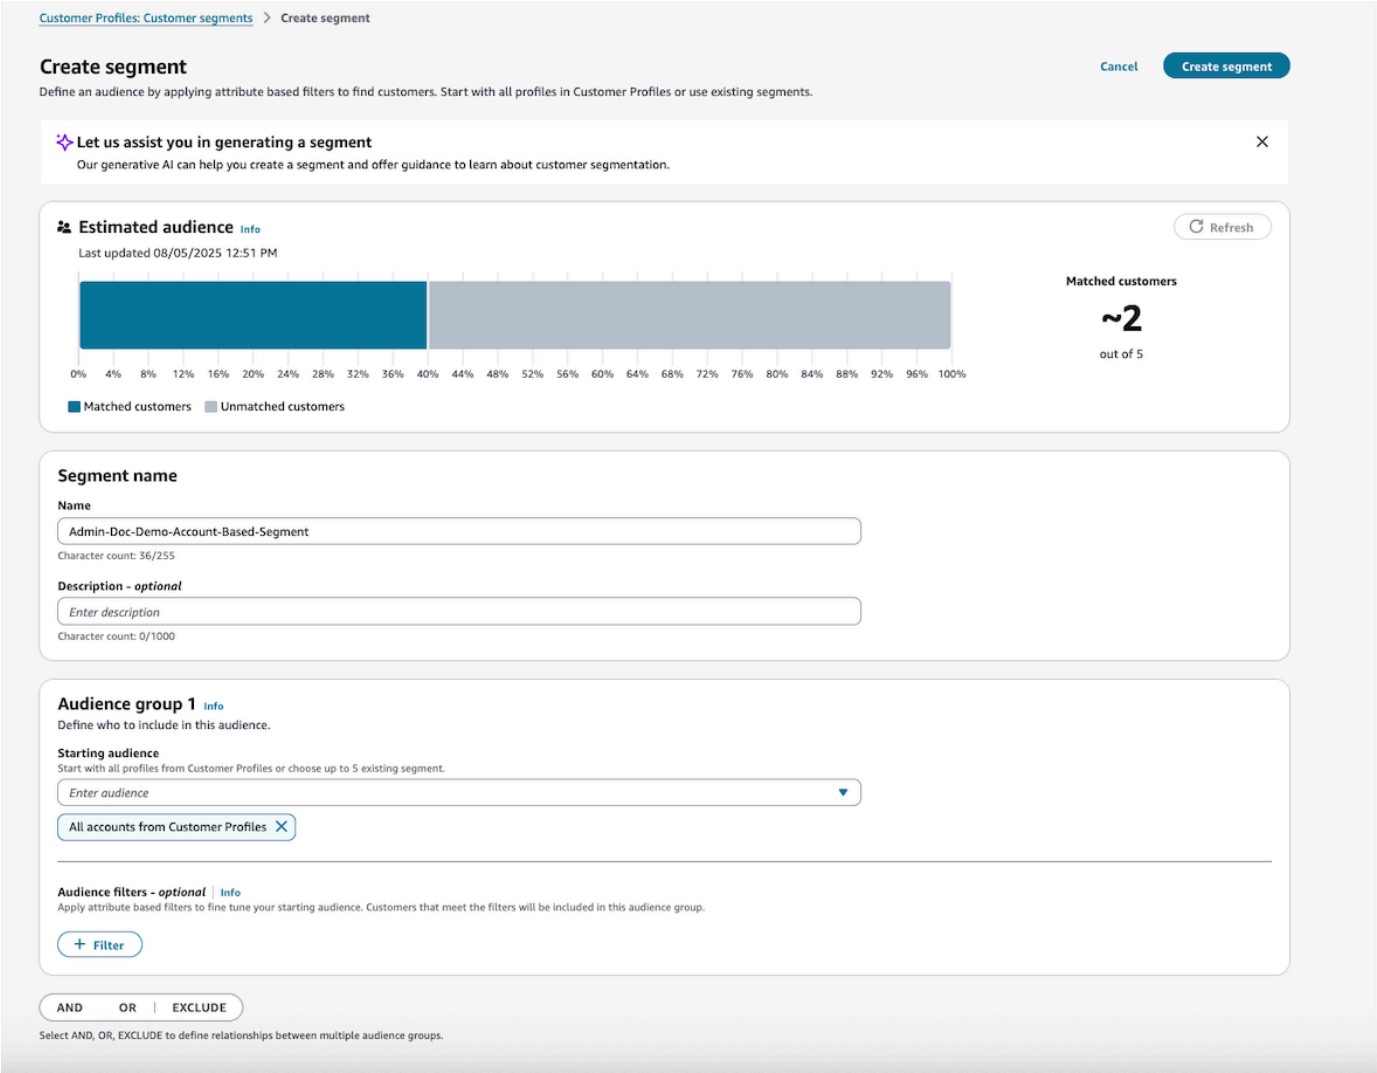
   > **Note**
   >
   > When you choose multiple segments as the starting audience, the segments are connected by OR relationships. For example, if you choose **Premium membership customers** and **Basic membership customers** segments as the starting audiences, all profiles who are in either of the segments will be the included.



2. To create a segment with ProfileType, start by using **All Accounts from Customer Profiles** as your initial audience. With this approach, you can filter account-based profiles effectively. It's important to note that unless you specify otherwise, the segmentation process will automatically export all profiles within the customer profiles domain. This default behavior ensures comprehensive coverage but can be adjusted to meet specific targeting needs.

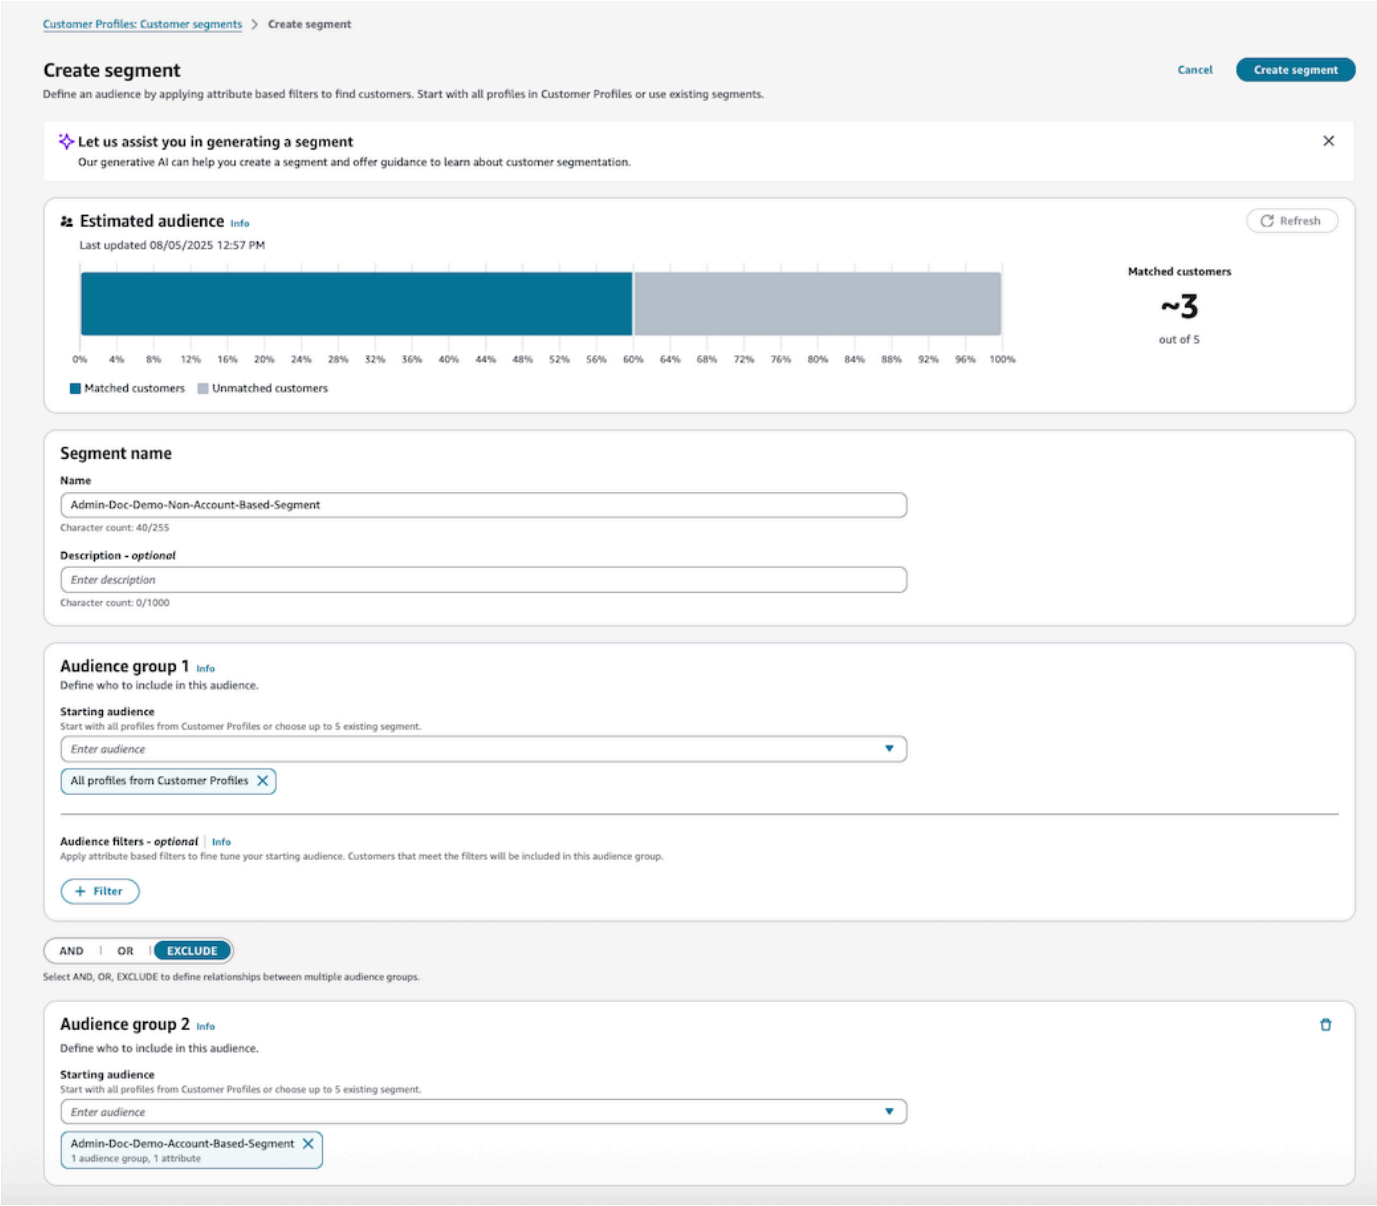
   The following is an example of how a segment definition can be created (either account- or standard-profiles based):

   Filters all account-based profiles (ProfileType=ACCOUNT_PROFILE)

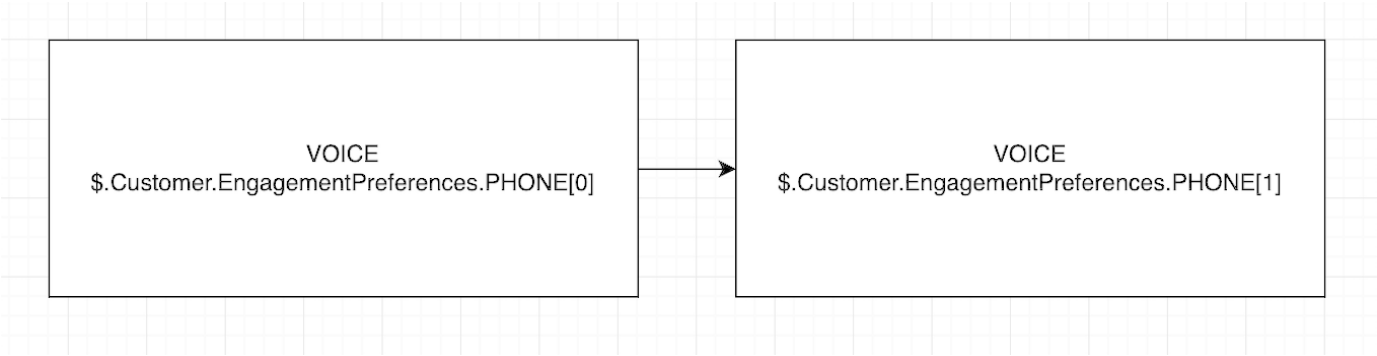


Note

To create a segment only with sub-profiles, create a new audience that excludes account-based profiles. For example, profiles with `ProfileType` is PROFILE or where `ProfileType` is empty.



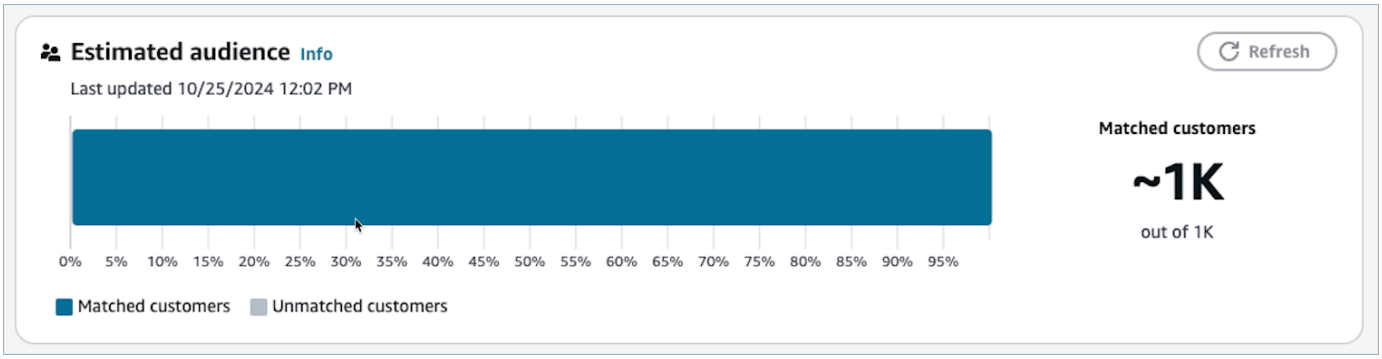
Sample Campaign that targets accounts to be reached out by using Phone



In this example, the campaign targets a single account with the following call sequence:

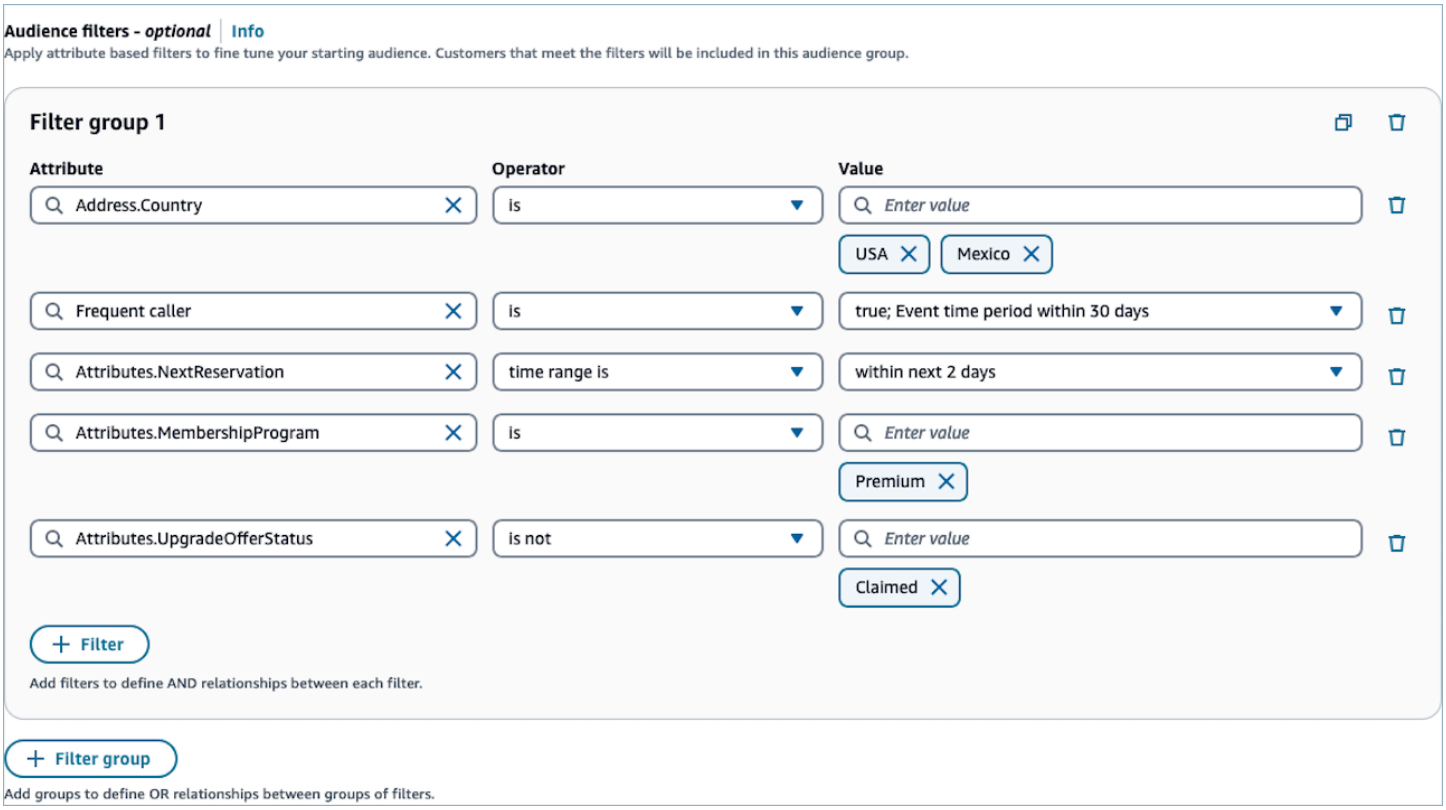
1. First attempts to reach John (ID: 2)
2. If John doesn't answer, then calls Sally (ID: 3) as a backup contact

3. After you choose a starting audience, the **Estimated audience** section updates to display the eligible profiles. After you edit the audience groups, you can choose **Refresh** button in the Estimated audience section to re-fetch the estimate.



Step 4: Choose and apply audience filters (optional)

After you've chosen your starting audiences, you can further refine the audiences by applying conditional logic to attributes. Segments supports standard profile attributes, custom profile attributes, and calculated attributes.



To choose and configure the audience filters

1. For **Attribute**, you can choose an attribute of the following types

   a. **Calculated attributes** - Filter the audience based on one of calculated attributes.

      See Set up calculated attributes in Connect Customer Customer Profiles to learn about the default Calculated Attributes and how to configure custom Calculated Attributes.

   b. **Standard attributes** - Filter the audience based on one of standard profile attributes.

      See Standard profile definition in the Connect Customer Customer Profiles for the list of standard profile attributes.

   c. **Custom attributes** - Filter the audience based on one of custom profile attributes.

> **Note**
>
> We store up to 1000 most recent profile attributes within the domain. If your domain contains a large amount of attributes the oldest attributes might not be displayed in this list.

2. Choose the **Operator**. Operators determines the relationship of the attribute to a value you enter. The following describes the available operators. Available operators change based on the type of value of the attribute you selected.

Supported type of attribute value	Operator	Description
Number	Greater than	Used for numeric attributes only. This operator filters results that are greater than the number passed. For example, *Customer's average hold time* is greater than 10 seconds.
	Greater than or equal	Used for numeric attributes only. This operator filters results that are greater than or equal to the number passed. For example, Customer's average hold time is greater than or equal to 10 seconds.
	Equals	Used for numeric attributes only. This operator filters the audience by numeric value equality. For example, *Customer's average hold time* equals 10 seconds.
	Less than	Used for numeric attributes only. This operator filters results that are less than the number passed. For example, *Customer's average hold time* is less than 10 seconds.
	Less than or equal	Used for numeric attributes only. This operator filters results that are less than or equal to the number passed. For example, *Customer's average hold* time is less than or equal to 10 seconds.
String	Is	Filters the audience the matches to the given string. For example, customer's *Address.Country* is USA.
	Is not	Filters the audience that does not match a given string. For example, customer's *Address.Country* is not USA.

Supported type of attribute value	Operator	Description
	Contains	Use this to filter the audience based on a substring within a string. For example, if you have a filter for *Address.Country* attribute, you could pass the US to return US or USA.
	Begind with	Filters the audience whose attribute begins with the given string. For example, customer's *Address.Country* begins with US.
	Ends with	Filters the audience whose attribute ends with the given string. For example, customer's EmailAddress ends with @amazon.com.
Date	Before	Filters the audience whose attribute has a date value that is before a specific date. For example, customer's whose *Attributes.NextReservation* is before 2024/10/01.
	On	Filters the audience whose attribute value matches with a specific date. For example, customer's whose *Attributes.NextReservation* is on 2024/10/01.
	After	Filters the audience whose attribute has a date value that is after a specific date. For example, customer's whose *Attributes.NextReservation* is after 2024/10/01.
	Time range is	Filters the audience whose attribute has a date value that is between a specific time range. You can either specify the time range in absolute time mode or relative time mode.
		Absolute time mode: you can specify an absolute time range. For example, between 2024/10/01 12:00 AM and 2024/10/07 12:00 AM.

Supported type of attribute value	Operator	Description
		Relative time mode: you can specify the relative time range of furture or past X hours, days, weeks, months, or years. - Future time direction: will filter audience whose attribute has a date value that is between now and a speficied future time. For example, within the next 2 days. - Past time direction: will filter audience whose attribute has a date value that is between a speficied past time and now. For example, within the last 2 days.
	Time range is not	Filters the audience whose attribute has a date value that is not between a specific time range. You can either specify the time range in absolute time mode or relative time mode. See "Time range is" operator in this table for more details.
List	Contains any of	Filters the audience whose list attribute contains any of the given values. For example, a customer's calculated attribute contains US or USA.
	Contains all of	Filters the audience whose list attribute contains all of the given values. For example, a customer's calculated attribute contains both US and USA.

Note

The **Contains any of** and **Contains all of** operators apply to list attributes. The admin website shows these operators for a calculated attribute only when its statistic is recent occurrences.

Note

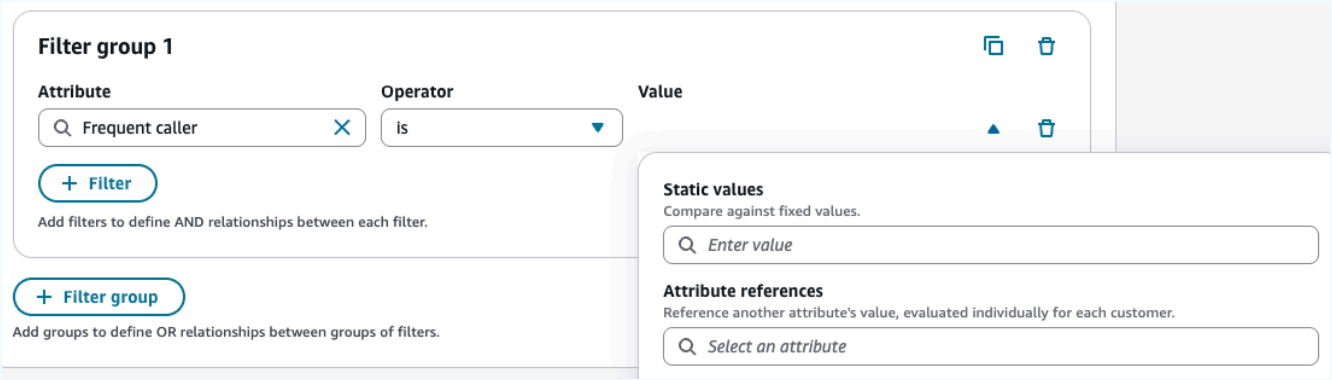
When you set the **Value** for a calculated attribute or profile attribute filter, you can choose one of the following options:

Static values

Compare against fixed values that you enter.

Attribute references

Reference another attribute's value, evaluated individually for each customer. Choose the profile attribute or calculated attribute that you want to reference from the list.



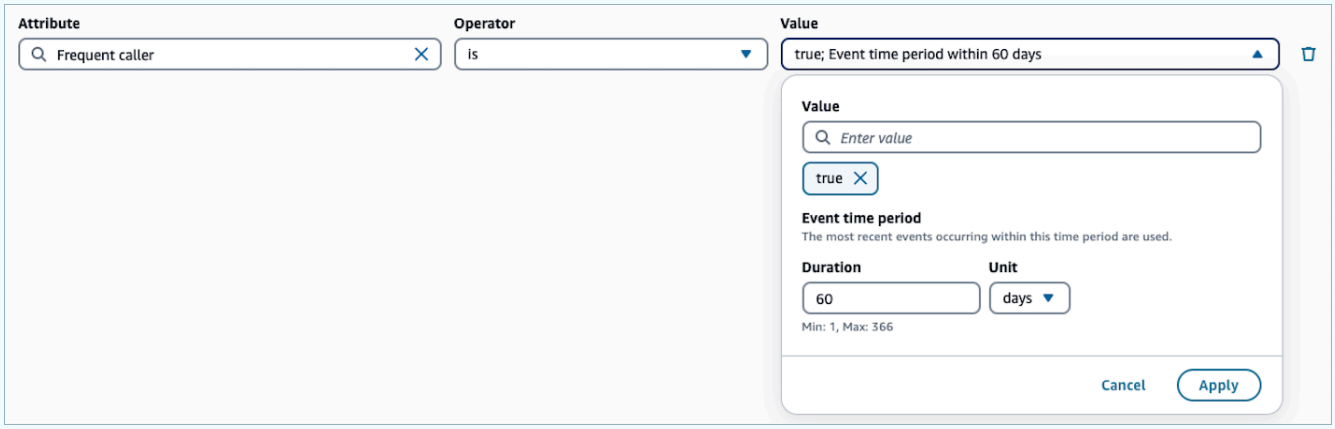
Note

Customer segments in the Connect Customer admin website uses UTC timezone and a default time of 00:00:00 UTC for all time-based filters. You can filter on dates but times are recorded as the same value. If you enter a date of 2024-01-01, the console passes the time as 2024-01-01T00:00:00Z.

Note

When you specify a filter for a calculated attribute, you can override the time period of the calculated attribute definition. For example, the filter `Frequent caller is true for the event time period of 60 days` will override the *Frequent caller* Default calculated attributes in Connect Customer Customer Profiles to evaluate the value

within the past 60 days instead of the time period configured in the calculated attribute definition. This override is specific to the segment, and does not affect the calculated attribute definition itself.



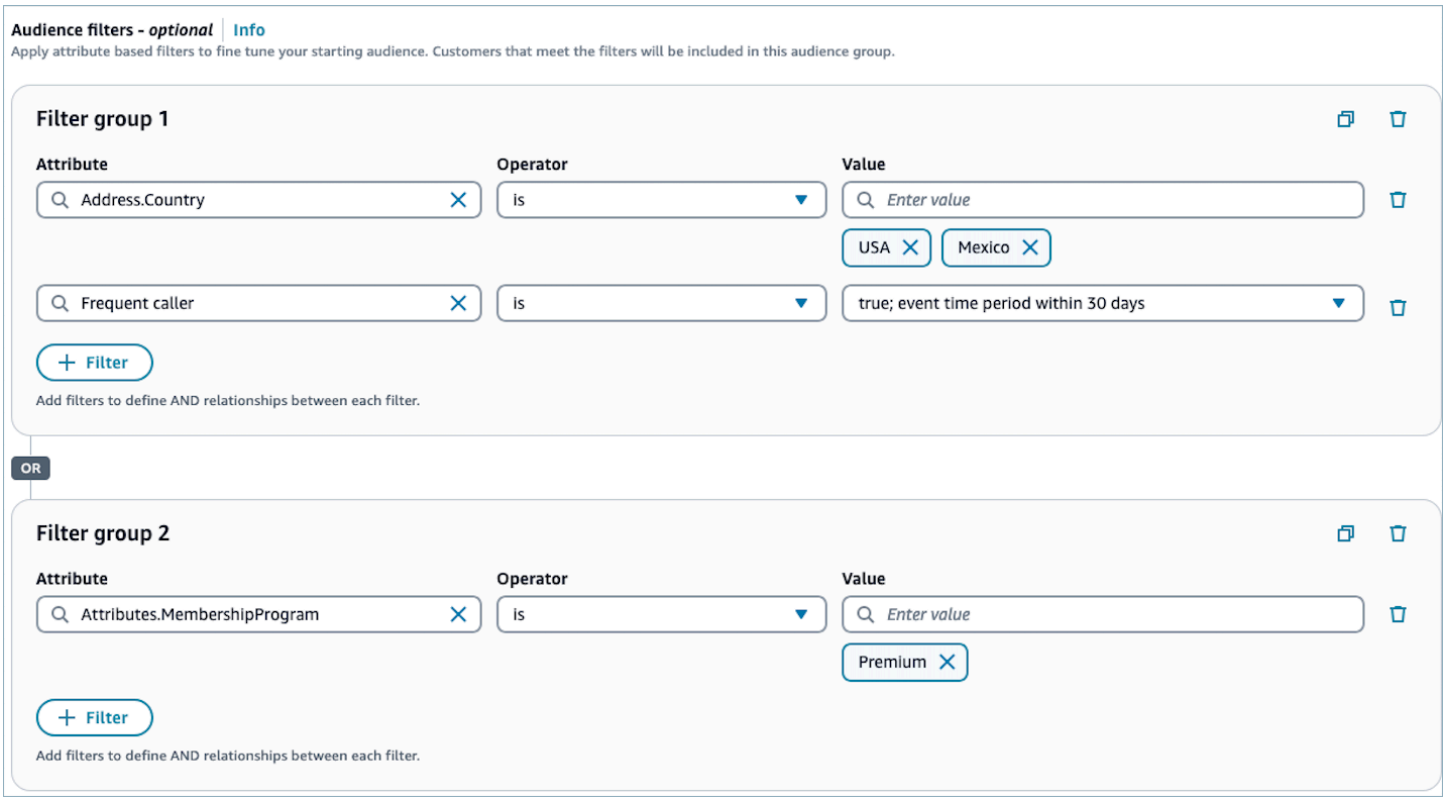
3. Specify the Value. You can specify multiple values connected by OR relationships. For example, `Address.Country` is USA or `Mexico`. The value input shows suggestions in the dropdown for string operators based on the customer profiles stored in the domain.

> **Note**
>
> Values are case-sensitive. For example, *Address.Country is US* returns different results than *Address.Country is us*.

4. (Optional) To apply additional attributes to this filter group, choose **+ Filter**. To create another group of filters, choose **+ Group**.

> **Note**
>
> When you have multiple filters in a filter group, the filters are connected by AND relationships. For example, a filter group containing 2 filters, "*Address.Country* is USA" and "*Customer's average hold time* is more than 10 seconds", the profiles whose *Address.Country* is USA **and** *average hold time* is more than 10 seconds will belong to the segment.

When you have multiple filter groups in an audience group, Customer segments in the Connect Customer admin website use OR relationships to connect between the filter groups.



5. When you're finished setting up the audience group, choose **Create segment**.

Step 5: Add the second audience group (optional)

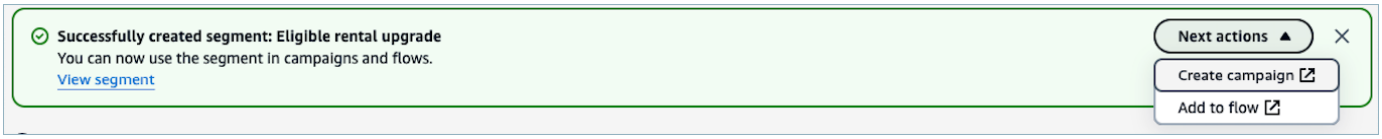
Optionally add the second audience group and define a relationship with audience group 1. When you create a customer segment by using the Connect Customer admin website, you can have a maximum of two audience groups per segment. If you add a second audience group to your segment, you can choose one of two ways to specify how the two audience groups are connected:

- **AND relationship** — If you use AND relationship to connect two audiences, your segment contains all profiles who meet the filters of both Audience group 1 and Audience group 2.
- **OR relationship** — If you use OR relationship to connect two audiences, your segment contains all profiles who meet the filters of either Audience group 1 or Audience group 2.
- **EXCLUDE relationship** — If you use EXCLUDE relationship to connect two audiences, the segment will contain profiles in Audience group 1 excluding the profiles in Audience group 2.

To configure second audience group

1. Choose **AND**, **OR**, or **EXCLUDE** relationship after configuring Audience group 1.

2. Choose the starting audience in Audience group 2. For reference, see Step 3: Choose the starting audiences to include in audience group 1.
3. (Optional) Choose the filters by which you want to narrow down your segments. For reference, see Step 4: Choose and apply audience filters (optional)
4. When you finish setting up the segment, choose **Create segment**. Segment is created and you can now use the segment in outbound campaigns or flows.



Step 6: Enable Sorting (optional)

Optionally configure sorting for your segment results. You can use sorting to control the order in which profiles appear in your segment output. You can sort by up to 10 attributes. Attributes are evaluated from top to bottom. When multiple profiles share the same value for an attribute, the next attribute in the list is used as a tiebreaker, and so on.

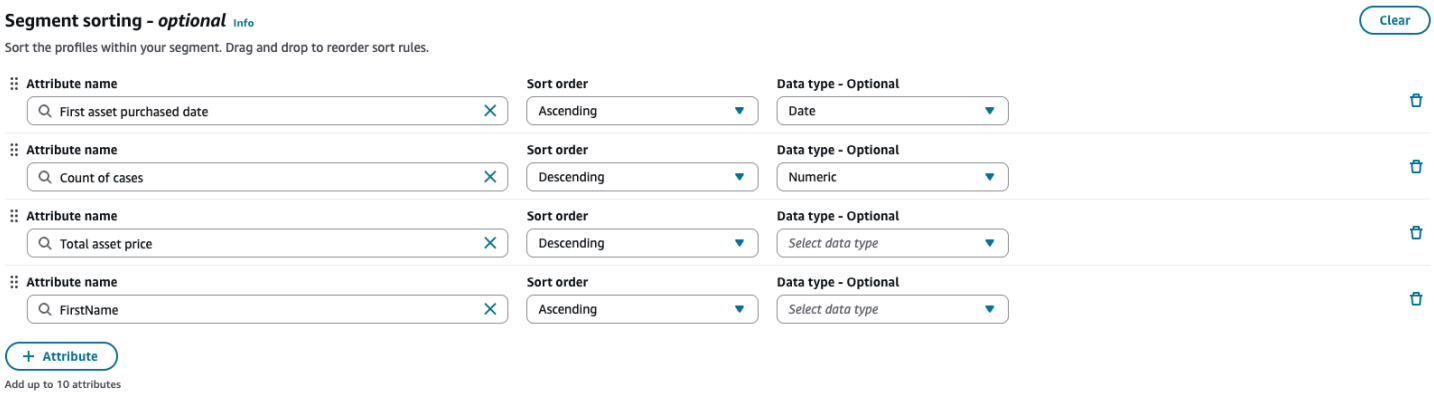
Outbound campaigns and journeys respect this sort order when executing, which means profiles are submitted for dialing in the order defined by the segment. For more information about using sorted segments with outbound campaigns, see Outbound campaign best practices. Sorting segments is useful when you want to:

- Prioritize high-value customers by sorting on attributes such as lifetime value or account tier.
- Contact customers with upcoming appointments first by sorting on appointment date.
- Process time-sensitive communications in a specific order.

> **Note**
>
> Segment sort order is respected only for voice campaigns and voice activities in journeys. Other communication channels process profiles in an unsorted order.

To enable sorting

1. Enter the attribute name you want to sort by. You can use an attribute from either standard or calculated attributes.
2. Specify the sort order: choose either **Ascending** or **Descending**.
3. (Optional) Specify the data type by choosing **String**, **Numeric**, or **Date**. If you do not specify a type, it is automatically inferred based on sampled data.



Creating segments powered by Spark SQL

With segments powered by Spark SQL, you can use complete Customer Profile data and expanded functionality to define segments. You can use standard profile object attributes and custom object attributes. You can also used SQL-based functionality such as joining standard and custom objects together to use data from various objects, filtering segments with statistics such as percentiles and standardizing date fields to make comparisons.

You can start by entering in a natural language prompt into Segment Assistant AI. Segment AI assistant will define the segment including its translation into Spark SQL. Segment Assistant AI will provide the steps it took to define the segment and you can validate it matches what you were aiming to create. You can also view the SQL, the SQL steps in natural language and a AI-generated summary of the Spark SQL to further help validate. If you want to make changes, you can update your natural language prompt or make edits to the Spark SQL directly.

You also have the option to create the Spark SQL segment directly.

Like Classic segmentation, segments powered by Spark SQL can be used in segment membership calls and Flow blocks. To use Outbound Campaigns or Journeys with Spark SQL segments, contact AWS Support to request access.

When you use a Spark SQL segment in a segment membership call, Flow block, or Outbound Campaign initiated by a customer event, it uses the last exported segment (segment snapshot). The segment snapshot used for membership expires 1 year after creation. If you receive a 4XX error, make sure you have exported the segment (segment snapshot).

> **Note**
>
> **SQL segmentation runs on Data store which has up to 10 years data. Classic segmentation uses latest data (data updated in past 3 years)**

> **Note**
>
> Segment exports for SQL segments can contain duplicate profiles. This can occur if your SQL query does not include deduplication logic for profiles. To avoid duplicates, ensure your query uses appropriate deduplication, such as `DISTINCT` or `GROUP BY`, on profile identifiers.

Step 1: Build a new segment

In the Segment AI assistant, select “How to create a segment” for more guidance on creating valuable segments or “I want to generate a segment” to enter a natural language prompt to create the segment.

Alternatively, use SQL to define a new segment in the query editor.

Step 2: Specify a name and description

For Name, enter a name for the customer segment to make it easy to recognize later.

> **Note**
>
> The Amazon Connect admin website uses the entered name as the `DisplayName` of the segment, and generates an identifier based on it. The generated identifier is used as the `SegmentDefinitionName` when you access the segment by using Customer Profiles APIs.

For Description, optionally enter a description for the customer segment.

Step 3: Review and validate the segment

Review the data the Segment AI assistant used and the steps the AI model it took to generate your segment. You can also review the SQL it created to define the segment in the query editor. If it was not able to create the segment, address the feedback it provided to help it create an accurate segment. After it has generated a segment, Customer Profiles will automatically create a segment estimate for you.

If you want to make edits, you can provide a new prompt by choosing “New conversation” or create/edit SQL in the query editor.

If you are not using the Segment AI assistant, you can validate the query and create the estimate by choosing on the “Validate and estimate query” button below the query editor.

> **Note**
>
> Segments powered by Spark SQL will take time depending on the amount of profile data you use in the segment and the SQL used, similar to other query engines (for example, multiple joins across objects usually take more time).

Step 4: Create segment

After you have build a segment and are satisfied, select “Create segment” button on the top right. After you have created the segment, you can select Actions - exporting to .csv, using the segment in Flows and using the segment in Outbound Campaigns.

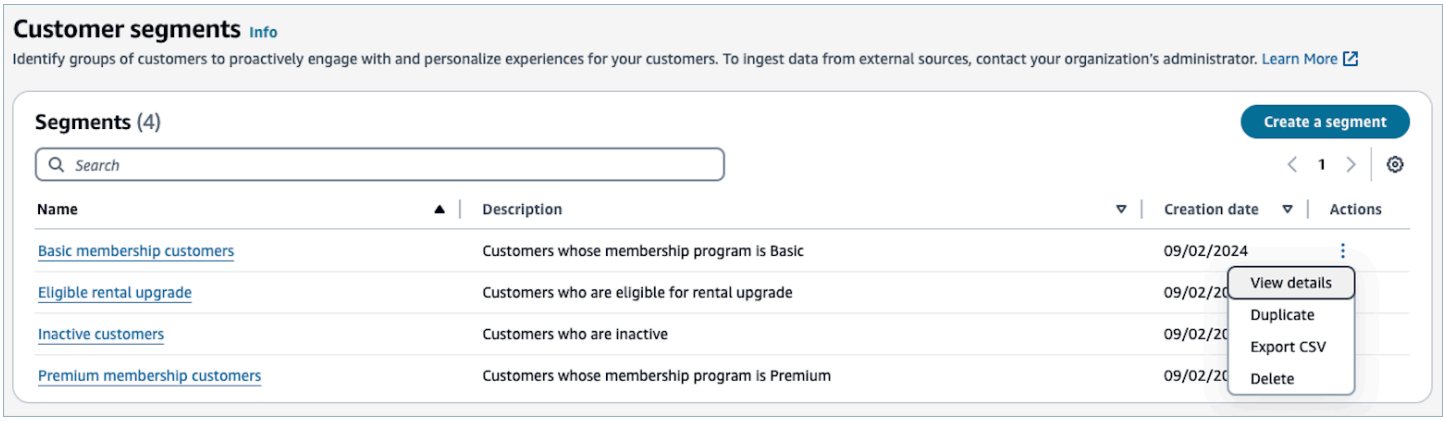
> **Note**
>
> If you use the segment in Outbound Campaigns or Flow blocks, it will check segment membership based on when the segment was last created. If you need real-time segment membership checks as the Flow or campaign is being executed, use Classic segmentation.

Manage customer segments in Connect Customer

You can use the Connect Customer admin website to create, view, copy, and perform other management tasks for customer segments. If you open a customer segment to view its settings, you can also quickly create a campaign that uses the segment. For more information on creating segments, see Build customer segments in Connect Customer in the Connect Customer Developer Guide.

To manage customer segments

1. On the **Customer segments** page, navigate to the segment that you want to manage, or choose an action.



2. On the **Actions** menu, the following options are available:
   a. **View details** — Choose this option to show information about the customer segment, including the date and time when the segment was created, and the date and time when the segment was last updated. The Connect Customer user needs the **CustomerProfiles.Segments.View** security profile permission to perform this action.
   b. **Duplicate** — Choose this option to create a new customer segment that's a copy of the selected segment. You can then modify any settings in the new segment,

without changing the original segment. The Connect Customer user needs the **CustomerProfiles.Segments.Create** security profile permission to perform this action.

c. **Export CSV** — Choose this option to export the customer segment to a file on your computer. For more information, see Export customer segments to a CSV file in Connect Customer. The Connect Customer user needs the **CustomerProfiles.Segments.Export** security profile permission to perform this action.

d. **Delete** — Choose this option to delete the customer segment permanently. You can't recover a segment after you delete it. The Connect Customer user needs the **CustomerProfiles.Segments.Delete** security profile permission to perform this action.

> **Important**
>
> If you delete a segment, any active campaigns that use the segment will fail. Similarly, any segments built on top of the segment will stop working. Before you delete a segment, it's a good idea to first verify that a segment isn't being used by any active campaigns or other segments.

Create segments from imported files in Connect Customer

> **Note**
>
> To access the segmentation builder experience in the Connect Customer admin website, make sure that the appropriate security profiles permissions are configured. For more information, see Assign security profile permissions to manage customer segments.

Customer segment import uses a CSV file containing profile data to create new profiles or update existing ones, which are then grouped into a segment. The CSV file must be under 1GB in size and include valid headers that map to standard profile attributes.

The following steps describe creating and configuring an imported customer segment:

1. Create a new segment
2. Upload CSV file
3. Configure segment details

4. Map customer attributes
5. Set profile expiry
6. Create and monitor segment import

Create a new segment

1. To create a segment, make sure that you have created security profiles permissions as a prerequisite. For more information, see Assign security profile permissions to manage customer segments.
2. In the Connect Customer admin website, navigate to **Customer Profiles+Customer segments**
3. Choose **Create segment** and select **From file upload** from the dropdown

Upload CSV file

Choose a CSV file by either:

- Choosing **Choose file** and selecting your file.
- Dragging and dropping your file into the upload area.

The file must be:

- In CSV format
- Under 1GB in size
- Contain headers
- UTF-8 encoded

> **Note**
>
> UTF-8 with BOM (Byte Order Mark) is not supported. If your import fails with a missing header error, re-save the file with UTF-8 encoding without BOM.

Configure segment details

For **Name**, specify a recognizable identifier for your segment. This field is required.

- Use only letters (a-z, A-Z), numbers (0-9), hyphens (-), or underscores (_)
- Begin with a letter or number (not an underscore)
- Maximum length of 255 characters

> **Note**
>
> The Connect Customer admin website uses this name as the `DisplayName` of the segment and generates a unique `SegmentDefinitionName` identifier. This identifier is used when accessing the segment through Connect Customer Customer Profiles APIs.

For **Description**, (optional), add details about your segment:

- Maximum length of 1000 characters

Map customer attributes

Object type mapping defines how Customer Profiles processes your CSV data. This mapping:

- Determines how CSV data populates standard profile objects.
- Specifies which fields to index for profile assignment.

For more information about object type mapping, see Create and ingest customer data into Customer Profiles.

Choose one of these options to map your CSV columns to Customer Profiles attributes:

Option 1: AI-powered mapping (Recommended)

1. Choose **Generate customer attributes**, then choose **Next**.
2. The system analyzes your CSV headers and suggests appropriate mappings to standard profile attributes.
3. Review the suggested mappings.
4. Optional: Customize the mappings:
   - Modify standard profile attribute mappings.
   - Add custom attributes using the format: `Attributes.`*`attribute-name`*.

- Update the unique identifier.

Option 2: Manual mapping

1. Map each CSV column header to a profile attribute:

   - Use standard profile attributes. For a complete list, see Standard profile definition in the Connect Customer Customer Profiles.
   - Create custom attributes using the format: `Attributes.attribute-name`.

   > **Note**
   >
   > You can map up to 25 attributes.

2. Choose one mapped attribute as the customer identifier (unique key).

Choose a customer identifier

After completing the mapping, choose one mapped attribute as the customer identifier. Connect Customer Customer Profiles uses this identifier to:

- Create new profiles or update existing ones.
- Match incoming data with existing profiles.

> **Note**
>
> Attribute mappings can be modified at any time during setup, whether using AI-powered or manual mapping.

Set profile expiry

Specify when imported profiles expire.

1. Choose an expiry option:

   - Default: 14 days from import date

- Custom: Select a date using the date picker

2. For custom expiry dates:

   - Minimum: 1 day after import
   - Maximum: 90 days after import

Customer Profiles removes expired profiles from the segment and the profiles domain. For more information, see Data expiration in Customer Profiles.

> **Note**
>
> Choose an expiry period that aligns with your data retention requirements. Consider whether the default 14-day period meets your business needs before selecting a custom date.

Create and monitor segment import

Create the segment

1. Review your configuration.
2. Choose **Create segment**.
3. The system will:

   - Upload your CSV file.
   - Create/update profiles based on the data.
   - Group the profiles into a segment.
   - Show progress by using a notification banner.

Monitor import progress

- View the import progress on the segment details page.
- The notification banner shows that the import job is in progress.
- The import job details table shows:
  - File name
  - Import job creation date

- Import job completion date
- Number of profiles processed
- Number of successful imports
- Number of failed imports

- You can cancel the import while in progress.
- The segment can be used in campaigns while the import job is still in progress.

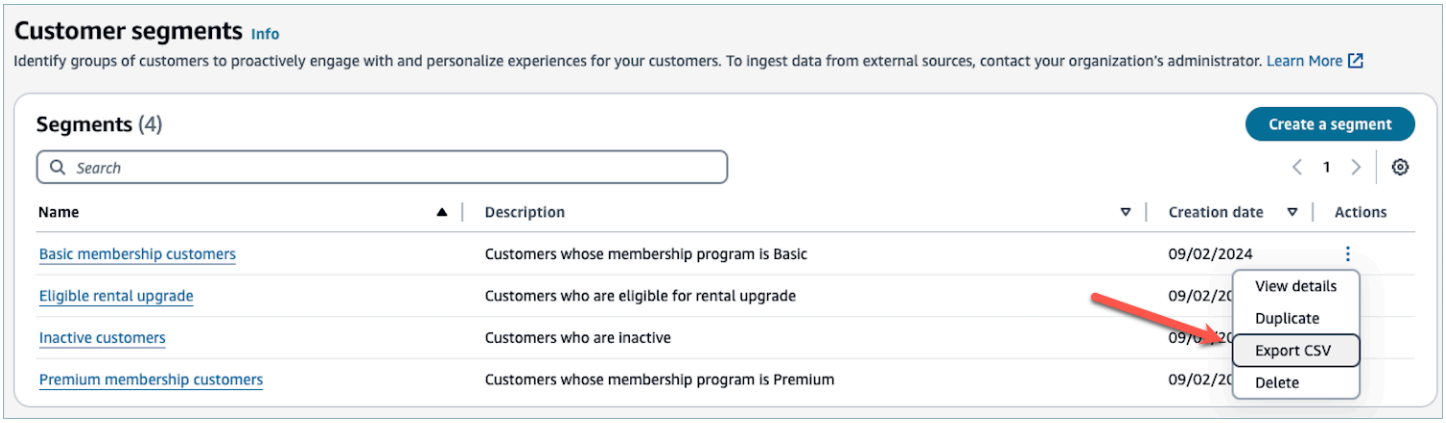
> **Note**
>
> Imported segments can be used like any other segment for outbound campaigns or exports after the import is complete. You can view the segment details, including import status and results, from the segment details page.

Export customer segments to a CSV file in Connect Customer

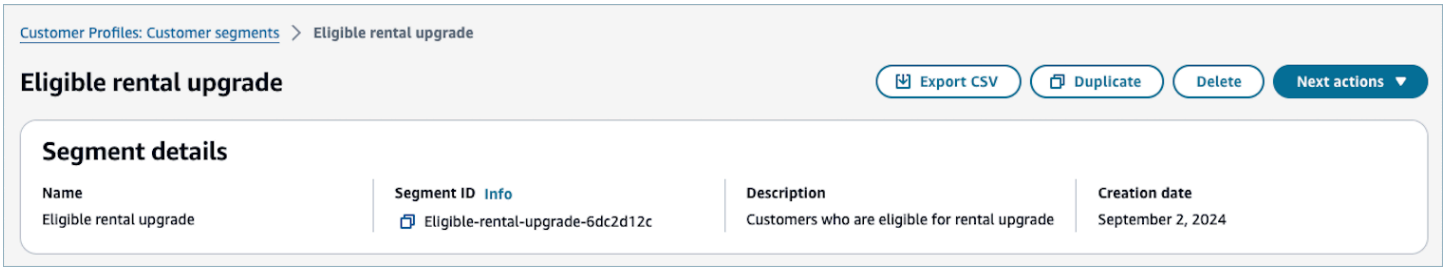
From the **Customer segments** page in the Connect Customer admin website, you can export an existing segment to a file on your computer. When you do, Customer Profiles exports all of the profile attributes that's associated with the profiles in the customer segment to a CSV file.

To export a customer segment

1. On Customer segments page, choose **Export CSV** in the actions dropdown.

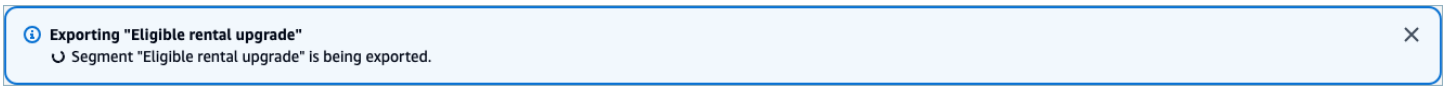


Alternatively, you can navigate to the **View details** page, and choose **Next actions**, **Download**.



> **Note**
>
> The Connect Customer admin website supports exporting a customer segment that contains up to 350,000 profiles. If you need to export a segment that contains a large number of profiles, use the `CreateSegmentSnapshot` operation in Customer Profiles API. The `CreateSegmentSnapshot` operation supports exporting a segment in ORC, JSONL, and CSV files to an S3 bucket. Note that the API outputs a test file in addition to the exported segment in the bucket.

2. After the export job begins, keep the window or tab containing the download open until the process completes.



3. After the export job completes, the Connect Customer admin website automatically starts downloading the file.

The exported CSV file contains all standard and customer profile attributes populated across the exported profiles.

Track segment membership changes in Connect Customer

You can subscribe a segment to receive notifications whenever the membership of the segment changes. A membership change occurs when a customer profile enters or exits the segment based

on the segment criteria. This can happen because of a change in a profile, an associated object, or a calculated attribute. Membership changes are determined in two ways:

- **Near real-time changes** — When membership changes because of a change to profile attributes, objects, or calculated attributes, Connect Customer Customer Profiles sends the event as a near real-time (`LIVE`) update.
- **Time-based changes** — When membership changes because of a time-based aspect of the segment criteria, Customer Profiles evaluates membership on a schedule and compares it against the previous known state to determine changes (`SCHEDULE`).

Customer Profiles sends both types of notification to the Amazon Kinesis data stream that you configure for segment membership changes, using the IAM role that you provide.

Note

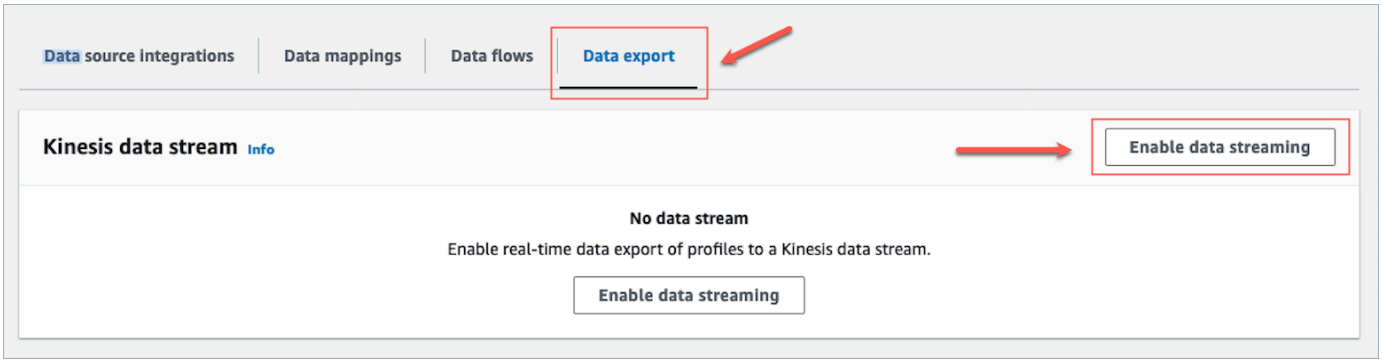
- To access the segmentation builder experience in the Connect Customer admin website, make sure that the appropriate security profile permissions are configured. For more information, see Assign security profile permissions to manage customer segments.
- Before you subscribe to membership events, you must enable segment membership streaming to set the destination Kinesis data stream for membership changes. For more information, see Set up segment membership streaming.
- You can create a subscription only after the segment is created. You can create a maximum of 10 segment subscriptions for each domain.

Set up segment membership streaming

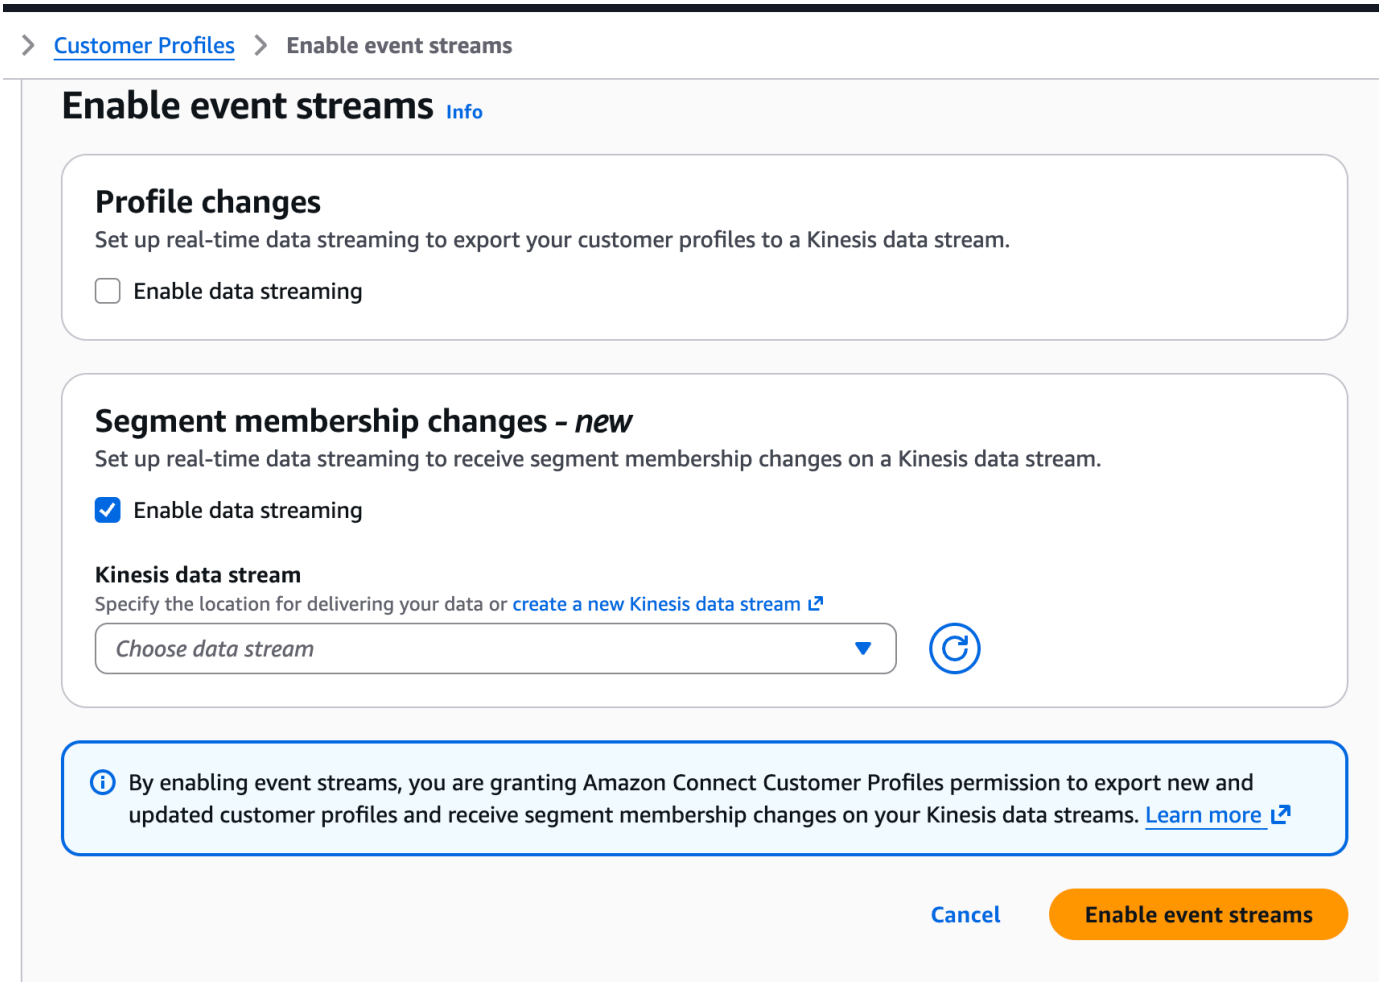
Enabling segment membership streaming is a one-time setup that an administrator performs for the domain. It sets the destination Kinesis data stream that membership events are delivered to. Enabling the stream does not enable membership events by default — you must also subscribe individual segments to receive notifications, and the same Kinesis data stream is shared across all subscribed segments in the domain.

To enable segment membership streaming for your domain

1. Open the Connect Customer Customer Profiles console.
2. Choose the **Data export** tab, and then choose **Enable event streaming**.



3. Under **Segment membership changes**, choose **Enable data streaming**, and then select an existing Kinesis data stream from the drop-down menu, or choose **create a new Kinesis data stream** to open the Kinesis console and create the stream. For more information, see Creating and managing streams.



4. For **Role name**, specify an IAM role that grants Customer Profiles permission to write to your Kinesis data stream, or choose **Create role in IAM** to create one.
5. Choose **Enable data streaming** to save your settings.

When you enable segment membership streaming, Customer Profiles assumes the role that you specify. Because of this, the IAM principal that enables streaming must have permission to pass that role to Customer Profiles. Grant the `iam:PassRole` action for the Kinesis role to the principal, scoped to the Customer Profiles service. The following is a sample statement to add to the principal's permissions.

```
{
    "Effect": "Allow",
    "Action": "iam:PassRole",
    "Resource": "arn:aws:iam::123456789012:role/my-segment-events-role",
    "Condition": {
        "StringEquals": {
            "iam:PassedToService": "profile.amazonaws.com"
        }
    }
}
```

The IAM role that you provide must trust the Customer Profiles service principal and grant permissions to write to the Kinesis data stream. The following is a sample trust policy for the Kinesis role.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Principal": {
                "Service": "profile.amazonaws.com"
            },
            "Action": "sts:AssumeRole"
        }
    ]
}
```

The following is a sample of the permissions to grant the Kinesis role.

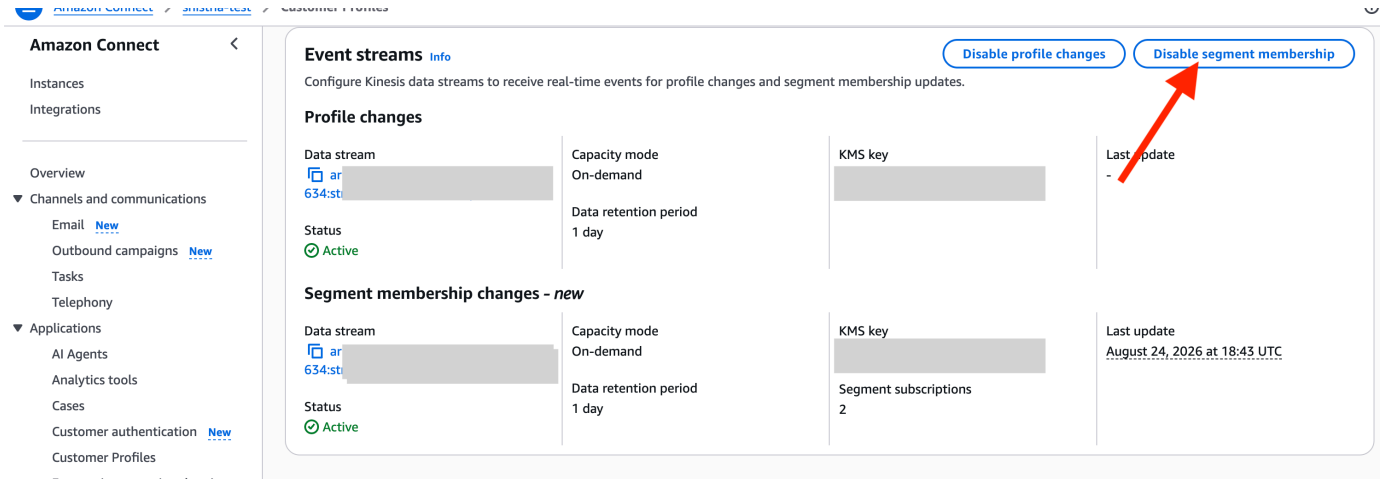
```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "kinesis:PutRecord",
                "kinesis:PutRecords",
                "kinesis:DescribeStreamSummary"
            ],
            "Resource": "arn:aws:kinesis:us-west-2:123456789012:stream/my-segment-
events-stream"
        }
    ]
}
```

If your Kinesis data stream is encrypted with a customer managed AWS KMS key, the role also needs permission to use that key to write to the stream. Add the following statement, scoped to your AWS KMS key, to the role's permissions.

```
{
    "Effect": "Allow",
    "Action": [
        "kms:GenerateDataKey",
        "kms:Decrypt"
    ],
    "Resource": "arn:aws:kms:us-
west-2:123456789012:key/1234abcd-12ab-34cd-56ef-123456SAMPLE"
}
```

To disable segment membership streaming for your domain

1. Open the Connect Customer Customer Profiles console.
2. Choose the **Data export** tab, and then choose **Disable segment membership**.



Key concepts

The following terms are important for understanding segment membership events.

Subscription

You enable a subscription on a segment to receive membership events that identify the change of state, along with a timestamp, for a given profile.

Initial snapshot

Before evaluating membership changes, Customer Profiles creates an initial snapshot that preserves the current membership status for existing profiles. This snapshot is the source of truth that is used to determine membership changes. While Customer Profiles takes the snapshot, the subscription is in the `STARTING` state. After it completes, you begin to see results.

SCHEDULE and LIVE events

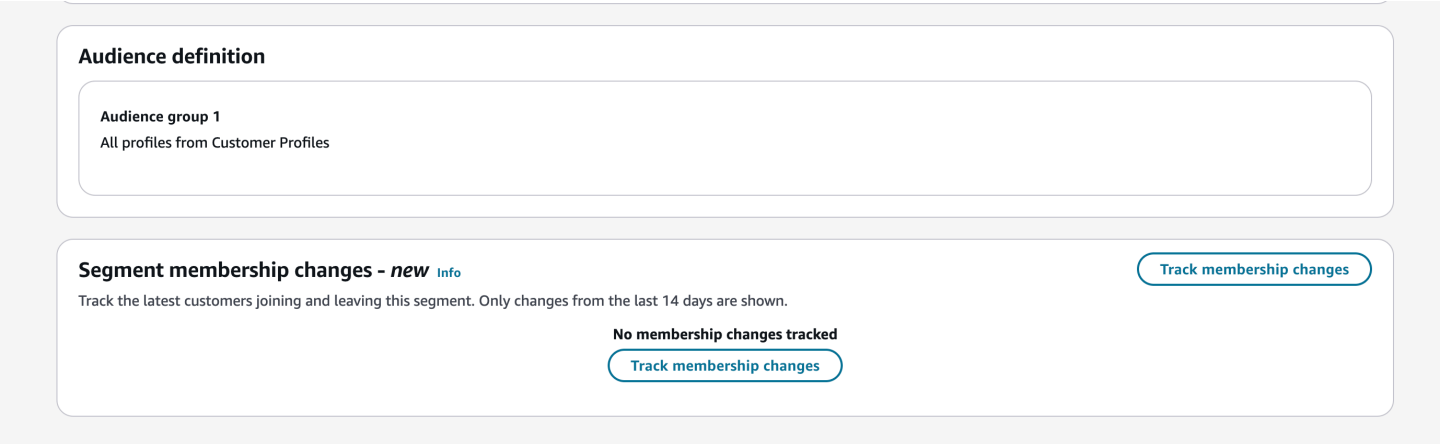
The type of event that you receive depends on when and how Customer Profiles evaluated the membership.

A `SCHEDULE` event is sent from a scheduled run. Scheduled runs occur every 24 hours by default when you subscribe through the API, and every hour by default from the Connect Customer admin website. You can configure the interval to a minimum of 1 hour and a maximum of 24 hours. Each scheduled run takes a fresh snapshot and compares the membership status of each profile against the previous snapshot. Scheduled runs are best-effort: the interval is a target cadence rather than a guaranteed run time, so a run might be delayed or skipped, for example if the previous scheduled run has not finished. Customer Profiles sends you a notification for any changes in membership.

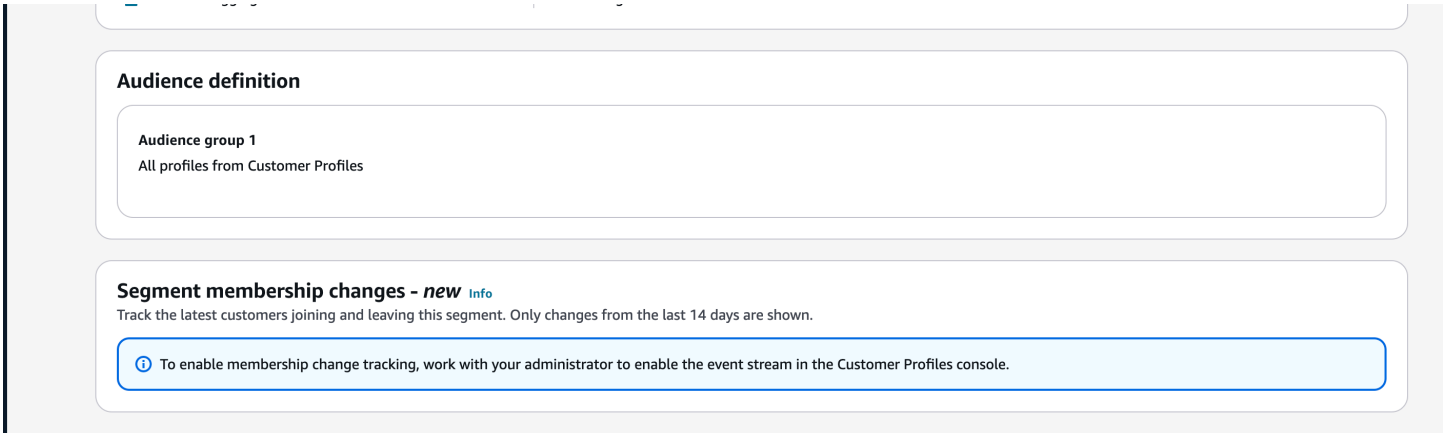
A `LIVE` event is sent in near real time, outside of the scheduled runs, when membership changes because of a change to a profile attribute, object, or calculated attribute. Customer Profiles evaluates the affected profile as the change occurs and sends a notification if its membership changed.

Enable and view events

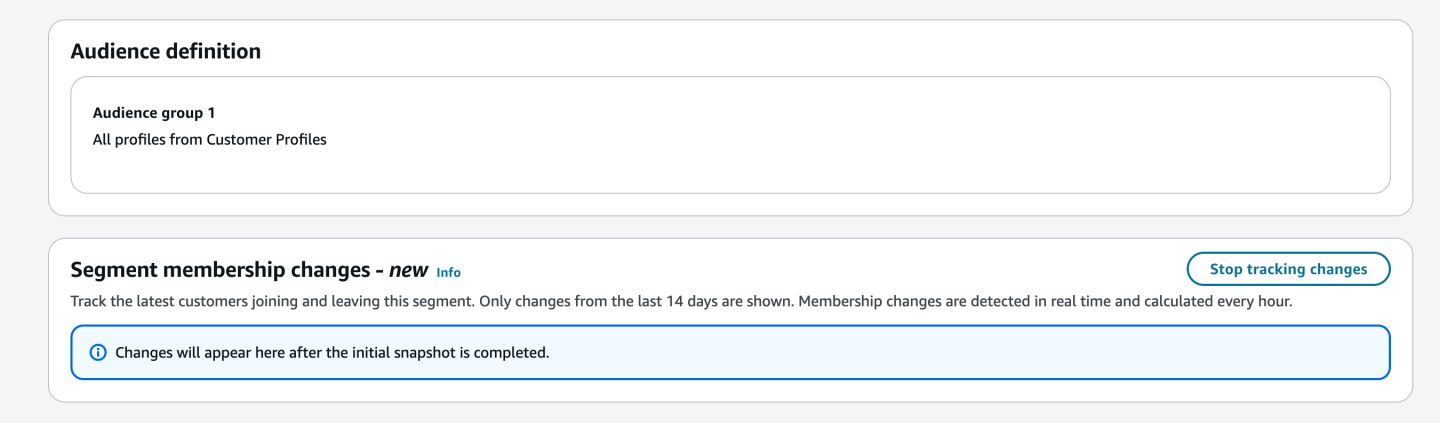
After a segment is created, you can enable the subscription from the Connect Customer admin website by choosing **Track membership changes**.



After you enable tracking, Customer Profiles sends notifications to the Kinesis data stream associated with segment membership changes. If your administrator has not configured a stream, a message prompts you to enable segment membership streaming first.

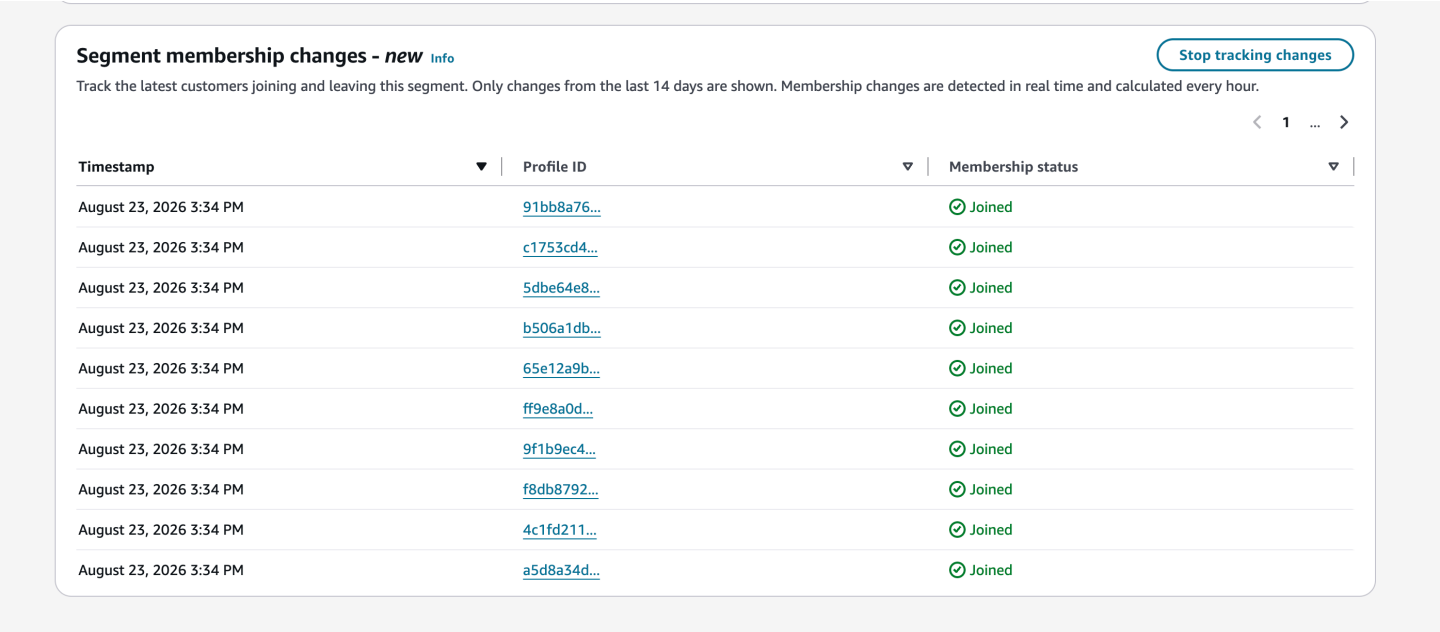


After tracking is enabled, you see messages that provide detail about the initial snapshot.



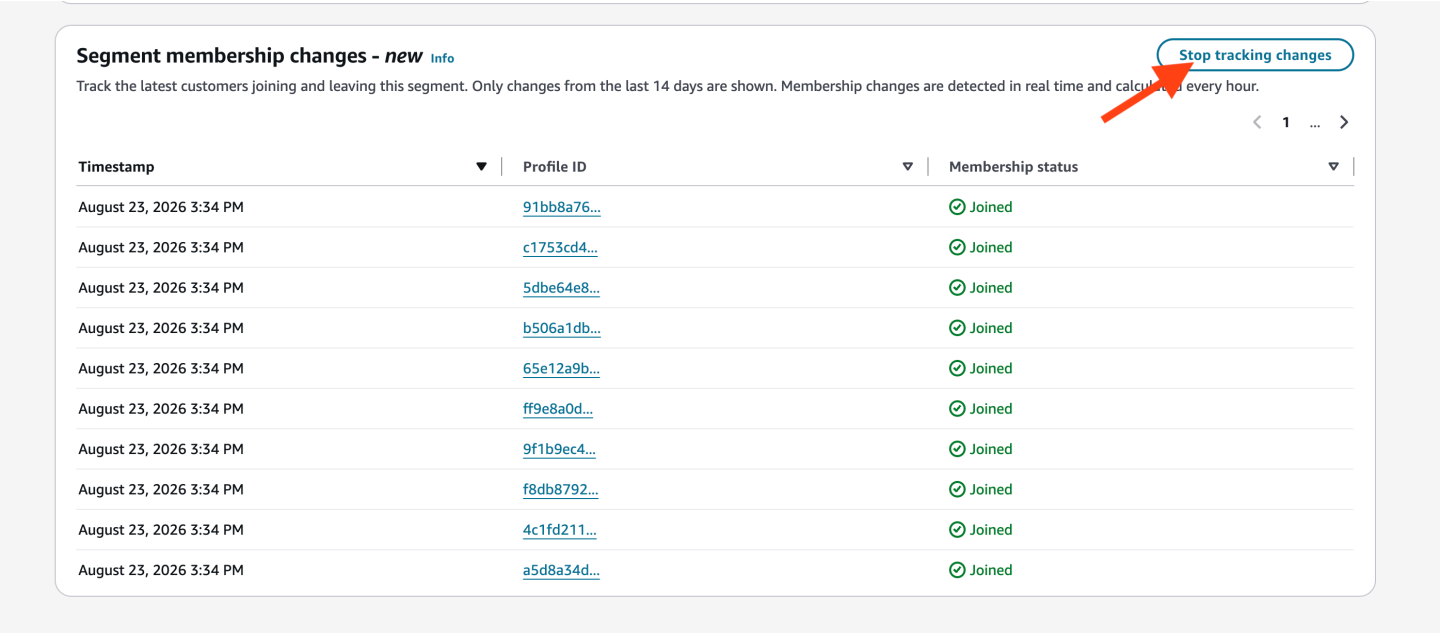
Viewing events

Events are published to the Kinesis data stream in your account. After the initial snapshot completes, you can also view streaming events from the same section, and you can view membership event details on individual profiles. There might be a delay between when a membership change occurs and when it appears in the list of streaming events.



Stop tracking changes

If you no longer want to receive notifications, choose **Stop tracking changes**.



CloudWatch metrics

You can view CloudWatch metrics for your segment membership events under your domain and segment. The following metrics are available.

`ProfilesJoined`

The number of profiles that entered the segment.

`ProfilesLeft`

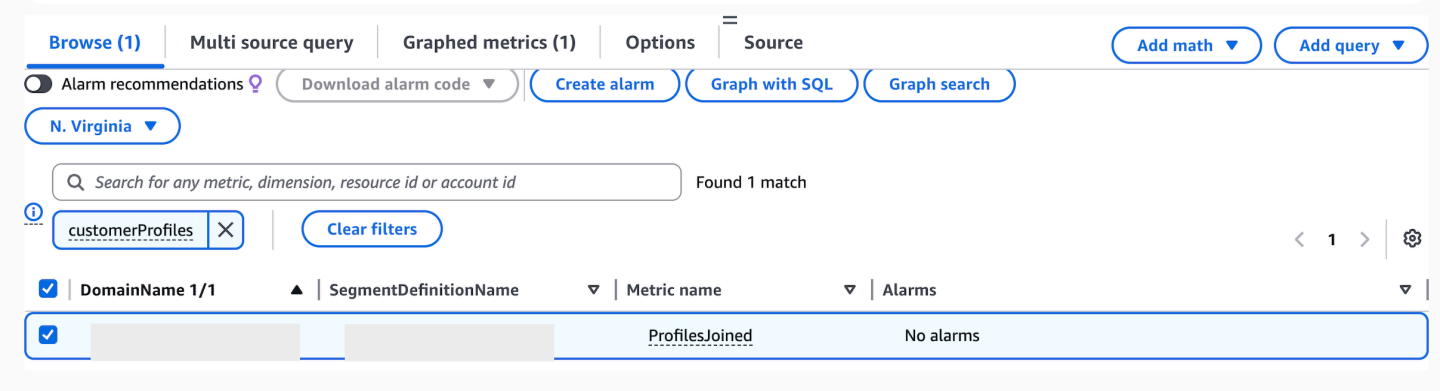
The number of profiles that left the segment.

`NotificationsFailed`

The number of notification events that failed.

`ScheduledRunsSucceeded`

The number of scheduled runs that succeeded.



Segment membership changes payload

Customer Profiles sends this event to your Kinesis data stream each time a customer profile enters or exits a segment. The following is a sample segment membership event in JSON.

```
{
    "AccountId": "123456789012",
    "DomainName": "cp-domain-prod",
    "SegmentDefinitionName": "PeopleInSeattle",
    "SegmentType": "CLASSIC",
    "ProfileId": "0d25b61368c64fb786347d7e7314c6f1",
    "OperationType": "JOINED",
    "MembershipCalculatedAt": 1773967675,
    "PreviousMembershipChangedAt": 1773965432,
    "EventType": "LIVE"
}
```

The following list describes the fields in the segment membership event payload.

AccountId

The AWS account receiving the event.

DomainName

The name of the Customer Profiles domain where the segment is defined.

SegmentDefinitionName

The name of the segment whose membership changed.

SegmentType

The type of segment that the notification came from.

- `CLASSIC`: A segment built with audience groups and filters. For more information, see Build customer segments in Connect Customer.
- `ENHANCED`: A segment defined with SQL.

ProfileId

The unique identifier of the profile whose membership changed.

OperationType

- `JOINED`: The profile became a member of the segment.
- `LEFT`: The profile is no longer a member of the segment.

MembershipCalculatedAt

The time at which the membership was evaluated.

PreviousMembershipChangedAt

The time at which the previous membership change was identified.

EventType

- `LIVE`: The membership was evaluated in near real-time.
- `SCHEDULE`: The membership was evaluated during a scheduled run, and this notification reflects the membership at the time of that run.

Default segments in Connect Customer

With Connect Customer, you have access to out-of-the-box default segments on every domain. You can use these segments immediately without any configuration. Connect Customer builds default segments from the default calculated attributes it provides. For more information about the calculated attributes that these segments reference, see Default calculated attributes in Connect Customer Customer Profiles.

Default segment names begin with the reserved `_default_` prefix. You cannot create a segment definition that uses this prefix, and you cannot delete a default segment.

Connect Customer evaluates default segments at contact disconnected time. As the contact ends, Connect Customer resolves each profile's membership in these segments. Connect Customer

then sends the segment memberships to Connect Customer Customer Analytics. You can use the segment memberships to filter and group data in dashboards.

Default lifetime value segments

The lifetime value segments classify profiles into high, medium, and low tiers based on the profile's total order value. These segments reference the `_lifetime_value_high` and `_lifetime_value_low` default calculated attributes, which track the order object.

To change which profiles fall into each tier, update the thresholds on the underlying `_lifetime_value_high` and `_lifetime_value_low` calculated attributes. The segments use the updated thresholds on subsequent evaluations.

> **Note**
>
> Important: Always configure the high threshold to be greater than the low threshold (`_lifetime_value_high > _lifetime_value_low`). If the high threshold is less than or equal to the low threshold, the tier boundaries overlap and profiles can be classified incorrectly.

The following example shows the High lifetime value default segment definition:

```
{
   "SegmentDefinitionName": "_default_lifetime_value_high",
   "DisplayName": "High lifetime value",
   "Description": "Customers whose total order value meets or exceeds the high lifetime
 value threshold.",
   "SegmentType": "CLASSIC",
   "SegmentGroups": {
      "Groups": [
         {
            "Type": "ALL",
            "Dimensions": [
               {
                  "CalculatedAttributes": {
                     "_lifetime_value_high": {
                        "DimensionType": "INCLUSIVE",
                        "Values": ["true"]
                     }
```

```
                  }
               }
            ]
         }
      ],
      "Include": "ALL"
   },
   "Tags": {
   }
}
```

The following example shows the Medium lifetime value default segment definition:

```
{
   "SegmentDefinitionName": "_default_lifetime_value_medium",
   "DisplayName": "Medium lifetime value",
   "Description": "Customers whose total order value falls between the high and low
 lifetime value thresholds.",
   "SegmentType": "CLASSIC",
   "SegmentGroups": {
      "Groups": [
         {
            "Type": "ALL",
            "Dimensions": [
               {
                  "CalculatedAttributes": {
                     "_lifetime_value_high": {
                        "DimensionType": "INCLUSIVE",
                        "Values": ["false"]
                     }
                  }
               },
               {
                  "CalculatedAttributes": {
                     "_lifetime_value_low": {
                        "DimensionType": "INCLUSIVE",
                        "Values": ["false"]
                     }
                  }
               }
            ]
```

```
         }
      ],
      "Include": "ALL"
   },
   "Tags": {
   }
}
```

The following example shows the Low lifetime value default segment definition:

```
{
   "SegmentDefinitionName": "_default_lifetime_value_low",
   "DisplayName": "Low lifetime value",
   "Description": "Customers whose total order value is at or below the low lifetime
 value threshold.",
   "SegmentType": "CLASSIC",
   "SegmentGroups": {
      "Groups": [
         {
            "Type": "ALL",
            "Dimensions": [
               {
                  "CalculatedAttributes": {
                     "_lifetime_value_low": {
                        "DimensionType": "INCLUSIVE",
                        "Values": ["true"]
                     }
                  }
               }
            ]
         }
      ],
      "Include": "ALL"
   },
   "Tags": {
   }
}
```

Default repeat caller segments

The repeat caller segment identifies profiles that have had more than one contact in the last 7 days (inbound or outbound). It references the `_call_count` default calculated attribute, which tracks the number of distinct inbound and outbound contacts a customer has had in the last 7 days.

To change how many contacts qualify a profile as a repeat caller, update the threshold on the `_call_count` calculated attribute. The segment uses the updated threshold on subsequent evaluations.

The following example shows the Repeat caller default segment definition:

```
{
   "SegmentDefinitionName": "_default_repeat_caller",
   "DisplayName": "Repeat caller",
   "Description": "Customers who have called multiple times.",
   "SegmentType": "CLASSIC",
   "SegmentGroups": {
      "Groups": [
         {
            "Type": "ALL",
            "Dimensions": [
               {
                  "CalculatedAttributes": {
                     "_call_count": {
                        "DimensionType": "GREATER_THAN",
                        "Values": ["1"]
                     }
                  }
               }
            ]
         }
      ],
      "Include": "ALL"
   },
   "Tags": {
   }
}
```

Use default segments in dashboards

You can filter and group data by default segment memberships in Connect Customer Analytics dashboards. For the full list of available dashboards and the data they report, see Dashboards in Connect Customer for getting contact center performance data.

Use the segment AI assistant in Connect Customer

Connect Customer Customer Profiles supports generative AI-powered segmentation, enabling non-technical business users to build audiences using natural language queries (segment AI assistant), and to receive recommendations based on trends in the customer data (inspiration cards for segment creation). These capabilities use advanced AI algorithms from Amazon Bedrock that help you improve customer satisfaction and drive revenue through proactive and personalized outreach. For example, you can create a segment of customers who reached out to customer support frequently last week with personalized service offers. You can also identify customers whose total spending increased and offer personalized discounts, fostering loyalty and also driving growth.

The following benefits are added by incorporating generative AI into the segmentation workflow:

- **Simplified segment creation**: Build complex customer segments using conversational language, making the process accessible to non-technical users and driving the efficiency.
- **Data-driven segment creation inspirations**: Receive AI-empowered segment inspirations based on trends in the customer data.
- **Enhanced personalization:** Easily identify and target specific customer groups for tailored communications and offers.

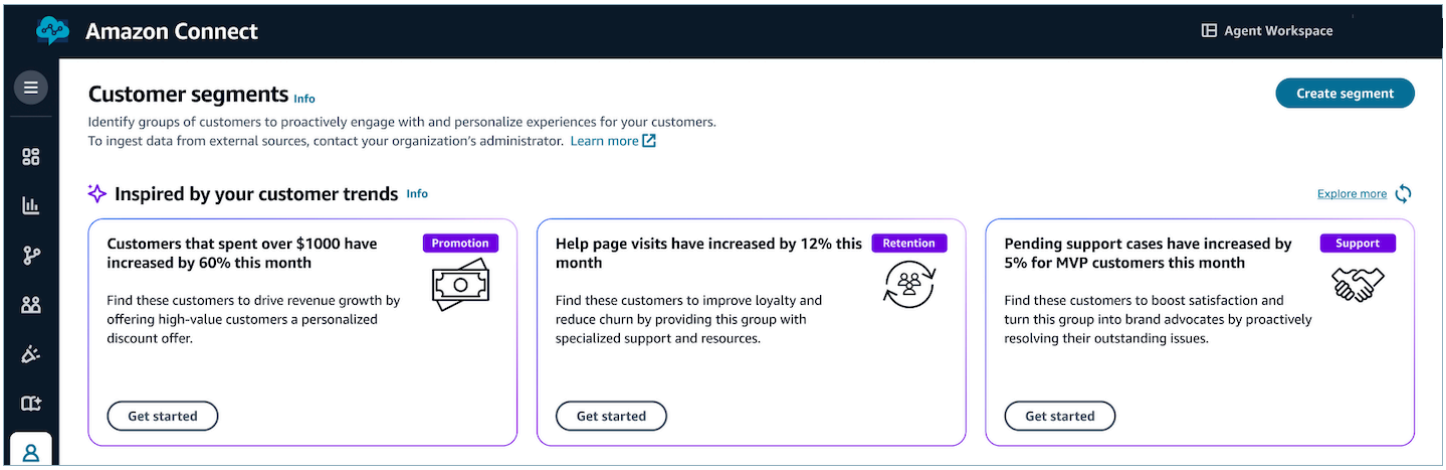
The following sections explain each feature, how to use them, and the benefits they provide to help you improve your customer segmentation efforts.

Note

- To use the segment AI assistant, users will need the permission for segment creation **CustomerProfiles.Segments.Create**.
- While these AI-powered tools offer valuable suggestions, it's important to review and adjust the recommended segments to make sure they align with the organization's specific business objectives and comply with its data usage policies.

Inspiration Cards for Segment Creation

Inspiration Cards are an AI-powered feature on the **Customer segments** page. They simplify and enhance the segment creation process. The following image shows an example of three inspiration cards.



These cards generate up to three categories of segment ideas each time, based on the Connect Customer Customer Profile data to inspire and streamline your segment creation process.

> **Note**
>
> The trend data is based on event ingestion dates of default calculated attributes.

Key features

- **Data-driven inspirations**: Each inspiration card presents a segment idea tailored to specific customer data and trends.
- Inspiration cards offer ideas across three business-focused themes:
  - **Promotion**: Ideas for targeting customers with specific promotional strategies.
  - **Retention**: Identify segments for customer retention efforts.
  - **Support**: Highlight customer groups that might need specialized attention for customer service.
- **Insight-based recommendations**: Use historical trends, data insights and generative AI to create meaningful, actionable insights.

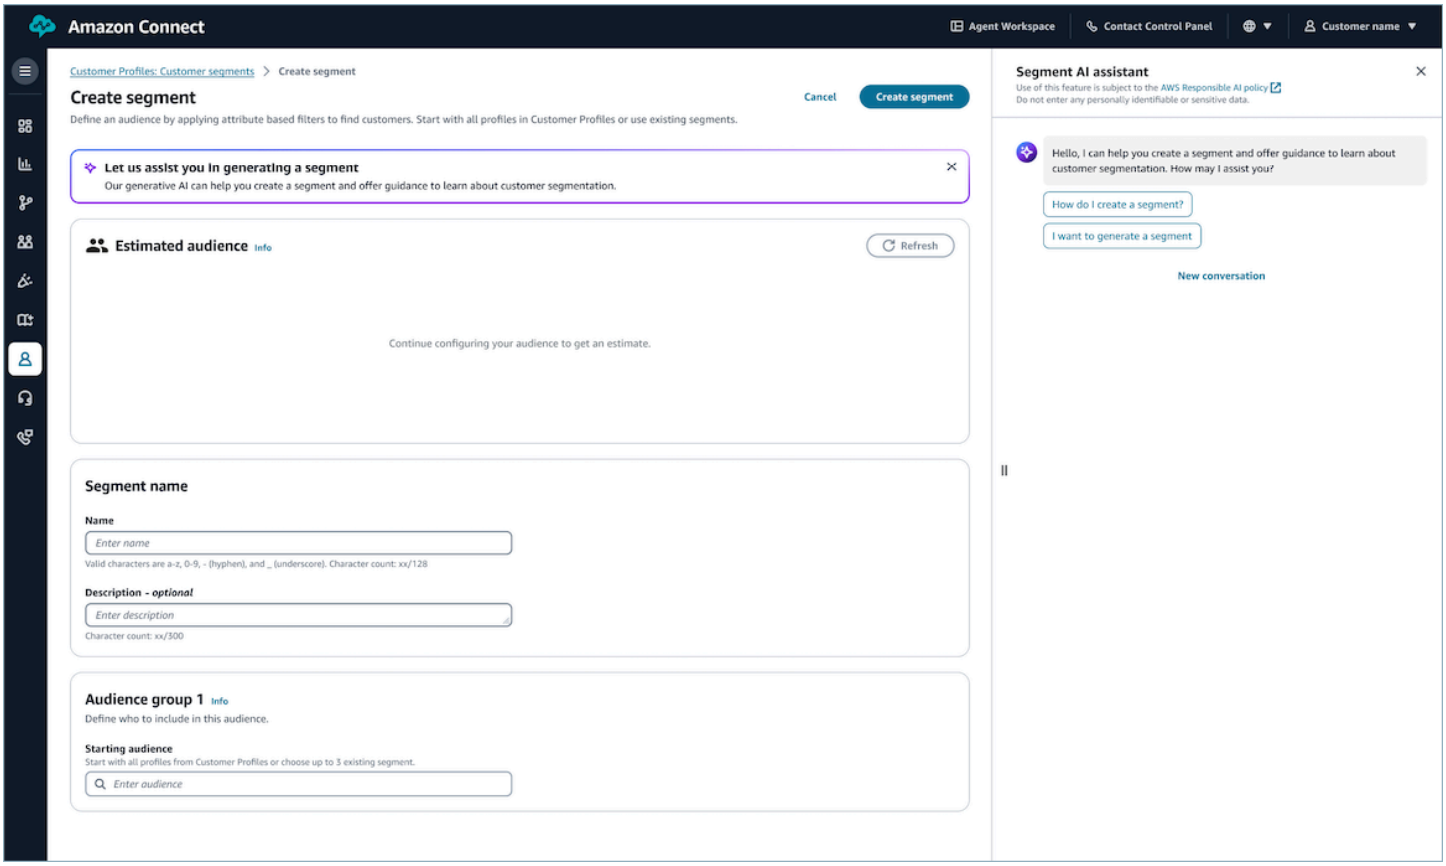
How to use inspiration cards

1. Navigate to the **Customer segments** page.
2. Locate the inspiration cards section. It displays three segment suggestions.
3. Review each card to understand the proposed segment and its potential applications.
4. When you find a card you want to use, choose **Get started** on that card.
5. Choose **Explore more** to generate additional inspiration cards. These can offer fresh segment ideas based on your Connect Customer Customer Profiles data.
6. When you choose **Get started**, you are automatically directed to the **Create Segment** page.
7. Your selected segment idea is populated in the segment builder, ready for your review and refinement.

Generate a segment by using natural language prompts

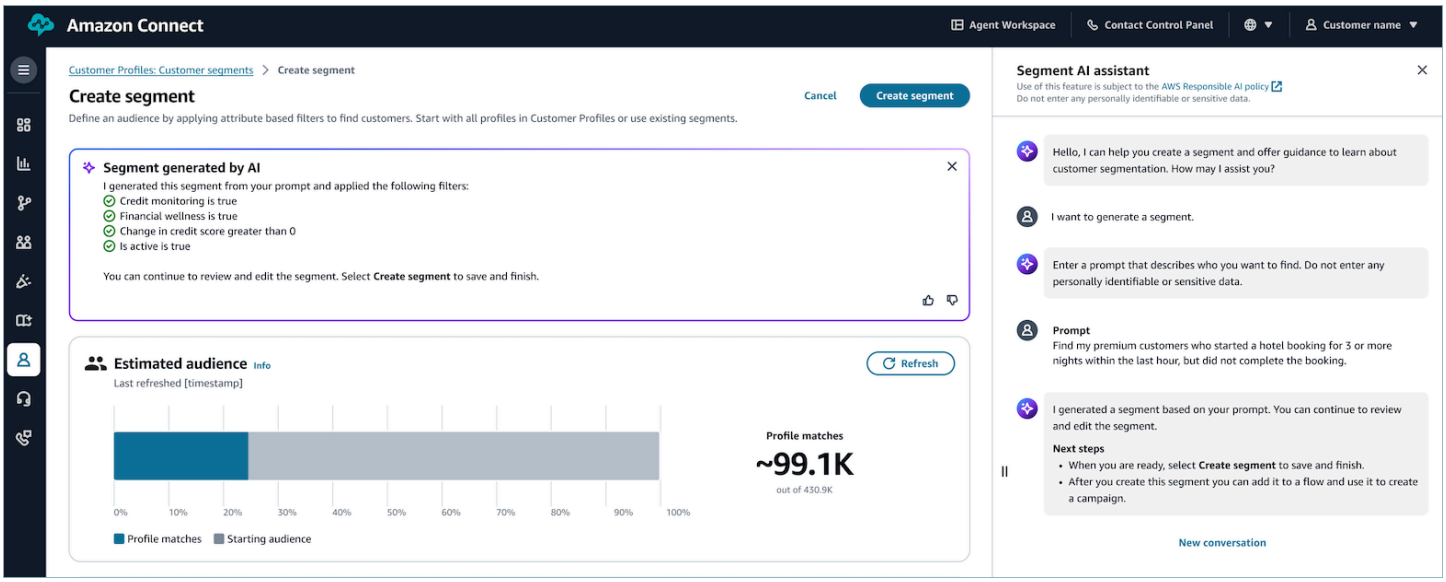
The segment AI assistant offers a guided approach to creating segments using natural language prompts, which simplifies the process of creating complex segments, allowing you to describe your target audience in natural language and receive a structured, actionable segment definition.

The following image shows an example of a segment AI assistant prompt.



To access this feature:

1. Navigate to the **Customer segment** page, and then choose **Create segment**.
2. Locate the segment AI assistant panel on the right side of the page, as shown in the following image.



Use the segment AI assistant

1. The assistant guides users through a series of questions to understand segmentation needs, all interaction paths with the assistant lead to generating a prompt.
2. Users can provide a textual description of the desired segment.
3. The prompt action step offers sample prompts as references for writing detailed descriptions.
4. Based on your input, Connect Customer generates a structured segment definition.
5. The generated segment definition is automatically applied to the segment builder.
6. You can further refine the generated segment using the standard segment builder tools. Modifying the filters on the segment builder overwrites the existing conditions previously generated.
7. After reviewing the generated segment and making any necessary adjustments, you can finalize the process by choosing **Create segment**. This action saves your segment and makes it available for use in your campaigns.

Best practices

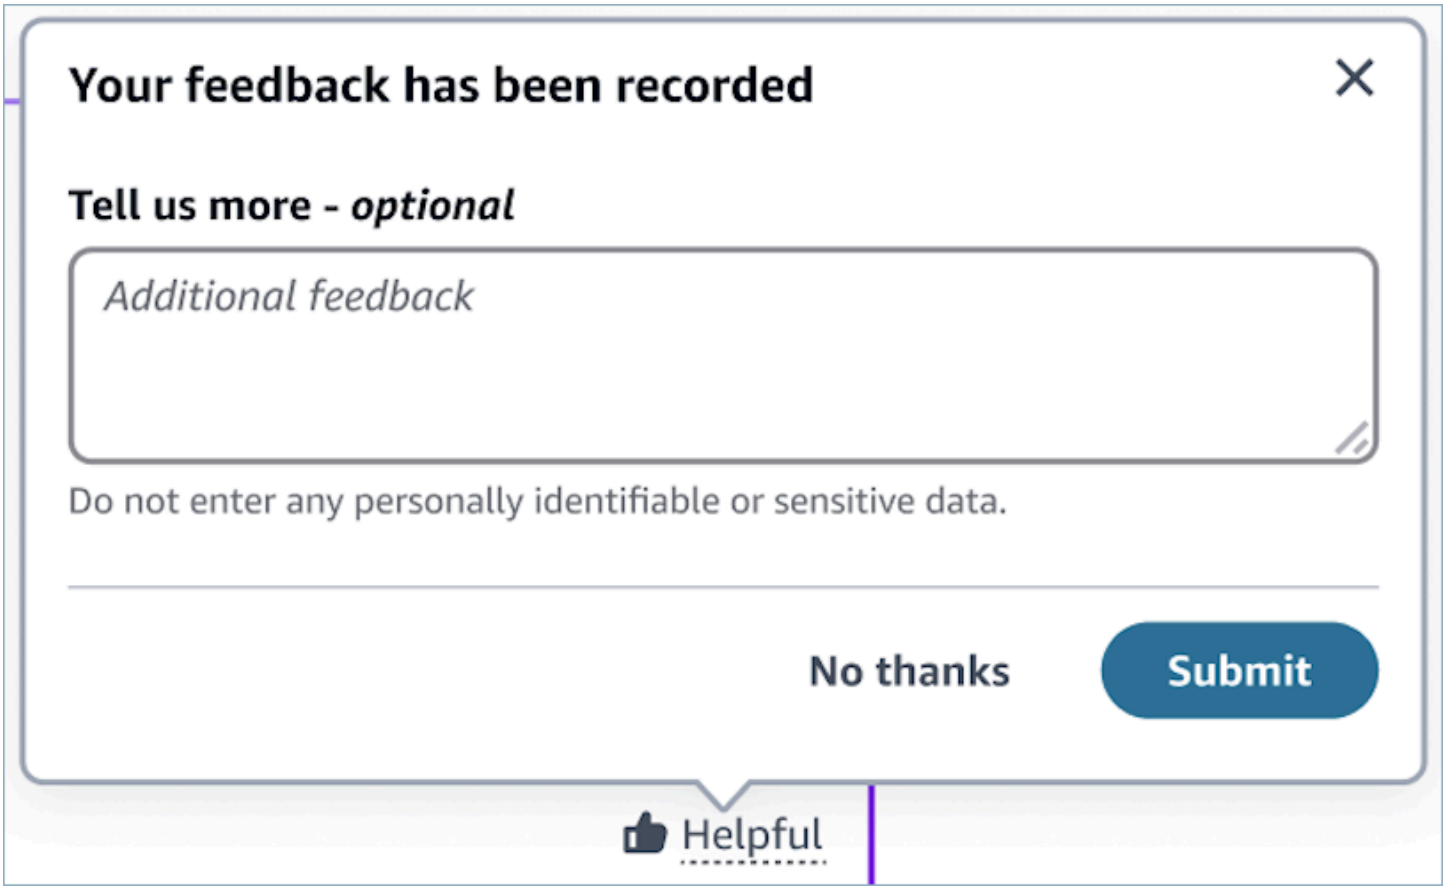
As you use the segment AI assistant, keep the following best practices in mind:

- Write specific descriptions. Segment AI assistant generates more accurate conditions when you use the names of existing attributes.
- Make sure that all attributes you reference exist in your domain.
- Start with simple prompts and try different prompts. If you don't receive what you want on the first try, rewrite your prompt. Submitting a new prompt replaces existing conditions, or by choosing **New conversation**.
- Allocate time for segment refinement and validation on the segment builder to ensure segments accurately reflect your actual data values.

> **Note**
>
> The segment AI assistant is designed to work with general descriptors and criteria. Always adhere to data protection regulations and company policies when describing segments. Make sure that your prompts and descriptions do not contain any sensitive or personal information.

Provide feedback on generated segments

After a segment is generated, users are encouraged to evaluate the feature's performance and provide feedback. This feedback mechanism helps improve the segment generation process and makes sure it meets business needs effectively. The following image shows a feedback page.



The feedback process consists of two stages:

1. **Initial reaction**: In the bottom right corner of the alert section, you'll find thumbs up and thumbs down icons. Choose on either of these to indicate your general satisfaction with the generated segment.
2. **Additional feedback**: After selecting either the thumbs up or thumbs down icon, you are presented with an option to provide more detailed feedback. This takes the form of a text input field where you can leave free-form comments.

We encourage you to use both the quick reaction (thumbs up/down) and the text input for a comprehensive evaluation, provide specific examples or use cases when applicable, focus on how the generated segment aligns with business objectives, and suggest improvements or additional features that would enhance the segment generation process.

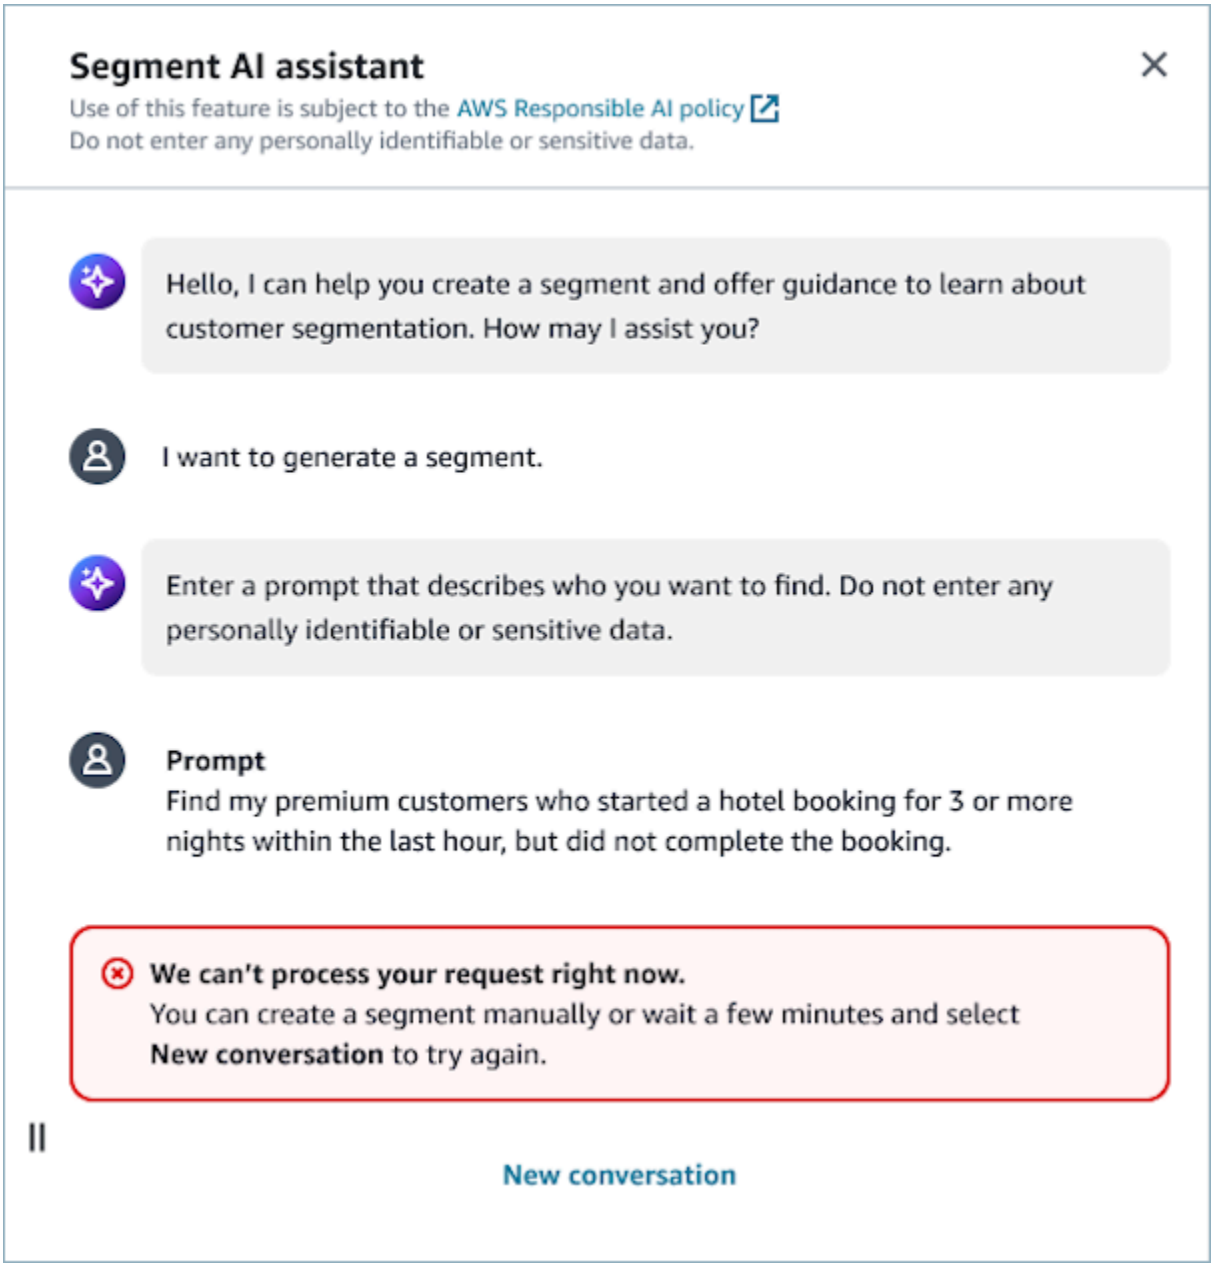
Suggest improvements or additional features that would enhance the segment generation process.

By actively participating in the feedback process, users contribute to the continuous improvement of the segment generation feature, ultimately leading to more effective customer segmentation and targeted marketing strategies.

Error handling

When using the segment AI assistant to generate customer segments, you might occasionally encounter an error message stating: **We can't process your request right now.** This error can occur even after providing a valid prompt for segment creation.

The following image shows an example of this error message.



Use the following steps help you understand and troubleshoot this error.

Possible causes:

- **High system load**: The segment AI assistant might be experiencing high demand or processing multiple requests simultaneously.
- **Temporary service disruption**: There could be a brief interruption in the service's ability to process new segment requests.
- **Complex query**: The system might need more time to process particularly complex or resource-intensive segment queries.

What to do:

- **Wait and retry**: The error message suggests waiting a few minutes before trying again. This allows time for the system to resolve any temporary issues.
- **Create a segment manually**: If you need the segment immediately, you can opt to create it manually using the segment builder

How to retry:

1. Wait for a few minutes.
2. Choose **New conversation** at the bottom of the chat interface.
3. Start a new conversation and re-enter your segment creation prompt.

Best practices

- If the error persists after multiple attempts, consider simplifying your segment criteria or breaking it down into smaller, more manageable requests.
- Try to avoid making repeated requests in quick succession, as this might contribute to system overload.
- If the issue continues, reach out to customer support for further assistance.

Remember, this error is typically temporary, and following the provided instructions, you can successfully create your desired segment.

Known limitations

Understanding the data processing lifecycle is crucial for effective use of the segment AI assistant. This section outlines what business users can expect during different phases of data integration and how it affects segment suggestions.

Data processing and quality impact: Segment AI assistant evolves through two main phases: initial data ingestion and post-processing. During initial ingestion, the system might not fully use actual attribute values, relying more on prompt interpretation. For example, a prompt for *VIP customers* might suggest a *VIP* segment instead of using the existing *Gold* tier from your data. After complete processing, the system uses actual attribute values, resulting in more accurate segment creation, reduces reliance on prompt interpretation and improves overall segmentation quality.

> **Note**
>
> Allow sufficient time for complete data processing before relying on advanced features. Regularly update customer profile data. Segment accuracy depends on the completeness and recency of customer data in Connect Customer Customer Profiles. The system flags any missing attributes in its responses.

System performance: During high-volume periods, expect potential delays in segment generation. The system is optimized for typical workloads, but businesses with extensive segmentation needs might need to adjust their processes accordingly.

Attribute availability: The quality of the generated segments is dependent on the customer data available in Connect Customer Customer Profiles. The more comprehensive and up-to-date the customer profile data, the more accurate the system can be in interpreting prompts and defining relevant segments. If there is an attribute that does not exist, we will return a message with the missing attribute.

Prompt complexity: For very complex or nuanced segment definitions, the natural language processing might have limitations. Customers should start with relatively straightforward prompts and gradually increase the complexity as they gain experience with the feature.

Segment refinement: Although the system-generated segments are a great starting point, customers might still want to review and refine the details to ensure the segment aligns perfectly with their business objectives. The segmentation interface allows for full customization after the initial generation.

Performance and scaling: Under high concurrency, there might be some latency in the segment generation process as the language model needs to process each prompt. The system is designed to handle typical segmentation workloads, but customers with extremely high segmentation demands might need to adjust their workflows accordingly

Troubleshooting customer segments in Connect Customer

The Customer segments option doesn't appear in the left navigation panel

If a **Customer segments** option does not exist in Connect Customer admin website left navigation panel, check if the user's security profiles has the **Customer segment - View** permission. For more information, see Assign security profile permissions to manage customer segments. After the permission is updated, refresh the Connect Customer admin website page to reflect the change.

Export CSV button not available, or export job timed out

Exporting a segment that contains more than 350,000 profiles is not supported in the Connect Customer admin website. Alternatively, we recommend exporting this type of segment to an Amazon S3 bucket using the `CreateSegmentSnapshot` API through the command line reference (CLI) or SDK.

Error: You reached the limit of 60 unique attributes

This error occurs when the number of unique attributes in the segment definition exceeds the quota. The number of unique attributes are counted including the starting audiences recursively.

Solutions

- Reduce the number of unique attributes by removing audience filters in the segment definition, or removing starting audiences that contains audience filters.
- Request a quota increase for the service quotas - Maximum number of unique attributes in segment

For more about default service quota, see Connect Customer Customer Profiles service quotas.

Error: You reached the limit of 10 unique calculated attributes

This error occurs when the number of unique calculated attributes in the segment definition exceeds the quota. The number of unique calculated attributes are counted including the starting audiences recursively.

Solutions

- Reduce the number of unique calculated attributes by removing audience filters on calculated attributes in the segment definition, or removing starting audiences that contains audience filters on calculated attributes.
- Request a quota increase for the service quotas - Maximum number of unique calculated attributes in segment.

For more about default service quota, see Connect Customer Customer Profiles service quotas.

Error: You reached the limit of 5 depth of starting audiences

This error occurs when the depth of starting audiences exceeds the quota. The depth is counted recursively for all of the starting audiences in your audience group. For example, if you select a segment "Eligible rental upgrade" as a starting audience, and the segment "Eligible rental upgrade" has another segment as a starting audience, the depth will be 2.

Solution

- Remove one or more starting audiences in your audience group that contains deeply nested starting audiences.

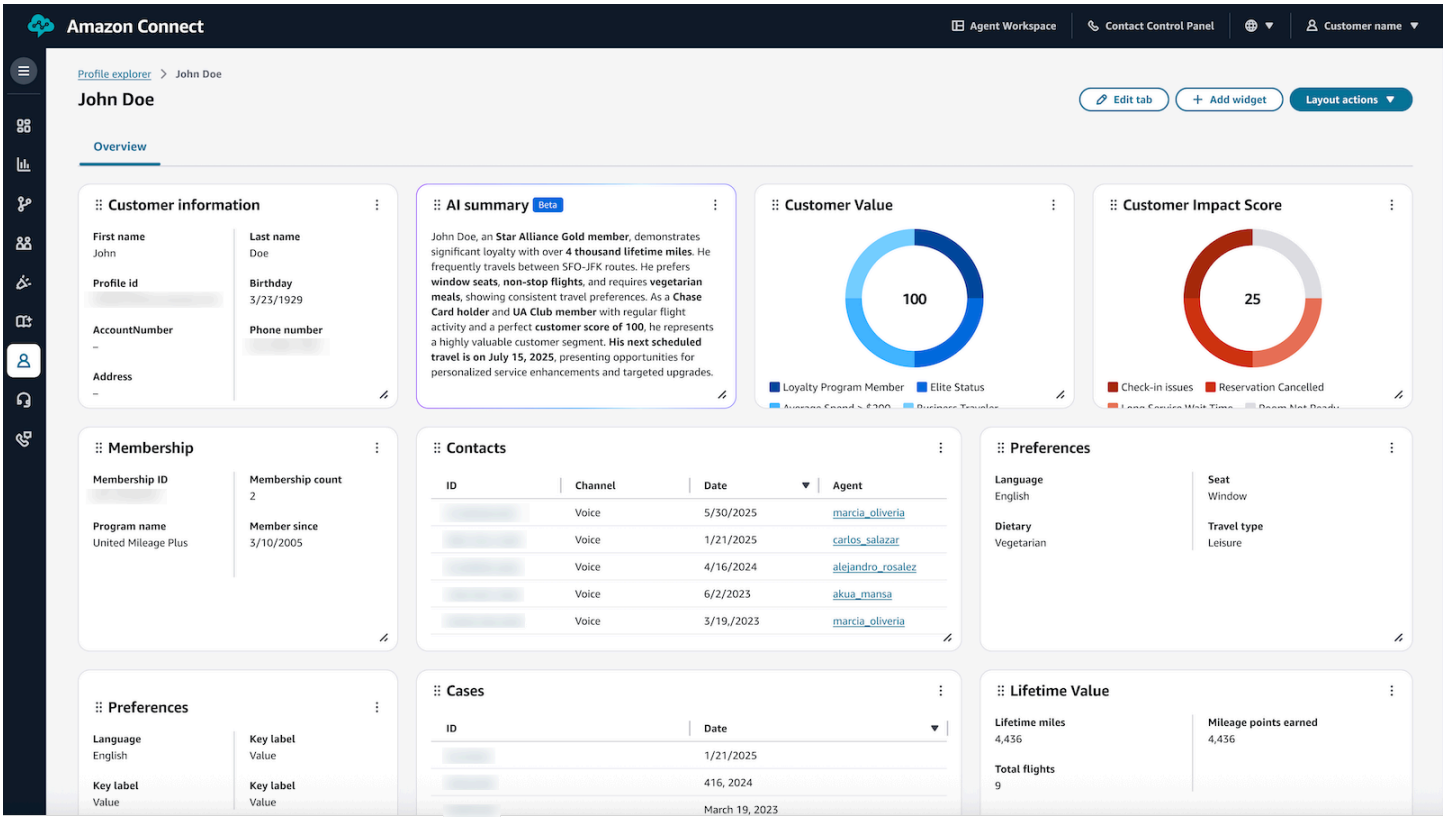
For more about default service quotas, see Connect Customer Customer Profiles service quotas.

Set up Profile Explorer in Customer Profiles

Profile Explorer is a dynamic, all-in-one dashboard that provides a comprehensive 360° view of your customers. It unifies fragmented customer data and allows organizations to customize data displays, track interactions, and transform customer information into actionable insights that drive business value and customer loyalty. Organizations in industries like travel and hospitality can use Profile Explorer to better understand and engage with their customers through this intuitive interface.

- **Find customers instantly** using multiple identifiers simultaneously (email, phone, booking reference) with real-time search results.
- **Customize views** to prioritize the most relevant information for specific business needs, design a domain-specific layout that highlights the most relevant customer data defined by you.

- **Access complete customer context** including demographic data, communication history, behavioral interactions, and segment membership with interactive visualizations and data displays.
- **Use AI-powered insights** with customer summaries highlighting key patterns, and personalized behavioral inferences.



Topics

- Enable Profile Explorer
- Get started with Profile Explorer
- Manage layouts
- Layout definition
- Show Profile Explorer in the agent workspace

Enable Profile Explorer

By following these steps, you can enable Profile Explorer for your administrators and users. This process involves setting up permissions for both layout configuration and viewing access.

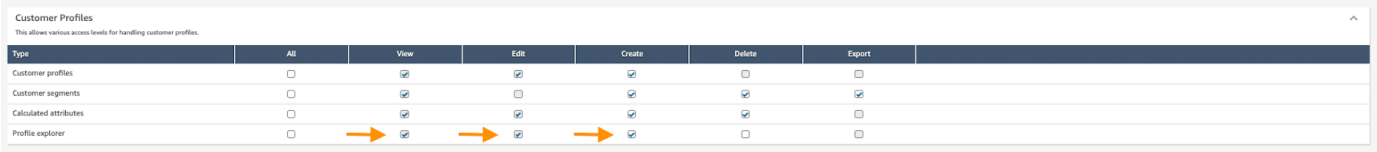
Topics

- Enable administrators to define a layout
- Enable users to view Profile Explorer
- Verify Setup

Enable administrators to define a layout

Administrators need specific permissions to create and edit Profile Explorer layouts:

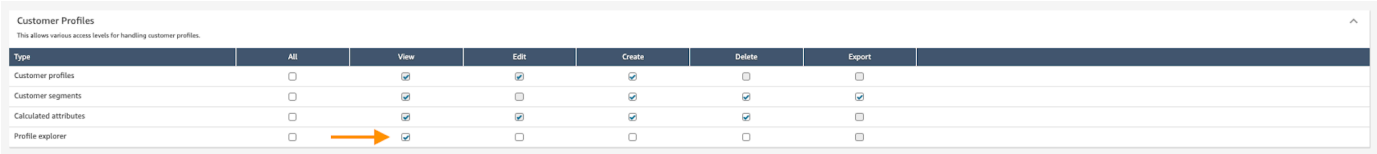
- Assign the following permissions within the Profile Explorer Security profile:
  - **Profile explorer - Edit**: Allows modification of existing Profile Explorer layout.
  - **Profile explorer - Create**: Enables creation of the Profile Explorer layout.
  - **Profile explorer - View**: Enables access to view configured Profile Explorer layout.



Enable users to view Profile Explorer

Users need appropriate permissions to access and interact with Profile Explorer layout:

- Assign the following permissions within the Profile Explorer Security profile:
  - **Profile explorer - View**: Enables access to view configured Profile Explorer layout.



Verify Setup

To confirm that Profile Explorer can be successfully enabled:

Log in as an administrator to verify you can:

- Access the Profile Explorer page.
- Create and modify your Profile Explorer layout.

Log in as a regular user to verify you can:

- Access Profile Explorer.
- View the Profile Explorer layout.
- Interact with enabled features.

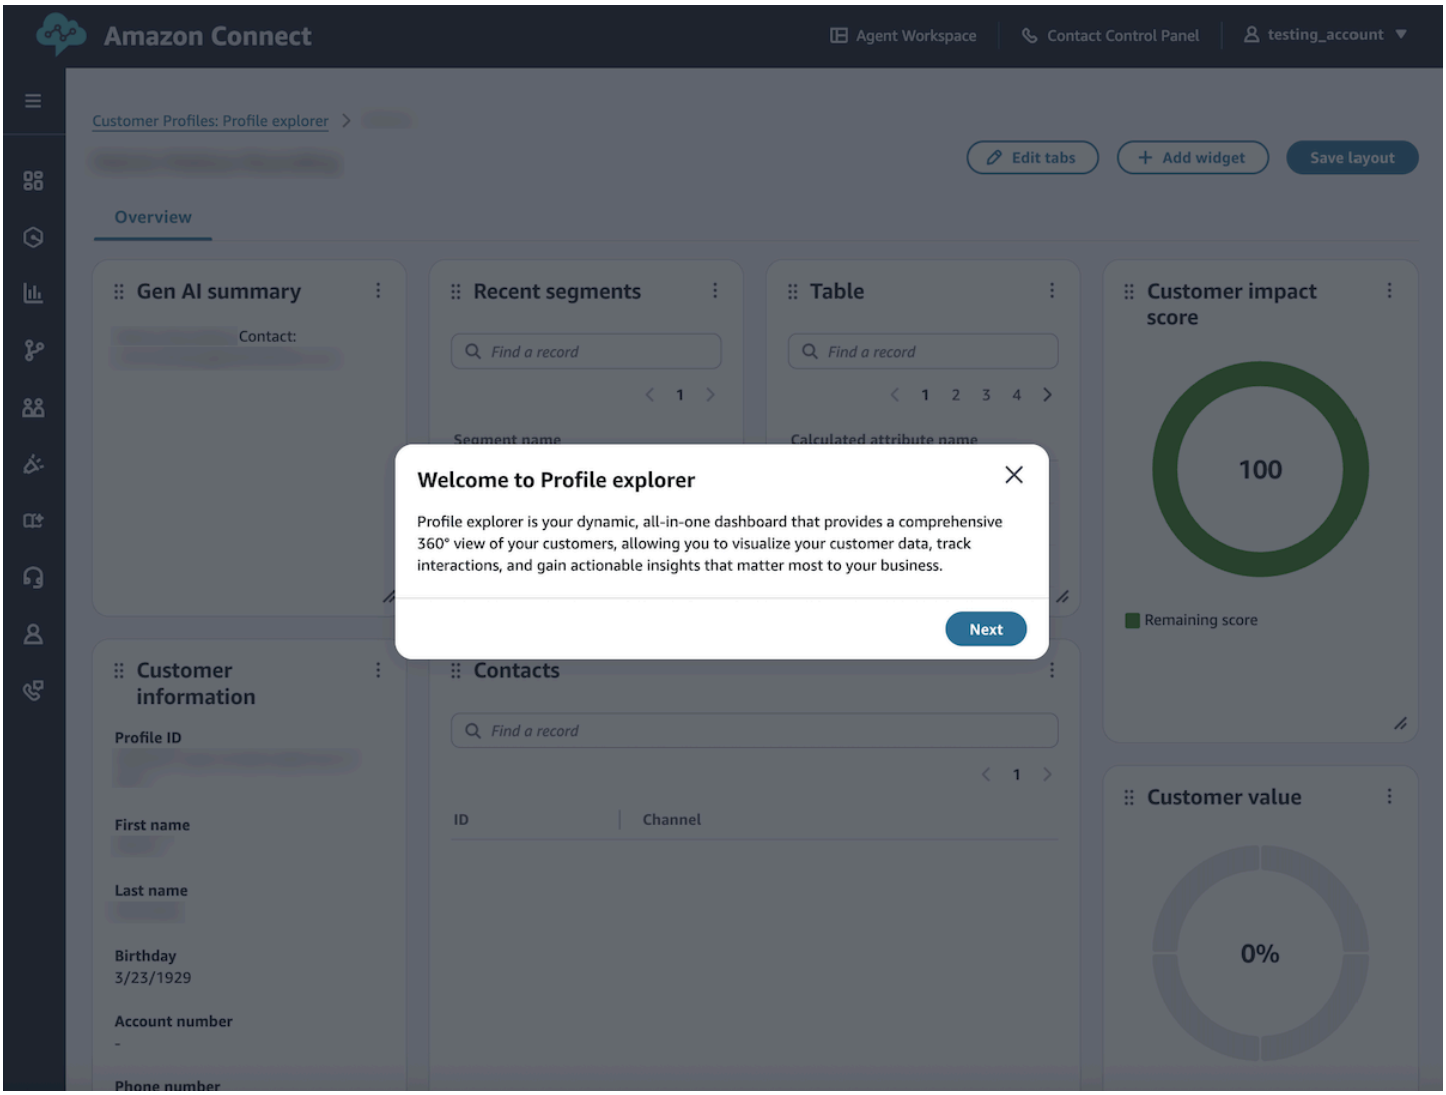
Get started with Profile Explorer

Get started with Profile Explorer and learn the basics of the interface.

Topics

- Layout controls
- Edit a layout
- Save a layout

Layout controls



Profile Explorer welcome console.

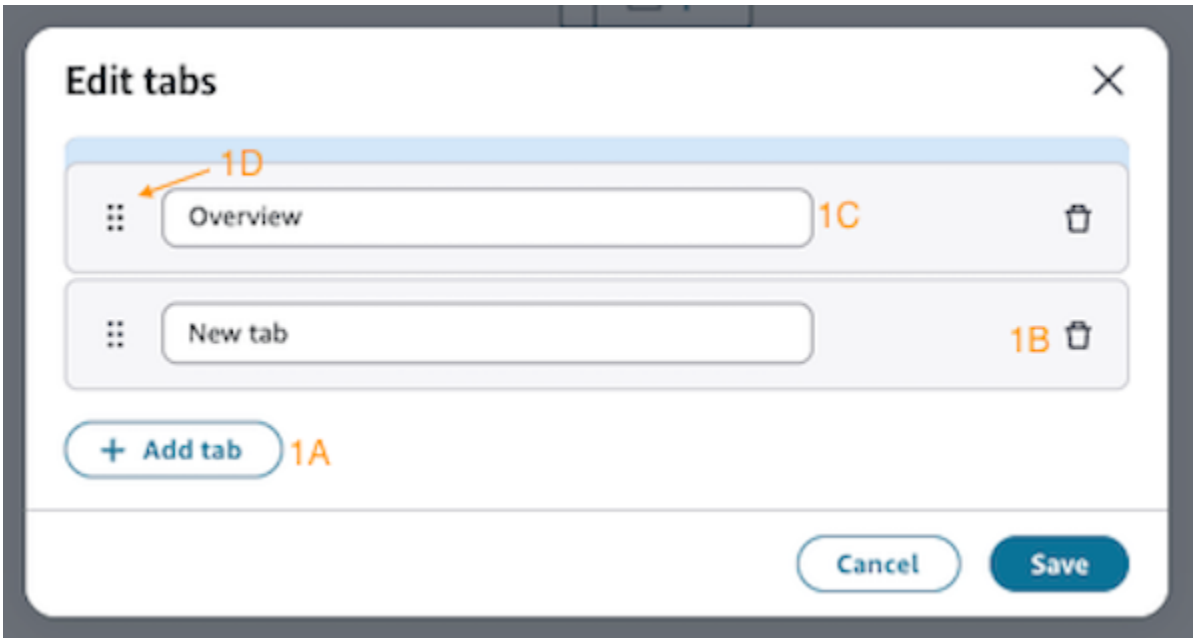
1. Edit Tabs
2. Add Widgets
3. Layout Actions

Edit Tabs

Organize your dashboard into logical sections using tab controls:

- **1a. Add Tab**: Create new tabs to separate different aspects of customer data
- **1b. Remove Tab**: Delete unnecessary tabs from your layout

- **1c. Rename Tab**: Customize tab names to reflect their content
- **1d. Reorder Tabs**: Drag and drop tabs to arrange them in your preferred order



Add widgets

Enhance your active tab with various data visualization widgets:

Available widgets

- Default widgets
  - Generative AI summary
  - Customer information
  - Calculated attribute
  - Contacts
  - Cases
  - Orders
  - Assets
- Custom widgets
  - Table
  - Key value pair
  - Key metric

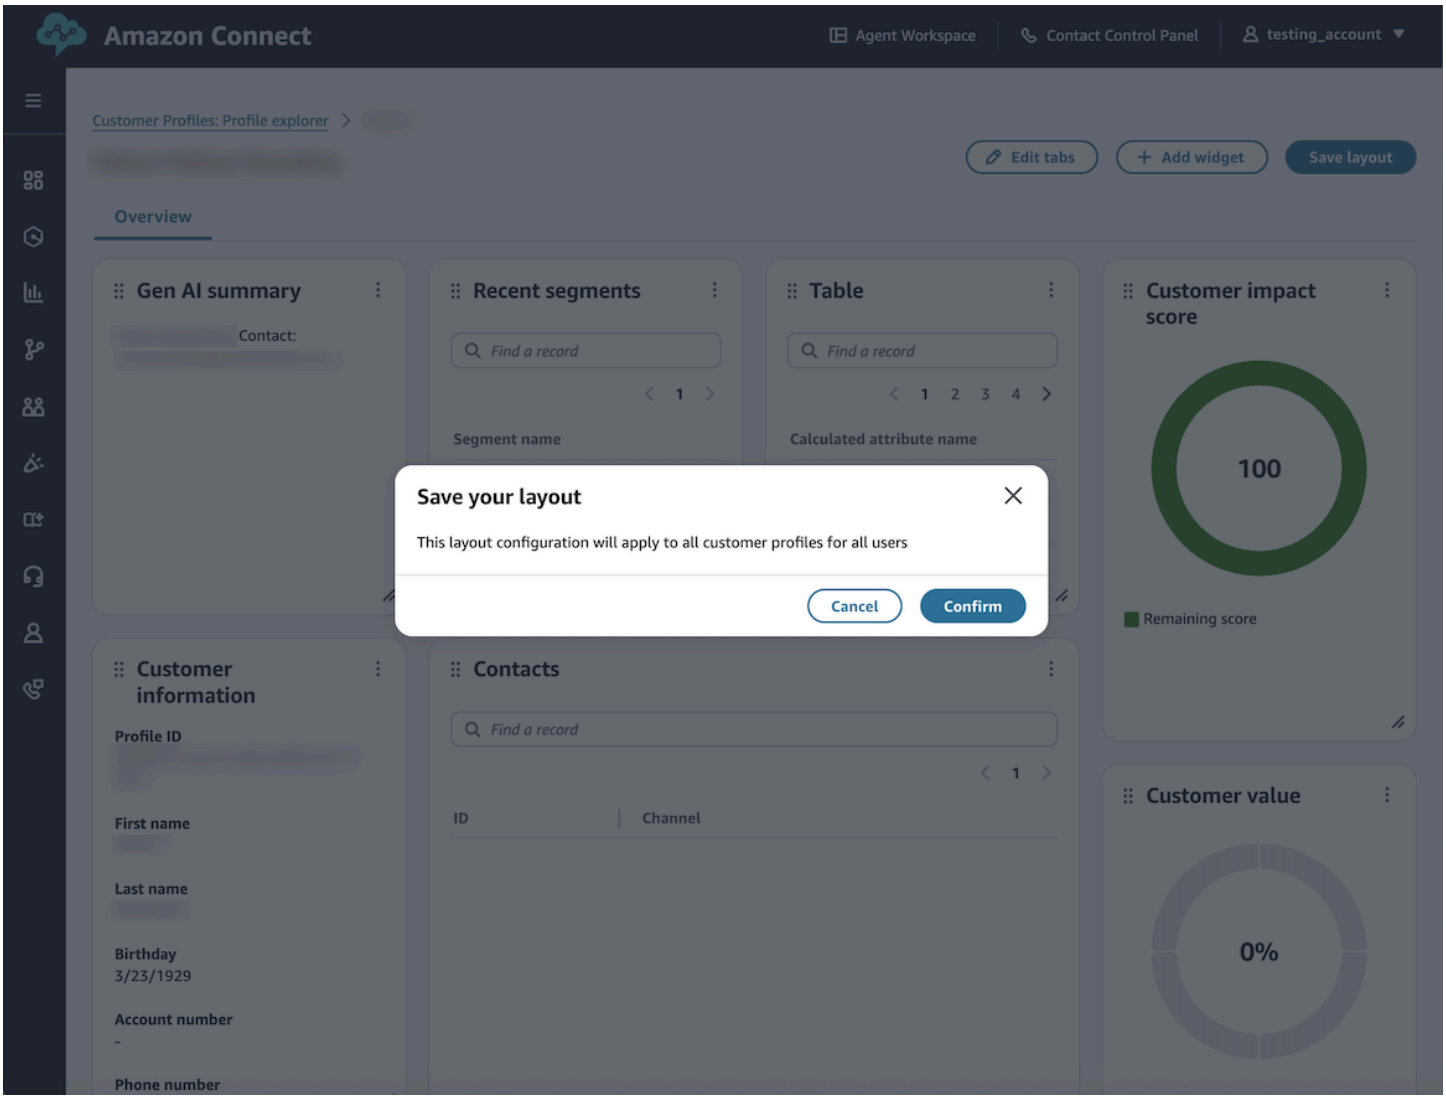
- Donut chart

Simply select a widget you would like to use, and begin exploring

Layout actions

Manage your overall dashboard configuration:

- **Save Layout**: Preserve your current dashboard configuration



> **Note**
>
> All changes are in a draft until saved.

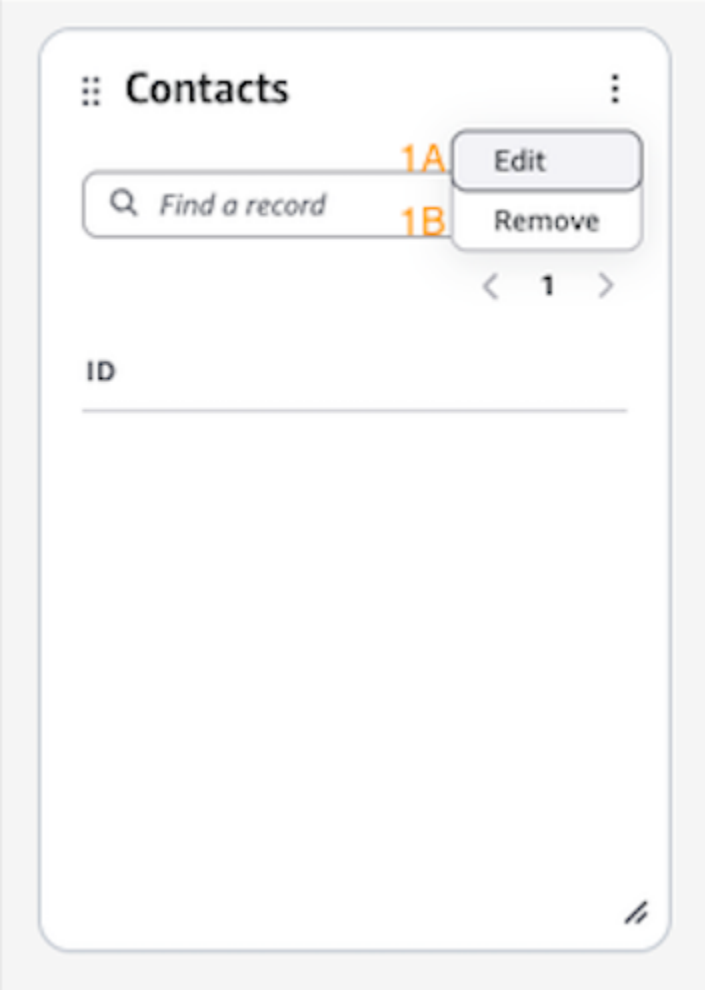
Edit a layout

Customize your Profile Explorer layout through simple, intuitive controls for managing widgets and their placement.

Widget controls

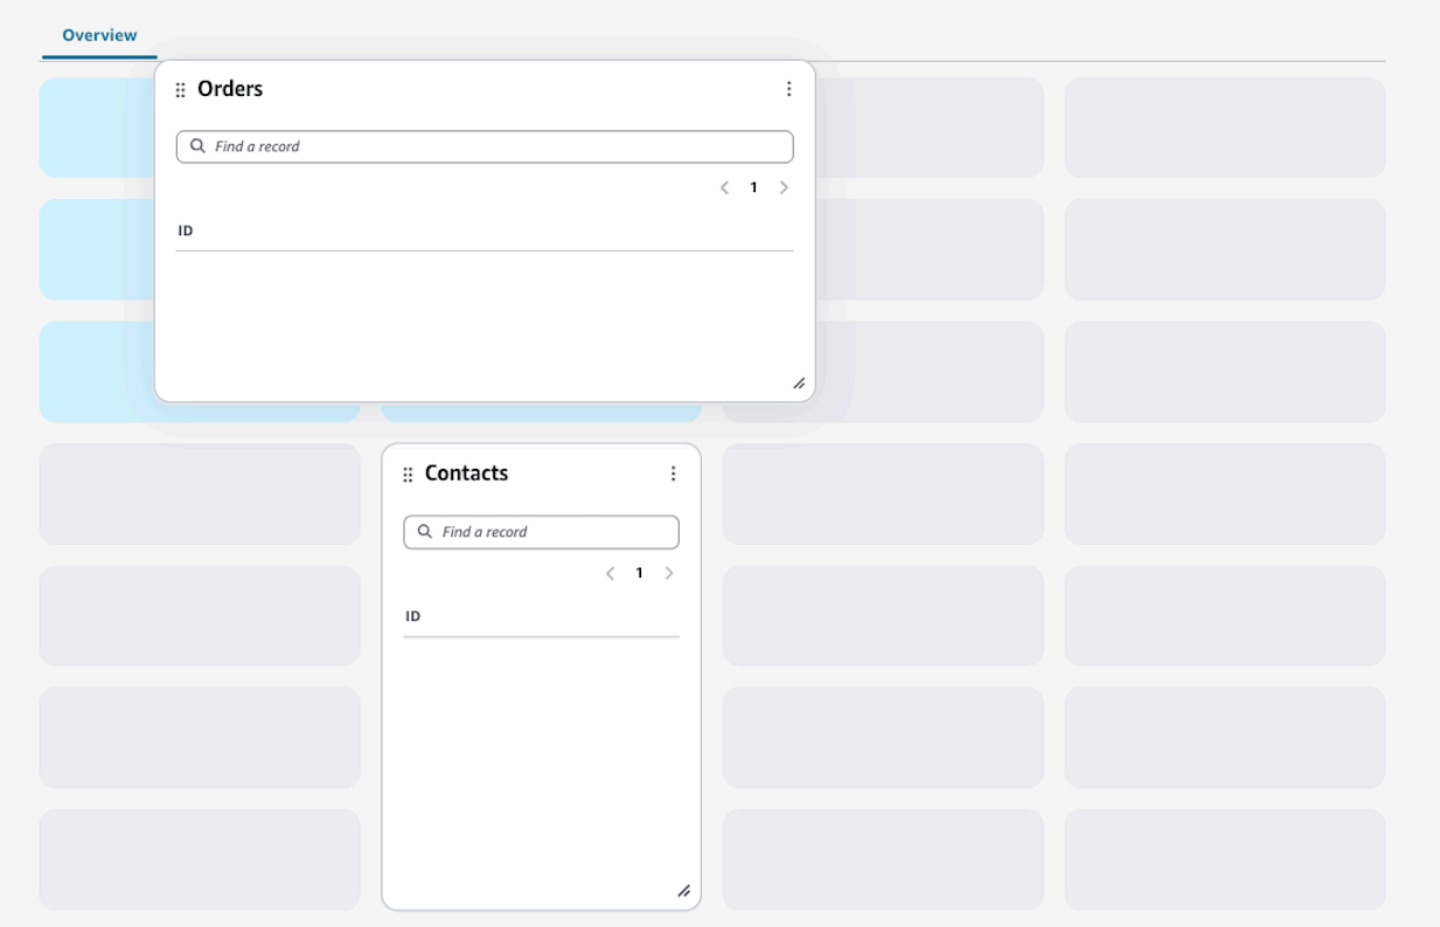
Each widget features a three-dot menu in the upper right corner, providing two primary options:

- **1A Edit**: Opens the configuration panel for that specific widget
- **1B Remove**: Deletes the widget from your layout



Widget customization

- **Drag & Drop**: Reposition widgets anywhere on your dashboard
- **Resize**: Chose and drag widget borders to adjust dimensions
- **Configuration**: Access detailed settings through the edit panel specific to each widget type



Note

Each widget type has unique configuration options. For detailed information about specific widget settings, refer to the widgets documentation.

Adding new widgets

To add new components to your layout, use the **Add Widgets** button in the control panel.

Save a layout

How to save and manage your Profile Explorer layout configurations.

Layout persistence

Changes made to your Profile Explorer layout must be saved to persist. Unsaved changes will be lost when navigating away from the page or refreshing your browser.

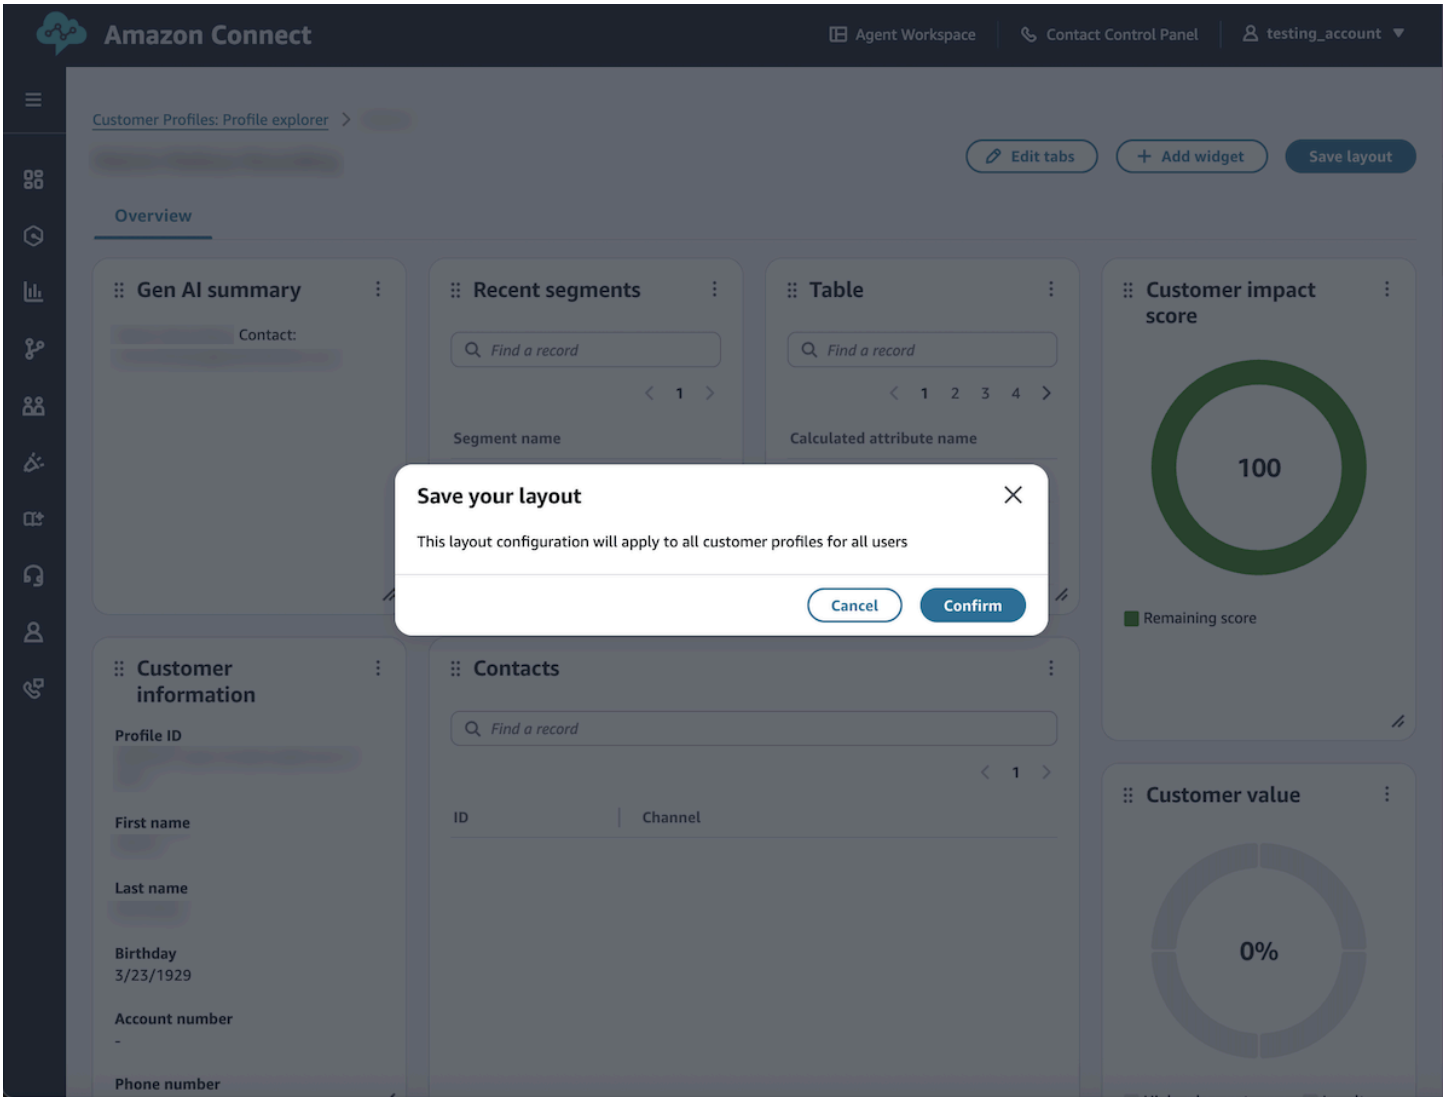
Default layout

Each Profile Explorer implementation includes one default layout. This serves as the base configuration for your organization and can be modified as needed.

Save changes

To save layout modifications:

1. Choose **Save** in the Layout Actions menu.
2. Confirm your changes in the save dialog.
3. The layout will update for all users upon save completion.



> **Note**
>
> The appropriate permissions are needed to save layout changes. For information about required permissions, see Enable Profile Explorer.

Manage layouts

Manage layouts lets administrators maintain multiple Profile Explorer layouts for a domain, choose which layout is shown to users by default, and create new layouts without disrupting the layout your users currently see. This is useful if you want to build and test a new layout before rolling it out, or if you want to keep multiple layouts on hand for different use cases.

Topics

- Default layout behavior
- Access Manage layouts
- Create a layout
- Security profiles needed to manage layouts

Default layout behavior

Each Connect Customer Customer Profiles domain has a single default Profile Explorer layout. This is the layout that all users with view access see when they open Profile Explorer for a customer profile. Only one layout can be the default at a time—setting a new layout as default automatically removes default status from the previous one.

When you open Profile Explorer, the board is read-only. To make changes, choose **Manage layouts** to create a new layout or edit an existing one. This keeps the layout your users see stable while you build and test changes.

If your domain doesn't have a default layout yet, Profile Explorer displays a system-provided starter layout until an administrator creates and sets a default. The first layout you save with **Set as default layout** selected becomes the default for your domain.

Access Manage layouts

Administrators with the required permissions (see Security profiles needed to manage layouts) can open the layouts list from the Profile Explorer landing page.

1. In Profile Explorer, choose **Manage layouts**.
2. The **Profile layouts** page lists every layout saved for your domain, including the layout name, whether it's the default layout, and when it was created.

Create a layout

Create additional layouts to design new dashboard configurations without affecting the layout currently shown to your users.

1. On the **Profile layouts** page, choose **Create layout**.
2. Use the layout editor to name your layout, add and arrange widgets, and organize tabs. For more information about editing a layout, see Get started with Profile Explorer.
3. When you're ready to save, choose **Save layout**.
4. In the **Save your layout** dialog, optionally select **Set as default layout** to immediately make this the layout your users see. Leave this option cleared to save the layout without changing your domain's current default.
5. Choose **Save**.

> **Note**
>
> You can leave the layout editor at any time by choosing **Cancel**. If you have unsaved changes, you're asked to confirm before your changes are discarded.

Set a layout as default

You don't have to set a layout as default when you create it. You can promote any saved layout to be the default at a later time.

1. On the **Profile layouts** page, select the layout you want to make the default.
2. Choose **Make default**.

> **Note**
>
> **Make default** is disabled if no layout is selected, or if the selected layout is already the default.

Delete a layout

Remove layouts that you no longer need from the **Profile layouts** page.

1. On the **Profile layouts** page, select the layout you want to remove.
2. Choose **Delete**.
3. Confirm the deletion. This action can't be undone.

Security profiles needed to manage layouts

Access to Manage layouts is controlled by the same Profile Explorer permissions described in Enable Profile Explorer. The following permissions determine what a user can do:

- **Profile explorer - View**: Required to open Profile Explorer and view the currently active default layout.
- **Profile explorer - Edit**: Required to see and open the **Manage layouts** button, access the **Profile layouts** page, and use the **Delete** and **Make default** actions on that page. This permission is also required, along with **Profile explorer - Create**, to see the layout editor toolbar (**Edit tabs**, **Add widget**, and **Save layout**).
- **Profile explorer - Create**: Required to see and choose the **Create layout** button on the **Profile layouts** page.

> **Note**
>
> There's no separate permission for deleting a layout or setting a layout as default—both actions are controlled by **Profile explorer - Edit**.

For instructions on assigning these permissions, see Enable administrators to define a layout.

Layout definition

Understanding the structure and components of Profile Explorer layouts.

Topics

- How it works
- Widgets

How it works

Profile Explorer offers various widgets to display customer information, layouts are stored as JSON definitions, representing the complete structure and configuration of your dashboard. Each widget and component in your visual layout corresponds to a specific JSON block within this definition.

Core components

Every component in the layout definition is comprised of five common elements:

- **Type**
  - Defines the component category
  - Determines how the component renders
  - Examples: BoardItem, Table, KeyValuePair
- **Id**
  - Unique identifier for each component
  - Used for component tracking and updates
  - Generated automatically when components are created in the builder
- **Props**
  - Component-specific properties
  - Controls appearance and behavior
  - Contains configuration settings
- **Children**
  - Nested components or content
  - Defines hierarchical relationships
  - Can contain multiple sub-components

- **DataSource**
  - Specifies data origin
  - Defines data retrieval parameters
  - Controls data binding for components

Example layout component definition

The following is a sample JSON structure for a dashboard table component:

```
{
    "Id": "unique-identifier",
    "Type": "BoardItem",
    "Props": {},
    "Children": [
        {
            "Id": "unique-identifier",
            "Type": "Table",
            "Props": {},
            "Children": [
                {
                    "Id": "unique-identifier",
                    "Type": "TextContent",
                    "Props": {},
                    "Children": ["string"]
                }
            ]
        }
    ],
    "DataSource": [
        {
            "Type": "source-type",
            "Params": {}
        }
    ]
}
```

Dynamic data configuration

Profile Explorer uses template expressions to access and display Customer Profiles data dynamically within your components.

Single value support

For components like Key Value Pairs and Key Metrics, you can access:

Standard profile information

```
{{Customer.<StandardProfileInfo>}}
```

Example usage:

- {{Customer.FirstName}}
- {{Customer.LastName}}
- {{Customer.PhoneNumber}}

Calculated Attributes

```
{{Customer.CalculatedAttributes.<attributeDefinitionName>}}
```

Example usage:

- {{Customer.CalculatedAttributes._cases_count}}
- {{Customer.CalculatedAttributes._new_customer}}

Tabular data support syntax

Calculated Attributes

```
{{Customer.CalculatedAttributes.DisplayName}}
```

```
{{Customer.CalculatedAttributes.CalculatedAttributeDefinitionName}}
```

Segments

```
{{Customer.CalculatedAttributes.DisplayName}}
```

```
{{Customer.CalculatedAttributes.SegmentDefinitionName}}
```

Profile objects

```
{{Customer.ObjectAttributes.<objectTypeName>.<fieldName>}}
```

Example usage:

- {{Customer.ObjectAttributes.CTR.contactId}}
- {{Customer.ObjectAttributes.Order.orderId}}

Implementation examples

Single value component

```
{
    "Type": "KeyValuePair",
    "Props": {
        "Items": [
            {
                "Label": {
                    "Content": {
                        "Type": "TextContent",
                        "Children": ["Customer Name"]
                    }
                },
                "Value": {
                    "Content": {
                        "Type": "TextContent",
                        "Children": ["{{Customer.FirstName}}"]
                    }
                }
            }
        ]
    }
}
```

Tabular component

```
{
    "Type": "Table",
    "Props": {
        "ColumnDefinitions": [
```

```
            {
                "Cell": {
                    "Content": {
                        "Type": "TextContent",
                        "Children": ["{{Customer.ObjectAttributes.CTR.contactId}}"]
                    }
                },
                "Header": "Contact ID"
            }
        ]
    }
}
```

> **Note**
>
> Make sure that the attributes, objects, and segments you reference exist in your Customer Profiles configuration before using them in your layout.

Widgets

Explore the different widget types available in Profile Explorer.

Overview

Widgets in Profile Explorer are composite elements built from JSON components within your layout definition. While these widgets represent complex JSON structures, our UI builder handles the technical composition automatically, making dashboard management straightforward and accessible.

Topics

- Available widgets
- Default widgets
- Custom widgets

Available widgets

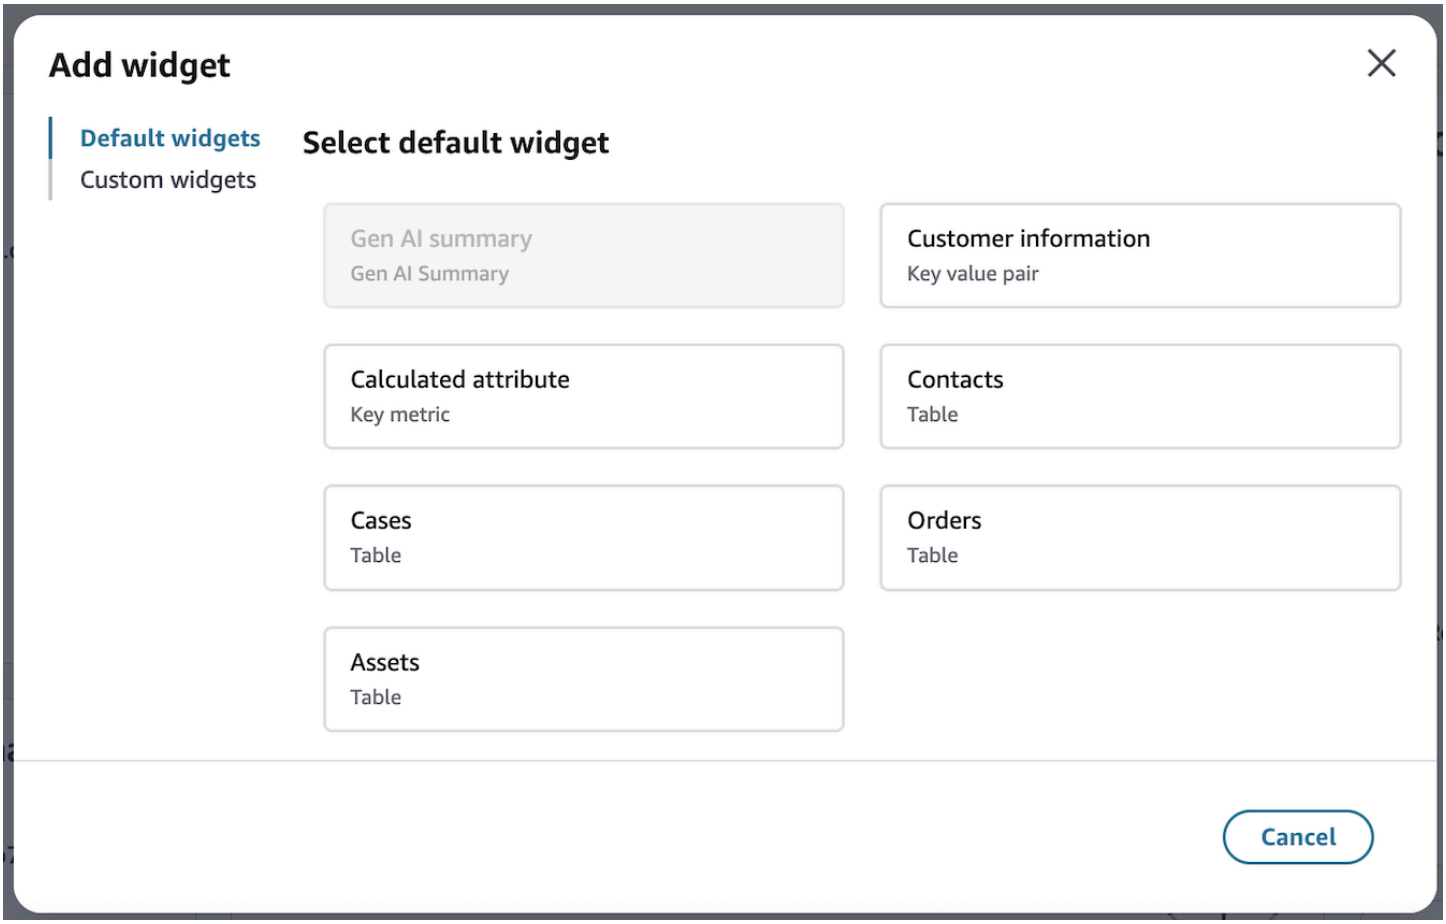
- Default widgets
  - Generative AI summary

- Customer information
- Calculated attribute
- Contacts
- Cases
- Orders
- Assets

- Custom widgets
  - Table
  - Key value pair
  - Key metric
  - Donut chart

Default widgets

Profile Explorer comes with a collection of pre-configured widgets designed to work seamlessly with Customer Profiles data. These default widgets offer immediate value with minimal setup, allowing you to build sophisticated dashboards in a few clicks.



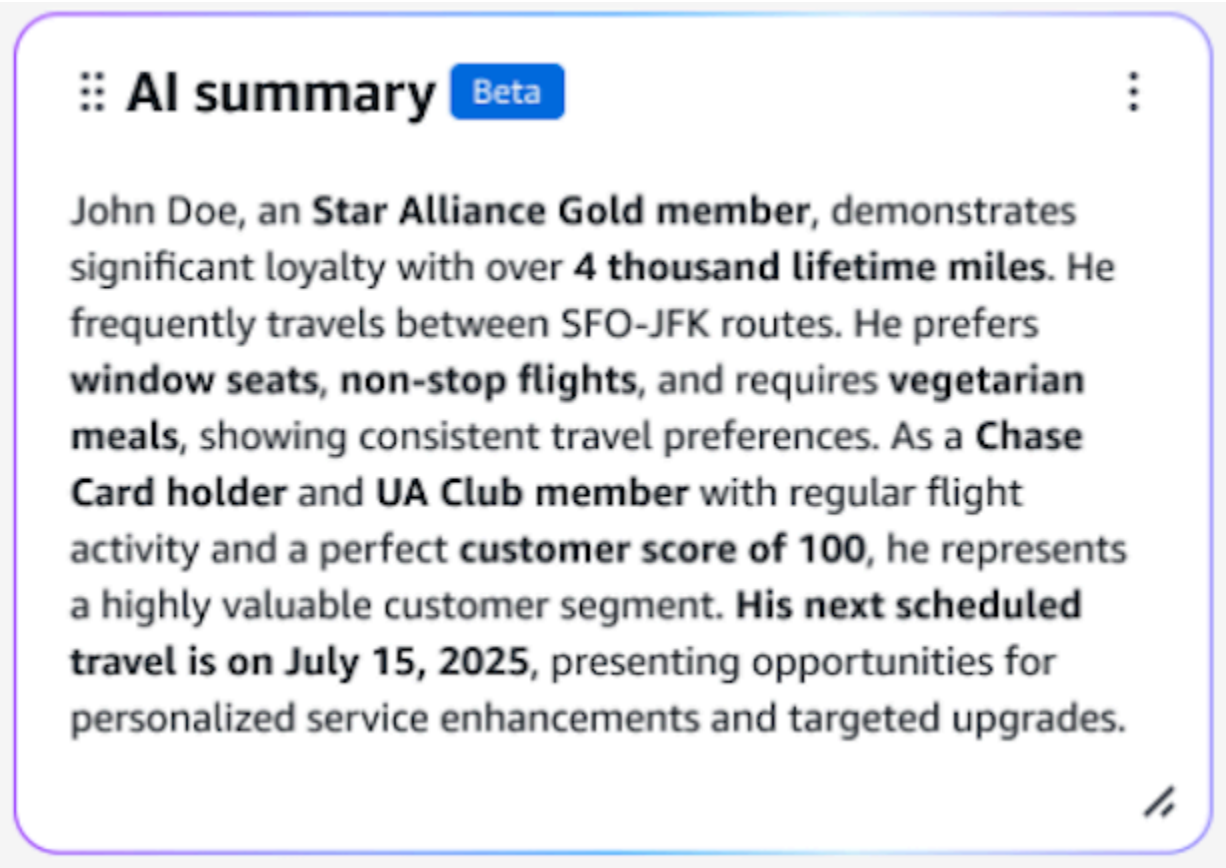
Ready-to-use widgets

- Generative AI summary
- Customer information
- Calculated attribute
- Contacts
- Cases
- Orders
- Assets

> **Note**
>
> While these widgets come pre-configured, you can still customize them to better match your specific needs. They serve as a starting point to allow for easy onboarding.

Generative AI summary

Profile Explorer delivers default AI-powered customer insights that generate concise summaries highlighting key behavioral patterns, provides personalized customer insights based on interaction history and surface actionable recommendations from customer 360 data. The AI-generated summaries help organizations make data-driven decisions by identifying patterns across multiple customer touchpoints, delivering personalized behavioral insights specific to each customer and supporting improved customer experiences and increased loyalty.



Customer information

The Customer Information widget provides a clear, organized view of standard Customer Profile data using key-value pair components. This default widget automatically displays essential customer information in an easily scannable format.

Overview

This widget uses the key value pair component to display customer attributes in a structured layout.

- First name

- Last name
- Email Address
- Phone Number
- Address
- Account number
- Profile ID

Data

The widget automatically connects to your Customer Profiles domain and pulls information from standard profile attributes. No additional configuration is required for basic functionality.

Note: While this widget comes pre-configured with standard profile attributes, you can customize which attributes from the standard Profile are displayed based on your specific needs.

Learn more

- Standard Profile Definition
- Key value pair

Calculated attribute

With the Calculated Attribute widget, you can display a key metrics component using data from your customer profiles' calculated attributes.

Overview

With the Calculated Attribute widget, you can display a key metrics component using data from your customer profiles' calculated attributes.

Component Features

- Display calculated metrics as single value indicators

Example use cases could be

- Campaigns delivered

- Cases opened
- Average call time
- Channel Preference

Configuration

Simply select your calculated attribute and choose your preferred display format

> **Note**
>
> Calculated attributes must be configured in your Customer Profiles domain before they can be used in this widget.

Learn more

- Key metric
- Set up calculated attributes

Contacts

Built using the Table JSON component, the Contacts widget displays your Customer Profiles contact object data in an organized, tabular format. This widget automatically connects to the Customer Profiles CTR data, showing key contact information and interaction history.

Features

- View all customer contact events
- Sort and filter contact records
- Customize displayed contact fields
- Access detailed contact information

For more information about Customer Profiles CTR objects, see Contact record templates in Connect Customer Customer Profiles

Cases

Built using the Table JSON component, the Cases widget displays your Customer Profiles case object data in an organized, tabular format. This widget automatically connects to the Customer Profiles Case data, showing support interactions and case management details.

Features

- View all customer cases
- Sort and filter case records
- Customize displayed case fields
- Access detailed case information

For more information about Customer Profiles Case objects, see Object type mapping for the standard case in Customer Profiles.

Orders

Built using the Table JSON component, the Orders widget displays your Customer Profiles order object data in an organized, tabular format. This widget automatically connects to the Customer Profiles Order data, showing purchase history and transaction details.

Features

- View all customer order events
- Sort and filter order records
- Customize displayed order fields
- Access detailed order information

For more information about Customer Profiles Order objects, see Object type mapping for the standard order in Connect Customer Customer Profiles

Assets

Built using the Table JSON component, the Assets widget displays your Customer Profiles asset object data in an organized, tabular format. This widget automatically connects to the Customer Profiles Asset data, showing customer-owned products and services.

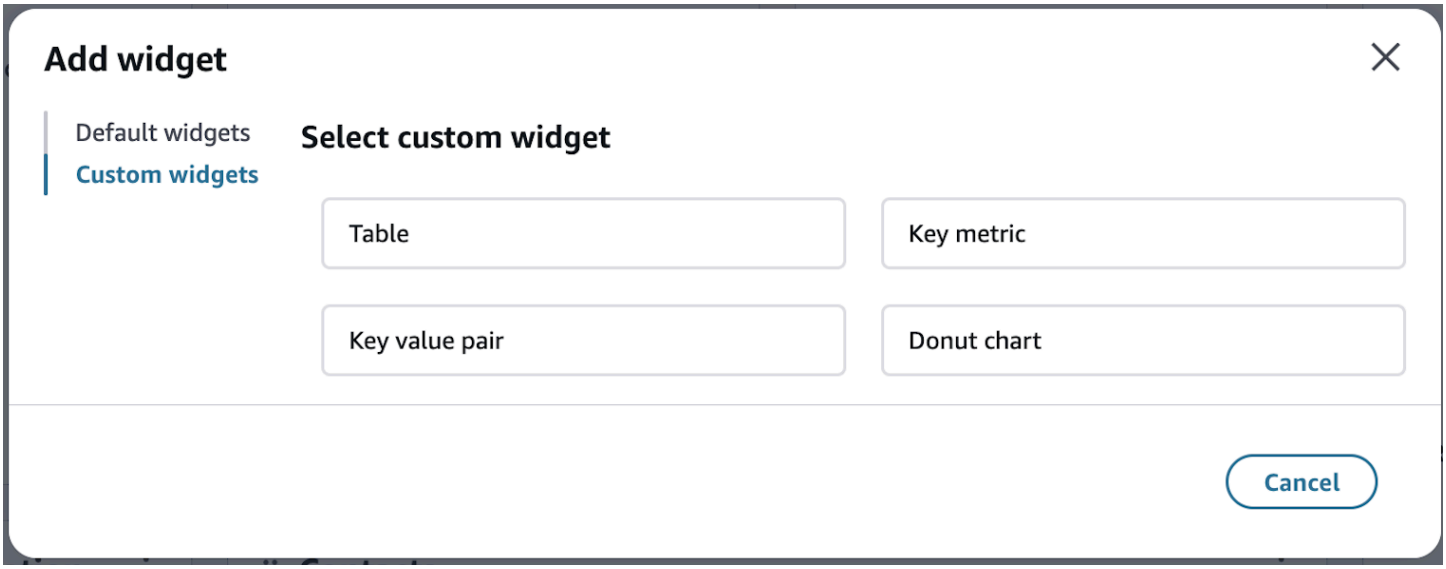
Features

- View all customer asset records
- Sort and filter asset data
- Customize displayed asset fields
- Access detailed asset information

For more information about Customer Profiles Asset objects, see Object type mapping for the standard asset in Customer Profiles

Custom widgets

Create tailored dashboard components from the ground up to meet your specific business needs. With custom widgets, you can build unique visualizations without any predefined data.



Available custom components

- Table
- Key value pair
- Key metric
- Donut chart

Building custom widgets

Each custom widget can be configured with:

- Custom data sources
- Custom displays
- Custom fields
- Custom item interactions

Table

The custom table component provides flexible configuration options for displaying your data in a tabular format, with advanced features for interaction and organization.

Features

1. **Column configurations**
   - Define custom column headers
   - Specify data for each column
   - Set data formatting options
   - Define column placement
2. **Filtering**
   - Quickly filter items within your table
3. **Linking**
   - Connect Resource Links
     - Seamless navigation to:
       - Segments
       - Calculated attributes
     - Opens in new tab
   - **External URL links**
     - Convert row item value into URLs that you can choose
     - Opens in new tab
     - Dynamically generate links based on row data
   - Drawer view links
     - Open detailed information in side drawer
     - View complete record details without leaving the page
4. Data organization

- Grouping
  - Group rows by specific field names
  - Persistent group settings
- Sorting
  - Sort by any column field
  - Ascending order organization
  - Persistent sort settings

            {
                "Header": "Table column header"
                "Cell": {
                    "Content": {
                        "Props": {
                            "Variant": "Link",
                            "LinkOptions": {
                                "LinkType": "Drawer"
                            }
                        },
                        "Type": "TextContent",
                        "Children": ["string"]
                    }
                },
            }
        ]
    }
}
```

Key value pair

With the Key Value Pair component, you can create organized displays of related data points in a flexible, readable format.

Overview

Create dynamic data displays by defining custom key-value relationships. This component is particularly useful for showing attribute pairs such as:

- Customer details
- Account information

Features

1. **Interactive link options**

- Connect resource links
  - Link directly to related resources
  - Seamless navigation to:
    - Calculated attributes
    - Segments
  - Opens in new tab
- External URL Links
  - Convert item value into URLs that you can choose
  - Opens in new tab
- Drawer View Links
  - Open detailed information in side drawer
  - View complete details without leaving the page

2. Column configuration
   - Define 1-4 columns of key-value pairs
3. Organize pairs in logical groupings

        "Items": [
            {
                "Label": {
                    "Content": {
                        "Type": "TextContent",
                        "Id": "UniqueId",
                        "Props": {
                            "FontWeight": "bold"
                        },
                        "Children": ["Profile id"]
                    }
                },
                "Value": {
                    "Content": {
                        "Type": "TextContent",
                        "Id": "UniqueId",
                        "Props": {},
                        "Children": ["[string]"]
                    }
                }
            }
        ]
    }
}
```

> **Note**
>
> This component does not currently support `ProfileObjects` in the UI builder.

Key metric

With the Key Metric component, you can prominently display critical business metrics, KPIs, and vital statistics in an easily digestible format.

Overview

Create high-visibility metric displays that highlight important data points, trends, or status indicators. This component is ideal for showcasing:

- Performance indicators
- Critical measurements
- Status summaries
- Trend indicators

Features

1. **Large display text**
2. **Metric format**
3. **Interactive link options**
   - Connect resource links
     - Link directly to related resources
     - Seamless navigation to:
       - Calculated attributes
       - Segments
     - Opens in new tab
   - External URL links
     - Convert item value into URLs that you can choose
     - Opens in new tab
   - Drawer view links
     - Open detailed information in side drawer
     - View complete details without leaving the page
4. **Organize metrics layout**

Donut chart

The donut chart component enables visualization of sentiment scoring through a circular donut chart.

Overview

Create dynamic sentiment visualizations by defining custom scoring criteria. This component is particularly useful for showing:

- Success metrics
- Achievement rates
- Risk assessments
- Performance indicators

Features

1. Sentiment Analysis Options
   - Positive Sentiment
     - Starts from zero
     - Tracks achievement against criteria:
       - Custom point values
       - Color-coded segments
       - Grey for unmet conditions
     - Shows success rate percentage
   - Negative Sentiment
     - Starts from maximum value
     - Tracks deductions:

    - Color-coded segments
    - Point reduction system
    - Green for remaining value
  - Shows final score
2. Calculated attribute value
3. Operator Options
   - Equal To
   - Not Equal To
   - Greater Than
   - Less Than
4. Value Condition
5. Allotted points per condition

Example configuration

```
{
    "Type": "DonutChart",
    "Props": {
        "Variant": "PositiveSentiment",
        "ConditionDefinitions": [
            {
                "Title": "Customer Satisfaction",
                "Color": "#4CAF50",
                "CalculatedAttribute": "satisfaction_score",
                "Operator": "GREATER_THAN",
                "ValueCondition": 8,
                "Points": 10
            }
        ]
    }
}
```

Note

- **Donuts only support Calculated attributes as a data source at this time.**
- **All condition definitions must include a title, color, calculated attribute, operator, value condition, and points value.**

Show Profile Explorer in the agent workspace

By default, the Customer Profiles app in the agent workspace uses a fixed layout. You can replace it with a Profile Explorer layout, so agents see the customer data that are relevant to their work. For example, a travel company might show loyalty status and upcoming trips, while a telecommunications provider might show churn risk and service addresses.

You choose the layout for each workspace. Agents see the layout after you assign the workspace to them.

Before you begin

- Create and save the Profile Explorer layout you want agents to see. For more information, see Create a layout.

- Give agents the **Profile explorer - View** permission in their security profile. For more information, see Enable users to view Profile Explorer.

Choose a Profile Explorer layout for a workspace

1. Open the Connect Customer admin workspace.
2. Go to **UI Management** > **Workspaces**, and choose the workspace.
3. In the **Pages** section, add or edit the **Agent Workspace** page. For more information, see Create a workspace and set the layout.
4. In the **Customize apps on Agent Workspace** section, for **Customer Profiles**, choose **Enhanced view (Profile Explorer)**.
5. For **Profile Explorer layout**, choose the layout.
6. Choose **Save**.

To return to the fixed layout, follow the same steps and choose **Legacy view** in step 4.

Predictive Insights (Preview)

Predictive Insights (Preview) is a feature of Amazon Connect Customer Customer Profiles that uses artificial intelligence to generate personalized product and content recommendations for your customers. By analyzing customer interaction data, Predictive Insights helps you provide more relevant experiences across all customer touchpoints.

How Predictive Insights works

Predictive Insights (preview) uses AI models to analyze customer behavior patterns and generate real-time recommendations. The service processes your customer interaction data, such as purchase history and browsing activity, to identify patterns and preferences.

- **Step 1:** Add interaction data to profiles using existing data connectors to train AI models with your customer interaction data
- **Step 2:** Add item catalog to S3 to allow Customer Profiles to access your item data through the AWS Management Console
- **Step 3:** Create recommendations by defining recommendation types (similar items, frequently paired items, popular items)

- **Step 4:** Apply recommendations across Connect Customer ecosystem including agent workspace, Flows, and Connect AI agents

Prerequisites

- **Enable Data Store in Customer Profiles**

  To train AI models using your Customer Profiles, you need to enable data store. See details under Customer Profile Data Store to learn more.
- **KMS**

  You have configured Customer Profiles to encrypt your data under a AWS KMS key.
- **Security Profiles**

  You have configured Security Profiles to support View (list and view predictive insights), Create (create recommendations), Delete (delete recommendations), and Edit (update recommendations) permissions with Predictive insights enabled.

Benefits of using Predictive Insights

Using Predictive Insights provides several key benefits:

- Improve customer experience with personalized recommendations
- Increase sales opportunities through relevant product suggestions
- Save agent time by automatically surfacing relevant recommendations
- Deliver consistent recommendations across all customer touchpoints
- Update suggestions in real time as customer behavior changes

Get started with Predictive Insights

To start using Predictive Insights, follow these steps:

Topics

- Step 1: Adding Interaction data into Customer Profiles
- Step 2: Adding Item Catalog data
- Step 3: Creating Predictive Insights

- Step 4: Using Predictive Insights across customer engagement channels

Step 1: Adding Interaction data into Customer Profiles

You can use the existing data connectors in Customer Profiles to map interactions data into standard Web Analytics Object.

For more information, see Object type mapping for the standard web analytics.

Step 2: Adding Item Catalog data

You can represent individual products in your catalog within the domain using Standard Catalog data. This catalog data exists at the domain level and is not tied to any specific customer profile. It serves as a structured representation of your products that can be leveraged for personalization features. You can import your product or item information as domain objects into Customer Profiles using data connectors that provide flexible options for ingesting and maintaining your catalog information, ensuring your product data remains current and accessible within the system.

For more information, see Object type mapping for Item Catalog.

Step 3: Creating Predictive Insights

With Connect Customer, you can build and deploy specialized AI models tailored to your specific product recommendation needs. These models can be configured through either the Connect Web UI or programmatically through APIs to match your unique business scenarios. Predictive Insights offers several types of recommendations:

1. **Recommended for you** - provides personalized recommendations tailored to a specific user. Recommendations are based on the user's past behavior such as clickstream events, purchase events, consumed content, and so on.
2. **Similar items** - uses generative AI to find items that are thematically similar to an existing item in the catalog. It is ideal for upselling or substitution use cases where customers want to provide alternative item recommendations to their users.
3. **Frequently paired items** - recommends items that are frequently co-interacted with an existing item in the catalog. It is ideal for cross-selling or complementary item recommendation use cases.
4. **Popular items** - designed to recommend the items that are most commonly interacted with by users.

5. **Trending now** - recommends items with the largest increase in velocity of engagement over a recent time period. It is designed to surface items that are experiencing virality in user interactions.

> **Note**
>
> Enabling AI models with Predictive Insights is available under preview. Additional pricing might apply in future.

Item Limits by Recommendation Type

The following table describes the maximum number of items considered for recommendation generation, depending on the recommendation type used.

Recommendation Type	Description	Limit
Recommended for you	Maximum number of items considered for predictive insights	40 million
Similar items	Maximum number of items considered for predictive insights	10 million
All other business scenarios	Maximum number of items considered for predictive insights	750,000

Diversity controls

By default, recommendations are ranked by predicted relevance alone, which can produce a result set dominated by a single brand, supplier, category, or content type. With diversity controls, you can cap how many recommended items share the same value of an item catalog column, so results reflect a balanced mix across your catalog.

Key capabilities

- **Group by any categorical column** – diversify on any categorical column in your item catalog, such as brand, supplier or merchant, category, content type, price tier, or a custom column that you define in your recommender schema.

- **Configurable limits** – set an absolute cap, such as a maximum of three items per group, or a percentage-based cap that limits each group to a percentage of the returned items.
- **Composable rules** – diversify on up to two columns at the same time, so a single request can enforce more than one constraint.
- **Runtime values** – define a cap as a placeholder when you create the recommender, then supply the value for each request so that one recommender can serve multiple experiences.
- **Applied during retrieval** – diversity is enforced while candidate items are retrieved and ranked, not as a post-filter that discards items after ranking. You receive a full set of relevant results.

Use case examples

- **Storefront or home page carousel**

  Group recommendations by a column such as brand, supplier, or merchant, with a maximum of three items per group. Without diversity controls, a single high-affinity brand or supplier can fill the whole carousel. With diversity controls, customers see breadth across your catalog, which helps them discover new brands and increases repeat engagement.

- **Balanced results within a single collection**

  Group recommendations by category within a collection, such as a product line, a service catalog, or a content library, and cap each category so the result set stays representative. Instead of returning 10 close variations of the same popular item, the recommender surfaces a balanced set that exposes complementary items customers would not have scrolled far enough to find, which can increase average order value or time spent engaging with your content.

Configuring diversity controls

You define diversity caps on the recommender, then enable diversity on each request:

1. When you create or update a recommender, add a `DiversityConfig` that specifies up to two item catalog columns to diversify on. Each column must be defined in the recommender schema. For each column, set the following:
   - `Name` – The name of the item catalog column.
   - `CapType` – Use `VALUE` to interpret the target as an absolute count of items. Use `PERCENTAGE` to interpret it as a percentage of the returned items.
   - `Target` – A number, such as 25, or a placeholder in the form `$`*`name`*.

For more information about parameters, see create-recommender and update-recommender in the *AWS CLI Command Reference*.

2. When you retrieve recommendations for a profile, include a `DiversityConfig` that enables diversity for the request and supplies a value for each placeholder cap that you defined on the recommender. For more information about parameters, see get-profile-recommendations in the *AWS CLI Command Reference*.

Step 4: Using Predictive Insights across customer engagement channels

Using Customer Profile Recommendations in Connect Flows

This section describes how you can use the Customer Profiles Get profile recommendations flow block to enrich user experience during a contact by generating AI-powered recommendations for a profile in real-time.

Flow Block Properties

The **Get profile recommendations** flow block has the following properties to configure:

1. **Profile ID (required):**

   A Profile ID is required for this block to function. The **Get profile recommendations** flow block generates recommendations for the Profile ID provided here. You have the option to manually input the Profile ID or use a pre-defined value stored in an attribute. If using a pre-defined value, make sure you provide the Profile ID by using a preceding **Get profile** block Use the **Get profile** block to pinpoint the specific profile before moving forward to generate recommendations in the subsequent block.

2. **Recommender name (required):**

   A recommender name is required for this block to function. This is the name of the recommender you want to use to generate recommendations for the given Profile ID. You can only use recommenders that are active to generate recommendations.

3. **Max results (required):**

   The maximum number of recommendations to generate for the given Profile ID. This can range between 1 to 3 recommendations.

4. **Recommendation attributes (required):**

Define which attributes of the recommendations response to persist in contact attribute.

5. **Item ID:**

   This is the Item ID provided as additional context to generate recommendations for the given Profile ID. Item ID is only required when using a "*Similar items*" or "*Frequently paired items*" recommender type. You have the option to manually input the Profile ID or use a pre-defined value stored in an attribute. If using a pre-defined value, make sure you provide the Item ID by using a preceding **Get calculated attributes** block. Use the **Get calculated attributes** block to pinpoint the specific Item ID before moving forward to generate recommendations in the subsequent block.

Flow Block Branches

The **Get profile recommendations** flow block can route contacts down the following branches:

1. **Success:**

   Recommendations were successfully generated for the provided Profile ID. Selected recommendation attributes were persisted to contact attribute $.Customer.Recommendations.

2. **Error:**

   An error was encountered while trying to generate recommendations. This might be due to a system error or how **Get profile recommendations** block is configured.

3. **None Found:**

   No recommendations could be generated.

Using Recommendations from the block

The recommendations response is persisted to the $.Customer.Recommendations contact attribute JSONPath as a JSON list of recommendation objects. Each recommendation object will contain the selected **Recommendation attributes**.

The following sample Python code snippet from a Lambda function shows how it can be used to transform recommendations from the **Get profile recommendations** block and persist into other contact attributes such that the recommendations can be used in subsequent blocks.

```
import boto3
import json

# Handle lambda request
def lambda_handler(event, context):
    print("Contact flow data: ", event)

    # Transform recommendations
    recommendations = event['Details']['Parameters']['Recommendations']
    contact_attributes = {}
    for i, rec in enumerate(recommendations):
        contact_attributes.update(flatten(rec, i))

    # Set contact attributes using each recommendation attribute value
    print("Setting contact attributes: ", contact_attributes)
    try:
        client = boto3.client('connect', region_name="us-west-2")
        client.update_contact_attributes(
            InstanceId=event['Details']['ContactData']['InstanceARN'].rsplit('/', 1)
[1],
            InitialContactId=event['Details']['ContactData']['InitialContactId'],
            Attributes=contact_attributes
        )
        print("Contact attributes set successfully.")
    except Exception as e:
        print("Error setting contact attributes: ", e)

    # Success response
    return {
        'statusCode': 200,
        'body': json.dumps('Success')
    }

# Flatten a nested object into a simple string:string object
def flatten(recommendation, index):
    flat = {}
    for key, value in recommendation.items():
        if isinstance(value, dict):
            flat.update(flatten(value, index))
        else:
            flat[f"Rec{index}_{key}"] = str(value)
    return flat
```

After you have set up your flow with the **Get profile recommendations** block, you can start using it to generate recommendations for your customers during their contacts.

Using Customer Profile Recommendations in Outbound Campaigns

You can integrate Predictive Insights with Connect Customer outbound campaigns to deliver personalized recommendations through email and SMS channels. When you create an event-triggered campaign, you can configure the Recommendations section to automatically generate AI-powered recommendations for customer profiles associated with the campaign.

This integration uses Web Analytics object mapping as the event category to capture customer interaction data, which enables the recommendation engine to provide relevant and targeted suggestions based on customer behavior.

For step-by-step instructions on configuring recommendations in event-triggered campaigns, see Create an outbound campaign using event triggers.

Setting Up Connect AI Agents for Sales Recommendations

Amazon Q in Connect enhances agent capabilities through its new "Orchestration" Agent type. This functionality is particularly valuable for creating a Sales AI Agent that can provide item recommendations, especially useful in upsell and cross-sell scenarios.

Getting Started

To begin implementation, access the AWS Management Console and navigate to Connect Customer. After logging into your Connect instance through the Access URL, locate Amazon Q from the left navigation pane and select AI agents. You'll find a pre-configured AI Agent of Type Orchestration (SalesAgent) in draft status on the QiC page under AI Agents. This template comes equipped with all necessary configurations for 1P tools and example prompts for recommendations.

Creating Your Custom Agent

To create a custom Sales Agent, begin by creating a new AI Agent of Orchestration Type and copy from the existing SalesAgent template. This process transfers all tools and configurations from the template to your new agent.

Customizing the Agent

When it comes to updating the agent's prompt, administrators have two primary options. They can either append their existing agent prompt to the Sales Agent Prompt and add upsell identification

instructions, or they can start fresh by removing the SalesAgent prompt and creating a new Orchestration prompt based on their current published Agent and adding the Sales agent prompt to it. This flexibility allows for tailored solutions that match specific business needs and domain requirements.

Flow Configuration and Integration

After finalizing the agent configuration and publishing it, the next step involves creating a Amazon Lex bot under Flows. The inbound flow needs to be updated to include the GetCustomerInput block with the created Lex bot. The new SalesAgent should be selected in additional options. You will need to add both the Customer Profile flow block for profile ID retrieval and the Set-Contact Attributes flow block, setting CustomerId as the key for the profile ID and value as $Customer.ProfileId.

The implementation supports both chat contacts and voice calls, with customer input seamlessly passing to the QIC agent on the Lex bot. This comprehensive setup enables AI-driven sales recommendations and upsell opportunities within your Connect Customer environment. The system's flexibility allows for customization based on specific industry needs while maintaining the core functionality of intelligent sales assistance. This solution provides a framework for enhancing customer interactions with AI-powered recommendations, ultimately supporting more effective sales and customer service operations. Administrators can further refine the implementation by adding domain-specific instructions and customizing recommendation types to match their business requirements.

Configuring SalesAgent to be used for Agent Assistance

You can configure the SalesAgent to be used within the Q in connect chat widget in the agent workspace. To do so you need to modify 2 main things.

1. Update the AIAgent prompt with instructions to access the contact transcript.
   a. Open the prompt associated with the SalesAgent in Prompt editor and update the prompt to add instructions to access the contact's transcript accessible by `<conversation>{{$.transcript}}</conversation>`
   b. Below is a sample prompt that you can append to the SalesAgent prompt.

```
**IMPORTANT**
        **Guide on how to process requests and information:**
        - The messages section contains YOUR conversation with the customer
 service agent
        - Respond to the agent's questions/requests in the messages section
```

```
        - The transcript below is background information about the agent's
conversation with their customer
        - Do not respond directly to the customer - you are helping the AGENT
        Background context from agent-customer conversation.
        The following transcript is for your information ONLY. Do not directly
respond to messages in this conversation, but instead look at the messages
section for what the agent requests you to do.
        IF YOU REFERENCE ANY INFORMATION FROM THIS SECTION: You should indicate so
by saying "According to your conversation with the customer ..."
        <conversation>
        {{$.transcript}}
        </conversation>
```

c. Update the AIAgent with the new prompt version and update the Default configuration → Agent Assistance use case with this agent.

> **Note**
>
> It is recommended to have 2 different Sales AIAGent for Self Service and Agent Assistance use case as both requires minor modifications to the prompt. And this can be done by cloning the agent and simply changing the prompt version and updating the default configuration to point to correct AI Agents for respective use case

2. Update the contact inbound flow.
   a. Remove the GetCustomerInput block and add the Connect assistant flow block instead
   b. Fill in the flow block config with the AIAssistant ARN and select the appropriate AIAGent.

Now you can use this flow as your regular inbound and the Q in connect chat widget should be able to provide recommendations to help with user's request.

Data Considerations

The following sections provide guidance on how to match use-cases and assess data readiness for Predictive Insights.

Have you matched your use cases to Predictive Insights?

Predictive Insights personalization types can address the following use cases:

- Generating personalized recommendations for a user

- Recommending similar or related items
- Recommending trending or popular items
- Re-ordering items by relevance

Do you have enough item interaction data?

For all use cases and personalization types, you must have at minimum 1,000 item interactions for 25 unique users with at least two interactions each. For quality recommendations, we recommend that you have at minimum 50,000 item interactions from at least 1,000 users with two or more item interactions each.

Do you have a real-time event streaming architecture in place?

If you have the ability to stream real-time events to Connect Customer Profiles, you will be able to take advantage of real-time personalization. With some personalization types, Predictive Insights can learn from your user's most recent activity and update recommendations as they use your application.

Is your data optimized for Predictive Insights?

We recommend you check for the following in your data:

- Check for missing values. We recommend that a minimum of 70% of your records have data for every attribute. We recommend columns that allow null values be at least 70% complete.
- Fix any inaccuracies or issues in your data, such as inconsistent naming conventions, duplicate categories for an item, mismatched IDs across datasets, or duplicate IDs. These issues can negatively impact recommendations or lead to unexpected behavior. For example, you might have both "N/A" and "Not Applicable" in your data, but filter out recommendations based on only "N/A". Items marked "Not Applicable" would not be removed by the filter.
- If an item, user, or action can have multiple categories, such as a movie with multiple genres, combine the categorical values into one attribute and separate each value with the | operator. For example, a movie's GENRES data might be Action | Adventure | Thriller.
- Avoid having more than 1000 possible categories for a column (unless the column contains data for only filtering purposes).

Web data tracker and web notification

Connect Customer offers two capabilities that work together with the Communications widget to help you understand website visitors and engage them with personalized messages:

- **Web data tracker** – Captures how visitors interact with your website (click interactions, search queries, form completion) and associates that activity with their profile in Customer Profiles.
- **Web notification** – Delivers personalized notifications to visitors directly in their browser through the Communications widget, with no need for them to start a conversation first.

How it works

1. The web data tracker captures visitor activity (click interactions, search queries, form completion) and associates it with the visitor's profile in Customer Profiles.
2. You define event trigger conditions in an outbound campaigns campaign, such as clicking certain buttons or entering specific search terms.
3. When the condition is met, a personalized notification is delivered to the visitor's browser through the Communications widget. The visitor can start a chat, follow a link, or dismiss the notification.

> **Note**
>
> Notifications are delivered through the Communications widget. Visitors do not install a plugin, extension, or app.

Prerequisites

Before you set up web data tracker and web notification, make sure that the following are in place on your Connect Customer instance:

- The Communications widget is configured. For more information, see Add a chat user interface to your website hosted by Connect Customer.
- Customer Profiles is enabled. For more information, see Enable Customer Profiles for your Connect Customer instance.

- Connect Customer outbound campaigns is enabled. For more information, see Enable outbound campaigns and Customer Profiles.

What the web data tracker captures

After you enable **Data collection**, you can begin emitting your own business events — such as "add to cart," "purchase," or any custom event types relevant to your use case. Note that this requires changes to your website.

Visitor activity	Capture mode	What is captured
Business events	Custom (API call)	Custom events such as Add to Cart, Purchase Completed, or View Product, configured using the `recordBusinessMetric` API. For more information, see Capture website visitor activity with the web data tracker.

The **Advanced Data Collection** automatically captures common website interactions without additional coding:

Visitor activity	Capture mode	What is captured
Clicks	Automatic	Links and buttons clicked, including the element text and destination URL.
Searches	Automatic	Search queries entered on your site through standard search input fields.
Form submissions	Automatic	When forms are submitted. Form field values, passwords, and payment information are never captured.

Common use cases

Common use cases include:

- Recover abandoned carts.
- Follow up on product interest.
- Deliver personalized recommendations based on browsing history.
- Offer proactive support when a visitor appears stuck.
- Drive promotional engagement based on browsing behavior.

Get started with web data tracker and web notification

Setup is split across two areas of the admin console.

- Configure web data tracking on your Communications widget and embed the widget on your website. For more information, see Capture website visitor activity with the web data tracker.
- Design the notification view, define event triggers in Customer Profiles, and create the campaign that delivers the notification. For more information, see Send web notifications with Connect Customer outbound campaigns.

Personalization options

You can personalize notifications with profile data from Customer Profiles: visitor name and identity attributes, browsing history, AI-powered product recommendations, and any custom attributes you store in the profile. For recommendations, see Predictive Insights (Preview).

Performance impact

The SDK loads asynchronously and does not block page rendering. The SDK batches and sends events in the background, typically within 1 to 5 seconds of capture, with sampling and deduplication to keep network usage low.

Measuring success

Track delivery rate, engagement rate, chat conversions, and dismissals in the Connect Customer analytics dashboard under the outbound campaigns performance section.

Limitations

- Web notification requires an active WebSocket connection. The browser tab must be open and the widget must be loaded; closing the tab or putting the device to sleep ends the connection.
- Concurrent active connections are subject to per-customer service quotas. Contact AWS Support to request a limit increase.
- For single-page applications (SPAs), embed the widget snippet once at the application root. For multi-page applications (MPAs), include the snippet on every page where you want tracking or notifications.
- Recommendation-based notifications require product catalog data to be ingested into Customer Profiles before the campaign runs. For more information, see Predictive Insights (Preview).
- Each event trigger can be linked to at most one campaign.
- Supported browsers: Google Chrome, Mozilla Firefox, and Safari.

Use the Connect Customer Customer Profiles API

For information about how to programmatically manage domains and profiles, see the Connect Customer Customer Profiles API Reference.

ListObjectTypeAttributeValues API

The ListObjectTypeAttributeValues API provides access to the most recent distinct values for any specified attribute, making it valuable for real-time data validation and consistency checks within your object types. This API works across domain, supporting both custom and standard object types. The API accepts the object type name, attribute name, and domain name as input parameters and returns values up to the storage limit of approximately 350KB.

Note:

- We store up to 350KB of attribute values per field, prioritizing the most recent values first. Once this limit is reached, older values will be automatically removed to make space for new entries.

GetObjectTypeAttributeValues API

The GetObjectTypeAttributeValues API delivers statistical insights about attributes within a specific object type, but is exclusively available for domains with Data store enabled. This API performs

daily calculations to provide statistical information about your attribute values, helping you understand patterns and trends in your data. The statistical calculations are performed once per day, providing a consistent snapshot of your attribute data characteristics.

Note:

- You'll receive null values in two scenarios:
  - During the first period after enabling data vault (unless a calculation cycle occurs, which happens once daily).
  - For attributes that don't contain numeric values.

We recommend using the CustomerProfileJS open source library when integrating Customer Profiles into a custom agent application. For more information, see the CustomerProfilesJS repo on Github.

For more information about how to integrate your existing apps with Connect Customer use Connect Customer Streams. You can embed the Contact Control Panel (CCP) components into your app.

Understanding IPv6 support in Connect Customer Customer Profiles

Public Connectivity

All Connect Customer Customer Profiles APIs fully support IPv4 and IPv6 calls.

```
profile.Region.api.aws
```

For example:

```
profile.us-east-1.api.aws
```

For AWS CLI, you'll need to use these endpoints explicitly:

```
aws customer-profiles list-domains \
    --endpoint https://profile.us-east-1.api.aws \
    --region us-east-1
```

The old APIs are still available as backward compatibility. They only support IPv4 calls.

```
profile.Region.amazonaws.com
```

For example:

```
profile.us-east-1.amazonaws.com
```

Private Connectivity

You can create a VPC endpoint for the Connect Customer Customer Profiles service using either the Amazon VPC console or the AWS Command Line Interface (AWS CLI). For more information, see Creating an interface endpoint in the AWS PrivateLink Guide.

Create a VPC endpoint for Connect Customer Customer Profiles using the following service name:

```
com.amazonaws.Region.profile
```

For example:

```
com.amazonaws.us-east-1.profile
```

If you enable private DNS for the endpoint, you can make API requests to Connect Customer Customer Profiles using its IPv4 and IPv6 supported DNS name for the Region, for example, profile.us-east-1.api.aws.

Alternatively, old DNS name for the Region is also supported as IPv4 only.

For example:

```
profile.us-east-1.amazonaws.com
```

Example: Programmatically integrate Amazon S3 with Connect Customer Customer Profiles

Using the Customer Profiles PutIntegration API, you can programmatically create integrations for S3, Salesforce, Marketo, and more.

In this topic we show how to create an S3 integration with a sync interval of 15 minutes, the minimum value currently supported.

Step 1: Create a JSON file

Create a JSON file with the following contents:

```
{
    "DomainName": "your-domain",
    "ObjectTypeName": "your-object-name",
    "FlowDefinition": {
        "FlowName": "your-flow-name",
        "KmsArn": "the key ARN is the same as your domain's key",
        "Description": "Created by Customer Profiles",
        "TriggerConfig": {
            "TriggerType": "Scheduled",
            "TriggerProperties": {
                "Scheduled": {
                    "ScheduleExpression": "rate(15minutes)",
                    "DataPullMode": "Incremental",
                    "ScheduleStartTime": 1634244800.435,
                    "FirstExecutionFrom": 1594166400
                }
            }
        },
        "SourceFlowConfig": {
            "ConnectorType":"S3",
            "SourceConnectorProperties": {
                "S3": {
                    "BucketName": "your-bucket",
                    "BucketPrefix": "your-prefix"
                }
            }
        },
        "Tasks": [
            {"TaskType":"Filter","SourceFields":["colA","colB"],"ConnectorOperator":
{"S3":"PROJECTION"}},
            {"ConnectorOperator":
{"S3":"NO_OP"},"DestinationField":"colA","TaskProperties":{},"SourceFields":
["colA"],"TaskType":"Map"},
            {"ConnectorOperator":
{"S3":"NO_OP"},"DestinationField":"colB","TaskProperties":{},"SourceFields":
["colB"],"TaskType":"Map"}
        ]
    }
}
```

To customize the JSON with your own values, follow these guidelines:

- `FlowName`: Can be STRING [a-zA-Z0-9][\w!@#.-]+
- `ScheduleStartTime`: Set to the current `DateTime` + 5 minutes in epoch time.
- `FirstExecutionFrom`: Go to S3, look at the file date, and use a date that is before the oldest date.
- `Tasks`: Define `TaskType`. In the `Sourcefields` field you have to supply ALL the columns you have in your CSV in that array. Then, for each of the items in that array, you need to specify the `ConnectorOperator`. This example is for a CSV document with two columns: `colA` and `colB`.

Step 2: Call the PutIntegration API

After you have created and customized the JSON file with your values, call the PutIntegration API, as shown in the following example:

```
aws customer-profiles put-integration --cli-input-json
 file:///put_integration_s3_cli.json --region us-west-2
```

The response from `PutIntegration` returns a flow URI. For example:

```
{
    "DomainName": "testDomain",
    "Uri": "arn:aws:appflow:us-west-2:9999999999999:flow/
Customer_Profiles_testDomain_S3_Salesforce-Account_1634244122247",
    "ObjectTypeName": "your objec type",
    "CreatedAt": "2021-10-14T13:51:57.748000-07:00",
    "LastUpdatedAt": "2021-10-14T13:51:57.748000-07:00",
    "Tags": {}
}
```

Step 3: Call the Amazon AppFlow StartFlow API

Use the flow URI to call the Amazon AppFlow StartFlow API. For example:

```
aws appflow start-flow –flow-name uri --region us-west-2
```

Set up Connect Customer outbound campaigns

This topic explains how to set up Connect Customer outbound campaigns, a feature of Connect Customer and formerly known as high-volume outbound communications.

Important things to know

- The phone numbers that outbound campaigns can call are based on the AWS Region where your Connect Customer instance is created. For a list of AWS Regions and countries, see Outbound Campaigns availability by Region in the *Availability of Connect Customer services by Region* topic.
- You must obtain pre-authorization by creating an AWS Support ticket to use Connect Customer outbound campaigns for event-driven mass notifications, such as severe weather warnings, evacuation notices, disaster response communications, or utility disruptions that impact several thousand of customers.

  This review process helps ensure the reliable delivery of these critical messages while maintaining service quality for all customers. While we might support these use-cases, they require additional technical validation due to their unique nature and implications, such as the impact on carrier networks for voice or SMS communications.

  Follow the instructions in Requesting a quota increase in the *Service Quotas User Guide* to open a ticket that contains a detailed description of your requirements. Additional charges might apply based on your location and anticipated notification volumes.

Before you begin

You need a few things to use outbound campaigns:

- Make sure your Connect Customer instance is enabled for outbound calling.
- Request a service quota increase for outbound campaign calls. By default, the service quota for concurrent campaign calls is 0. To submit a request, see Requesting a quota increase in the *Service Quotas User Guide*.
- Create a dedicated outbound campaigns queue to handle any contacts that will be routed to agents as a result of the campaign.
- Assign the queue to the agent's routing profile.

- Create and publish a flow that includes a Check call progress block. With this block, you can branch based on whether a person or a machine answered a call, for example.

Create an AWS KMS key

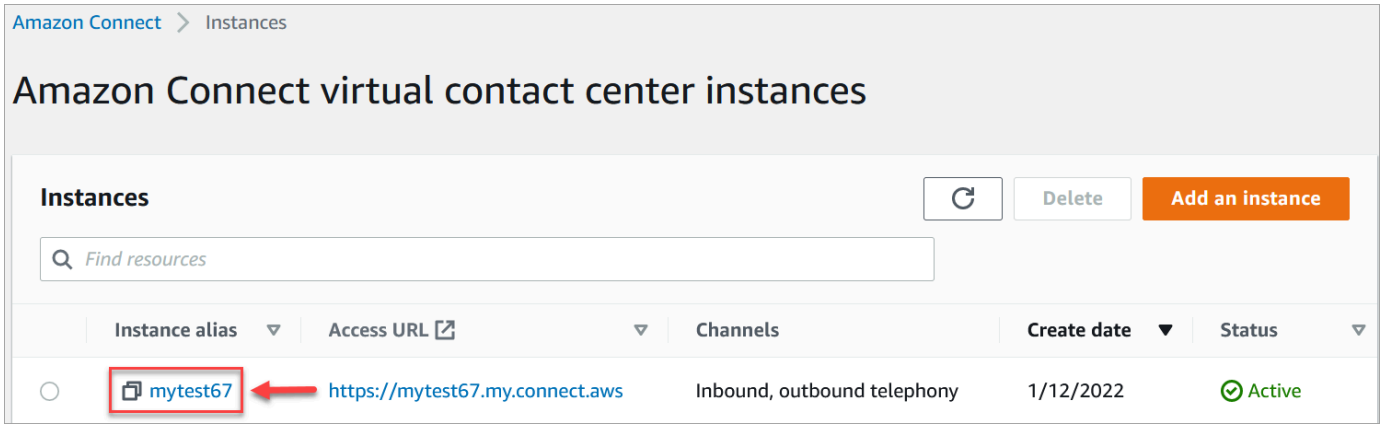
When you enable outbound campaigns, you can provide your own AWS KMS key. You create and manage these keys, and AWS KMS charges apply. You can also use an AWS owned key.

When using an API to enable or disable outbound campaigns, make sure the API user is either the administrator or has the following permissions: `kms:DescribeKey`, `kms:CreateGrant`, and `kms:RetireGrant` for the key.

> **Note**
>
> To switch the KMS key that is associated with outbound campaigns, first you need to disable outbound campaigns, and then re-enable it using a different AWS KMS key.

Configure outbound campaigns

1. Open the Connect Customer console at https://console.aws.amazon.com/connect/.
2. On the instances page, choose the instance alias. The instance alias is also your **instance name**, which appears in your Connect Customer URL. The following image shows the **Connect Customer virtual contact center instances** page, with a box around the instance alias.



3. In the navigation pane, choose **Channels and communications**, **Outbound campaigns**.
4. On the **Outbound campaigns** page, choose **Enable**. If you don't see this option, then check whether outbound campaigns is available in your AWS Region.

5. Under **Encryption**, enter your own AWS KMS key or choose **Create an AWS KMS key**.

   If you choose **Create an AWS KMS key**:

   - A new tab in your browser opens for the Key Management Service (KMS) console. On the **Configure key** page, choose **Symmetric**, and then choose **Next**, as shown in the following image.

   - On the **Add labels** page, add a name and description for the key, and then choose **Next**.
   - On the **Define key administrative permissions** page, choose **Next**.
   - On the **Define key usage permissions** page, choose **Next**.
   - On the **Review and edit key policy** page, choose **Finish**.

     In the following example, the key ID starts with **bcb6fdd**:

   - Return to the tab in your browser for the Connect Customer console, **Enable outbound campaigns** page. Choose or tap in the **AWS KMS key** for the key you created to appear in a dropdown list. Choose the key you created.

6. Choose **Enable outbound campaigns**.

7. It takes a few minutes for outbound campaigns to be enabled. When it's successfully enabled, you can create outbound campaigns in Connect Customer for voice calls. If it does not enable, verify you have the required IAM permissions.

Create an outbound campaign

With Connect Customer outbound campaigns, you can reach customers proactively across voice, SMS, email, and WhatsApp channels. You define a target audience using Customer Profiles segments, configure a campaign flow that controls the communication sequence, and schedule when the campaign runs. Campaigns support delivery status tracking, retry logic for failed communications, and multichannel fallback—for example, sending an email if an SMS bounces.

Connect Customer provides two ways to create an outbound campaign:

- **Visual Journey Builder**: Design multi-channel, multi-step campaigns using an intuitive drag-and-drop canvas. Ideal for complex journeys that span multiple channels and include branching logic.
- **Guided Campaign Builder**: Create single-channel campaigns with step-by-step guidance. Best for straightforward outreach on a single channel.

You can create an outbound campaign using the Connect Customer admin website or programmatically using the AWS CLI or API. Choose your preferred method:

- the section called “Using the admin website”—Step-by-step instructions using the Connect Customer admin website.
- the section called “Using the API or CLI”—CLI commands, flow definitions, and code examples.

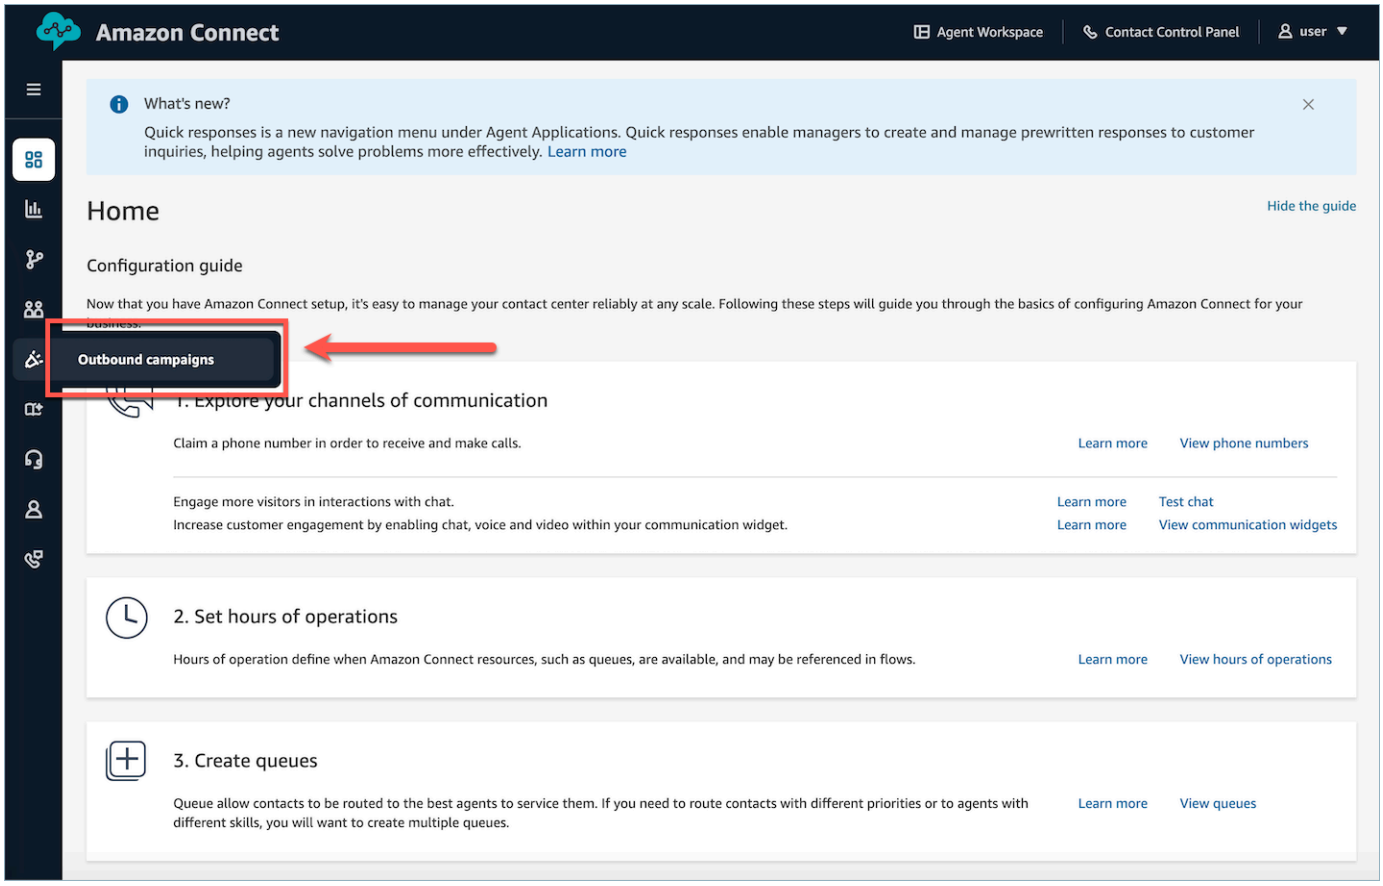
Create an outbound campaign using the admin website

The Connect Customer admin website provides two builders for creating outbound campaigns:

- the section called “Guided Campaign Builder”—Create single-channel campaigns with step-by-step guidance. Best for straightforward outreach on a single channel.
- the section called “Visual Journey Builder”—Design multi-channel, multi-step campaigns using an intuitive drag-and-drop canvas. Ideal for complex journeys that span multiple channels and include branching logic.

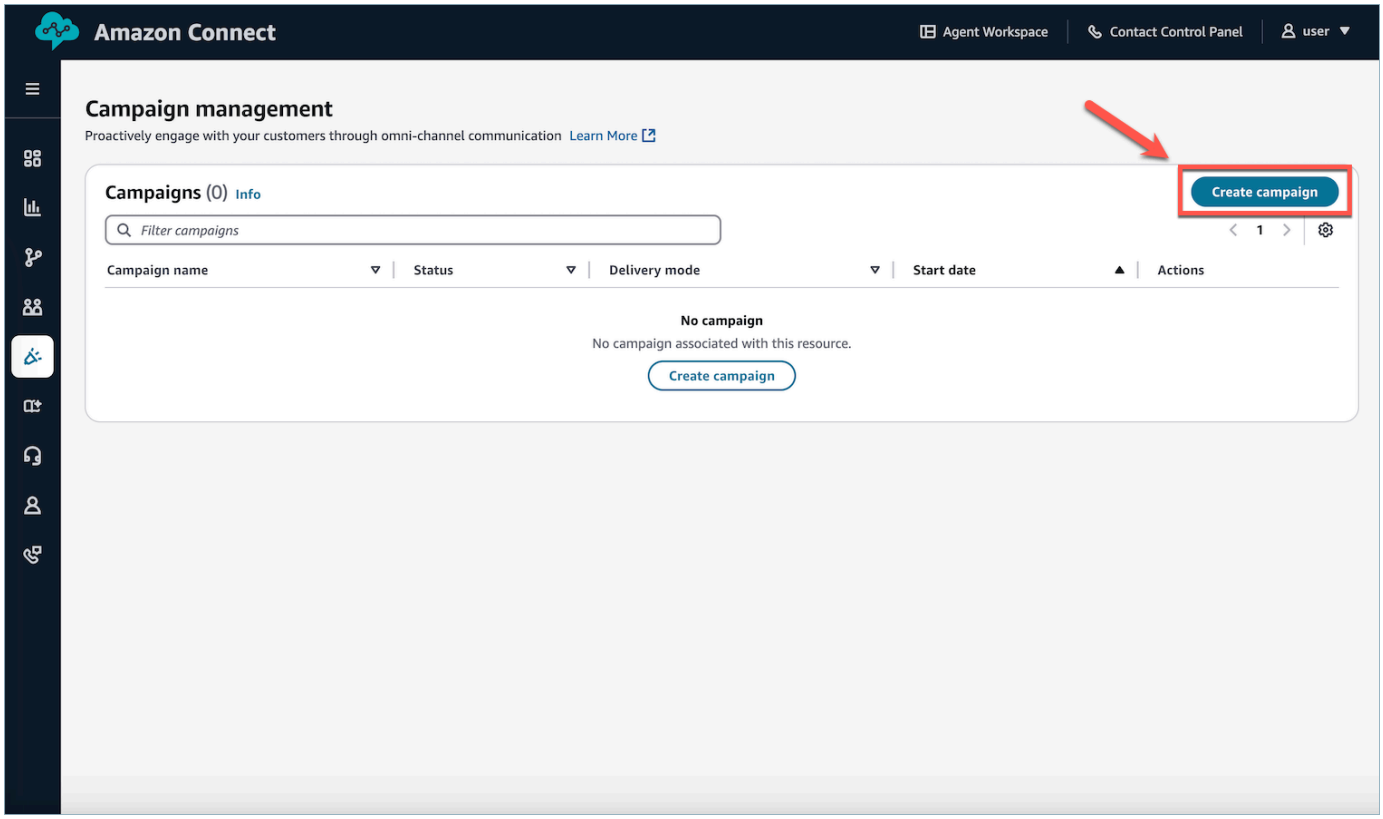
Guided Campaign Builder

1. Open the Connect Customer Outbound campaigns page from the Connect Customer admin website.



2. From the **Output Campaigns**, choose Create Campaign.

   You have two options to create an outbound campaigns. Use visual journey builder to create multi-channel and multi-steps using an intuitive drag-and-drop canvas, or use guided campaign builder to create a single-channel using step-by-step guidance.



3. Enter a campaign **Name**.

> **Note**
>
> You can also use your own recipient list or campaign management tool by choosing **Host external campaign**. For more information on setting up a campaign with your own resources, see the High Volume Outbound Communication with Connect Customer Outbound Campaigns blog post.
>
> >

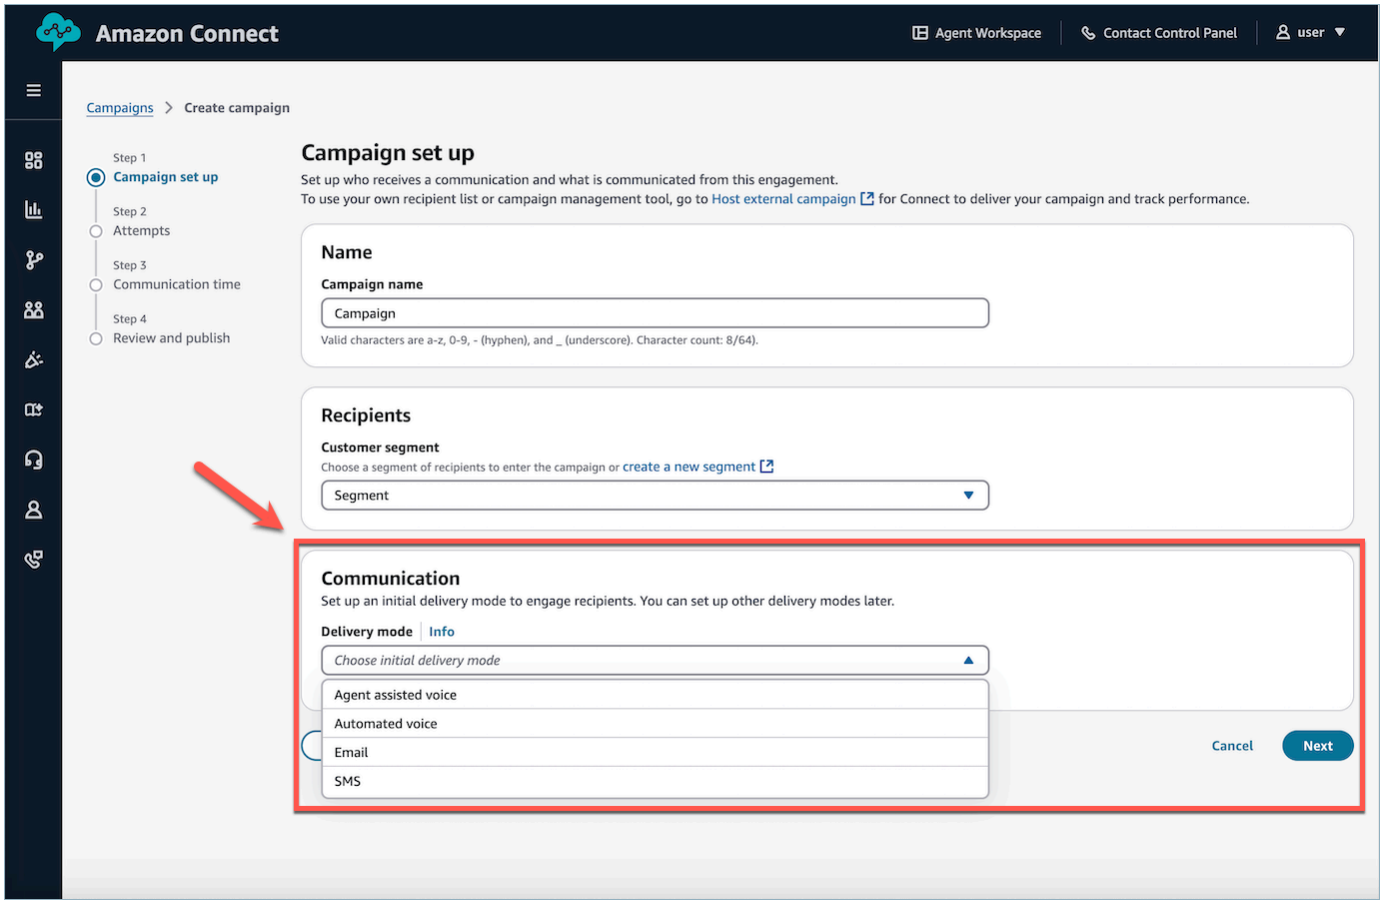
4. Select a **Customer Segment** to use for this campaign. Recipients for the campaign will be determined at the campaign's scheduled start time using the chosen segment.

> **Spark SQL segments not supported**
>
> Managed campaigns do not support the use of Spark SQL segments. You must use Classic segments.

5. Choose the **Channel** for the main communication of the campaign. The supported channels include **Agent assisted voice**, **Automated voice**, **Email**, and **SMS**.



Note

Recipients with incorrect or invalid endpoints are dropped from the communication. For example, for an Email campaign, a recipient with email address "jane.doe@abc!com" is not valid and will not be processed.

Outbound campaigns channel configurations

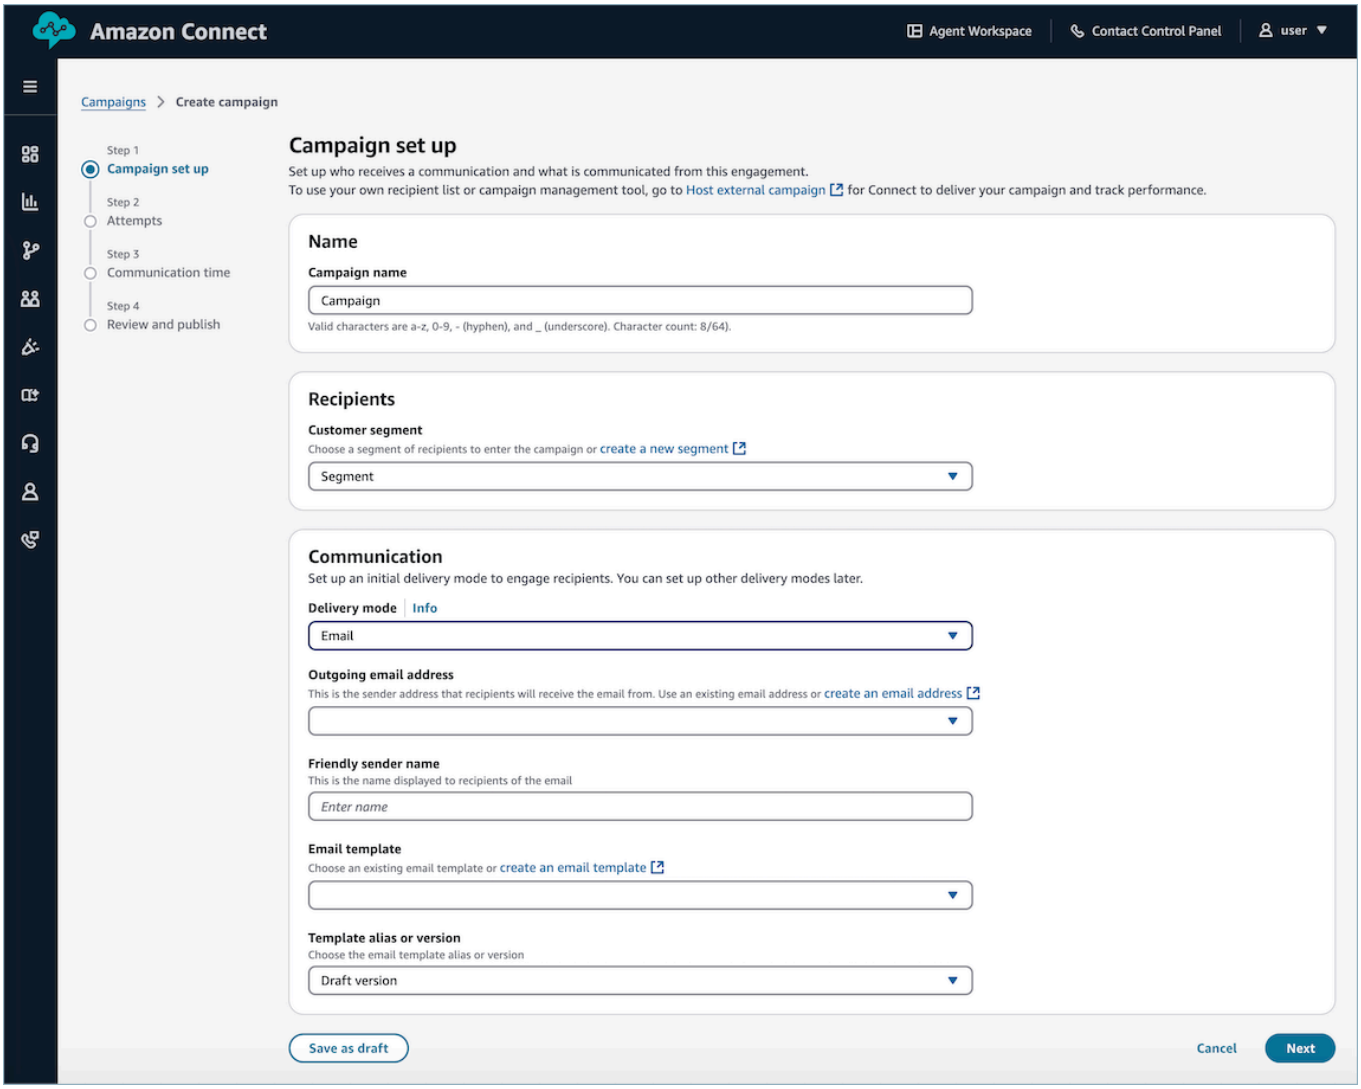
Outbound campaigns supports the following channels. Choose the channel that matches how you want to reach your customers, and then complete the configuration on the corresponding tab:

- **Email**: Send an email message to your customers by using an email template.
- **Agent Assisted Voice**: Place an outbound call that routes to an agent queue so that a live agent speaks with the customer. Use this channel when your use case requires a live agent, such as sales or collections.

- **Automated Voice**: Place an outbound call that a flow handles from start to finish, with no agent. Use this channel for self-service messages, such as appointment reminders or payment notifications.
- **SMS**: Send a text message to your customers by using an SMS template.
- **WhatsApp**: Send a WhatsApp message to your customers by using a WhatsApp message template.

Email

1. Select an Outgoing email address to send the email from. This address must be one already added to your Connect Customer Instance.
2. Optionally enter a **Friendly Sender Name**. This is the name that the recipients' email client will display.
3. Select an **Email Message Template** to use when sending.
4. Select the **Template Alias or Version** number to use with the campaign. If you select an alias, then the contents of emails sent by the campaign might change when the alias is updated to point to a new template version. If you select a version, the campaign will always send the exact same content for the life of the campaign.



Agent Assisted Voice

1. Select the **Contact Flow** to use for the outbound call. If you want reattempts, call classification, or waiting for a prompt, then the flow must contain a Check call progress block. The Check call progress block is not supported for preview dialing mode.
2. Select an **Agent Queue** to use for the outbound calls. Any call originating from the campaign is routed to agents assigned to this queue.
3. Select a **Source Phone Number**. This is a phone number associated with the Connect Customer instance.

Important

- Not all phone numbers can be used for Connect Customer Outbound campaigns. Outside of the US, UK, Japan, you need to check whether your number is outbound campaigns capable. If you have problems with a specific number not working, contact AWS Support to verify whether your number can be enabled for Outbound campaigns calls.
- Telecom regulations in certain countries dictate use of phone numbers from specific carriers for outbound calling. For more information, see the Connect Customer Telecoms Country Coverage Guide to learn more.
- Select the dialing mode. See Best practices for Outbound Campaigns for more information on the dialing modes.
- Disable call classification when using preview dialing mode.
- Enable call classification and waiting for a prompt.
- Input the desired **Dialing Capacity Allocation**. Allocates dialing capacity for this campaign between multiple active campaigns.

  The purpose of this field is you can indicate the most telecom capacity to be allocated for that specific campaign by the predictive dialer algorithm.

  For example, if there are 3 campaigns concurrently running, and this field has been configured to say:

  - 50% for Campaign1
  - 70% for Campaign2
  - 90% for Campaign3

  The dialer will allocate the most capacity to Campaign3 (up to 90%), then to Campaign2 (up to 70%) and then to Campaign1 (up to 50%) of the telecom capacity dynamically available.

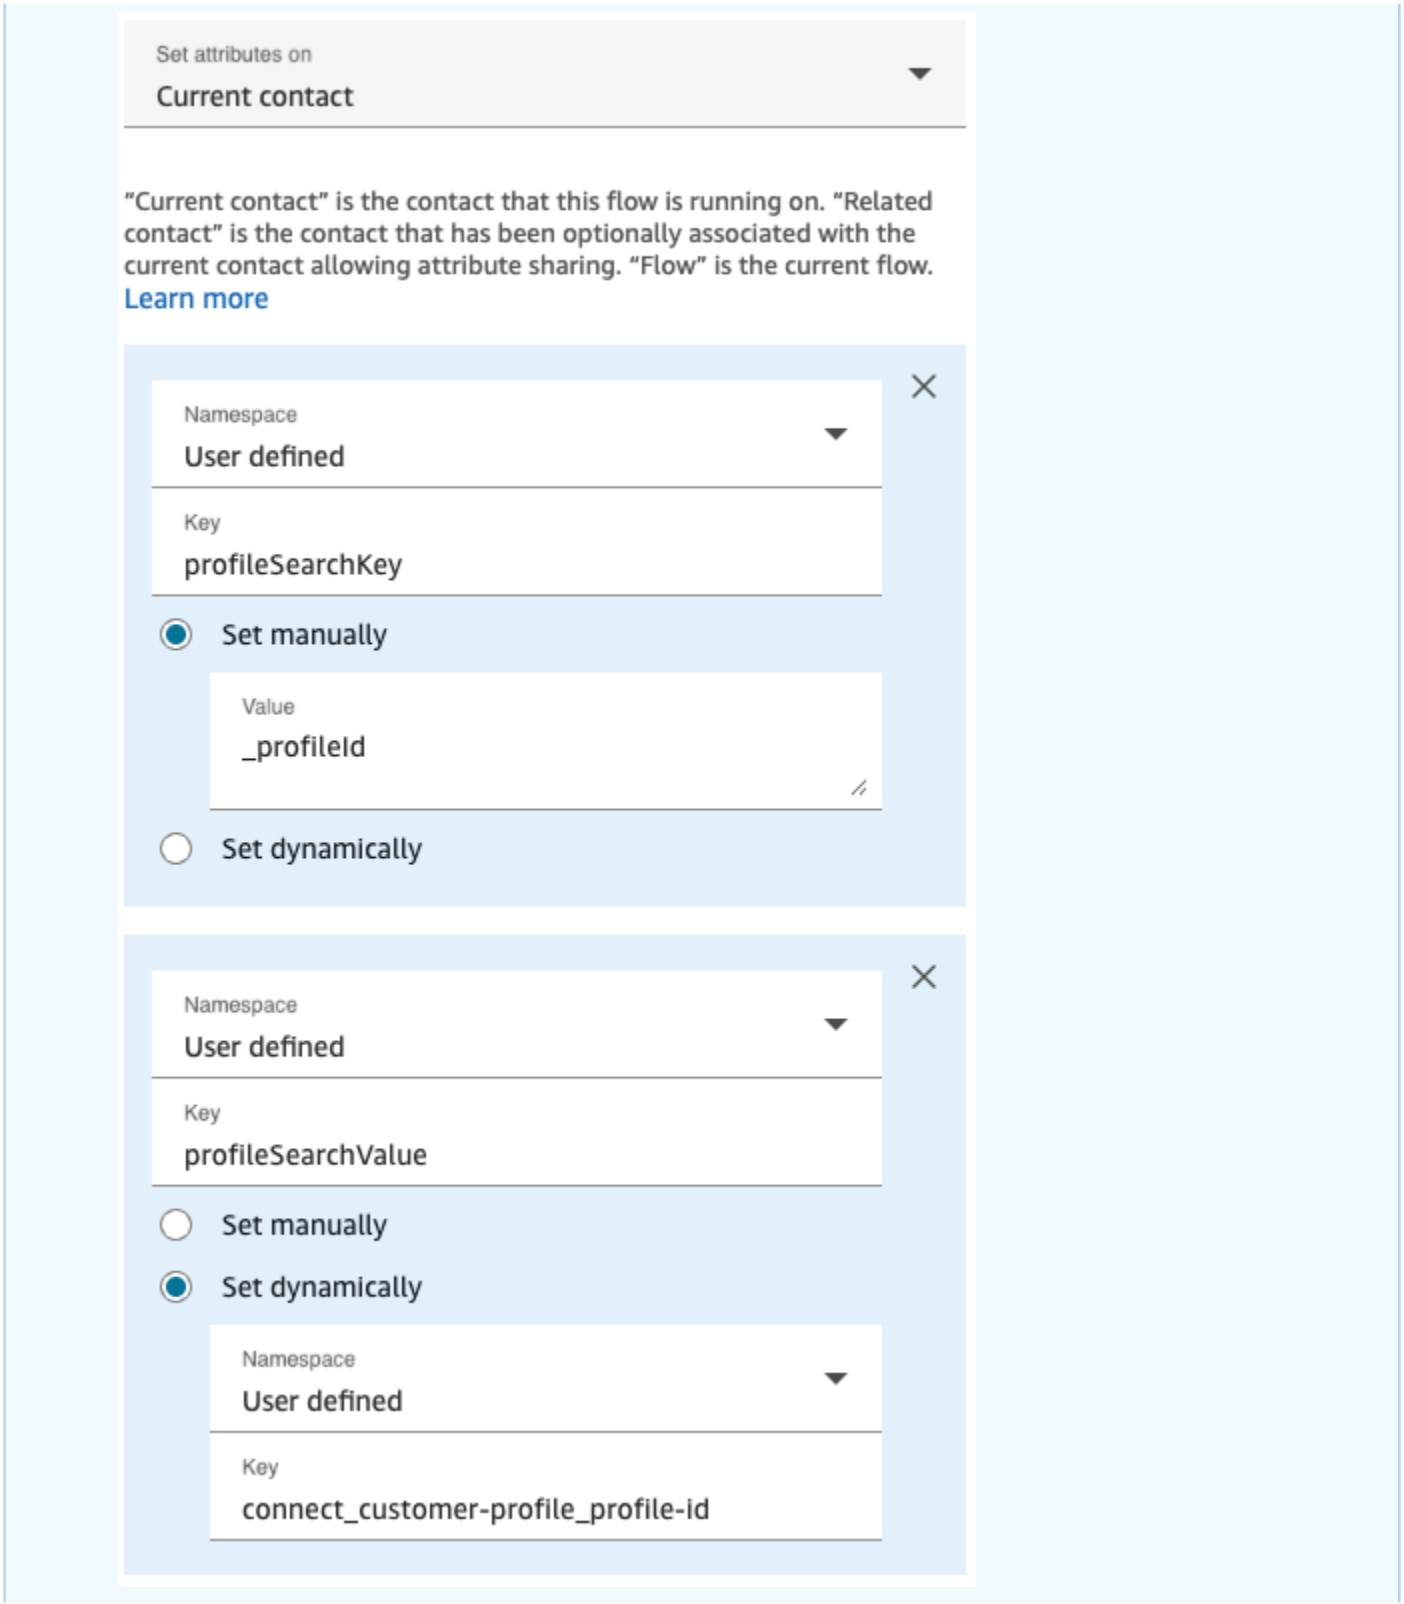
  If two campaigns are idle and only third one has contacts, it get full capacity. Its capacity reduces if any other campaigns start actively dialing.
- Enter the desired **Agent Allocation**. This allocation is a weight assigned to this campaign and used to determine the total number of *available* agents belonging to the provided queue for which an outbound call should be placed. This allocation is

converted to a percentage based on the allocation provided to all other campaigns using the same queue.

Note

- To reduce call connection latency between your customers and available agents we recommend disabling the use of call classification.
- If you disable call classification, and if your flow includes the Check call progress block, the contact is routed down the Error branch.
- For preview dialing mode, a contact is enqueued only when there is a Transfer to queue set in the flow. For a list of supported blocks, see **Chat** channel of Supported channels for flow blocks in Connect Customer.
- Preview dialing mode does not support agent whisper flow, however the outbound whisper flow can play the intended whisper to the agent.
- For preview dialing mode, please adjust contact flow to use profile id as the default search key in the agent workspace. For more information, see Use contact attributes to autopopulate customer profiles.

```
{
  "profileSearchKey": "_profileId",
  "profileSearchValue": "$.Attributes.connect_customer-profile_profile-id"
}
```



Set attributes on
Current contact
"Current contact" is the contact that this flow is running on. "Related contact" is the contact that has been optionally associated with the current contact allowing attribute sharing. "Flow" is the current flow.

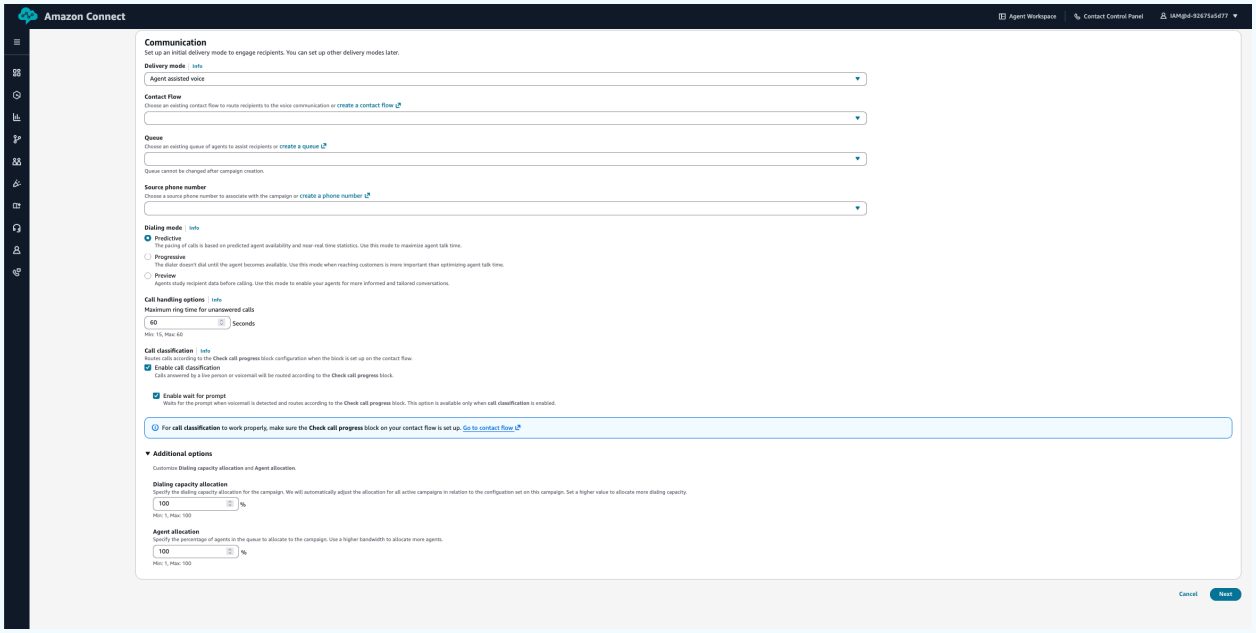
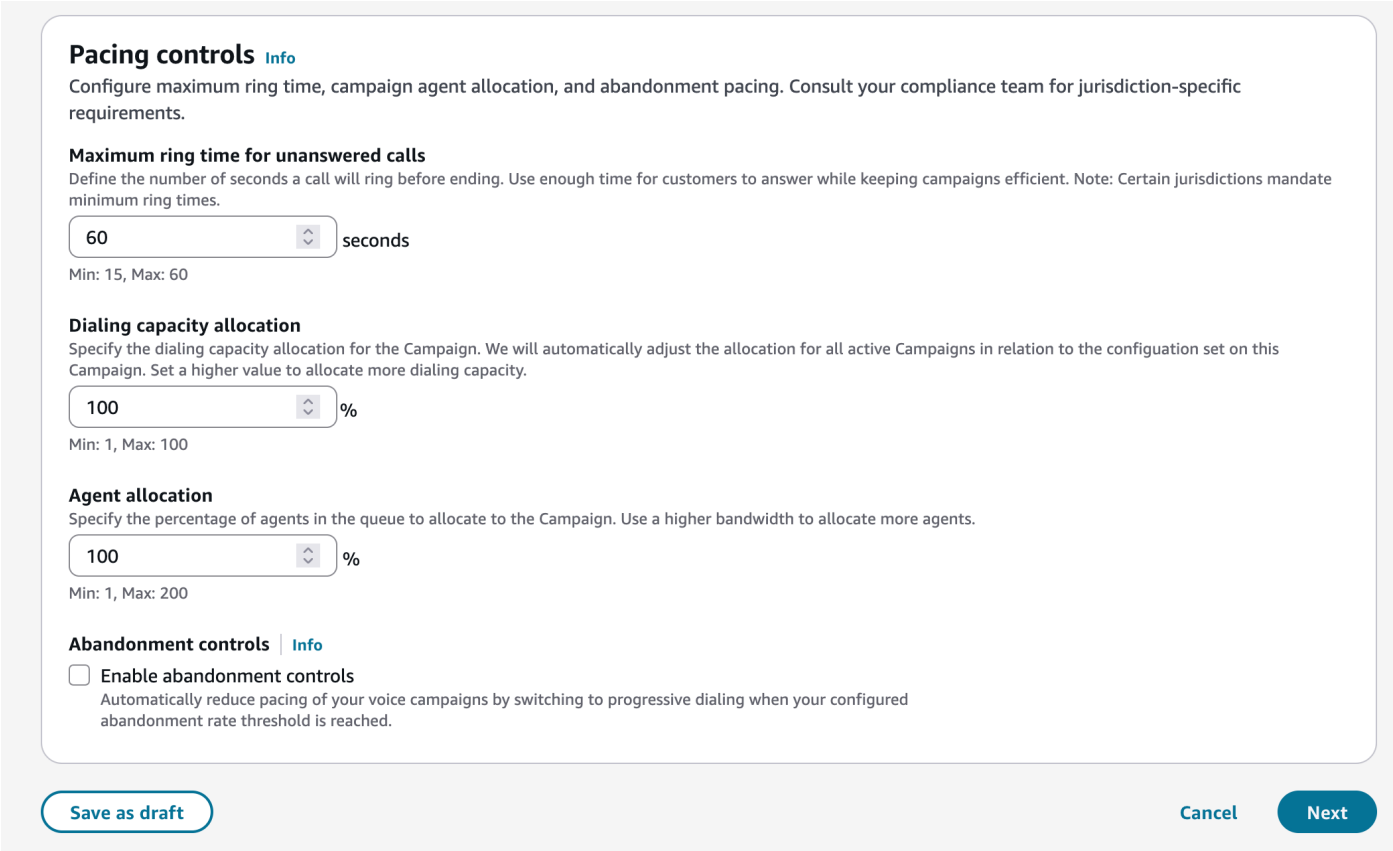
- Ensure **Enable wait for prompt** is selected. If it is not selected, the ML-powered call classifier won't listen for a voicemail prompt, and instead the next block in the flow will be triggered immediately.



Pacing controls

When you select predictive dialing mode, the **Pacing controls** section helps you configure maximum ring time, dialing capacity allocation, agent allocation, and abandonment rate thresholds:

The following image shows the pacing controls section.

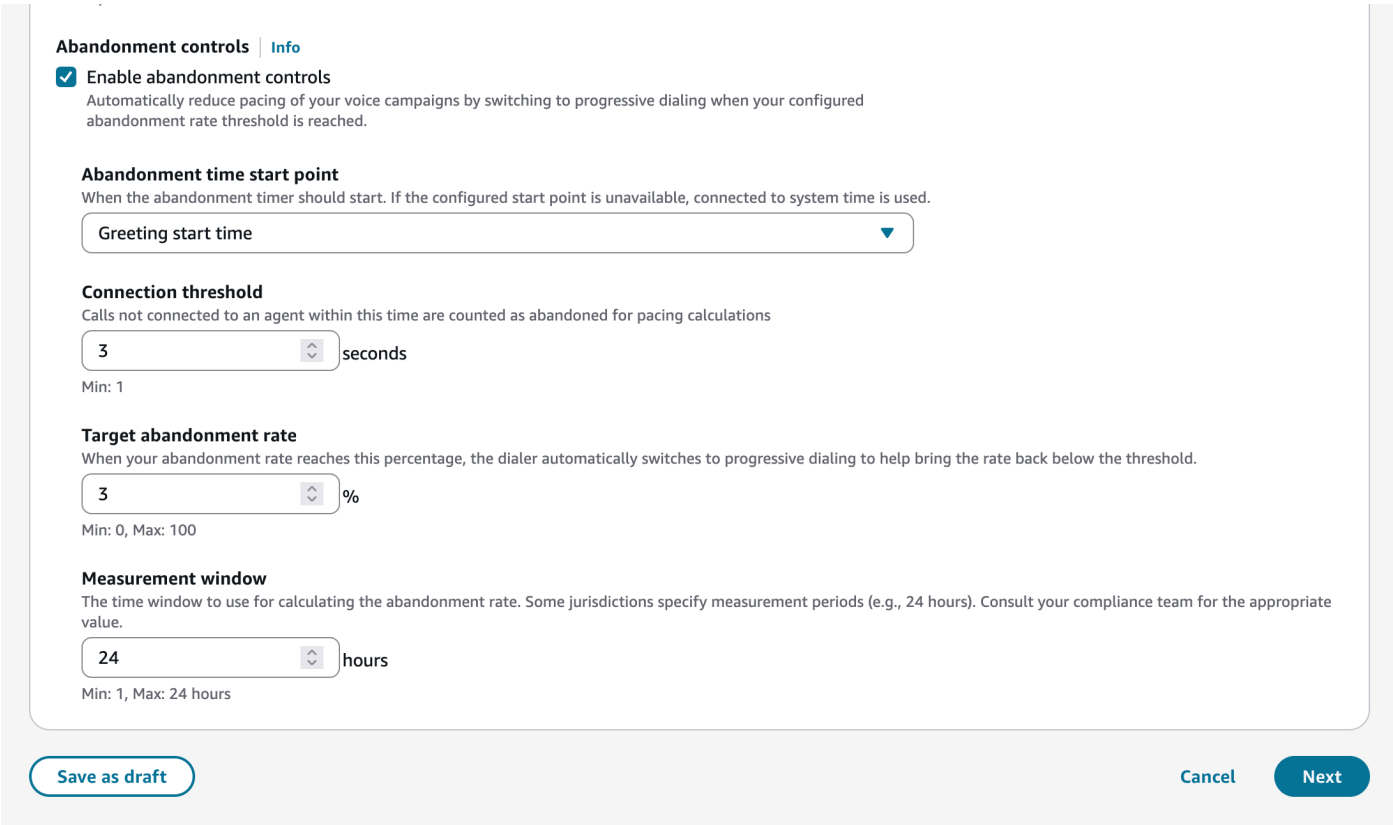


- **Maximum ring time for unanswered calls** – The maximum number of seconds a call will ring before ending. Valid values: 15 to 60 seconds.
- **Dialing capacity allocation** – Allocates telecom dialing capacity for this campaign relative to other active campaigns. When multiple campaigns run concurrently, the dialer distributes capacity proportionally based on each campaign's allocation value. Valid values: 1% to 100%.
- **Agent allocation** – A weight assigned to this campaign that determines the proportion of available agents belonging to the provided queue for which outbound calls are placed. Valid values: 1% to 200%.

Abandonment controls

For predictive dialing mode, you can enable abandonment controls to automatically reduce pacing when your configured abandonment rate threshold is reached. Select the **Enable abandonment controls** checkbox to configure these settings:

The following image shows the abandonment controls settings.



- **Abandonment time start point** – When the abandonment timer starts. The available options depend on whether call classification is enabled:
  - **Greeting start time** – Timer starts when the customer begins speaking.
  - **Greeting end time** – Timer starts when the customer finishes their greeting.
  - **Connected to system time** – Timer starts when the customer is connected to the system. This option is only available when call classification is disabled.

> **Important**
>
> The start point options change based on the call classification setting:
>
> - When call classification is **enabled**, only **Greeting start time** and **Greeting end time** are available. The **Connected to system time** option is hidden because the call classifier can detect when the customer's greeting begins and ends.
> - When call classification is **disabled**, all three options are available. However, if you select a greeting-based start point and the call classifier is unavailable at runtime, the system automatically falls back to connected to system time.

- If you enable call classification after selecting **Connected to system time**, the start point automatically resets to **Greeting start time**.

- **Connection threshold** – The number of seconds a call must remain unconnected to an agent before it is counted as abandoned. Minimum value: 1 second.
- **Target abandonment rate** – The abandonment rate percentage at which the dialer automatically switches to progressive dialing to bring the rate back below the threshold. Valid values: 0% to 100%.
- **Measurement window** – The time window used for calculating the abandonment rate. Some jurisdictions specify measurement periods (for example, 24 hours). Consult your compliance team for the appropriate value. Valid values: 1 to 24 hours.

Note

Consult your compliance team for jurisdiction-specific requirements when configuring abandonment controls. Regulations vary by country and might specify requirements for abandonment rate thresholds, measurement windows, and what constitutes an abandoned call.

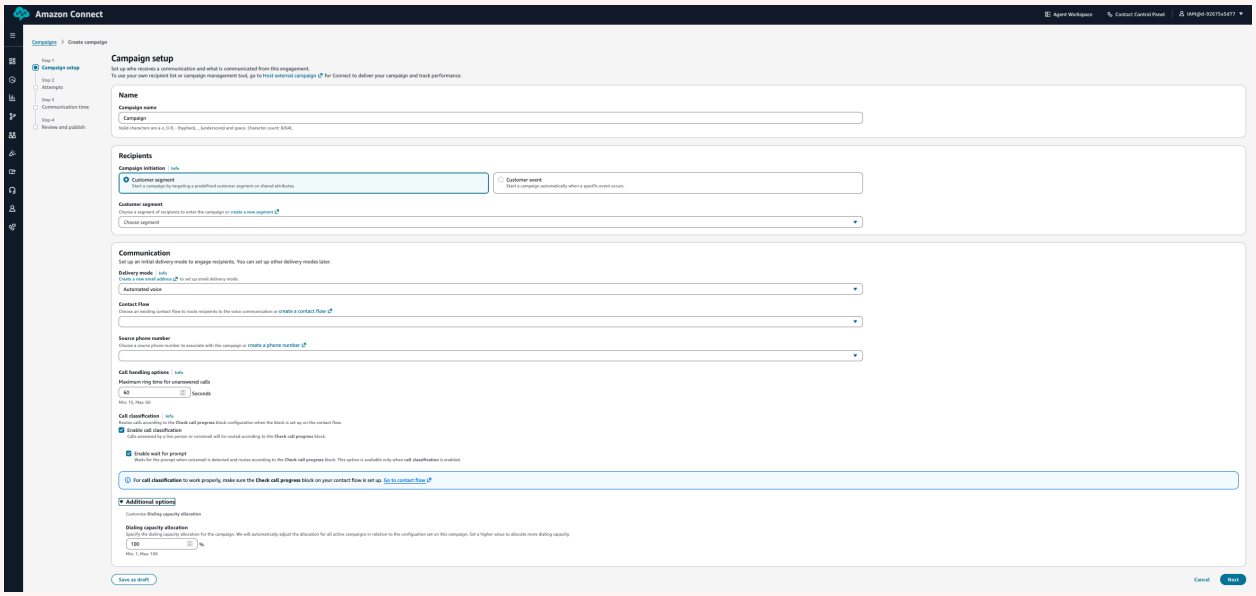
Automated Voice

1. Select the **Contact Flow** to use for the outbound call. If **Reattempts**, call classification, or waiting for a prompt is desired, then the flow must contain a Check call progress block.
2. Select a **Source Phone Number**. This is a phone number associated with your Connect Customer instance.

Important

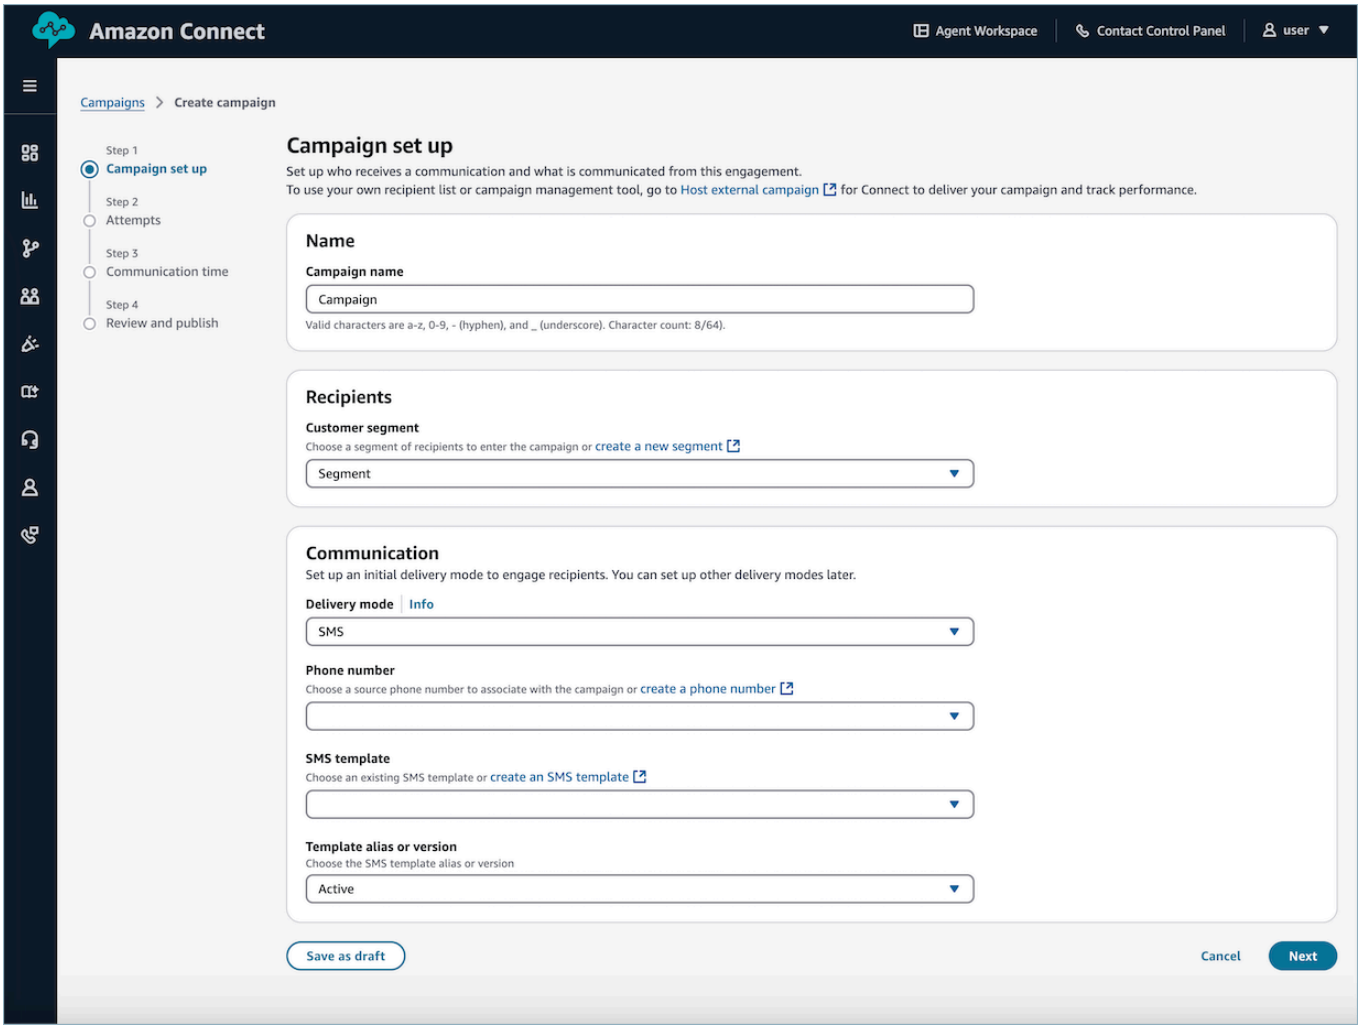
- Not all phone numbers can be used for Connect Customer Outbound campaigns. Outside of the US, UK, Japan, you need to check whether your number is outbound campaigns capable. If you have problems with a specific number not working, contact AWS Support to verify whether your number can be enabled for Outbound campaigns calls.

- Telecom regulations in certain countries dictate use of phone numbers from specific carriers for outbound calling. For more information, see the Amazon Connect Telecoms Country Coverage Guide to learn more.
- Enable call classification if desired.



SMS

1. Select an **Originator**. This is the phone number used to *send* the text messages. For more information, see Step 1: Request a number in AWS End User Messaging SMS.
2. Select an **SMS Message Template** to use when sending.
3. Select the **Template alias or version** number to use with the campaign. If you select an alias, then the contents of SMS sent by the campaign might change when the alias is updated to point to a new template version. On the other hand, if select a version, the campaign will always send the exact same content for the life of the campaign.

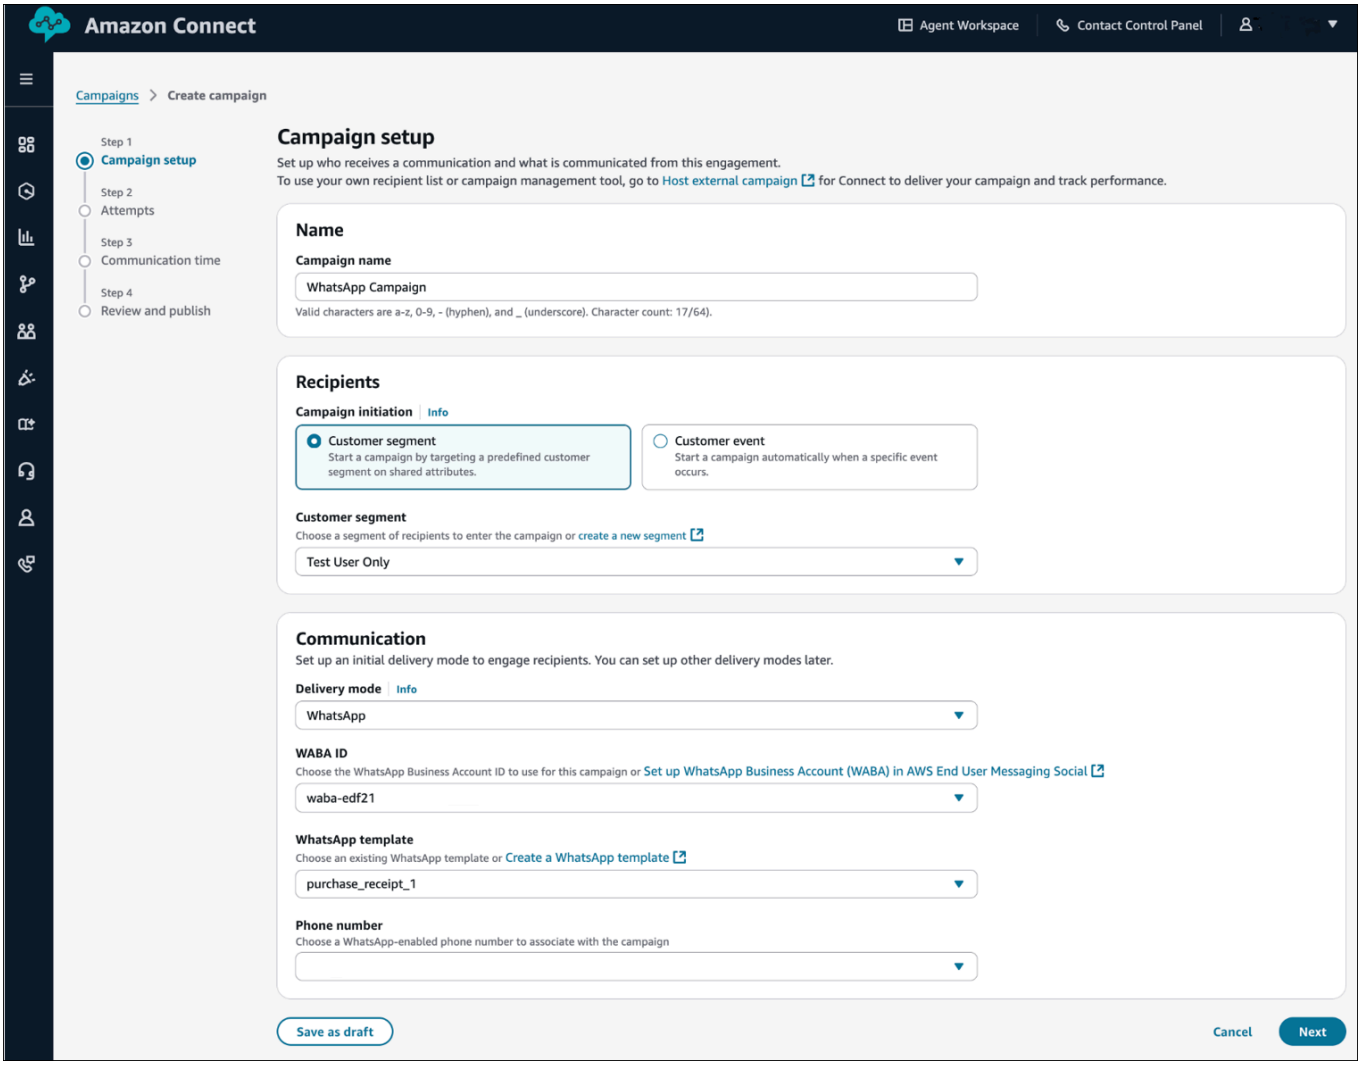


WhatsApp

> **Important**
>
> To enable Connect Customer Outbound Campaigns to send messages and Amazon Q Connect to manage and create WhatsApp message templates, your WhatsApp Business Account (WABA) in AWS End User Messaging Social must be tagged with `AmazonConnectEnabled: True`.
>
> If you linked your WABA to Connect Customer after WhatsApp support for Connect Customer Outbound Campaigns was launched, this tag is automatically applied. For WABAs linked before this launch, you must manually add this tag to enable these capabilities.

For information about adding tags to your WABA, see Getting started with AWS End User Messaging Social.

1. Select an **Originator**. This is the phone number used to *send* the text messages. For more information, see Set up WhatsApp Business messaging.
2. Select a **WhatsApp Message Template** to use when sending.
3. Select the **Template alias or version** number to use with the campaign. If an alias is selected, then the contents of WhatsApp sent by the campaign might change when the alias is updated to point to a new template version. If a Version is selected, the campaign will always send the exact same content for the life of the campaign.



Outbound campaigns attempts

Communications per recipient

You can control how often each recipient is contacted by setting communication limits for the campaign. Simply specify the maximum number of messages a recipient can receive within a defined time frame (for example, per day, week, or month). If a recipient has already received the maximum number of communications within any of the time frames you set, Amazon Connect Outbound Campaigns will automatically skip that recipient and they won't receive additional messages from the campaign.

Example:

If you set a limit of 4 communications per 2 days and 6 communications per 2 weeks (14 days), any recipient who has already received 4 messages in the last 2 days or 6 messages in the last 14 days will not be contacted again by this campaign.

Amazon Connect Outbound Campaigns considers any time a recipient has been contacted, regardless of the recipients interaction with the message, as a communication. For example, a phone call ending in a voicemail is still considered a communication. Amazon Connect Outbound Campaigns will adjust the count of communications if it can determine that the message never reached the end user, and will always err on the side of over-counting.

In addition to setting communication limits for individual campaigns, you can also define **Total Communication Limits** at the instance level. These limits control how many messages a recipient can receive across **all campaigns** running within your Amazon Connect instance over a specific time frame. If a recipient reaches the specified limit—for example, 10 communications per week—they will be excluded from further messaging across all campaigns until the time window resets. This helps make sure that overall message volume stays within acceptable boundaries.

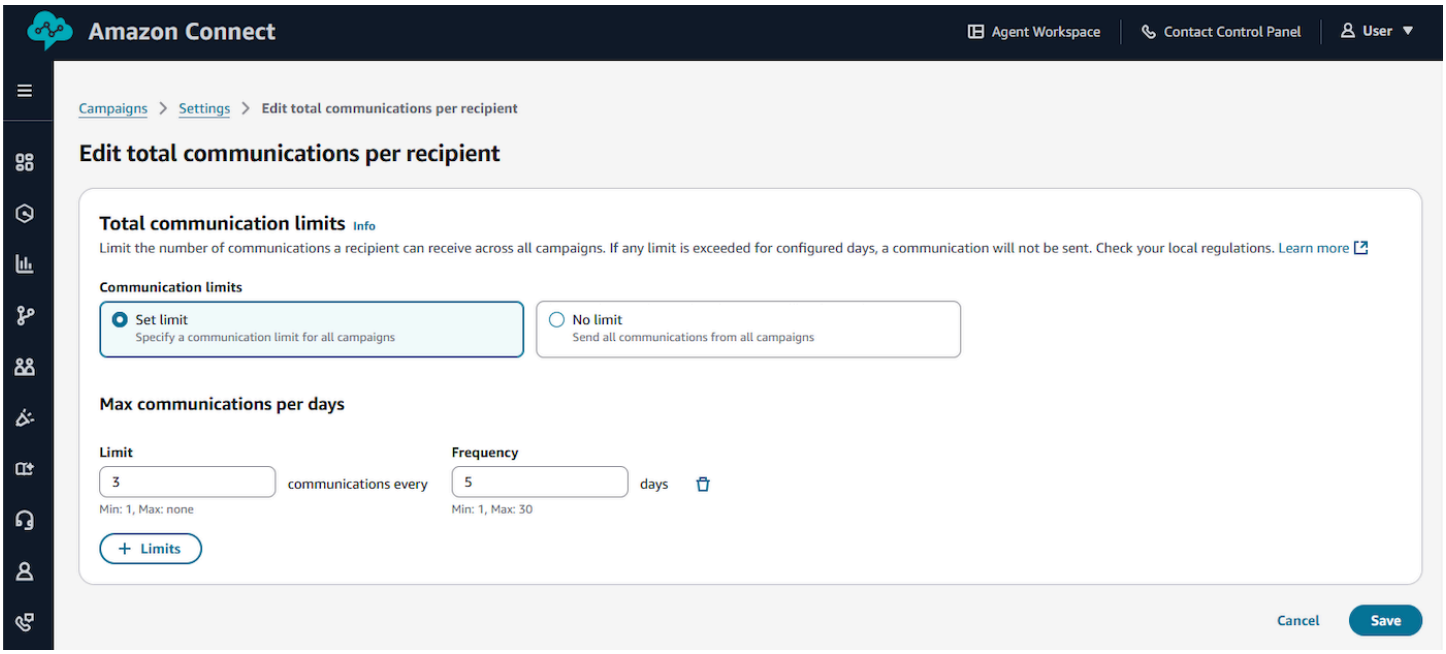
For **critical campaigns**, you have the option to **opt out** of total communication limits by enabling the **Ignore total limits** setting. This allows these campaigns to bypass the instance-wide limits, ensuring important messages are delivered without being blocked by other ongoing campaigns.

Note

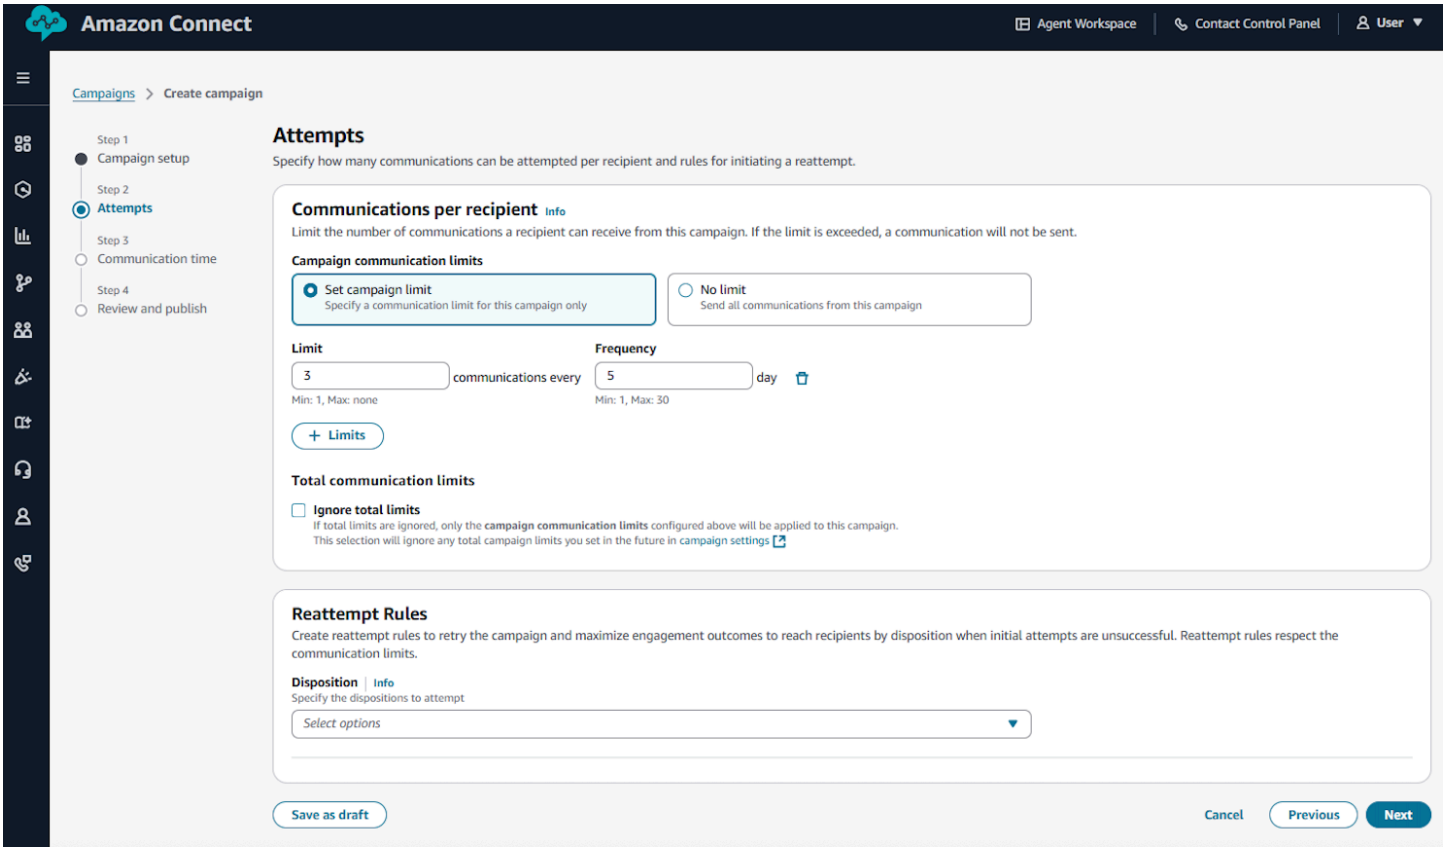
- The total count of messages across campaigns will not necessarily be incremented immediately, but will eventually be accurate. For example, if two campaigns target the same user at the same moment in time, the first campaign's communication might not be reflected in the total communication count by the time the second campaign checks.

- All communications across all campaigns in the active state are considered when determining if a recipient has breached their total limits.
- Connect Customer Outbound Campaigns measures a day as a rolling 24 hour window from the current moment.
- Any communications sent from a campaign that **ignores total limits** will **not count** toward the instance's total communication limits. These campaigns are treated as **outside the scope** of instance-level limits.

Total Communication Limits



Campaign Communication Limits frames



Outbound campaigns reattempt rules

Outcomes for communication result in disposition codes. You can select a subset of those disposition codes for which you would like to re-attempt a communication. The **Dispositions** dropdown is pre-populated with possible codes to use.

- **Retry**: Select the channel on which to retry. After the channel is selected, the possible additional configuration appears.
- **Start**: Select an optional wait time before re-attempting.

Following is a list of disposition codes that are available in the **Disposition** dropdown menu for you to configure a retry rule.

- **Voice channel (Agent and Automated Voice)**

Disposition code in the UI	Campaign event ID (the AMD status)	Description
Busy	`SIT_TONE_BUSY`	The number dialed was busy. The retry behavior for busy numbers can vary. For some campaigns you might want to retry busy numbers, others you might not. It will depend on your specific campaign configuration.
Invalid number	`SIT_TONE_INVALID_NUMBER`	The number dialed was not a valid number.
Unanswered	`AMD_UNANSWERED`	The number dialed kept ringing, but the call was not picked up. Typically this status triggers a retry to reach the customer again later.

Voicemail	`VOICEMAIL_BEEP`
	
	`VOICEMAIL_NOBEEP`
		The number dialed was answered by voicemail with a beep and without a beep.
		
		Typically this status triggers a retry to reach the customer again later.

Note

By default, you can only re-attempt one time unless you configure engagement preferences and upload data into Customer Profiles.

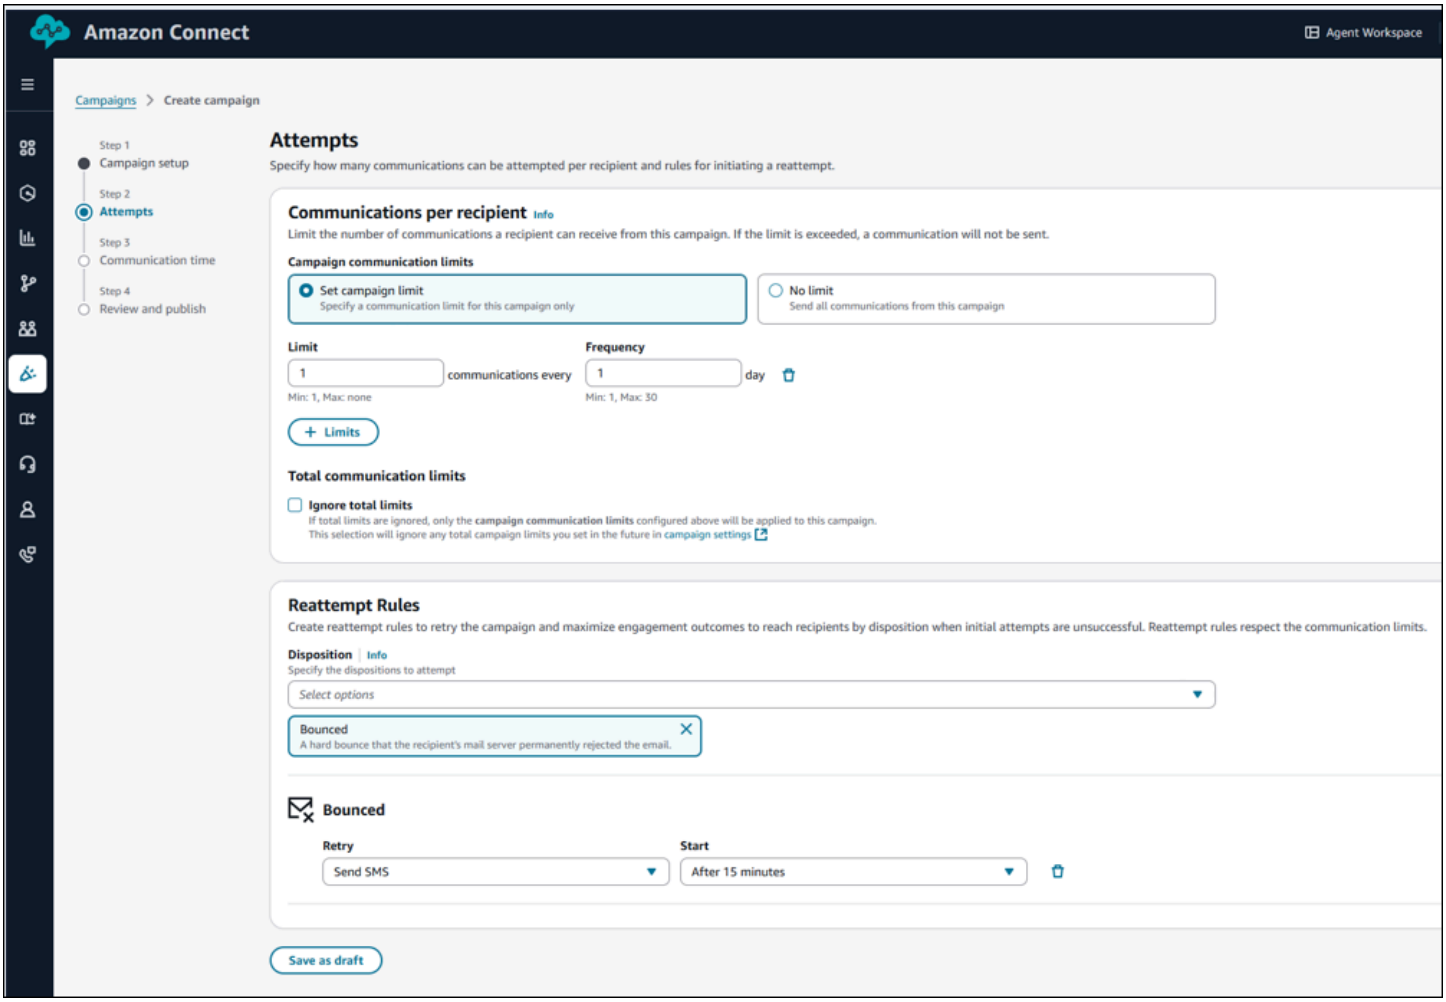
- **Email channel**

Disposition code in the UI	Campaign event ID	Description
Bounced	`Bounce`	An issue related to the recipient's email or server permanently rejected the email, preventing Connect Customer from delivering the message.

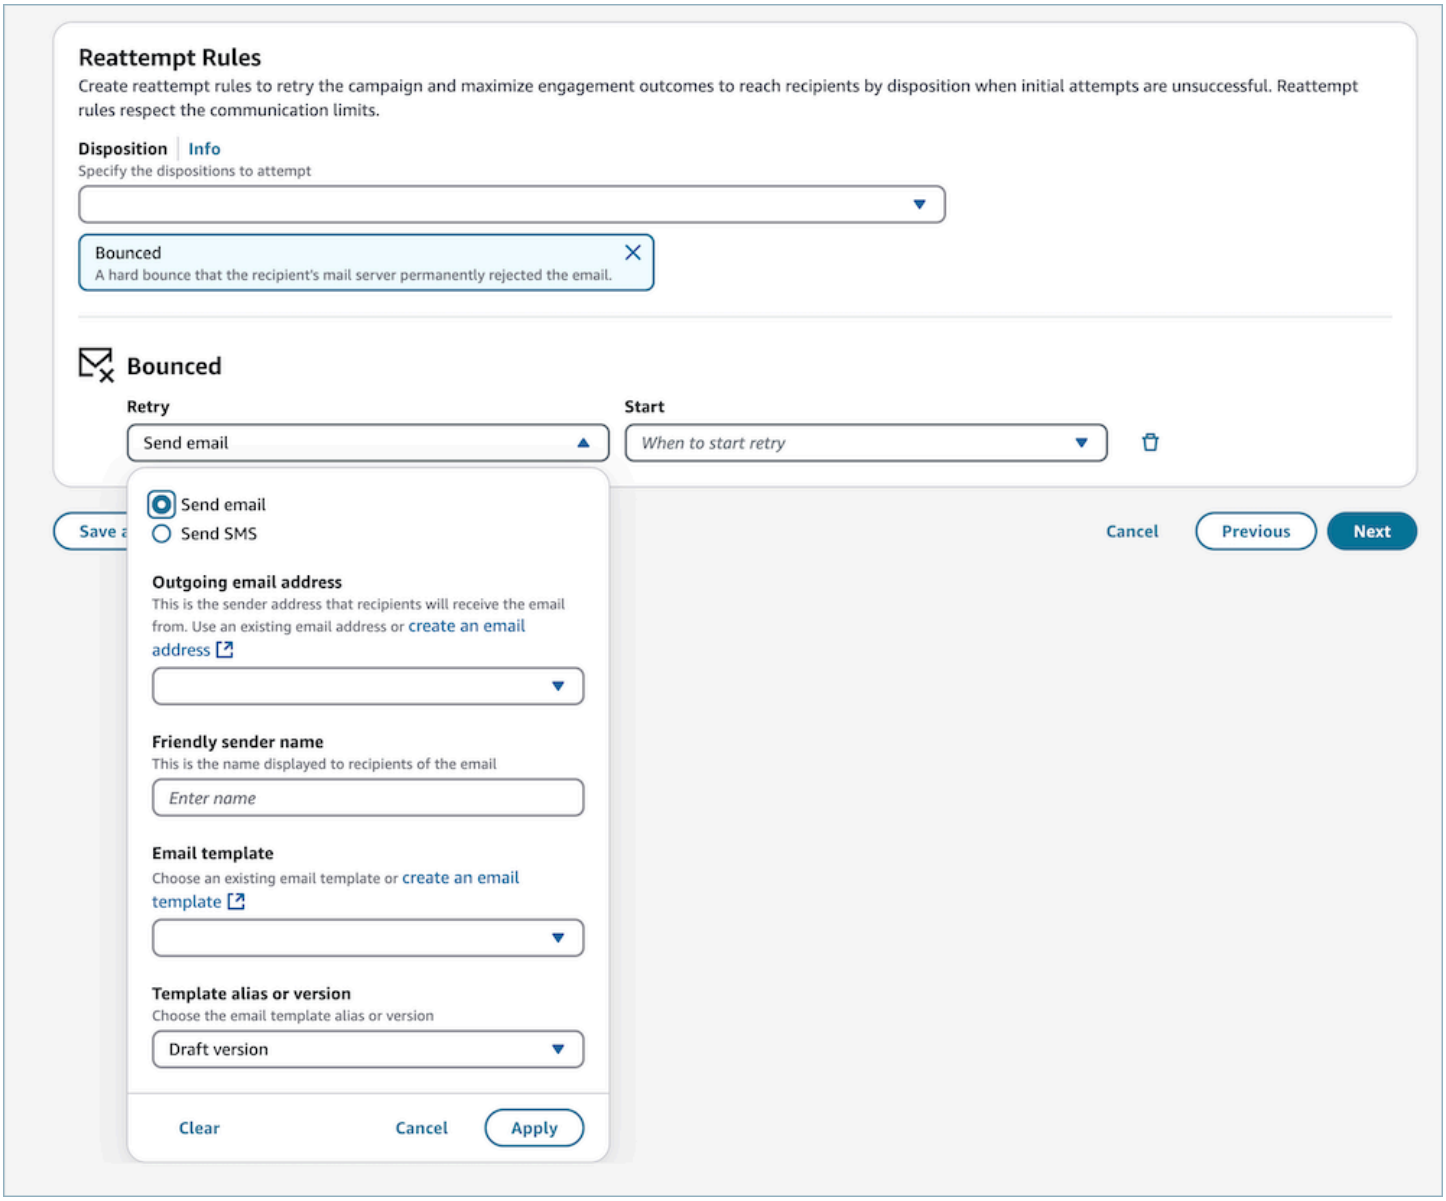
- **SMS channel**

Disposition code in the UI	Campaign event ID	Description
Blocked	`TEXT_BLOCKED`	The recipient's device or carrier is blocking SMS messages.
Invalid number	`TEXT_INVALID`	The destination phone number is not valid.
Unreachable	`TEXT_UNREACHABLE`	Unreachable events occur when the recipient's device is currently unavailable. For example, the device might be powered off, or might be disconnected from the network.

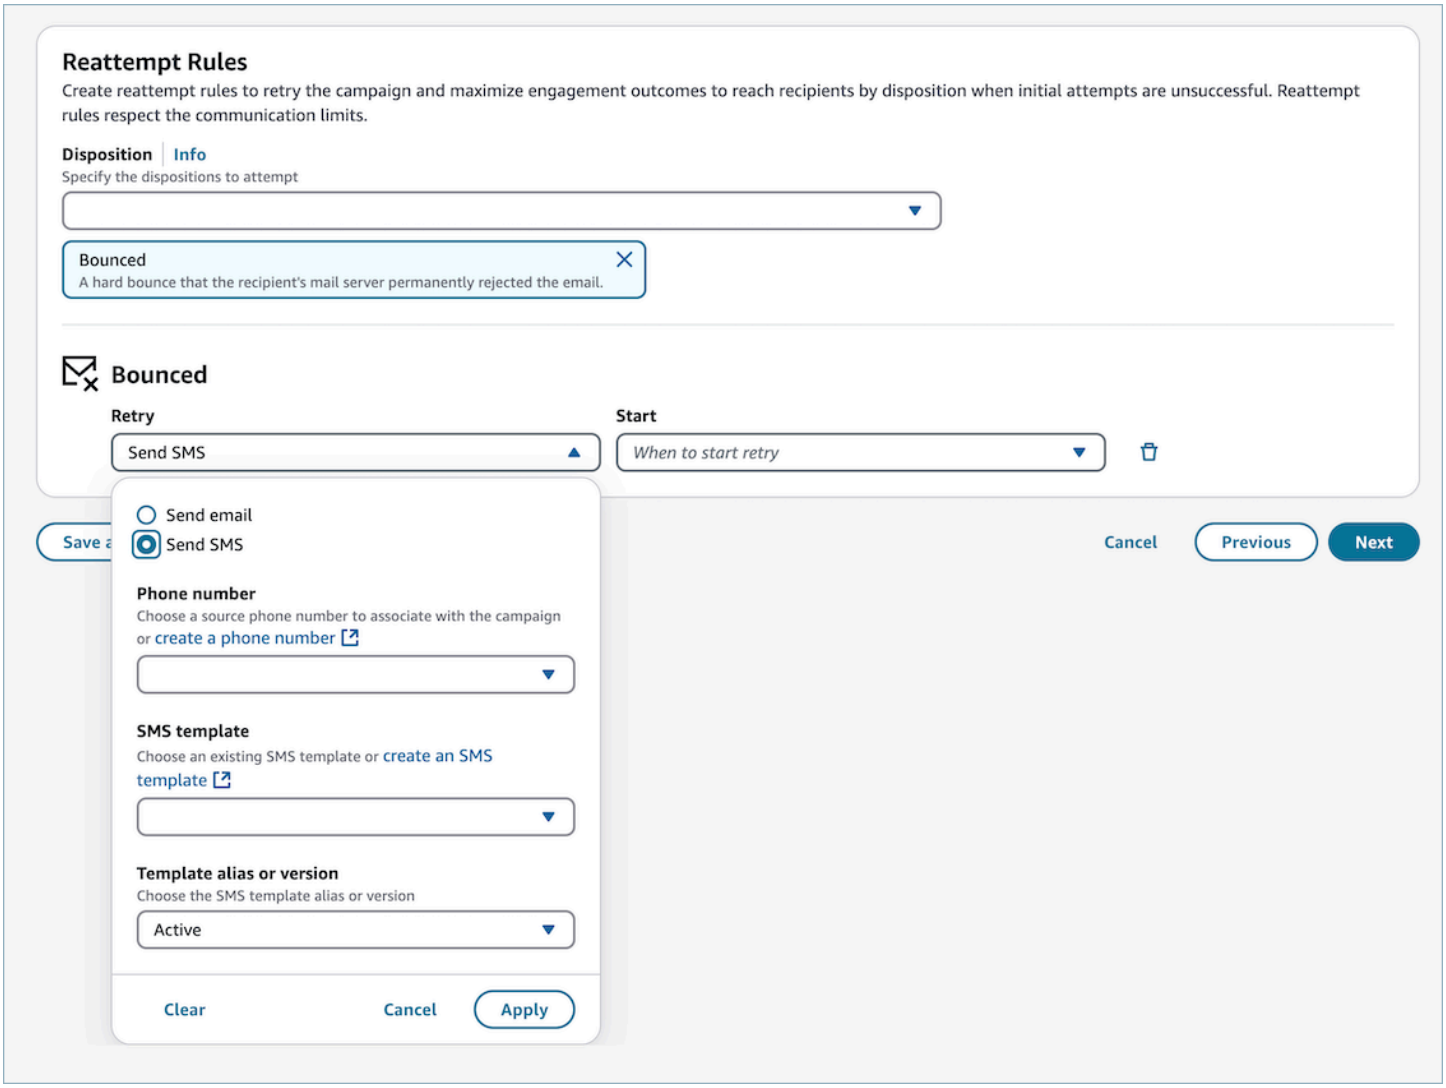
The following image shows an example of setting the **Retry** rule for **Bounced** email.



The following image shows if you choose **Send email** in response to a **Bounced** email, you are prompted to provide the **Outgoing email address**, **Friendly sender name**, **Email template**, and version.



The following image shows if you choose **Send SMS** in response to a **Bounced** email, you are prompted to provide the **Phone number**, **SMS template**, and **Template alias or version**.



Campaign set up and Cycling through recipient contact types for communication

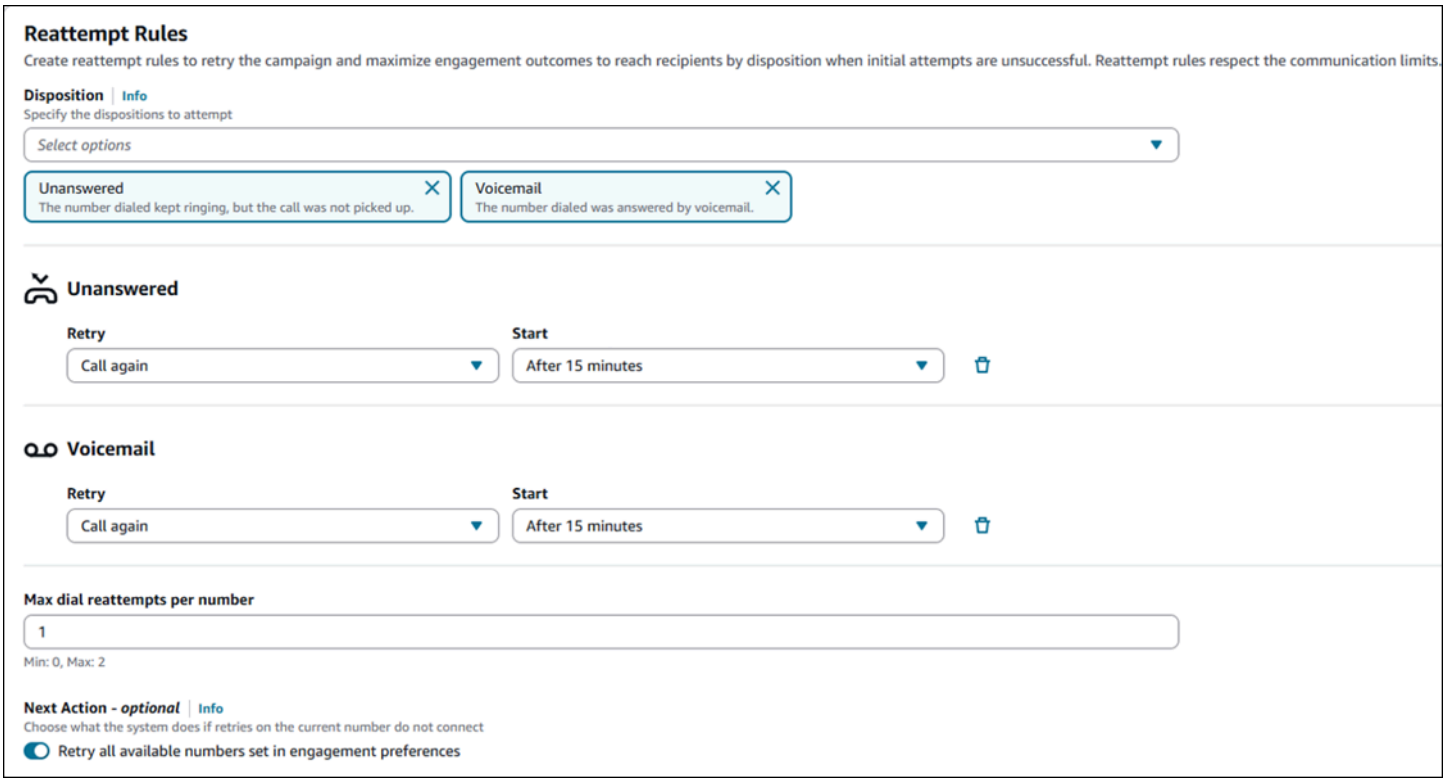
The purpose of this section is to showcase how you can configure the campaign to cycle through multiple contact types for each recipient.

> **Note**
>
> Configure engagement preferences and upload data into Customer Profiles. For details about customer profile ingestion before to creating a campaign, see Ingesting account-based profiles.

- The **Max dial re-attempts per number** defines the count of reattempts for each contact type across all dispositions.

- **Next action - optional** enables switching to the next available contact type for the profile/account as provided using engagement preferences in Customer Profiles

> **Note**
>
> You can set the number of retry attempts and next actions, but communications will not exceed the maximum limits set for each recipient.

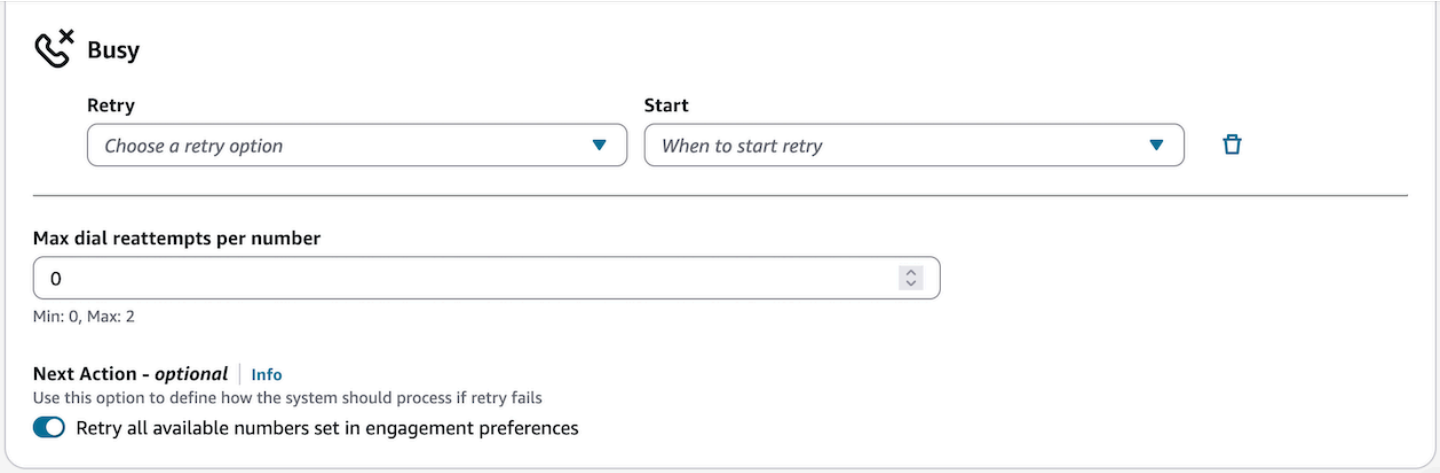


Example scenarios

Priority dialing order (in Customer Profile):

- Primary (Mobile)
- Secondary (Home)
- Tertiary (Work)

Scenario A - Call Attempts: All numbers fail with "Busy"- Retry action: Call again. Max dial attempts per number: 0. Toggled to retry all available numbers for the recipient.



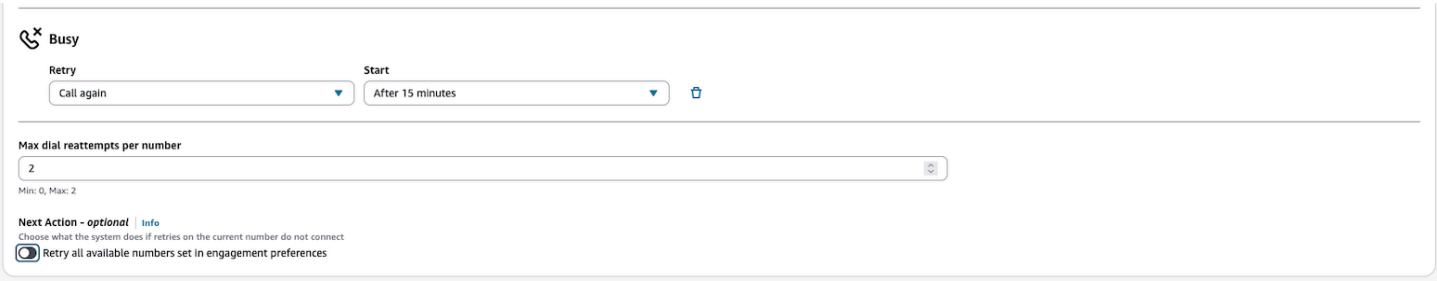
Attempt	Phone Number	Disposition	Action Taken	Total Attempts
1	Mobile	Busy	Move on to next number (home)	1
2	Home	Busy	Move on to next number (work)	2
3	Work	Busy	End - max dial attempts reached	3

Scenario B - Call Attempts: All numbers fail with "Busy"- Retry action: Call again. Max dial attempts per number: 2. Toggled to retry all available numbers for the recipient.

Attempt	Phone Number	Disposition	Action Taken	Total Attempts
1	Mobile	Busy	Wait 15 mins, call again	1

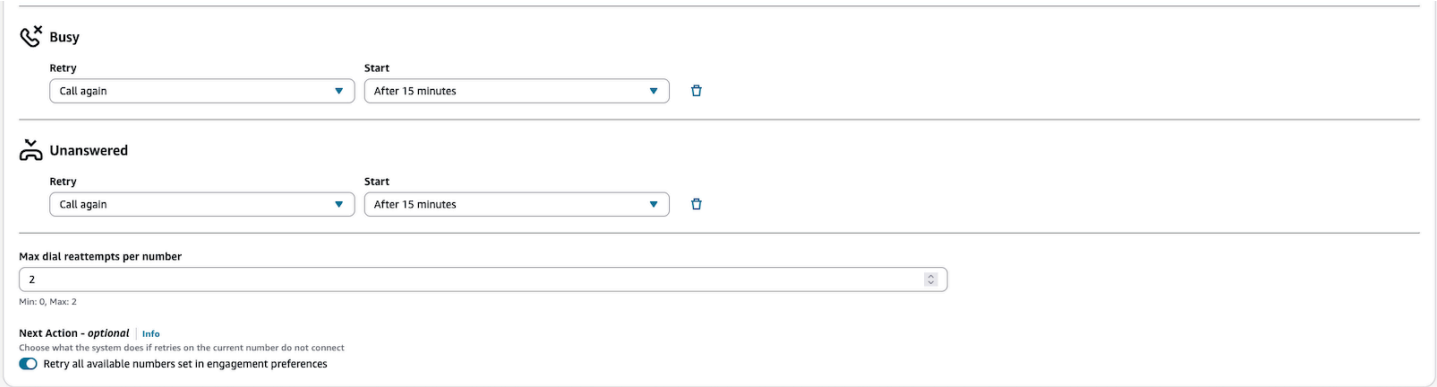
Attempt	Phone Number	Disposition	Action Taken	Total Attempts
2	Mobile	Busy	Wait 15 mins, call again	2
3	Mobile	Busy	Move on to next number (Home)	3
1	Home	Busy	Wait 15 mins, call again	4
2	Home	Busy	Wait 15 mins, call again	5
3	Home	Busy	Move on to next number (Work)	6
1	Work	Busy	Wait 15 mins, call again	7
2	Work	Busy	Wait 15 mins, call again	8
3	Work	Busy	End - max dial attempts reached	9

Scenario C - Call Attempts: All numbers fail with "Busy"- Retry action: Call again. Max dial attempts per number: 2. Toggled NOT to retry all available numbers for the recipient.



Attempt	Phone Number	Disposition	Action Taken	Total Attempts
1	Mobile	Busy	Wait 15 mins, call again	1
2	Mobile	Busy	Wait 15 mins, call again	2
3	Mobile	Busy	End - max dial attempts reached	3

Scenario D - Call Attempts: Mixed disposition between "Unanswered", "Busy"- Retry action: Call again. Max dial attempts per number: 2. Toggled to retry all available numbers for the recipient.



Attempt	Phone Number	Disposition	Action Taken	Total Attempts
1	Mobile	Unanswered	Wait 30 mins, call again	1
2	Mobile	Busy	Wait 15 mins, call again	2
3	Mobile	Busy	Move on to next number (Home)	3
1	Home	Busy	Wait 15 mins, call again	4

Attempt	Phone Number	Disposition	Action Taken	Total Attempts
2	Home	Unanswered	Wait 30 mins, call again	5
3	Home	Unanswered	Move on to next number (Work)	6
1	Work	Busy	Wait 15 mins, call again	7
2	Work	Busy	Wait 15 mins, call again	8
3	Work	Busy	End - max dial attempts reached	9

Communication Time

You can specify valid times to attempt to contact your users. The **Active communication time** specifies those valid times, based on the day of the week. **Exceptions to communication time**, an optional setting, specifies specific days of the year during which you want no communications sent, even if that day happens to fall in an active communication time.

Time zone

In order for the Campaign to determine appropriate time to attempt communication with a particular recipient, you need to provide a **Time Zone**. You might either select a **Standard time zone**, which will be used for all recipients, or you might specify the **Recipient's local time zone**. Recipients with no time zone specified are excluded from message deliveries.

- **Standard time zone**:

  The time zone selected will be used for all recipients. Select this option if you know the time zone of all recipients in your segment or if you want to send all communications in the same time zone.

- **Recipient's local time zone**:

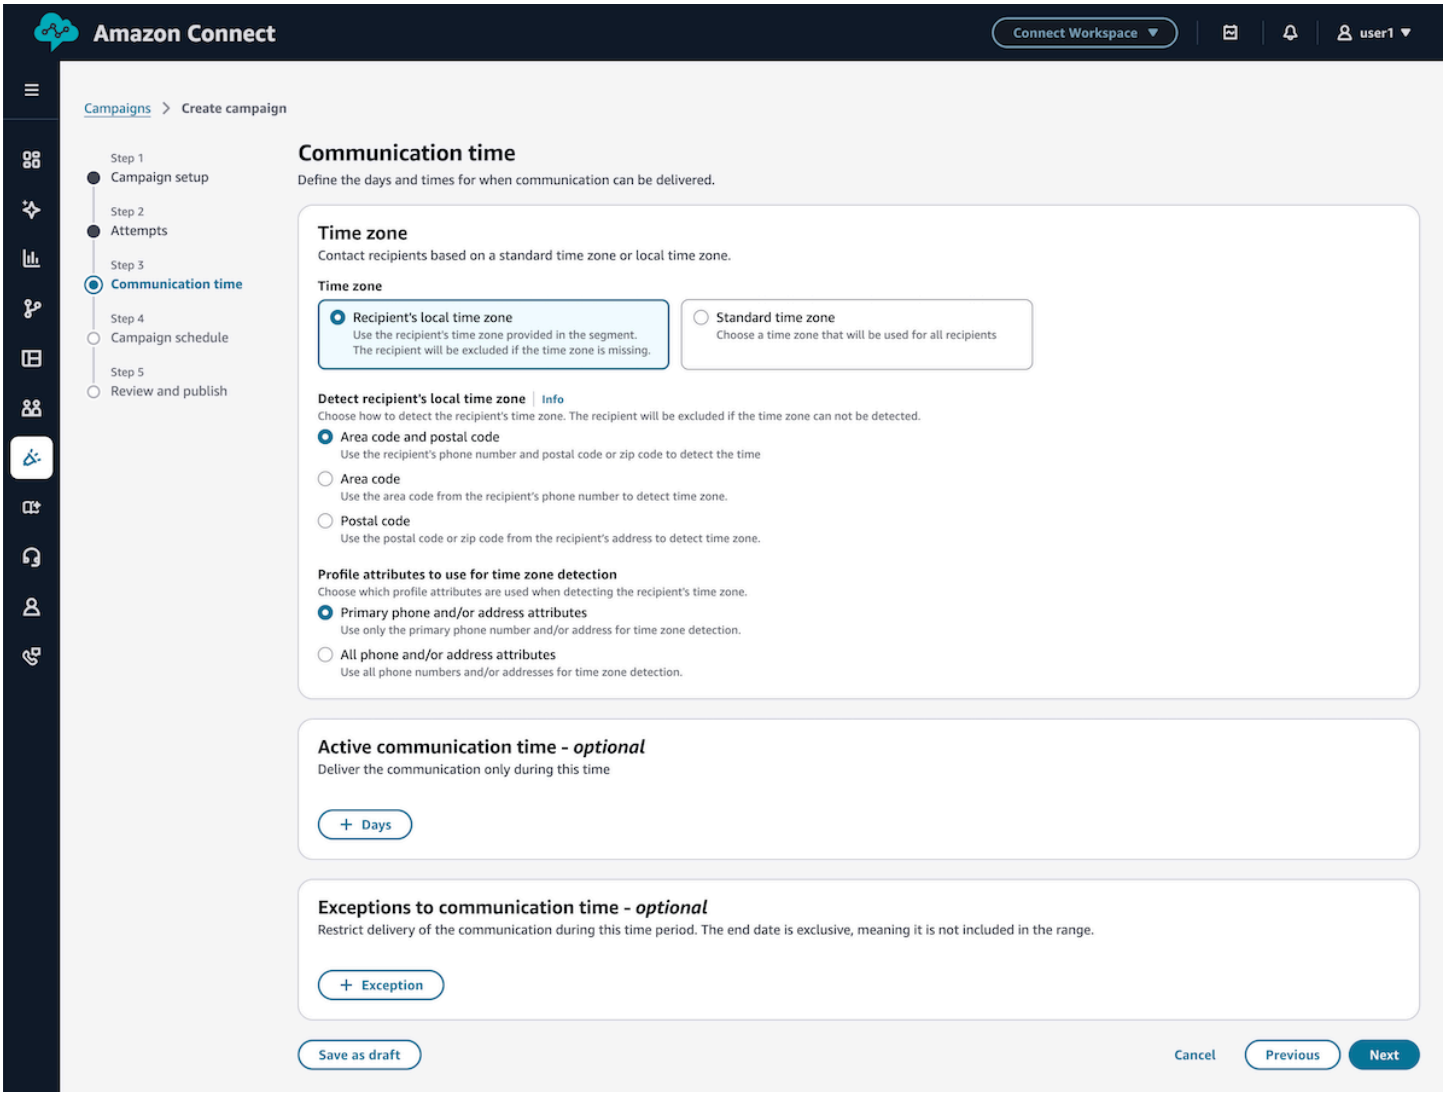
Connect Customer Outbound Campaigns use the provided Address or the area code from the Phone Number to infer the recipients time zone. If the time zone can't be determined (for example, if either the Address or Phone Number is missing or is invalid), the recipient will be dropped from the Campaign. Select this option if it's important to send communications to recipients only during their specific local times.

When you select **Recipient's local time zone**, you configure the following settings:

- **Detect recipient's local time zone** — Choose the method used to detect the recipient's time zone. Connect Customer Outbound Campaigns use a profile's Address or Phone Number's area code to infer the recipient's time zone.

  To detect a recipient's time zone from their postal code, you must populate the profile's `Address.Country` together with `Address.PostalCode`. Postal code-based time zone detection requires `Country`; other detection methods do not require `Country`. If `Country` is missing, we cannot determine the recipient's time zone from the postal code. We drop the recipient from the Campaign with a `DROPPED_MISSING_TIMEZONE` status.

- **Profile attributes to use for time zone detection** — Choose the scope of profile attributes used for time zone detection:
  - **Primary only** — Uses only the primary phone number or address attributes from the recipient's customer profile to determine the time zone.
  - **All available** — Uses all phone number or address attributes from the recipient's customer profile to determine the time zone.



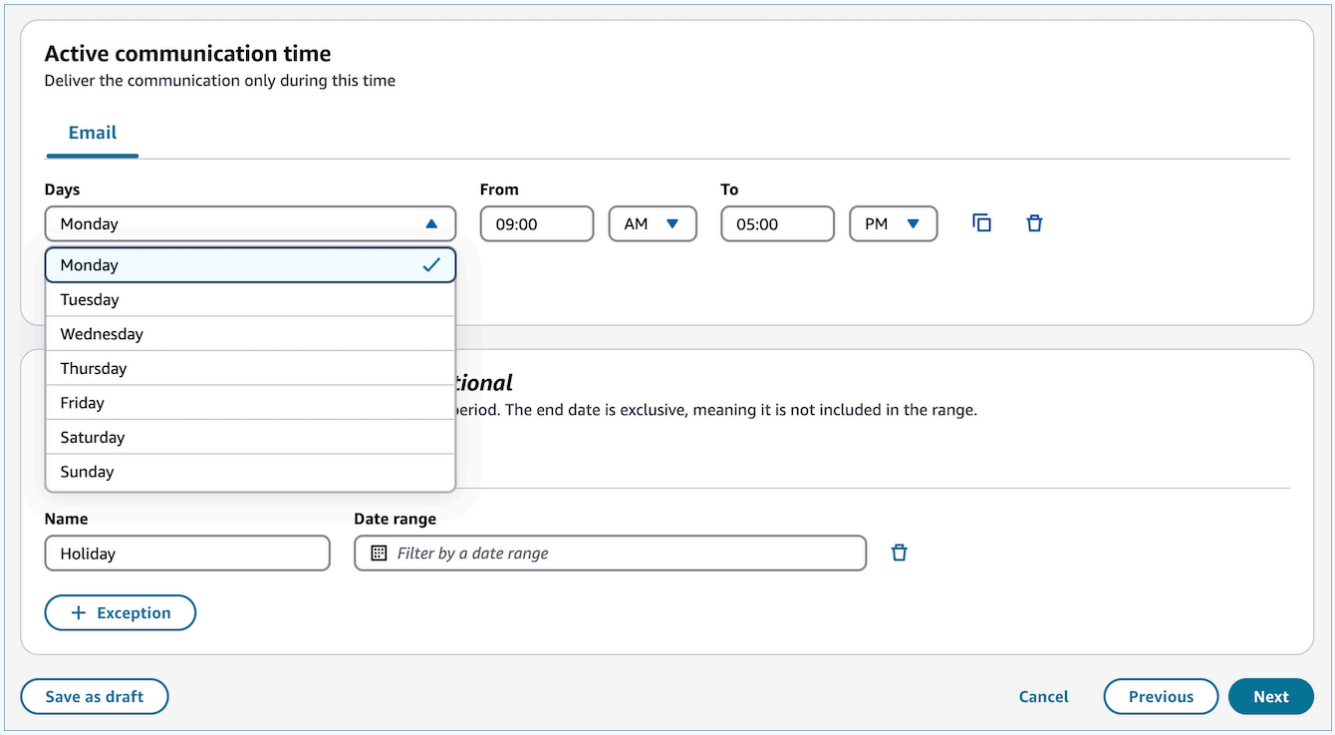
Active communication time

The **Active communication time** represents the times during which Connect Customer Outbound campaigns might send communications for this campaign. To add active communication times:

1. Select the channel. Alternatively, select **Apply to all channels** to apply the active communication times to each channel.
2. Select the day of the week to configure. You can add multiple active communication times for each day, if desired.
3. Select the time frame during which Connect Customer Outbound campaigns can send communications on the given day.

Note

- Connect Customer Outbound campaigns will evaluate the **From** and **To** times relative to either the **Standard time zone** or the **Recipient's local time zone**, whichever is specified.
- If you don't provide an **Active communication time**, communications to intended recipients are attempted as soon as the campaign is published.

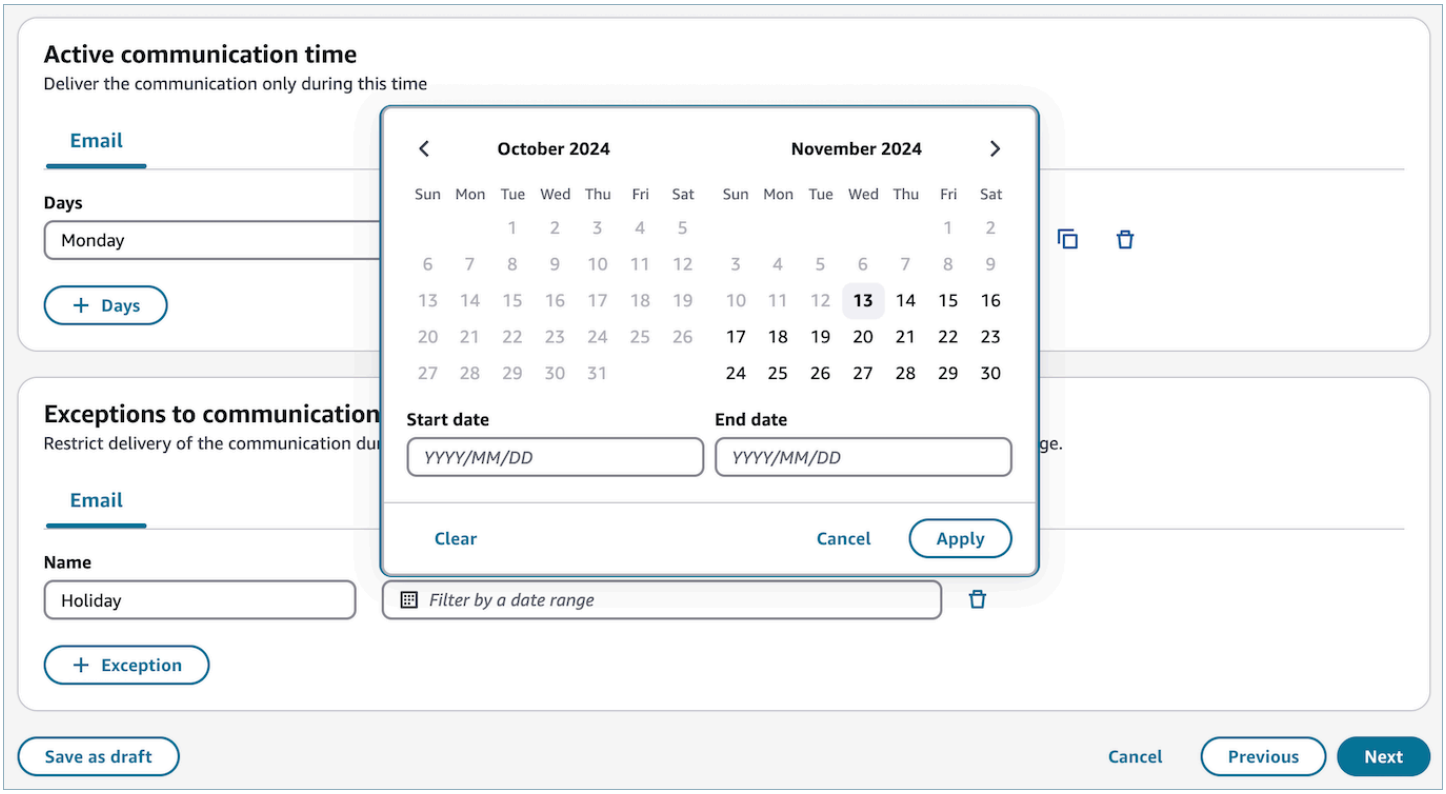


Exceptions to communication time - (optional)

Exceptions to communication time is an optional set of specific calendar days for which you do not want communications sent. If exceptions are included in the Campaign, then active communication times must also be specified. To add exceptions to communication time:

1. Select the channel.
2. Add a **Name** for the exception. This name is only for informational purposes and does not affect the running of the campaign.
3. Select the **Date range** for the exception.

> **Important**
>
> The end date is exclusive. For example, if you select July 12 - 13, it blocks all communications only from 00:00 July 12 to 23:59 July 12. **July 13 would have no exception**.



Review and publish

Take a moment to review your campaign before publishing.

> **Important**
>
> These settings cannot be changed after your campaign has been published.

After you have reviewed your campaign, choose **Publish** to schedule your campaign.

Schedule campaign

Specify when you want your campaign to begin:

- **Start now**: Start the campaign right away.
- **Start later**: Select the specific day and time for the campaign to begin.
- **Expiry Date and Time**: The date and time at which Connect Customer Outbound campaigns should end the campaign. An expired campaign appears with a **Completed** status a few moments after expiry time.

The start and end times of a campaign that starts now or a campaign that starts later are based on your local time zone.

Repeats

If you want your campaign to repeat running, select the **Repeats** radio button and choose a **Frequency**. Connect Customer Outbound campaigns will then refresh profiles in the segment specified for this campaign at the same frequency you select. For example, if you schedule your campaign to start at 7:03AM EST and use a Daily Frequency, then profiles will be refreshed in the segment daily at 7:03AM EST.

Important

- A recipient can be active only in a campaign once at any given time. So if they are still waiting to exit the campaign when the next Segment Snapshot is created, and are a member of that Snapshot, they are **NOT** allowed to enter the campaign as a part of the second Snapshot.
- If a recipient is a part of a segment Snapshot and is not currently in the campaign, they are allowed to enter, regardless of whether they have previously gone through the campaign.

Entry limits

Entry limits control how many times and how often the same profile can enter the campaign. By default, profiles can enter the campaign unlimited times with no interval restriction. To customize entry limits, select the **Customize entry limits** checkbox.

- **Entry limit**: The maximum number of times the same profile can enter the campaign. Set to 0 for unlimited entries.
- **Entry interval limit**: The minimum time that must pass before a profile can enter the campaign again. Specify a numeric value and select a time unit (hours or days). Set to 0 for no minimum interval. If the entry interval limit is shorter than the refresh frequency, the refresh frequency takes precedence.

Example: Consider a campaign that targets profiles whose subscription expires within 7 days. With a refresh frequency of 1 hour, an entry limit of 3, and an entry interval of 3 hours:

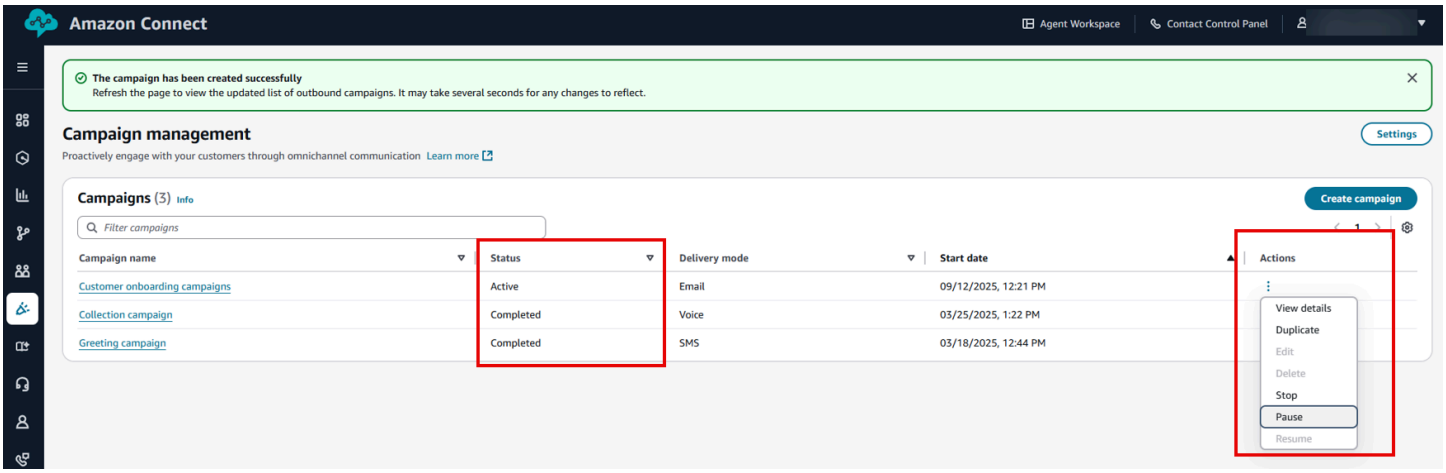
- The segment is re-evaluated every hour.
- Each profile can enter the campaign up to 3 times.
- A profile won't enter again for at least 3 hours, even though the campaign refreshes hourly.

Publish

Choose **Publish** to schedule your campaign.

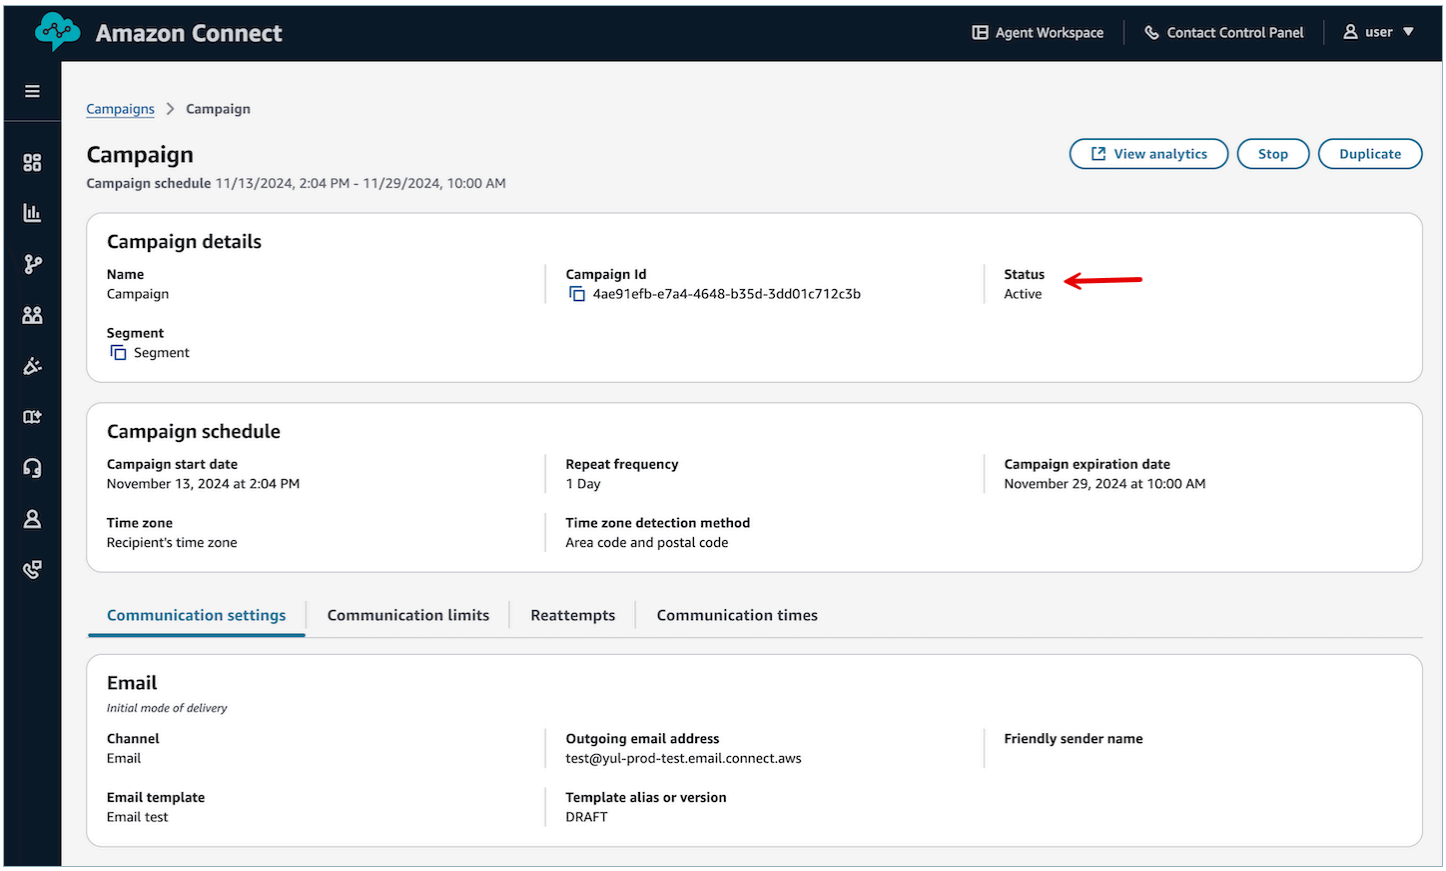
Campaign states

After a campaign is running, you can stop it. You can also delete a campaign at any time.



Following is a description of each campaign state:

- **Draft**: The campaign is being developed and hasn't been published yet.
- **Active**: The campaign has been developed and published. Depending on the campaign's schedule, the campaign might currently be running or scheduled to start running at a later time.
- **Stopped**: The campaign is stopped. You can't resume a campaign that is stopped.
- **Error**: An error state caused the campaign to fail.
- **Completed**: The campaign has finished running. All participants have entered the campaign and no participants are waiting to complete the campaign.



Visual Journey Builder

Using Spark SQL segments in Journeys

By default, Spark SQL segments aren't available for use in Journeys. To enable them, contact AWS Support to request access.

Before using Spark SQL segments in a journey, consider the following limitations:

- Spark SQL segment processing can take up to 2 hours to complete. However, Outbound Campaigns waits only 30 minutes for segment processing to complete. If Spark SQL segment processing exceeds this 30-minute timeout, the journey fails.
- If you use a Spark SQL segment for the dial criteria parameter in the Send Communication voice block, the criteria won't reflect the latest state of the segment.

A journey is an automated, multi-step outbound campaign. It reaches your customers across more than one channel, such as SMS, email, and voice. Each step can branch based on how a customer responds, so you can guide different customers down different paths.

Use the Visual Journey Builder to create a journey when your outreach needs more than a single message on one channel. For example, you can send a promotional SMS, and then email the customers who do not respond. To create a single-channel campaign instead, use the the section called “Guided Campaign Builder”.

The following steps show you how to create a journey with the Visual Journey Builder.

1. From the **Outbound Campaigns** page, choose **Create Journey**.
2. Enter a journey **Name**.
3. Select a Customer Segment or Customer event to use for this journey. Recipients for the journey will be determined at the journey's scheduled start time using the chosen segment or customer event.
4. To connect with a journey, first create a **journey flow** that supports multi-step experiences triggered by events or audience segments, then select the flow you want to connect to this journey.
5. If you haven't created a journey flow yet, you can choose "create journey flow" and will take you to the flow canvas. Please refer to **Journey flow blocks definition** for details.
6. If the selected journey flow has voice channel, you will use the **Voice setup** option to define the details.
7. You can choose Agent assisted voice or automated voice and complete the channel configuration. Please refer to details on the section called “Outbound campaigns channel configurations”.

Delivery guardrails

You can control how often each recipient is contacted by setting communication limits for the Journey. Simply specify the maximum number of messages a recipient can receive within a defined time frame (for example, per day, week, or month). If a recipient has already received the maximum number of communications within any of the time frames you set, Connect Customer Outbound Campaigns will automatically skip that recipient and they won't receive additional messages from the Journey.

Example:

If you set a limit of 4 communications per 2 days and 6 communications per 2 weeks (14 days), any recipient who has already received 4 messages in the last 2 days or 6 messages in the last 14 days will not be contacted again by this Journey.

Connect Customer Outbound Campaigns considers any time a recipient has been contacted, regardless of the recipients interaction with the message, as a communication. For example, a phone call ending in a voicemail is still considered a communication. Amazon Connect Outbound Campaigns will adjust the count of communications if it can determine that the message never reached the end user, and will always err on the side of over-counting. In addition to setting communication limits for individual journeys, you can also define **Total Communication Limits** at the instance level. These limits control how many messages a recipient can receive across all journeys running within your Amazon Connect instance over a specific time frame. If a recipient reaches the specified limit—for example, 10 communications per week—they will be excluded from further messaging across **all journeys** until the time window resets. This helps make sure that overall message volume stays within acceptable boundaries.

For **critical journeys**, you have the option to **opt out** of total communication limits by enabling the **Ignore total limits** setting. This allows these journeys to bypass the instance-wide limits, ensuring important messages are delivered without being blocked by other ongoing journeys.

> **Note**
>
> The total count of messages across journeys will not necessarily be incremented immediately, but will eventually be accurate. For example, if two journeys target the same user at the same moment in time, the first journey's communication might not be reflected in the total communication count by the time the second campaign checks.
> All communications across all journeys in the active state are considered when determining if a recipient has breached their total limits.

Connect Customer Outbound Campaigns measures a day as a rolling 24 hour window from the current moment.
Any communications sent from a journey that **ignores total limits** will not count toward the instance's total communication limits. These journeys are treated as **outside the scope** of instance-level limits.

Communication time

You can specify valid times to attempt to contact your users. The **Active communication time** specifies those valid times, based on the day of the week. **Exceptions to communication** time, an optional setting, specifies specific days of the year during which you want no communications sent, even if that day happens to fall in an active communication time.

Time zone

In order for the Journey to determine appropriate time to attempt communication with a particular recipient, you need to provide a **Time Zone**. You might either select a **Standard time zone**, which will be used for all recipients, or you might specify the **Recipient's local time zone**. Recipients with no time zone specified are excluded from message deliveries.

- **Standard time zone**: The time zone selected will be used for all recipients. Select this option if you know the time zone of all recipients in your segment or if you want to send all communications in the same time zone.
- **Recipient's local time zone**: Connect Customer Outbound Campaigns use profile attributes to infer each recipient's time zone. If the time zone cannot be determined, the recipient will be dropped from the Journey. Select this option if it's important to send communications to recipients only during their specific local times.

  When you select **Recipient's local time zone**, you configure the following settings:

  - **Detect recipient's local time zone** — Choose the method used to detect the recipient's time zone. Connect Customer Outbound Campaigns use a profile's Address or Phone Number's area code to infer the recipient's time zone.

    To detect a recipient's time zone from their postal code, you must populate the profile's `Address.Country` together with `Address.PostalCode`. Postal code-based time zone detection requires `Country`; other detection methods do not require `Country`. If `Country` is missing, we cannot determine the recipient's time zone from the postal code. We drop the recipient from the Journey with a `DROPPED_MISSING_TIMEZONE` status.

- **Profile attributes to use for time zone detection** — Choose the scope of profile attributes used for time zone detection:
  - **Primary only** — Uses only the primary phone number or address attributes from the recipient's customer profile to determine the time zone.
  - **All available** — Uses all phone number or address attributes from the recipient's customer profile to determine the time zone.

Active communication time (optional)

The **Active communication time** represents the times during which Connect Customer Outbound campaigns might send communications for this journey. To add active communication times: Select the channel. Alternatively, select Apply to all channels to apply the active communication times to each channel. Select the day of the week to configure. You can add multiple active communication times for each day, if desired. Select the time frame during which Amazon Connect Outbound campaigns can send communications on the given day.

Exceptions to communication time (optional)

Exceptions to communication time is an optional set of specific calendar days for which you do not want communications sent. If exceptions are included in the Journey, then active communication times must also be specified. To add exceptions to communication time:

Select the channel. Add a **Name** for the exception. This name is only for informational purposes and does not affect the running of the journey. Select the **Date range** for the exception.

Review and publish

Take a moment to review your journey before publishing.

> ⚠ **Important**
>
> These settings cannot be changed after your journey has been published.

After you have reviewed your journey, choose **Publish** to schedule your journey.

Schedule journey

Specify when you want your journey to begin:

- **Start now**: Start the journey right away.
- **Start later**: Select the specific day and time for the journey to begin.
- **Expiry Date and Time**: The date and time at which Connect Customer Outbound campaigns should end the journey. An expired journey appears with a **Completed** status a few moments after expiry time. The start and end times of a journey that starts now or a journey that starts later are based on your local time zone.

Repeats

If you want your journey to repeat running, select the **Repeats** radio button and choose a **Frequency**. Connect Customer Outbound campaigns will then refresh profiles in the segment specified for this journey at the same frequency you select. For example, if you schedule your journey to start at 7:03AM EST and use a Daily Frequency, then profiles will be refreshed in the segment daily at 7:03AM EST.

> **Important**
>
> A recipient can be active only in a journey once at any given time. So if they are still waiting to exit the journey when the next Segment Snapshot is created, and are a member of that Snapshot, they are **NOT** allowed to enter the journey as a part of the second Snapshot.
> If a recipient is a part of a segment Snapshot and is not currently in the journey, they are allowed to enter, regardless of whether they have previously gone through the journey.

Choose **Publish** to schedule your journey.

Edit a journey

You can edit a journey that is in the **Active** or **Paused** state. You can edit the following fields:

- **Journey flow**
- **Segment**
- **Communication limits**
- **Active communication time**
- **Exceptions to communication time**

To edit a journey, complete the following steps:

1. View the journey's details.
2. Choose **Edit**.

Create an outbound campaign using the API or CLI

You can create and manage outbound campaigns programmatically using the AWS CLI or the Amazon Connect Outbound Campaigns API. This topic explains how to create a Connect Customer outbound campaign, define campaign flows, and reference lifecycle commands using the CLI.

> **Note**
>
> We recommend using the V2 API to create campaigns, which is available in all AWS Regions where outbound campaigns is supported. The capabilities described on this page are available only through the V2 API.

Prerequisites

Before you create a campaign using the API or CLI, make sure you have the following:

- An Connect Customer instance with outbound calling enabled.
- An AWS KMS key configured for outbound campaigns. See Create an AWS KMS key.
- Outbound campaigns enabled on your instance. See Configure outbound campaigns.
- A Customer Profiles segment ARN for your campaign recipients.
- Message templates created in your agent assist knowledge base. For more information, see Create message templates.
- The AWS CLI version 2 installed and configured. For more information, see Installing the AWS CLI.

Create a campaign flow

Campaign flows define the sequence of actions that run for each recipient. You create flows using the CreateContactFlow API with the flow type set to `CAMPAIGN`. For detailed information about each action type, see Journey flow block definitions.

Simple flow (no retries)

A simple flow sends a single communication to each recipient without checking delivery status. This is the simplest flow structure:

```
{
  "Version": "2019-10-30",
  "StartAction": "SendSMS",
  "Actions": [
    {
      "Identifier": "SendSMS",
      "Type": "SendSMS",
      "Parameters": {
        "Message": {
          "MessageSourceType": "TEMPLATE",
          "TemplatedMessage": {
            "WisdomKnowledgeBaseArn": "arn:aws:wisdom:us-east-1:123456789012:knowledge-
base/your-kb-id",
            "WisdomMessageTemplateArn": "arn:aws:wisdom:us-east-1:123456789012:message-
template/your-kb-id/your-template-id"
          }
        },
        "SourceEndpoint": {
          "Address": "arn:aws:connect:us-east-1:123456789012:phone-number/your-phone-
number-id",
          "Type": "CONNECT_PHONENUMBER_ARN"
        }
      },
      "Transitions": {
        "NextAction": "EndFlow",
        "Conditions": [],
        "Errors": [
          {
            "NextAction": "EndFlow",
            "ErrorType": "NoMatchingError"
          }
        ]
      }
    },
    {
      "Identifier": "EndFlow",
      "Type": "EndFlowExecution",
      "Parameters": {}
```

```
    }
  ]
}
```

Flow with delivery status check and retries

For flows that check delivery status and retry on failure, use the following structure. The flow sends a communication, waits for a delivery receipt, retrieves the communication status, and then branches based on the result.

The key actions in a retry flow are:

1. **SendSMS**, **SendOutboundEmail**, or **PutDialRequest**—Sends the outbound communication.
2. **Wait**—Waits for the delivery receipt.
3. **GetOutboundCommunicationStatus**—Retrieves the delivery status of the most recent communication.
4. **Compare**—Evaluates the delivery receipt and branches based on the result (for example, retry on bounce, end on success).
5. **EndFlowExecution**—Terminates the flow. All flow paths must end with this action.

The following example shows a flow for a `MANAGED` campaign that sends an SMS, waits for a delivery receipt, checks the status, and retries with an email if the message bounced:

```
{
  "Version": "2019-10-30",
  "StartAction": "SendSMS",
  "Actions": [
    {
      "Identifier": "SendSMS",
      "Type": "SendSMS",
      "Parameters": {
        "Message": {
          "MessageSourceType": "TEMPLATE",
          "TemplatedMessage": {
            "WisdomKnowledgeBaseArn": "arn:aws:wisdom:us-east-1:123456789012:knowledge-
base/your-kb-id",
            "WisdomMessageTemplateArn": "arn:aws:wisdom:us-east-1:123456789012:message-
template/your-kb-id/your-sms-template-id"
          }
```

```
        },
        "SourceEndpoint": {
          "Address": "arn:aws:connect:us-east-1:123456789012:phone-number/your-phone-
number-id",
          "Type": "CONNECT_PHONENUMBER_ARN"
        }
      },
      "Transitions": {
        "NextAction": "Wait",
        "Conditions": [],
        "Errors": [
          {
            "NextAction": "EndFlow",
            "ErrorType": "NoMatchingError"
          }
        ]
      }
    },
    {
      "Identifier": "Wait",
      "Type": "Wait",
      "Parameters": {
        "TimeLimitSeconds": "900"
      },
      "Transitions": {
        "NextAction": "GetOutboundCommunicationStatus",
        "Conditions": [
          {
            "NextAction": "GetOutboundCommunicationStatus",
            "Condition": {
              "Operator": "Equals",
              "Operands": ["WaitCompleted"]
            }
          }
        ],
        "Errors": [
          {
            "NextAction": "EndFlow",
            "ErrorType": "NoMatchingError"
          }
        ]
      }
    },
    {
```

```
      "Identifier": "GetOutboundCommunicationStatus",
      "Type": "GetOutboundCommunicationStatus",
      "Parameters": {
        "OutboundCommunicationIds": ["$.OutboundCommunication.Latest.Id"]
      },
      "Transitions": {
        "NextAction": "Compare",
        "Conditions": [],
        "Errors": [
          {
            "NextAction": "EndFlow",
            "ErrorType": "NoMatchingError"
          }
        ]
      }
    },
    {
      "Identifier": "Compare",
      "Type": "Compare",
      "Parameters": {
        "ComparisonValue": "$.DeliveryReceipts[``
$.OutboundCommunication.Latest.Id`'].Bounce"
      },
      "Transitions": {
        "NextAction": "EndFlow",
        "Conditions": [
          {
            "NextAction": "SendEmail",
            "Condition": {
              "Operator": "Exists",
              "Operands": []
            }
          }
        ],
        "Errors": [
          {
            "NextAction": "EndFlow",
            "ErrorType": "NoMatchingCondition"
          }
        ]
      }
    },
    {
      "Identifier": "SendEmail",
```

```
      "Type": "SendOutboundEmail",
      "Parameters": {
        "EmailMessage": {
          "MessageSourceType": "TEMPLATE",
          "TemplatedMessage": {
            "WisdomKnowledgeBaseArn": "arn:aws:wisdom:us-east-1:123456789012:knowledge-
base/your-kb-id",
            "WisdomMessageTemplateArn": "arn:aws:wisdom:us-east-1:123456789012:message-
template/your-kb-id/your-email-template-id"
          }
        },
        "FromEmailAddress": {
          "EmailAddress": "noreply@example.com"
        }
      },
      "Transitions": {
        "NextAction": "EndFlow",
        "Conditions": [],
        "Errors": [
          {
            "NextAction": "EndFlow",
            "ErrorType": "NoMatchingError"
          }
        ]
      }
    },
    {
      "Identifier": "EndFlow",
      "Type": "EndFlowExecution",
      "Parameters": {}
    }
  ]
}
```

Important

- If your flow uses multiple channel types (for example, SMS and email), include all channels in the `--channel-subtype-config` parameter when creating the campaign.
- For flows used in campaigns with type `MANAGED` that check delivery status, the required action sequence is: **Wait** → **GetOutboundCommunicationStatus** → **Compare**. The `Wait` action pauses the flow for a specified duration to allow time for the delivery receipt to

arrive. The `GetOutboundCommunicationStatus` action retrieves the delivery status. The `Compare` action branches based on the result.

- The `OutboundCommunicationIds` parameter in `GetOutboundCommunicationStatus` must reference `$.OutboundCommunication.Latest.Id`. Delivery receipt references in `Compare` actions must use the same key. For example: `$.DeliveryReceipts[`` $.OutboundCommunication.Latest.Id``].Bounce`.
- `MANAGED` campaigns that use voice channels require `dialCriteriaRules` in the `PutDialRequest` action:

```
{
  "Identifier": "PutDialRequest",
  "Type": "PutDialRequest",
  "Parameters": {
    "dialCriteriaRules": [
      {
        "type": "CheckSegmentMembershipForCustomerProfile",
        "segmentArn": "arn:aws:profile:us-east-1:123456789012:domains/your-
domain/segments/your-segment"
      }
    ]
  },
  ...
}
```

Create a campaign flow version

After you create a campaign flow, you must create a version of the flow. The versioned flow ARN is required when creating a campaign. Use the CreateContactFlowVersion API to create a version.

The versioned flow ARN includes a version suffix. For example: `arn:aws:connect:us-east-1:123456789012:instance/your-instance-id/contact-flow/your-flow-id:1`

For more information, see the create-contact-flow-version CLI reference.

Create an outbound campaign

Use the `create-campaign` command to create a campaign. The following example creates an SMS campaign with agentless outbound mode:

```
aws connectcampaignsv2 create-campaign \
  --name "My SMS Campaign" \
  --connect-instance-id "your-instance-id" \
  --type MANAGED \
  --connect-campaign-flow-arn "arn:aws:connect:us-east-1:123456789012:instance/your-
instance-id/contact-flow/your-flow-id:1" \
  --source '{"customerProfilesSegmentArn": "arn:aws:profile:us-
east-1:123456789012:domains/your-domain/segments/your-segment"}' \
  --channel-subtype-config '{
    "sms": {
      "outboundMode": {"agentless": {}},
      "defaultOutboundConfig": {
        "connectSourcePhoneNumberArn": "arn:aws:connect:us-east-1:123456789012:phone-
number/your-phone-number-id",
        "wisdomTemplateArn": "arn:aws:wisdom:us-east-1:123456789012:message-template/
your-kb-id/your-template-id"
      }
    }
  }' \
  --schedule '{"startTime": "2026-07-01T09:00:00", "endTime": "2026-07-01T17:00:00",
 "refreshFrequency": "PT30M"}' \
  --communication-time-config '{
    "localTimeZoneConfig": {"defaultTimeZone": "America/New_York"},
    "sms": {
      "openHours": {
        "dailyHours": {
          "MONDAY": [{"startTime": "T09:00", "endTime": "T17:00"}],
          "TUESDAY": [{"startTime": "T09:00", "endTime": "T17:00"}],
          "WEDNESDAY": [{"startTime": "T09:00", "endTime": "T17:00"}],
          "THURSDAY": [{"startTime": "T09:00", "endTime": "T17:00"}],
          "FRIDAY": [{"startTime": "T09:00", "endTime": "T17:00"}]
        }
      }
    }
  }' \
  --region us-east-1
```

On success, the command returns the campaign ID and ARN:

```
{
  "id": "campaign-id",
  "arn": "arn:aws:connect-campaigns:us-east-1:123456789012:campaign/campaign-id"
}
```

Note

The `--type` parameter specifies the campaign type. Use `MANAGED` for outbound campaigns. Use `JOURNEY` for multi-step, multi-channel journeys—see Visual Journey Builder.

Note

You can also specify `--communication-limits-override` to control how many times a recipient can be contacted. For the full list of parameters, see the create-campaign CLI reference.

To manage campaign lifecycle operations (start, stop, pause, resume, delete), see the AWS CLI reference for connectcampaignsv2.

Journey flow block definitions
