What are Security Hub and Security Hub CSPM?

AWS Security Hub and AWS Security Hub CSPM are AWS services that protect your cloud environment. The services complement each other. When used together, they provide valuable insight into the security posture of your AWS environment.

Security Hub CSPM provides a comprehensive view of your security posture and helps you evaluate your cloud environment against security industry standards and best practices. Security Hub provides a unified experience that helps you prioritize and respond to critical security issues. Security Hub CSPM findings are routed to Security Hub automatically, where they're correlated with findings from other security services, such as Amazon Inspector, to generate exposures. This helps you identify the most critical risks in your environment. Security Hub also provides automated workflow capabilities, which help you incorporate Security Hub CSPM findings into your operational workflows.

As a best practice, we recommend enabling both services. You can enable Security Hub CSPM without enabling Security Hub if your primary focus is identifying misconfigurations and evaluating your security posture. However, if you enable Security Hub without enabling Security Hub CSPM, Security Hub cannot use Security Hub CSPM findings to provide information about risks and exposures in your AWS environment. For the optimal experience, we recommend not only enabling Security Hub and Security Hub CSPM, but also enabling these other security services: Amazon GuardDuty, Amazon Inspector, and Amazon Macie.

Introduction to AWS Security Hub

AWS Security Hub is a unified cloud security solution that prioritizes your critical security issues and helps you respond at scale. Security Hub detects security issues by automatically correlating and enriching security signals from multiple sources. These sources include posture management, vulnerability management (Amazon Inspector), sensitive data (Amazon Macie), and threat detection (Amazon GuardDuty). Use Security Hub to prioritize active risks in your cloud environment through automated analyses and contextual insights. Through intuitive visualizations, Security Hub transforms complex security signals into actionable insights, which enables you to make informed decisions about your security quickly. Security Hub also includes automated response workflows to help you remediate risks, improve team productivity, and minimize operational disruptions.

Features

Unified security solution

Gain broader visibility across your cloud environment through centralized management in a unified cloud security solution.

Actionable security insights

Gain actionable security insights through advanced analytics to learn about security risks associated with your environment.

Reduced response times

Streamline response times with automated workflows and an integrated ticketing system.

Exposure findings

Security Hub correlates findings from Security Hub CSPM control checks, Amazon Inspector, and other AWS services to detect exposures associated with AWS resources.

Unused access analysis

Security Hub automatically identifies IAM roles, users, access keys, and permissions that have not been used within a 90-day lookback period. When you enable Security Hub, the service creates a service-linked IAM Access Analyzer in your account. Unused access findings help you implement least-privilege access by highlighting over-provisioned IAM principals. For unused permissions

findings, Security Hub can generate least-privilege policy recommendations that show you a scoped-down replacement policy.

Findings are formatted in the Open Cybersecurity Schema Framework (OCSF)

Security Hub generates findings in OCSF and receives findings in OCSF from Security Hub CSPM and other AWS services:

- Amazon GuardDuty
- Amazon Macie
- Amazon Inspector

Dashboard

The Security Hub console provides a comprehensive view of your exposures, threats, security coverage, and resources, as well as an interactive visualization called the attack path graph, which shows how potential attackers can access and take control of resources associated with an exposure finding.

Integrations with third-party products

You can enhance your security posture with Security Hub integrations. For example, if you use Jira Cloud or ServiceNow ITSM, you can use this feature to create tickets from findings.

Integrations

Security Hub receives findings from the following AWS services.

- AWS Security Hub CSPM
- Amazon GuardDuty
- Amazon Inspector
- Amazon Macie
- IAM Access Analyzer

Accessing Security Hub

Security Hub is available in most AWS Regions. For a list of Regions where Security Hub is currently available, see Security Hub endpoints and quotas in the *AWS General Reference*. For information

about managing AWS Regions for your AWS account, see Specifying which AWS Regions your account can use in the *AWS Account Management Reference Guide*.

You can enable Security Hub for individual accounts or accounts in your organization. In each Region, you can access and use Security Hub in any of the following ways:

Security Hub console

The Security Hub console is a browser-based interface you can use to create and manage AWS resources. In this console, you can access your account, data, and resources.

Security Hub API

The Security Hub API gives you programmatic access to your account, data, and resources. You can send HTTPS requests directly to Security Hub.

AWS CLI

With the AWS CLI, you can run commands in your system command line to perform tasks and build scripts that perform tasks. In some cases, the AWS CLI can be more useful than the Security Hub console.

AWS SDKs

AWS SDKs consist of libraries and sample code for various programming languages and platforms (C++, Go, Java, .NET, and Python). They provide programmatic access to Security Hub and other AWS services in your preferred language and can help you manage tasks such as managing errors, signing requests, and retrying requests.

Security Hub concepts

In Security Hub, we build on common AWS concepts and terminology and use these additional terms.

Account

The standard AWS account containing your AWS resources. Sign in to AWS with your AWS account to enable Security Hub.

If your account is enrolled in AWS Organizations, your organization designates a Security Hub administrator account. This account can enable other organization accounts as member accounts.

An organization can only have one administrator account. An account cannot be an administrator account and a member account simultaneously.

Security Hub supports the following accounts:

- Organization management account — an AWS account that administers an AWS organization.
- Delegated administrator account — an AWS account that manages the use of an AWS service for an AWS organization.
- Member account — an AWS account that is a member of an AWS organization.
- Standalone account — an AWS account without AWS Organizations enabled.

Administrator account

This type of AWS account can view findings for associated member accounts.

This type of AWS account becomes an administrator account when the account is designated by an organization management account as the Security Hub administrator account. The Security Hub administrator account can enable any organization account as a member account and can also invite other accounts to be member accounts.

An organization can only have one administrator account. An account cannot be an administrator account and a member account simultaneously.

Aggregation Region

An aggregation Region allows you to view security findings from multiple AWS Regions in a single pane of glass.

The aggregation Region is the AWS Region where you view and manage findings. Findings are aggregated in the aggregation Region from linked Regions. Updated findings are replicated across Regions.

In the aggregation Region, the dashboard and inventory pages include data from all linked Regions. The automations page can only be used to define automation rules in the aggregation region. Third-party ticketing integrations can only be configured in the aggregation region.

Archived finding

A finding with a status of `ARCHIVED`. These findings indicate the finding provider or customer investigating the finding believes the finding is no longer relevant.

Finding providers can archive findings they create. Customers can archive any findings that they believe are no longer relevant using the BatchUpdateFindingsV2 operation of the Security Hub API or by updating the status in the Security Hub console.

In the Security Hub console, default filter settings exclude archived findings from finding lists and tables. You can update the filters to include archived findings. If you retrieve findings by using the GetFindingsV2 operation, the operation retrieves both archived and active findings. The following example shows how to exclude archived findings in the results.

```
{
    "StringFilters":
    [
        {
            "FieldName": "status",
            "Filter":
            {
                "Value": "Archived",
                "Comparison": "EQUALS"
            }
        }
    ]
}
```

Cross-Region aggregation

The aggregation of findings and resources from linked Regions to an aggregation Region. You can view all of your data from the aggregation Region and update findings from the aggregation Region.

Delegated administrator account

In AWS Organizations, the delegated administrator account for a service is able to manage the use of a service for the organization.

In Security Hub, the Security Hub administrator account is also the delegated administrator account for Security Hub. When the organization management account first designates the Security Hub administrator account, Security Hub calls Organizations to make that account the delegated administrator account.

The organization management account must then choose the delegated administrator account as the Security Hub administrator account in all Regions.

Exposure

Exposures are broader weaknesses in security controls, misconfigurations, or other areas that could be exploited by active threats.

Examples of exposures include:

- Misconfigured control plane for a resource.
- Presence of a software vulnerability that has a high potential for exploitability.
- Publicly accessible resource (network or API).

Exposure finding

A type of finding that describes an exposure present in your environment. An exposure finding includes traits and signals. A signal can include one or more types of exposure traits. AWS Security Hub generates an exposure finding when signals from AWS Security Hub CSPM, Amazon Inspector, Amazon GuardDuty, Amazon Macie, or other AWS services, indicate the presence of an exposure. A resource can be involved in one or more exposure findings. If a resource does not have any exposure traits or has insufficient traits, Security Hub does not generate an exposure finding for that resource.

An example of an exposure finding is: An EC2 instance that is reachable from the internet and has software vulnerabilities which have a high likelihood of exploitation.

Finding

The observable record of a security check or security-related detection. Security Hub generates and updates findings through the correlation of other security findings. These are called *exposure findings*. Findings can also come from integrations with other AWS services and third-party products.

Finding ingestion

The import of findings into Security Hub . Finding ingestion events include both new findings and updates to existing findings.

Linked Region

When you enable cross-Region aggregation, a linked Region is a region that aggregates findings and resource inventory to the aggregation Region.

In a linked Region, the dashboard and inventory pages only contain findings for that AWS Region.

Open cybersecurity schema framework (OCSF)

The Open Cybersecurity Schema Framework (OCSF) is a collaborative, open-source effort by AWS and leading partners in the cybersecurity industry. OCSF provides a standard schema for common security events, defines versioning criteria to facilitate schema evolution, and includes a self-governance process for security log producers and consumers. For more information, see OCSF findings in Security Hub.

Member account

An AWS account that granted permission to an administrator account to view and take action on their findings. This kind of AWS account becomes a member account when the Security Hub administrator account enables it as a member account.

Signal

A finding that contributes to an exposure finding. A signal can be referred to as a *contributing finding*. A signal can originate in Security Hub CSPM, AWS Config, or other AWS services, such as Amazon Inspector.

Service-linked configuration recorder

A type of AWS Config recorder that is used to record configuration data on service-specific resources. Security Hub uses these recorders in an event-driven approach to obtain resource configuration items for exposure analysis coverage, resource inventory reporting, and posture management control evaluations. This capability is provided to all Security Hub customers as part of the Essential plan pricing. After you enable Security Hub, the following service-linked configuration recorders are created in your account:

- In each AWS account and AWS Region, a service-linked configuration recorder named `AWSConfigurationRecorderForSecurityHubAssets` is created.
- For global resource types, an additional service-linked configuration recorder named `AWSConfigurationRecorderForSecurityHubAssetsGlobal` is created in the us-east-1 AWS Region.
- If Security Hub and Security Hub CSPM are both enabled in an AWS account and AWS Region, a service-linked configuration recorder named `AWSConfigurationRecorderForSecurityHubCSPM` is created.

For more information, see Considerations for service-linked configuration recorders and Recording regional and global resources.

Service-linked analyzer

An IAM Access Analyzer that Security Hub creates and manages on your behalf. When you enable Security Hub, it automatically creates a service-linked unused access analyzer to identify IAM roles, users, access keys, and permissions that have not been used within a 90-day lookback period. The analyzer runs in US East (N. Virginia) because IAM is a global service. Security Hub replicates unused access findings to all Regions where you have enabled Security Hub. You do not need to separately enable IAM Access Analyzer or take any additional action. This capability is provided to all Security Hub customers as part of the Essential plan pricing. You can view the service-linked analyzer in the IAM Access Analyzer console, but you cannot modify or delete it while Security Hub is enabled. Security Hub deletes the analyzer when you disable the service in all regions of an AWS account. For more information, see the section called “Unused access findings”.

Trait

A security deviation that results in an exposure finding. Trait types include **Assumability**, **Misconfiguration**, **Reachability**, **Sensitive Data**, and **Vulnerability**. A trait is associated with one signal, and a signal can contain multiple traits. For example, a Security Hub CSPM control indicates a customer-managed policy allows administrative access control. This signal contains a misconfiguration trait.

Unused access finding

A finding that identifies an IAM role, user, access key, or set of permissions that has not been used within a 90-day lookback period. Security Hub generates unused access findings using a service-linked IAM Access Analyzer. There are four types of unused access findings: unused IAM roles, unused IAM user access keys, unused IAM user passwords, and unused permissions.

AWS Security Hub Cost Estimator

The Security Hub cost estimator is a console feature that provides estimates for Security Hub capabilities across your AWS environment. The cost estimator shows you what your individual service costs are across AWS Security Hub CSPM, Amazon Inspector, and Amazon GuardDuty and what your estimated costs would be in Security Hub with Security Hub's simplified pricing plans. You can adjust estimated usage and resource counts to match your AWS usage to increase the accuracy of your estimate. The cost estimator is available in all regions where Security Hub is available.

The cost estimator estimates monthly costs for security capabilities using two pricing models:

- **Individual services pricing** – Pay for each security feature separately (GuardDuty, Amazon Inspector, Security Hub CSPM).
- **Security Hub simplified pricing** – Unified pricing across 3 pricing plans, essentials plan with per-resource pricing, threat analytics with per-event and per-GB logs pricing, and Lambda Code scanning with per-resource pricing.

The estimator uses AWS Cost Explorer data when available. When Cost Explorer data is unavailable, you can manually enter usage data. Cost estimates are based on observed and user provided usage, and public pricing information. Estimates might not reflect enterprise discounts.

Key benefits of the cost estimator include:

- See how the cost with unified pricing, when enabling Security Hub, compares against cost with individual service without enabling Security Hub
- Estimate costs before enabling capabilities
- Adjust usage parameters to model different scenarios
- Export estimates as PDF for stakeholder review

Access by account type

> **Note**
>
> For Delegated administrator and member accounts, the cost estimator opens in edit mode by default, allowing you to immediately enter usage data. Management account and standalone accounts open in view mode when Cost Explorer data is available.

This feature automatically retrieves information on actual past usage to estimate the cost for certain account types. See the following table for details on each of the account types and the data that is available for each account type.

Access permissions by account type

Account Type	Cost Explorer Data	Data Entry	Scope
Management Account (MA)	Auto-populated	Manual override available	Organization-wide
Delegated Administrator (DA)	Auto-populated via cross-account role*	Manual override available	Organization-wide
Member Account	Auto-populated via cross-account role*	Manual override available	Organization-wide
Standalone Account (SA)	Auto-populated	Manual override available	Single account

* Requires cross-account IAM role configuration in management account. See Setting up cross-account access section below.

Prerequisites

Required IAM permissions

To use all of the cost estimator's capabilities, your IAM principal must have the following permissions:

Required IAM permissions for Cost Estimator

API Operation	Service	Purpose
`ce:GetCostAndUsage`	AWS Cost Explorer	Retrieve historical usage and cost data
`pricing:GetProducts`	AWS Pricing	Get current pricing rates
`organizations:ListAccounts`	AWS Organizations	Count accounts in organization

API Operation	Service	Purpose
`organizations:DescribeOrganization`	AWS Organizations	Determine account type
`securityhub:ListOrganizationAdminAccounts`	Security Hub	List organization admin accounts
`iam:GetRole`	IAM	Check cross-account role existence (Management account only)*
`sts:AssumeRole`	IAM	Assume cross-account role (Delegated administrator/Member account only)**

* Required only for Management Account users to verify cross-account role status.

** Required only for Delegated Administrator and Organization Member accounts using cross-account access.

Additional requirements

Cost Explorer

Must be enabled for automatic data population (24-hour processing delay after enablement).

Setting up cross-account access

Delegated administrator and member accounts can access organization-wide AWS Cost Explorer data from the management account by configuring a cross-account IAM role. This configuration allows these accounts to view actual usage data without switching to the management account.

Prerequisites

The following items and information are needed in advance of setting up cross-account access for the cost estimator:

- Management account must have AWS Cost Explorer enabled.

- IAM permissions to create roles in the management account.
- Knowledge of the delegated administrator or member account ID that will be granted cross-account access.

Setup steps

The cost estimator provides guided setup instructions directly in the console. To access the instructions navigate to the cost estimator page at https://console.aws.amazon.com/securityhub/v2/home#/costEstimator in your organization management account. Locate the **Cross-account access** section and follow the steps outlined for setting up the cross account role.

Role configuration

Cross account access for the cost estimator requires setting up an IAM role with a trust policy and a permissions policy. The cross-account role must be created in the management account with the following configuration:

Role name (exact name required) – AwsSecurityHubCostEstimatorCrossAccountRole

Recommended trust policy:

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Principal": {
            "AWS": "arn:aws:iam::{ACCOUNT_ID}:role/{ROLE_NAME}"
            },
            "Action": "sts:AssumeRole"
        }
    ]
}
```

Edit the policy by replacing the following values in the policy example:

- Replace *{ACCOUNT_ID}* with the delegated administrator or member account ID that you are granting cross-account access to.

- Replace *{ROLE_NAME}* with the IAM role name in the delegated administrator or member account that you are granting access to.

Recommended permissions policy:

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": "ce:GetCostAndUsage",
            "Resource": "*"
        }
    ]
}
```

Note

The trust policy restricts access to a specific account and role. Only the specified IAM principal can assume this role, preventing unauthorized access.

Verification

After creating the role in the management account use the following steps to confirm the setup is working.

1. Sign into the delegated administrator or member account.
2. Navigate to the Security Hub cost estimator at https://console.aws.amazon.com/securityhub/v2/home#/costEstimator
3. The page should automatically:
    a. Detect the management account in your organization.
    b. Assume the cross-account role.
    c. Load Cost Explorer data with organization-wide usage.

If successful, actual usage data appears instead of manual entry fields.

Troubleshooting

This section covers common issues and solutions that can occur when setting up cross-account access.

Organizational usage data is not available for this account

This alert indicates the cross-account role is not accessible. Possible causes of this alert are:

1. **Role does not exist:** Management account has not created the role yet.
   - **Solution:** Contact your management account administrator to create the role using the setup guidance.
2. **Role name mismatch:** Role name does not match exactly.
   - **Solution:** Verify role name is `AwsSecurityHubCostEstimatorCrossAccountRole`.
3. **Trust policy incorrect:** Trust policy does not allow your account to assume the role.
   - **Solution:** Verify trust policy includes your account ID and role name.
4. **Missing AssumeRole permission:** Your IAM principal lacks `sts:AssumeRole`.
   - **Solution:** Contact your administrator to add `sts:AssumeRole` permission.

To view detailed setup instructions: Choose **View instructions** in the alert to open a modal with step-by-step guidance and policy templates.

Workaround: You can still use the Cost Estimator by manually entering usage values in edit mode.

Using the cost estimator

Accessing the cost estimator

To access the Cost Estimator from the Security Hub landing page

1. Sign in to your AWS account with your AWS organization management or delegated administrator account credentials. Open the Security Hub console in the us-east-1 region at https://console.aws.amazon.com/securityhub/v2/home.
2. On the landing page, locate the **Pricing** card.
3. Choose **Estimate cost**.

To access the Cost Estimator during Security Hub enable and configuration steps

1. Locate the **Pricing in the new Security Hub** card in the onboarding interface.
2. Choose **View estimates**.

To access the cost estimator from GuardDuty, Amazon Inspector, or Security Hub CSPM consoles

1. Navigate to the service dashboard or summary page.
2. Choose **Compare pricing** in the pricing information card.

Understanding the cost estimator interface

Page layout

The Cost Estimator page contains three main sections:

- **Overview section** – Explains unified security management and cost optimization benefits.
- **Pricing information** – Expandable panel with capability categories and pricing tiers.
- **Pricing comparison table** – Side-by-side cost comparison with capability details.

Pricing comparison table

The table header includes view/edit mode controls and a reset option. The table displays costs in two columns:

- **Individual services** – Current or estimated costs for separate security services.
- **Security Hub** – Estimated costs using simplified pricing model.

Pricing region

The first column displays pricing context information, including a note that estimates use us-east-1 pricing for calculations. A badge indicates that enterprise discounts are not included in the estimates.

Viewing cost estimates

When using the cost estimator you can view, edit, reset, and export estimates.

The cost estimator opens in view mode by default.

To view cost estimates

1. Access the Cost Estimator using one of the methods described in Accessing the cost estimator.
2. Review the total monthly costs in the summary row.
3. Review capability groups and their detailed cost breakdowns.
4. Choose capability names to view descriptions in a popover.

Data sources in view mode

The estimator displays data from multiple sources, indicated by labels:

- **Default** – Data from AWS Cost Explorer (past 30 days).
- **$-/mo** – Cost data unavailable (shown when Cost Explorer access is not available).
- **Custom usage** – User-entered values.
- **Not enabled** – Shows when Cost Explorer permissions do not exist.

Account-specific behavior

The following describes how the cost estimator functions across different types accounts and configurations.

Delegated administrator and member accounts

With cross-account access configured:

- Cost Explorer data is available with organization-wide usage.
- Opens in view mode by default (same as management account). You can switch to edit mode to modify estimates.

Without cross-account access configured:

- Alert displays: "Organizational usage data is not available for this account".
- Opens in edit mode by default for manual entry.
- Choose **View instructions** in the alert for setup guidance.

Management account

With cross-account role created:

- "Cross-account access" section shows configured state.
- Displays recommended policies for verification.
- Provides link to view role in IAM console.

Without cross-account role created:

- "Cross-account access" section displays setup guide.
- Provides step-by-step instructions with pre-populated policies.
- Direct link to IAM console for role creation.

Unable to verify role status:

- If there is no permission to call `iam:GetRole`, the console cannot determine if you have created the necessary role.
- Shows “Unable to verify” with corresponding error message.

Standalone account

Without cross-account role created:

- No changes to existing behavior.
- Cost Explorer data is available when enabled.
- Opens in view mode by default.

Editing usage values

Edit mode allows you to modify dimension values and see real-time cost updates.

To edit usage values

1. Choose **Edit** in the table header.
2. Enter values in the dimension input fields.
3. View updated costs automatically.

4. Choose **View** to return to view mode.

> **Important**
>
> - Edits are not saved when you leave the cost estimator page
> - Modified estimates use us-east-1 (N. Virginia) pricing and do not include enterprise discounts
> - Editing in "Show current cost only" mode automatically switches back to estimated mode

Resetting the estimator

This action clears all custom values and reloads default data from Cost Explorer.

To reset all values to defaults

1. Choose **Reset** in the table header.
2. In the confirmation dialog, choose **Reset**.

Exporting estimates

While in the cost estimator the data for your estimate can be exported to a PDF file.

To export cost estimates

1. Ensure you are in view mode.
2. Choose **Download PDF** in the page header.

The PDF downloads automatically with filename: `SecurityHub-Cost-Estimate-YYYY-MM-DD.pdf`.

Troubleshooting

This section covers common issues and solutions that can occur when using the cost estimator

No Cost Explorer data available

Problem

Alert displays "No cost data available for your account".

Solutions by account type

The solution depends on your account type:

Solutions for missing Cost Explorer data

Account Type	Solution
Management Account	Enable Cost Explorer and wait 24 hours for data processing
Delegated Administrator	Contact Management Account administrator to request access
Member Account	Contact Management Account or Delegated Administrator for access
Standalone Account	Enable Cost Explorer and wait 24 hours for data processing

Workaround

Enter custom values in edit mode.

Cross-account access not working

Problem

Delegated administrator or member account displays "Organizational usage data is not available for this account" alert.

Review the following common causes and their solutions:

Cross-account role does not exist in management account

Contact Management Account administrator to create the role. The cost estimator provides guided setup instructions for management account users.

Role name does not match exactly

Required role name: `AwsSecurityHubCostEstimatorCrossAccountRole`. Verify role name in IAM console matches exactly (case-sensitive).

Trust policy does not allow your account

Verify trust policy principal includes your account ID and role name. Format: `arn:aws:iam::{YOUR_ACCOUNT_ID}:role/{YOUR_ROLE_NAME}`.

Missing AssumeRole permission

Verify your IAM principal has `sts:AssumeRole` permission. Contact your AWS administrator to add this permission.

Workaround:

Enter custom values in edit mode to manually estimate costs without Cost Explorer data.

Getting detailed instructions

- Choose **View instructions** in the alert to open a modal with:
  - Step-by-step setup guidance
  - Pre-populated policy templates
  - Troubleshooting tips specific to your error

Permission errors

Problem

"Access denied" error for specific API operations.

To resolve permission errors

1. Note the denied operation from the error message (for example, `ce:GetCostAndUsage`).
2. Choose **Copy** to copy the error details.
3. Send the error details to your AWS administrator.
4. Request the required IAM permissions listed in Required IAM permissions.

> **Note**
>
> You can still use edit mode to enter manual values when permissions are missing, except when Pricing API access is denied (prevents all cost estimates).

Capability shows "Not enabled"

Problem

Capability displays "Not enabled" status.

Explanation

This status appears when you have Cost Explorer access but the capability is not currently active. If you see $-/mo instead, this indicates that Cost Explorer data is not available for your account type.

To view cost estimates

1. Choose **Edit** to enter edit mode.
2. Enter dimension values for the capability.
3. View updated cost estimates.

Capability shows "Not applicable"

Problem

Capability displays "Not applicable" in Individual services column.

Explanation

This capability is only available through Security Hub simplified pricing, not as a standalone service.

Modified costs do not match Cost Explorer

Problem

Edited costs differ from original Cost Explorer values.

Explanation

Modified estimates use us-east-1 (N. Virginia) pricing rates and do not include enterprise discounts. Cost Explorer data reflects actual costs with applicable discounts.

Important notes

- **Estimates are based on observed and user provided usage, and public pricing information** – Actual costs might vary based on usage patterns and enterprise agreements
- **30-day look back** – Cost Explorer data reflects the past 30 days of usage
- **Pricing region** – All estimates use us-east-1 (N. Virginia) rates
- **No impact on settings** – Changes in the estimator do not affect your current Security Hub or service configurations
- **Enterprise discounts** – Modified estimates do not include enterprise discounts; only Cost Explorer data reflects actual discounted costs
- **Data refresh** – Cost Explorer data updates daily; refresh the page to see the latest data

Enabling Security Hub

You can enable Security Hub for any AWS account. This section of the documentation describes all the steps required to enable Security Hub for an AWS Organization, or a standalone account.

> **Important**
>
> When you enable AWS Security Hub, Security Hub uses the data available to it (including findings, configuration data, software inventory, and other data from your AWS environment) to power the capabilities you turn on. As we enhance existing capabilities or add new ones, Security Hub may draw on additional data already within its reach to deliver

a better experience, such as more accurately assessing the real-world impact of exposures in your environment, at no additional cost. You can manage your integrations and enabled capabilities at any time. See the Security Hub documentation for details, or reach out to your AWS account team or AWS Support with any questions.

Enable Security Hub for an AWS Organization

This section includes three steps:

- In **Step 1**, the AWS organization management account designates a delegated administrator for their AWS Organization, creates the delegated administrator policy, and optionally enables Security Hub for their own account.
- In **Step 2**, the delegated administrator for the organization enables Security Hub for their own account.
- In **Step 3**, the delegated administrator for the organization configures all member accounts in the organization, for Security Hub and other supported security services.

Step 1. Delegating an administrator account and optionally enabling Security Hub in the AWS organization management account

Note

Complete this step in one Region of the organization management account.

When assigning the delegated administrator account for Security Hub, the account you can choose for your delegated administrator depends on how you have configured a delegated administrator for Security Hub CSPM. If you have configured a delegated administrator for Security Hub CSPM, and that account is not the organization management account, then that account is automatically set as the Security Hub delegated administrator and a different account cannot be chosen. If the delegated administrator account for Security Hub CSPM is set as the organization management account or is not set at all, you can choose which account to assign as your Security Hub delegated administrator account, except for the organization management account.

For information about designating a delegated administrator in Security Hub, see Designating a delegated administrator account in Security Hub. For information about creating the delegated

administrator policy in Security Hub, see Creating the delegated administrator policy in Security Hub.

To designate an administrator for Security Hub

1. Sign in to your AWS account with your AWS organization management account credentials. Open the Security Hub console at https://console.aws.amazon.com/securityhub/v2/home.
2. From the Security Hub homepage, choose **Security Hub**, and then choose **Get started**.
3. In the **Delegated administrator** section, choose an administrator account based on the provided options. As a best practice, use the same delegated administrator across security services for consistent governance.
4. Choose the **Trusted access** checkbox. Choosing this option grants your delegated administrator account the ability to configure certain capabilities, such as GuardDuty Malware Protection, on member accounts. If you uncheck this option, Security Hub cannot enable these features on your behalf and you must enable them directly through the service that the feature is associated with.
5. (Optional) For **Account enablement**, select the box to enable Security Hub for your AWS account.
6. For **Delegated administrator policy**, choose one of the following options to add the policy statement.

    a. (Option 1) Choose **Update this for me**. Select the box under the policy statement to confirm that Security Hub automatically creates a delegation policy granting all required permission to the delegated administrator.

    b. (Option 2) Choose **I want to attach this manually**. Choose **Copy and attach**. In the AWS Organizations console, under **Delegated administrator for AWS Organizations**, choose **Delegate**, and paste the resource policy in the delegation policy editor. Choose **Create Policy**. Open the tab where you are in the Security Hub console.
7. Choose **Configure**.

Step 2. Enable Security Hub in the delegated administrator account

The delegated administrator account completes this step. After the AWS Organization management account designates a delegated administrator for their organization, the delegated administrator must enable Security Hub for their own account before enabling for the entire AWS Organization.

To enable Security Hub in the delegated administrator account

1. Sign in to your AWS account with your delegated administrator credentials. Open the Security Hub console at https://console.aws.amazon.com/securityhub/v2/home.
2. From the Security Hub homepage, choose **Get started**.
3. The security capabilities section outlines the capabilities that are automatically enabled and included in the base per-resource price of Security Hub.
4. (Optional) For **Tags**, determine whether to add a key-value pair to the account setup.
5. Choose **Enable Security Hub** to finish enabling Security Hub.
6. (Recommended) from the popup choose **Configure my organization** and proceed to Step 3.

Step 3. Create a policy that enables Security Hub in all member accounts

After enabling Security Hub in the delegated administrator account for an organization you need to create a policy that defines which services and capabilities are enabled in the organization member accounts. For more information, see Enabling a configuration for Security Hub.

After you enable Security Hub, the following resources are created in your account:

- A service-linked role called AWSServiceRoleForSecurityHubV2.
- Service-linked configuration recorders. See Service-linked recorder in the Security Hub concepts documentation for more details.
- A service-linked analyzer. See Service-linked analyzer in the Security Hub concepts documentation for more details.

Enable Security Hub in a standalone account

This procedure describes how to enable Security Hub in a standalone account. A standalone account is an AWS account that has not enabled AWS organizations.

To enable Security Hub in a standalone account

1. Sign in to your AWS account with your account credentials. Open the Security Hub console at https://console.aws.amazon.com/securityhub/v2/home.
2. From the Security Hub homepage, choose **Get started**.
3. In the **Security capabilities** section do one of the following:

a. (Option 1) Choose **Enable all capabilities**. This turns on all of the Security Hub essential capabilities, threat analytics, and additional capabilities.

b. (Option 2) Choose **Customize capabilities**. Select the capabilities to turn on from the Security management, Threat analytics, and Vulnerability management sections. You cannot deselect any capabilities that are part of the Security Hub essential plan capabilities.

4. In the **Regions** section, choose **Enable all Regions** or **Enable specific Regions**. If you choose **Enable all Regions**, you can determine whether to automatically enable new Regions. If you choose **Enable specific Regions**, you must choose which Regions you want to enable.
5. (Optional) For **Resource tags**, add tags as key-value pairs to help you easily identify the configuration.
6. Choose **Enable Security Hub**.

After you enable Security Hub, the following resources are created in each account where you enabled the service:

- A service-linked role called AWSServiceRoleForSecurityHubV2.
- Service-linked configuration recorders. See Service-linked recorder in the Security Hub concepts documentation for more details.
- A service-linked analyzer. See Service-linked analyzer in the Security Hub concepts documentation for more details.

Designating a delegated administrator in Security Hub

In the AWS organization management account, you can designate a delegated administrator for your organization. As a best practice, use the same delegated administrator across security services for consistent governance.

The procedure in this topic describes how to designate a delegated administrator in Security Hub. It assumes you previously enabled Security Hub but did not designate a delegated administrator during the enablement workflow.

Considerations

Consider the following when designating a delegated administrator in Security Hub:

- The AWS organization management account can designate itself as the delegated administrator in Security Hub CSPM, but cannot designate itself as the delegated administrator in Security Hub. In this scenario, the management account must designate another AWS account as the delegated administrator in Security Hub.
- If the AWS organization management account designates a delegated administrator in Security Hub CSPM, that delegated administrator automatically becomes the delegated administrator in Security Hub. In this scenario, Security Hub only allows this particular AWS account to serve as the delegated administrator.

> **Note**
>
> Removing the delegated administrator through either the Security Hub CSPM console, the Security Hub console, or the AWS Organizations API removes it from both services. When the delegated administrator is removed from Security Hub CSPM, Central Configuration automatically opts out.

Designating a delegated administrator after enabling Security Hub

This procedure is for the AWS organization management account to complete. It assumes the AWS organization management account previously enabled Security Hub but did not designate a delegated administrator during the enablement workflow.

> **Note**
>
> After you complete this procedure, you must create a policy allowing the delegated administrator for your organization to configure Security Hub and perform specific actions in AWS Organizations. For more information, see Creating the delegated administrator policy in Security Hub.

To designate a delegated administrator in Security Hub

1. Sign in to your AWS account with your organization management account credentials, and open the Security Hub console at https://console.aws.amazon.com/securityhub/v2/home.
2. From the navigation pane, choose **General**.

3. In **Delegated administrator**, choose **Configure**. Select one of the provided AWS accounts, or enter the 12-digit AWS account number for the AWS account that you want to designate as the delegated administrator for your organization. Choose **Save**.

Creating the delegated administrator policy in Security Hub

The AWS organization management account can create a policy allowing the delegated administrator to configure Security Hub and perform specific actions in AWS Organizations. The procedure in this topic describes how to create the policy. When completing the procedure, you can allow Security Hub to create the policy for you or manually create the policy. Allow Security Hub to create the policy unless you want to customize it for a particular use case.

Complete this procedure only if the organization management account enabled Security Hub and designated a delegated administrator, but skipped creating the policy during the enablement workflow. For information about how to update this policy, see Update a resource-based delegation policy with AWS Organizations in the *AWS Organizations User Guide*.

> **Note**
>
> After you complete this procedure, the delegated administrator can create a policy to manage member accounts in your organization. For more information, see Creating a policy as the delegated administrator to manage member accounts.

To create the delegated administrator policy

1. Sign in to your AWS account with your organization management account credentials. Open the Security Hub console at https://console.aws.amazon.com/securityhub/v2/home.
2. From the navigation pane, choose **General**.
3. For **Delegated administrator policy**, do one of the following:

   - Choose **Create policy**. Select the box under the policy statement to confirm that Security Hub automatically creates a delegation policy granting all required permission to the delegated administrator.
   - Open the policy. Choose **Copy and attach**. In the AWS Organizations console, under **Delegated administrator for AWS Organizations**, choose **Delegate**, and paste the resource

policy in the delegation policy editor. Choose **Create Policy**. Open the tab where you are in the Security Hub console, and choose **Configure**.

Managing configuration of member accounts in an AWS Organization

The delegated administrator for an AWS Organization can configure security capabilities across member accounts and Regions. You can currently control configuration for AWS Security Hub, AWS Security Hub CSPM, Amazon Inspector, and Amazon GuardDuty.

Security Hub configuration catalog

The configuration catalog of Security Hub offers multiple options to help configure your AWS Organization accounts for the security capabilities provided by Security Hub.

The following table lists the options in the Security Hub configuration catalog. To view the steps for a configuration, choose its name, and then expand its section.

Security Hub configuration catalog options

Configuration	Type	Description
Security Hub (essential and add-on capabilities)	Policy	This is the recommended configuration to deploy for Security Hub. This configuration turns on Security Hub's essential security management, posture management, threat analytics, and vulnerability management capabilities. It optionally enables add-on capabilities.
Threat analytics from Amazon GuardDuty	Policy	Turn on selected Amazon GuardDuty capabilities to continuously monitor, analyze, and process AWS data sources and logs in your AWS environment.
Posture management from AWS Security Hub CSPM	Policy	This configuration turns on Security Hub CSPM's standards and controls, which detect when your AWS accounts and resources deviate from security best practices.

Configuration	Type	Description
Vulnerability management from Amazon Inspector	Policy	This configuration turns on selected Amazon Inspector capabilities that automatically discover workloads, instances, container images, and other resources, and scans them for vulnerabilities and network exposure.

Enabling configurations for member accounts

You can create a configuration for your AWS Organization accounts from the configuration catalog. Before you create a configuration, you must create the delegated administrator policy in the AWS Organization management account. For information about creating the delegated administrator policy in Security Hub, see Creating the delegated administrator policy in Security Hub.

When you create your first configuration, Security Hub automatically enables the required AWS Organizations policy types for your organization.

Each configuration starts from the **Configurations** page in the Security Hub console. To open this page, in the navigation pane, choose **Management**, and then choose **Configurations**.

We recommend that you use the Security Hub configuration to manage your organization's configuration. It includes configuration options for AWS Security Hub CSPM, Amazon Inspector, and Amazon GuardDuty, so you can manage all of these services from one configuration. To manage only one of these services, use the steps for that service's configuration.

> **Important**
>
> If you're enabling Security Hub for the first time, you must use the steps in Enabling a configuration for Security Hub.

To view the steps for a configuration, expand its section.

Enabling a configuration for Security Hub

This configuration turns on Security Hub essential security management, posture management, threat analytics, and vulnerability management capabilities. It optionally enables add-on capabilities.

To create a policy that enables member accounts

1. Sign in using your AWS account with your delegated administrator credentials. Open the Security Hub console at https://console.aws.amazon.com/securityhub/v2/home.
2. From the navigation pane, choose **Management**, and then choose **Configurations**.
3. From the **Configuration catalog**, choose **Security Hub (essential and add-on capabilities)**.
4. On the **Configure Security Hub** page, configure the following settings:

   a. For **Configuration action**, choose **Enable**.

   b. Add-on capabilities are charged separately from the essential plan. Some are billed through Security Hub, and others through their respective services, such as Amazon GuardDuty and Amazon Inspector. For **Security capabilities**, choose one of the following options:

   - **Enable essential** – Turns on only the essential capabilities that are included in the base price. This option doesn't turn on any add-on capabilities.
   - **Enable all** – Turns on the essential capabilities and all add-on capabilities, which incur additional charges.
   - **Enable specific** – Choose which capabilities to turn on from the **Essential capabilities** and **Add-on capabilities** sections. Add-on capabilities that you choose incur additional charges.

   c. For **Account selection**, choose one of the following options:

   - **All organizational units and accounts** – Applies the configuration to your entire organization.
   - **Specific organizational units and accounts** – Use the search bar or organizational structure tree to select the organizational units and accounts where the policy applies.
   - **No organizational units or accounts** – Does not apply the configuration to any organizational unit or account.

   d. For **Region selection**, choose one of the following options:

   - **Enable in all currently available Regions** – Optionally, select **Auto-enable new Regions**. Auto-enabling new Regions doesn't turn on threat analytics or posture management features in those Regions.
   - **Enable in some Regions** – For **Enabled Regions**, choose the Regions to enable.

e. (Optional) For **Advanced settings**, see Inheritance operators in the *AWS Organizations User Guide*.

f. For **Details**, enter a **Name** for the policy, and optionally a **Description**. The name must be unique for all policies in your organization.

g. For **Resource tags**, optionally add tags as key-value pairs to help you identify the configuration. Then, choose **Next**.

5. If **Security Hub CSPM checks** is selected, the **Configure Posture Management** page appears. This capability is selected by default, and you can clear it only when you choose **Enable specific**. Configure the following settings:

a. For **Security standards**, choose the standards to enable. By default, AWS Foundational Security Best Practices v1.0.0 and CIS AWS Foundations Benchmark v5.0.0 are selected. (Optional) For **Advanced settings**, see Inheritance operators in the *AWS Organizations User Guide*.

b. For **Controls**, choose one of the following options:

- **Enable all controls** – Evaluates all controls in your enabled standards, including newly released controls. We recommend this option.
- **Customize** – Choose **Enable all by default (disable specific)** or **Disable all by default (enable specific)**. Then, select the controls to disable or enable.

(Optional) For **Advanced settings**, see Inheritance operators in the *AWS Organizations User Guide*.

c. (Optional) For **Custom control parameters**, select **Customize control parameters**. Choose a control, and then set its parameter values. To customize more controls, choose **Customize additional control**. Controls that you don't customize use their default parameter values.

d. (Optional) To apply different settings in specific Regions, in **Region-specific customizations**, choose **Add region customization**. In the dialog box, for **Regions**, choose the Regions. Configure **Security standards**, **Controls**, and **Custom control parameters** as described in the previous substeps. Then, choose **Save**.

A customization must differ from the baseline settings before you can save it. Each Region can belong to only one customization. Regions without a customization use the baseline standards and controls.

e. Choose **Next**.

6. (Optional) On the **Configure Cross-Region aggregation** page, for **Home Region**, choose **No home Region** or the current Region. You can only choose the current Region as your home Region. To use a different home Region, open Security Hub in that Region. Then, choose **Next**.
7. On the **Review and apply** page, review your settings. To change the settings for a step, choose **Edit** for that step. Then, choose **Apply**.

   Security Hub creates a separate policy for each capability area. Each policy name is your policy name followed by the capability area. For example, *name* - Security management, *name* - Vulnerability management, and *name* - Posture management.

   The configuration status of your policy displays at the top of the Policies page. Each capability provides a status indicating whether it was configured successfully. To view the effective policy at the account level, review the **Organization** tab on the **Configurations** page.

> **Note**
>
> After you enable and configure Security Hub, you can use the following configurations to apply additional settings for individual services.

Configuring AWS Security Hub CSPM

This configuration turns on AWS Security Hub CSPM standards and controls, which detect when your AWS accounts and resources deviate from security best practices.

To manage this service along with the other Security Hub capabilities, we recommend that you use the steps in Enabling a configuration for Security Hub instead.

To create a configuration for AWS Security Hub CSPM

1. Sign in using your AWS account with your delegated administrator credentials. Open the Security Hub console at https://console.aws.amazon.com/securityhub/v2/home.
2. From the navigation pane, choose **Management**, and then choose **Configurations**.
3. From the **Configuration catalog**, choose **Posture management from AWS Security Hub CSPM**.
4. On the **Configure CSPM policy** page, configure the following settings:

a. For **Details**, enter a **Name** for the policy, and optionally a **Description**. The name must be unique for all policies in your organization.

b. For **Resource tags**, optionally add tags as key-value pairs to help you identify the configuration. Then, choose **Next**.

5. On the **Accounts and Regions** page, configure the following settings:

a. For **Account selection**, choose one of the following options:

- **All organizational units and accounts** – Applies the configuration to your entire organization.
- **Specific organizational units and accounts** – Use the search bar or organizational structure tree to select the organizational units and accounts where the policy applies.
- **No organizational units or accounts** – Does not apply the configuration to any organizational unit or account.

b. For **Regions**, choose one of the following options:

- **Enable in all currently available Regions** – Enables AWS Security Hub CSPM in all currently available Regions. We recommend this option. Optionally, select **Auto-enable new Regions** to automatically enable AWS Security Hub CSPM in new Regions.
- **Specify Regions in which to enable or disable** – Choose the Regions in which to enable or disable AWS Security Hub CSPM.
- **Disable in all currently available Regions** – Disables AWS Security Hub CSPM in all currently available Regions.

c. (Optional) For **Advanced settings**, see Inheritance operators in the *AWS Organizations User Guide*.

d. Choose **Next**.

6. On the **Standards and controls** page, configure the following settings:

a. For **Security standards**, choose the standards to enable. By default, AWS Foundational Security Best Practices v1.0.0 and CIS AWS Foundations Benchmark v5.0.0 are selected. (Optional) For **Advanced settings**, see Inheritance operators in the *AWS Organizations User Guide*.

b. For **Controls**, choose one of the following options:

- **Enable all controls** – Evaluates all controls in your enabled standards, including newly released controls. We recommend this option.
- **Customize** – Choose **Enable all by default (disable specific)** or **Disable all by default (enable specific)**. Then, select the controls to disable or enable.
- **Disable all controls** – Disables all controls in your enabled standards.

c. (Optional) For **Custom control parameters**, select **Customize control parameters**. Choose a control, and then set its parameter values. To customize more controls, choose **Customize additional control**. Controls that you don't customize use their default parameter values.

d. Choose **Next**.

7. On the **Regional overrides** page, optionally add Region-specific customizations. To apply different settings in specific Regions, choose **Add region customization**. In the dialog box, for **Regions**, choose the Regions. Configure **Security standards**, **Controls**, and **Custom control parameters** as described in the previous step. Then, choose **Save**.

   A customization must differ from the baseline settings before you can save it. Each Region can belong to only one customization. Regions without a customization inherit the baseline standards and controls.

   Choose **Next**.

8. On the **Review and create** page, review your settings. To change the settings for a step, choose **Edit** for that step. Then, choose **Create**.

Configuring Amazon Inspector

This configuration turns on selected Amazon Inspector capabilities that automatically discover workloads, instances, container images, and other resources, and scans them for vulnerabilities and network exposure.

To manage this service along with the other Security Hub capabilities, we recommend that you use the steps in Enabling a configuration for Security Hub instead.

To create a configuration for Amazon Inspector

1. Sign in using your AWS account with your delegated administrator credentials. Open the Security Hub console at https://console.aws.amazon.com/securityhub/v2/home.

2. From the navigation pane, choose **Management**, and then choose **Configurations**.
3. From the **Configuration catalog**, choose **Vulnerability management from Amazon Inspector**.
4. On the **Configure vulnerability management policy** page, configure the following settings:

   a. For **Capability selection**, select the capabilities for this policy to configure. You can select **EC2 scanning**, **ECR scanning**, **Lambda scanning**, **Lambda code scanning**, **Code security**, and **Machine images**. **Lambda code scanning**, **Code security**, and **Machine images** incur additional charges. For each capability that you select, choose one of the following options for **Policy action**:

   - **Enable** – Enforces the capability as enabled. Member accounts can't disable it.
   - **Disable** – Enforces the capability as disabled. Member accounts can't enable it.
   - **Custom** – Enables the capability in some Regions and disables it in others.

   To set all capabilities to the same policy action, under **Quick actions**, choose **Enable all** or **Disable all**. You can then change the policy action for individual capabilities. This policy doesn't configure capabilities that you don't select.

   If you enable **Code security**, it requires additional configuration. For more information, see Amazon Inspector Code Security in the *Amazon Inspector User Guide*.

   b. For **Account selection**, choose one of the following options:

   - **All organizational units and accounts** – Applies the configuration to your entire organization.
   - **Specific organizational units and accounts** – Use the search bar or organizational structure tree to select the organizational units and accounts where the policy applies.
   - **No organizational units or accounts** – Does not apply the configuration to any organizational unit or account.

   c. For **Region selection**, choose how to set Regions:

   - If all selected capabilities use the same policy action, choose **Across all selected capabilities** to use the same Regions for all capabilities. To set Regions for each capability, choose **Per capability**.
   - If the selected capabilities use different policy actions, the console uses **Per capability**, and **Across all selected capabilities** isn't available. Expand each capability to set its Regions.

For **Regions**, set the Regions based on the policy action:

- **Enable** – Choose **Enable in all currently available Regions** or **Enable in some Regions**. We recommend the first option. Optionally, select **Auto-enable new Regions**.
- **Disable** – Choose **Disable in all currently available Regions** or **Disable in some Regions**. We recommend the first option. Optionally, select **Auto-disable new Regions**.
- **Custom** – For **Enabled Regions**, choose **Enable all Regions and auto-enable new Regions** or **Enable specific Regions**. For **Disabled Regions**, choose the Regions to disable. If you select a Region as both enabled and disabled, the Region is disabled.

d. (Optional) For **Advanced settings**, see Inheritance operators in the *AWS Organizations User Guide*.

e. For **Details**, enter a **Name** for the policy, and optionally a **Description**. The name must be unique for all policies in your organization.

f. For **Resource tags**, optionally add tags as key-value pairs to help you identify the configuration. Then, choose **Next**.

5. On the **Review and create** page, review your settings. To change your settings, choose **Edit**. Then, choose **Create**.

Configuring Amazon GuardDuty

This configuration turns on selected Amazon GuardDuty capabilities to continuously monitor, analyze, and process AWS data sources and logs in your AWS environment.

To manage this service along with the other Security Hub capabilities, we recommend that you use the steps in Enabling a configuration for Security Hub instead.

To create a configuration for Amazon GuardDuty

1. Sign in using your AWS account with your delegated administrator credentials. Open the Security Hub console at https://console.aws.amazon.com/securityhub/v2/home.
2. From the navigation pane, choose **Management**, and then choose **Configurations**.
3. From the **Configuration catalog**, choose **Threat analytics from Amazon GuardDuty**.
4. On the **Configure threat detection policy** page, configure the following settings:

   a. For **Region scope**, choose one of the following options:

- **Set a default for all Regions** – Applies one default configuration to every AWS Region. You can override specific Regions in **Regional overrides**.
- **No default — manage only specific Regions** – This policy manages only the Regions that you add in **Regional overrides**. It doesn't manage other Regions. You must add at least one regional override.

b. If you chose **Set a default for all Regions**, for **Default configuration**, select the protection plans for this policy to manage. For each protection plan that you select, choose one of the following options for **Policy action**:

- **Enable** – Enforces the protection plan as enabled. Member accounts can't disable it.
- **Disable** – Enforces the protection plan as disabled. Member accounts can't enable it.

To set all protection plans to the same policy action, under **Quick actions**, choose **Enable all** or **Disable all**. You can then change the policy action for individual protection plans. This policy doesn't manage protection plans that you don't select. **Foundational threat detection** is always selected. It must be enabled if you enable any other protection plan.

c. For **Regional overrides**, choose **Add regional override**. This step is optional if you set a default, and required if you chose **No default — manage only specific Regions**. In the dialog box, choose the Regions for the override. Under **Protection plans**, select the protection plans and policy actions in the same way as for the default configuration. Then, choose **Save**.

A regional override fully replaces the default configuration for the Regions that you choose. Specify every protection plan that you want this policy to manage in those Regions. The same configuration applies to all of the Regions in the override.

d. For **Account selection**, choose one of the following options:

- **All organizational units and accounts** – Applies the configuration to your entire organization.
- **Specific organizational units and accounts** – Use the search bar or organizational structure tree to select the organizational units and accounts where the policy applies.
- **No organizational units or accounts** – Does not apply the configuration to any organizational unit or account.

e. For **Details**, enter a **Name** for the policy, and optionally a **Description**. The name must be unique for all policies in your organization.

f. For **Resource tags**, optionally add tags as key-value pairs to help you identify the configuration. Then, choose **Next**.

5. On the **Review and create** page, review your settings. To change your settings, choose **Edit**. Then, choose **Create**.

   After you create the policy, it manages the auto-enable settings for GuardDuty protection plans. While the policy is active, you can't change these settings independently on the **Protection plans** page in the GuardDuty console.

Editing a configuration policy

You can edit the capabilities, Regions, and accounts associated with a configuration policy. When you open a policy for editing, the console displays its current configuration.

On the **Configured policies** tab of the **Configurations** page, each policy has a policy type: Security Hub, Security Hub CSPM, Inspector, or GuardDuty. Your organization might have several policies. Choose the policy that you want to edit, and then expand the following section that matches its policy type.

Editing a Security Hub policy

To edit a Security Hub policy

1. Sign in using your AWS account with your delegated administrator credentials. Open the Security Hub console at https://console.aws.amazon.com/securityhub/v2/home.
2. From the navigation pane, choose **Management**, and then choose **Configurations**.
3. In the **Configured policies** tab, choose the radio button for the policy you want to edit, and then choose **Edit**.
4. On the **Edit security management policy** page, configure the following settings:

   a. For **Capability selection**, select the capabilities for this policy to configure. **Security Hub** is always selected. You can also select **Network reachability scanning**. For each capability that you select, choose one of the following options for **Policy action**:

   - **Enable** – Enforces the capability as enabled. Member accounts can't disable it.
   - **Disable** – Enforces the capability as disabled. Member accounts can't enable it.
   - **Custom** – Enables the capability in some Regions and disables it in others.

To set all capabilities to the same policy action, under **Quick actions**, choose **Enable all** or **Disable all**. You can then change the policy action for individual capabilities.

Enabling **Network reachability scanning** grants AWS permissions to run network tests against resources that are supported by this feature.

b. For **Account selection**, choose one of the following options:

- **All organizational units and accounts** – Applies the configuration to your entire organization.
- **Specific organizational units and accounts** – Use the search bar or organizational structure tree to select the organizational units and accounts where the policy applies.
- **No organizational units or accounts** – Does not apply the configuration to any organizational unit or account.

c. For **Region selection**, choose how to set Regions:

- If all selected capabilities use the same policy action, choose **Across all selected capabilities** to use the same Regions for all capabilities. To set Regions for each capability, choose **Per capability**.
- If the selected capabilities use different policy actions, the console uses **Per capability**, and **Across all selected capabilities** isn't available. Expand each capability to set its Regions.

For **Regions**, set the Regions based on the policy action:

- **Enable** – Choose **Enable in all currently available Regions** or **Enable in some Regions**. We recommend the first option. Optionally, select **Auto-enable new Regions**.
- **Disable** – Choose **Disable in all currently available Regions** or **Disable in some Regions**. We recommend the first option. Optionally, select **Auto-disable new Regions**.
- **Custom** – For **Enabled Regions**, choose **Enable all Regions and auto-enable new Regions** or **Enable specific Regions**. For **Disabled Regions**, choose the Regions to disable. If you select a Region as both enabled and disabled, the Region is disabled.

d. (Optional) For **Advanced settings**, see Inheritance operators in the *AWS Organizations User Guide*.

e. For **Details**, enter a **Name** for the policy, and optionally a **Description**. The name must be unique for all policies in your organization. Then, choose **Next**.

5. On the **Review and apply** page, review your changes. To change your settings, choose **Edit**. Then, choose **Update**.

Editing an AWS Security Hub CSPM policy

To edit an AWS Security Hub CSPM policy

1. Sign in using your AWS account with your delegated administrator credentials. Open the Security Hub console at https://console.aws.amazon.com/securityhub/v2/home.
2. From the navigation pane, choose **Management**, and then choose **Configurations**.
3. In the **Configured policies** tab, choose the radio button for the policy you want to edit, and then choose **Edit**.
4. On the **Configure CSPM policy** page, for **Details**, enter a **Name** for the policy, and optionally a **Description**. The name must be unique for all policies in your organization. Then, choose **Next**.
5. On the **Accounts and Regions** page, configure the following settings:

   a. For **Account selection**, choose one of the following options:

   - **All organizational units and accounts** – Applies the configuration to your entire organization.
   - **Specific organizational units and accounts** – Use the search bar or organizational structure tree to select the organizational units and accounts where the policy applies.
   - **No organizational units or accounts** – Does not apply the configuration to any organizational unit or account.

   b. For **Regions**, choose one of the following options:

   - **Enable in all currently available Regions** – Enables AWS Security Hub CSPM in all currently available Regions. We recommend this option. Optionally, select **Auto-enable new Regions** to automatically enable AWS Security Hub CSPM in new Regions.
   - **Specify Regions in which to enable or disable** – Choose the Regions in which to enable or disable AWS Security Hub CSPM.
   - **Disable in all currently available Regions** – Disables AWS Security Hub CSPM in all currently available Regions.

c. (Optional) For **Advanced settings**, see Inheritance operators in the *AWS Organizations User Guide*.

d. Choose **Next**.

6. On the **Standards and controls** page, configure the following settings:

a. For **Security standards**, choose the standards to enable. By default, AWS Foundational Security Best Practices v1.0.0 and CIS AWS Foundations Benchmark v5.0.0 are selected. (Optional) For **Advanced settings**, see Inheritance operators in the *AWS Organizations User Guide*.

b. For **Controls**, choose one of the following options:

- **Enable all controls** – Evaluates all controls in your enabled standards, including newly released controls. We recommend this option.
- **Customize** – Choose **Enable all by default (disable specific)** or **Disable all by default (enable specific)**. Then, select the controls to disable or enable.
- **Disable all controls** – Disables all controls in your enabled standards.

c. (Optional) For **Custom control parameters**, select **Customize control parameters**. Choose a control, and then set its parameter values. To customize more controls, choose **Customize additional control**. Controls that you don't customize use their default parameter values.

d. Choose **Next**.

7. On the **Regional overrides** page, optionally add Region-specific customizations. To apply different settings in specific Regions, choose **Add region customization**. In the dialog box, for **Regions**, choose the Regions. Configure **Security standards**, **Controls**, and **Custom control parameters** as described in the previous step. Then, choose **Save**.

   A customization must differ from the baseline settings before you can save it. Each Region can belong to only one customization. Regions without a customization inherit the baseline standards and controls.

   Choose **Next**.

8. On the **Review and create** page, review your changes. To change the settings for a step, choose **Edit** for that step. Then, choose **Update**.

Editing an Amazon Inspector policy

To edit an Amazon Inspector policy

1. Sign in using your AWS account with your delegated administrator credentials. Open the Security Hub console at https://console.aws.amazon.com/securityhub/v2/home.
2. From the navigation pane, choose **Management**, and then choose **Configurations**.
3. In the **Configured policies** tab, choose the radio button for the policy you want to edit, and then choose **Edit**.
4. On the **Edit vulnerability management policy** page, configure the following settings:

   a. For **Capability selection**, select the capabilities for this policy to configure. You can select **EC2 scanning**, **ECR scanning**, **Lambda scanning**, **Lambda code scanning**, **Code security**, and **Machine images**. **Lambda code scanning**, **Code security**, and **Machine images** incur additional charges. For each capability that you select, choose one of the following options for **Policy action**:

   - **Enable** – Enforces the capability as enabled. Member accounts can't disable it.
   - **Disable** – Enforces the capability as disabled. Member accounts can't enable it.
   - **Custom** – Enables the capability in some Regions and disables it in others.

   To set all capabilities to the same policy action, under **Quick actions**, choose **Enable all** or **Disable all**. You can then change the policy action for individual capabilities. This policy doesn't configure capabilities that you don't select.

   If you enable **Code security**, it requires additional configuration. For more information, see Amazon Inspector Code Security in the *Amazon Inspector User Guide*.

   b. For **Account selection**, choose one of the following options:

   - **All organizational units and accounts** – Applies the configuration to your entire organization.
   - **Specific organizational units and accounts** – Use the search bar or organizational structure tree to select the organizational units and accounts where the policy applies.
   - **No organizational units or accounts** – Does not apply the configuration to any organizational unit or account.

   c. For **Region selection**, choose how to set Regions:

- If all selected capabilities use the same policy action, choose **Across all selected capabilities** to use the same Regions for all capabilities. To set Regions for each capability, choose **Per capability**.
- If the selected capabilities use different policy actions, the console uses **Per capability**, and **Across all selected capabilities** isn't available. Expand each capability to set its Regions.

For **Regions**, set the Regions based on the policy action:

- **Enable** – Choose **Enable in all currently available Regions** or **Enable in some Regions**. We recommend the first option. Optionally, select **Auto-enable new Regions**.
- **Disable** – Choose **Disable in all currently available Regions** or **Disable in some Regions**. We recommend the first option. Optionally, select **Auto-disable new Regions**.
- **Custom** – For **Enabled Regions**, choose **Enable all Regions and auto-enable new Regions** or **Enable specific Regions**. For **Disabled Regions**, choose the Regions to disable. If you select a Region as both enabled and disabled, the Region is disabled.

d. (Optional) For **Advanced settings**, see Inheritance operators in the *AWS Organizations User Guide*.

e. For **Details**, enter a **Name** for the policy, and optionally a **Description**. The name must be unique for all policies in your organization. Then, choose **Next**.

5. On the **Review and apply** page, review your changes. To change your settings, choose **Edit**. Then, choose **Update**.

Editing an Amazon GuardDuty policy

To edit an Amazon GuardDuty policy

1. Sign in using your AWS account with your delegated administrator credentials. Open the Security Hub console at https://console.aws.amazon.com/securityhub/v2/home.
2. From the navigation pane, choose **Management**, and then choose **Configurations**.
3. In the **Configured policies** tab, choose the radio button for the policy you want to edit, and then choose **Edit**.
4. On the **Edit threat detection policy** page, configure the following settings:

   a. For **Region scope**, choose one of the following options:

- **Set a default for all Regions** – Applies one default configuration to every AWS Region. You can override specific Regions in **Regional overrides**.
- **No default — manage only specific Regions** – This policy manages only the Regions that you add in **Regional overrides**. It doesn't manage other Regions. You must add at least one regional override.

b. If you chose **Set a default for all Regions**, for **Default configuration**, select the protection plans for this policy to manage. For each protection plan that you select, choose one of the following options for **Policy action**:

- **Enable** – Enforces the protection plan as enabled. Member accounts can't disable it.
- **Disable** – Enforces the protection plan as disabled. Member accounts can't enable it.

To set all protection plans to the same policy action, under **Quick actions**, choose **Enable all** or **Disable all**. You can then change the policy action for individual protection plans. This policy doesn't manage protection plans that you don't select. **Foundational threat detection** is always selected. It must be enabled if you enable any other protection plan.

c. For **Regional overrides**, choose **Add regional override**. This step is optional if you set a default, and required if you chose **No default — manage only specific Regions**. In the dialog box, choose the Regions for the override. Under **Protection plans**, select the protection plans and policy actions in the same way as for the default configuration. Then, choose **Save**.

A regional override fully replaces the default configuration for the Regions that you choose. Specify every protection plan that you want this policy to manage in those Regions. The same configuration applies to all of the Regions in the override.

d. For **Account selection**, choose one of the following options:

- **All organizational units and accounts** – Applies the configuration to your entire organization.
- **Specific organizational units and accounts** – Use the search bar or organizational structure tree to select the organizational units and accounts where the policy applies.
- **No organizational units or accounts** – Does not apply the configuration to any organizational unit or account.

e. For **Details**, enter a **Name** for the policy, and optionally a **Description**. The name must be unique for all policies in your organization. Then, choose **Next**.

5. On the **Review and create** page, review your changes. To change your settings, choose **Edit**. Then, choose **Update**.

   When you update the policy, you change the auto-enable settings that it manages for GuardDuty protection plans. These settings on the **Protection plans** page in the GuardDuty console remain managed by the policy, and you can't change them independently.

Deleting a configuration policy

You can delete a configuration policy. When you delete a policy, the service removes all attached accounts and organizational units from the policy.

To delete a configuration policy

1. Sign in using your AWS account with your delegated administrator credentials. Open the Security Hub console at https://console.aws.amazon.com/securityhub/v2/home.
2. From the navigation pane, choose **Management**, and then choose **Configurations**.
3. In the **Configured policies** tab, select the policy you want to delete, and then choose **Delete**.
4. Enter `delete` in the confirmation box, and then choose **Delete**.

Removing the delegated administrator account in Security Hub

You can remove the delegated administrator account in the Security Hub console at any time. However, this action removes the delegated administrator from both Security Hub and Security Hub CSPM. We recommend only performing this action when you have confirmed this operation with your security account.

> **Note**
>
> If you are using an account other than the organization management account as the Security Hub CSPM delegated administrator, removing it through either the Security Hub CSPM console or the AWS Organizations API also removes it from Security Hub. Similarly, if you remove the Security Hub delegated administrator through either the Security Hub Console or AWS Organizations API, it is also removed from Security Hub CSPM. When the delegated administrator is removed from Security Hub CSPM, Central Configuration automatically opts out.

To remove the delegated administrator account

1. Sign in to your AWS account with your organization management account credentials. Open the Security Hub console at https://console.aws.amazon.com/securityhub/v2/home.
2. From the navigation pane, choose **General**.
3. In **Delegated administrator**, choose **Remove delegated administrator**. In the confirmation dialog box, enter *remove*, and choose **Remove**.

Re-enabling Security Hub

Before re-enabling Security Hub on accounts that were previously disabled using a Security Hub policy, you must first detach the disable policy. If you attempt to re-enable Security Hub while a disable policy is still attached to the account or organizational unit, the disable policy overrides the enablement and Security Hub remains disabled.

To remove the Security Hub disable policy for an organization or an account

1. Sign in using your AWS account with your organization management account credentials. Open the AWS Organizations console at https://console.aws.amazon.com/organizations/v2/home.
2. From the navigation panel choose **AWS accounts**.
3. If the current Security Hub disable policy was for your entire organization, choose **Root** under the **Organizational structure**. If the current Security Hub disable policy is for specific accounts, choose the specific account under the **Organizational structure** and then follow the remaining steps for each account.
4. In the **Policies** tab, find the section titled **Security Hub policies**.
5. Choose the radio button next to the policy that disables Security Hub. Choose **Detach**.

After you detach the policy from your organization or accounts, you can re-enable Security Hub. See Managing configuration of member accounts in an AWS Organization for details on re-enabling Security Hub.

Security Hub recommendations

The following security services in AWS send findings to Security Hub in the OCSF format. After you enable Security Hub, enable these AWS services for additional security.

Security Hub CSPM

When you enable Security Hub CSPM, you get a comprehensive view of your security state in AWS. This helps you assess your environment against security industry standards and best practices. Although you can get started with Security Hub without enabling Security Hub CSPM, enabling Security Hub CSPM allows Security Hub to correlate security signals from Security Hub CSPM to improve your posture management.

If you enable Security Hub CSPM, we also recommend enabling the AWS Foundational Security Best Practices standard for your account. This standard consists of a set of controls that detect when your AWS accounts and resources deviate from security best practices. When you enable the AWS Foundational Security Best Practices standard for your account, AWS Security Hub CSPM automatically enables all of its controls, including controls for the following resource types:

- Account controls
- Amazon DynamoDB controls
- Amazon Elastic Compute Cloud controls
- AWS Identity and Access Management (IAM) controls
- AWS Lambda controls
- Amazon Relational Database Service (Amazon RDS) controls
- Amazon Simple Storage Service controls

You can disable any of the controls in this list. However, if you disable any of these controls, you cannot receive exposure findings for supported resources. For information about controls that apply to the AWS Foundational Security Best Practices standard, see AWS Foundational Security Best Practices v1.0.0 (FSBP) standard.

GuardDuty

When you enable GuardDuty, you can view all of your threats and security coverage findings in the dashboard of the Security Hub console. If you enable GuardDuty, GuardDuty automatically begins sending data to Security Hub in the OCSF format.

Amazon Inspector

When you enable Amazon Inspector, you can view all of your exposures and security coverage findings in the dashboard of the Security Hub console. If you enable Amazon Inspector, Amazon Inspector automatically begins sending data to Security Hub in the OCSF format.

We recommend activating Amazon EC2 scanning and Lambda standard scanning. When you activate Amazon EC2 scanning, Amazon Inspector scans Amazon EC2 instances in your account for package vulnerabilities and network reachability issues. When you activate Lambda standard scanning, Amazon Inspector scans Lambda functions for software vulnerabilities in package dependencies. For more information, see Activating a scan type in the *Amazon Inspector User Guide*.

Macie

When you enable Macie, you can detect additional exposures for your Amazon S3 buckets. We recommend configuring automated sensitive data discovery, so Macie can evaluate your Amazon S3 bucket inventory on a daily basis.

Account coverage in Security Hub

The **Account coverage** page shows which accounts and Regions in your organization have Security Hub and its integrated security capabilities enabled. These capabilities include services such as Amazon Inspector, Amazon GuardDuty, AWS Security Hub CSPM, and Amazon Macie. Use this page to identify coverage gaps and track capability adoption across your organization.

Account coverage page

With the account coverage page, you can view aggregated coverage metrics. Use the Accounts tab for account-level details and the Coverage findings tab to review specific coverage gaps.

To access the Security Hub Account coverage page

1. Open the Security Hub console at https://console.aws.amazon.com/securityhub/v2/home.
2. From the navigation pane, under **Settings** choose **Account coverage**.

Overview section

The **Overview** section displays aggregated security coverage metrics across all monitored accounts. For delegated administrator accounts, this section displays Security Hub enablement details across the organization, providing visibility into coverage for all member accounts. This high-level visualization shows the percentage of accounts with Security Hub and each security capability enabled, offering a comprehensive view of your security posture. You can select the percentage of Security Hub coverage to view a breakdown of enabled accounts by Region. You can select each capability percentage to filter coverage findings by that capability.

The percentages in the Overview section are determined using the following calculations:

- **Security Hub enablement** = (Number of account and Region pairs where Security Hub is enabled) ÷ (Total accounts in your organization × Regions where Security Hub is available)
- **Services coverage** = (Number of enabled account and configured Region pairs where the capability is enabled) ÷ (Total number of enabled account and configured Region pairs, in configured Regions where account is enabled, and capability is available)

> **Configured Regions**
>
> For a home Region setup, configured Regions include the home Region and linked Regions. For all other setups, configured Regions refers to the current Region only.

Accounts tab

This tab is available only in the Security Hub delegated administrator account. Use the **Accounts** tab to analyze account-specific coverage. The Security Hub column shows the number of Regions where Security Hub is enabled for each account. This column is not displayed when viewing the tab in opt-in Regions (Regions that are disabled by default). Each security capability displays a coverage percentage that, when selected, reveals a detailed breakdown of individual features and their coverage percentage within that capability. When you select these percentages, Security Hub filters the results to display coverage for that capability and account.

The percentages in the Accounts tab are determined using the following calculation:

Accounts tab coverage = (Number of Regions where the capability is enabled) ÷ (Regions where the capability is available)

There are several cases where the coverage percentage might show as 0%:

- Security Hub is not enabled in the account and so no coverage findings are being ingested.
- Security Hub is waiting for coverage findings to be generated.

Coverage findings tab

The **Coverage findings** tab lists informational findings for security capabilities that are enabled or disabled across your accounts and Regions. These findings help identify areas where security

coverage can be enhanced. Each finding shows the finding title, the affected account and Region, and the current status. Each finding also has a configure link that takes you to the individual service where you can manage the configuration for that capability, or to the Security Hub configurations page where you can update your configurations for security services.

You can suppress coverage findings with a **Not covered** status if that security capability is not applicable for the account-Region combination. Security Hub excludes suppressed findings from the security coverage percentage calculation.

For more information about coverage findings and how to suppress them, see Coverage findings in Security Hub.

Security coverage widget

Account coverage can also be viewed via the **Security coverage widget** in the Security Hub summary dashboard. For more information, see Security coverage widget.

Security Hub Extended plan

With the Security Hub Extended plan, you can protect your entire enterprise estate across cloud, endpoint, network, identity, data, email, and browser. Use AWS Security Hub as the center of an integrated security operations experience. With the Security Hub Extended plan, you can select partner solutions that address your security needs and sign up for flexible pay-as-you-go pricing with no upfront investments or long-term commitments required. You can add or remove partner solutions as your business needs evolve.

The Security Hub Extended plan is available to all customers who have enabled the Security Hub Essentials plan. Charges for Security Hub Extended plan appear on your monthly AWS bill with AWS as the seller of record.

Security Hub Extended plan pricing for all solutions is available on the Extended plan tab of the Security Hub pricing details page.

Permissions for the Security Hub Extended plan

To subscribe to a partner product from the Security Hub Extended plan, you need the following permissions, in addition to your Security Hub permissions:

- `aws-marketplace:ViewSubscriptions`
- `aws-marketplace:Subscribe`

To unsubscribe from a partner product in the Security Hub Extended plan, you need the following permissions, in addition to your Security Hub permissions:

- `license-manager:ListReceivedLicenses`
- `aws-marketplace:ListAgreementCharges`
- `aws-marketplace:Unsubscribe`

For more information on AWS Marketplace permissions, see Controlling access to AWS Marketplace subscriptions in the *AWS Marketplace Buyer Guide*.

Reviewing and signing up for Extended plan partners

The Security Hub Extended plan is accessible through the Security Hub delegated administrator account or standalone accounts. On the Security Hub Extended plan page, you can view details about each partner, initiate a subscription to a partner solution, and begin the onboarding process to each partner's solution through the partner's onboarding page.

To access the Security Hub Extended plan and sign up for a partner's product

1. Sign in to the AWS Management Console using your delegated administrator or standalone account credentials.
2. Open the Security Hub console at https://console.aws.amazon.com/securityhub/v2/home.
3. In the navigation pane, choose **Management**, and then choose **Extended plan**.
4. For each partner solution that you want to sign up for, choose **View product**.
5. Review the product pricing details, and then choose **Subscribe** when you are ready to start the process of onboarding to the partner product.
6. After the subscription process completes, choose **Set up your account** to be redirected to the partner's sign-up page.
7. Provide the necessary information for the partner sign-up page, and follow the next steps, provided by the partner, for completing the onboarding steps.

> **Important**
>
> You are not billed for the partner solution until you complete the onboarding process for the partner product.

Unsubscribing from an Extended plan partner

If you no longer want to use an Extended plan partner solution, you can unsubscribe from the partner listing.

To unsubscribe from a partner solution, follow the guidance at Canceling your SaaS subscription in the *AWS Marketplace Buyer Guide*.

> **Important**
>
> In addition to canceling your subscription, follow any additional offboarding steps that are required for the partner solution, based on how you configured the solution for your company.

Understanding cross-Region aggregation in Security Hub

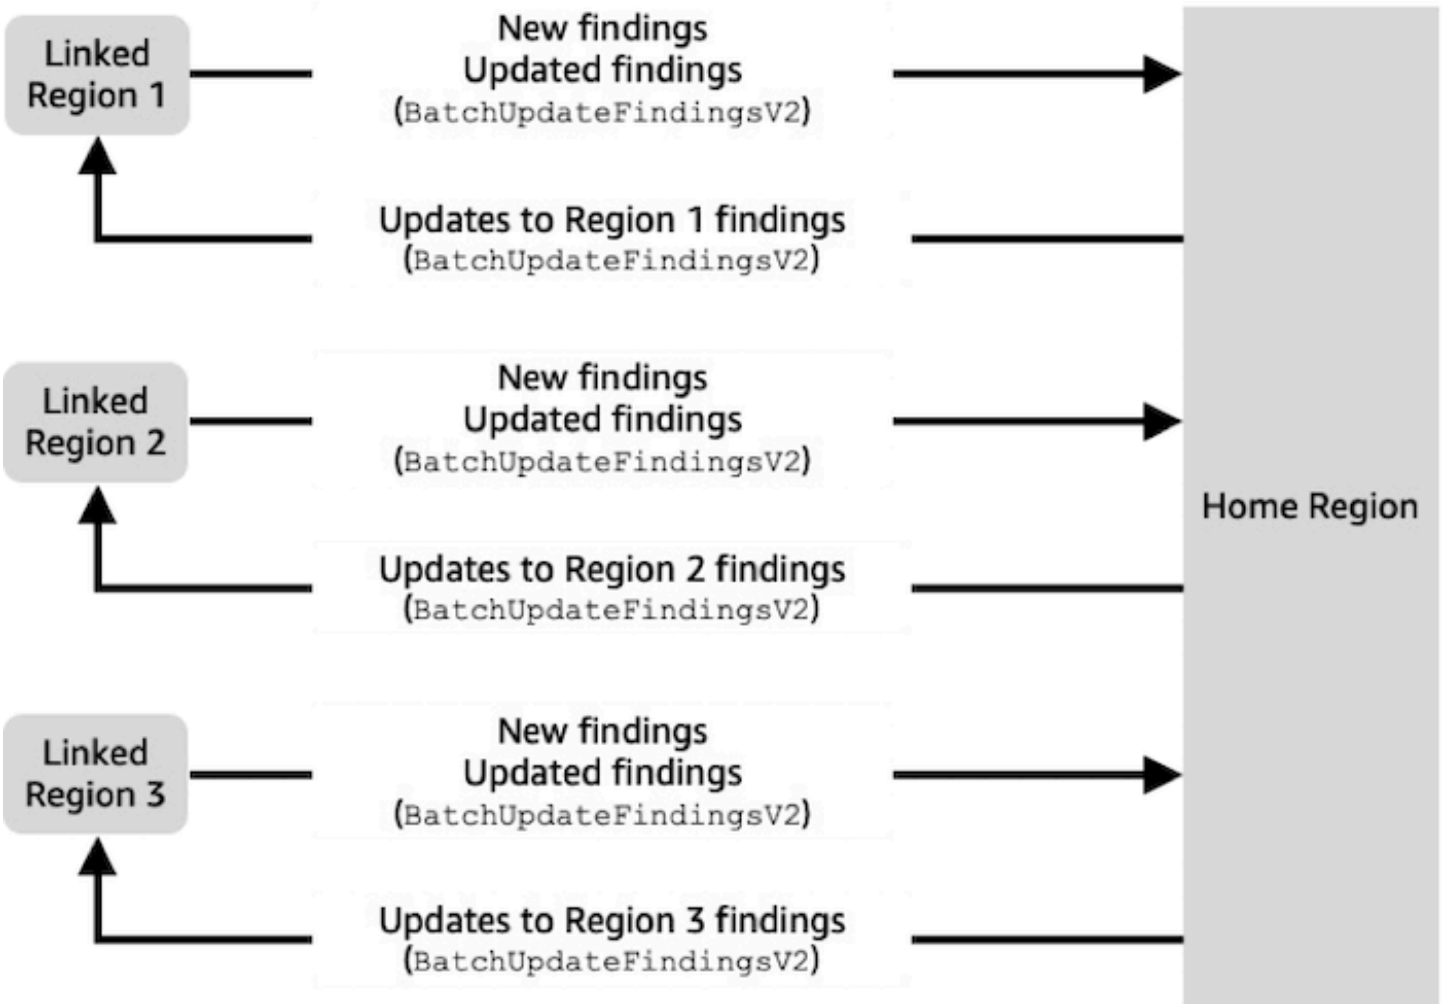
When you enable cross-Region aggregation in Security Hub, you designate a home Region. The home Region collects findings, resources, and trends from one or more linked Regions. You can then manage all security data from a single Region.

Suppose you set US East (N. Virginia) as the home Region, and US West (Oregon) and US West (N. California) as the linked Regions. When you view the Findings page in US East (N. Virginia), you see the findings from all three Regions. Updates to those findings are also reflected in all three Regions.

Types of data that are aggregated

When cross-Region aggregation is enabled with one or more linked Regions, Security Hub replicates the following data from the linked Regions to the home Region. This occurs in every account that has cross-Region aggregation enabled.

- Findings
- Resources
- Trends
- Software and package inventory (beginning in November 2026)



In addition to new data in the previous list, Security Hub also replicates updates to this data between the linked Regions and the home Region. Updates that occur in a linked Region are replicated to the home Region. Updates that occur in the home Region are replicated back to the linked Region. If there are conflicting updates in the home Region and the linked Region, then the most recent update is used.

Any findings that existed in a Region at the time that it becomes a linked Region are not replicated to the home Region unless there is an update to the finding. After a Region is linked to a home Region, there is a difference in findings between the home Region and the linked Region until findings in the linked Region are updated or they age out.

Any resources that existed in a Region at the time that it becomes a linked Region are replicated to the home Region, typically within 24-48 hours after the Region becomes linked to a home Region.

When removing a linked Region, any findings or resources for that Region remain in the home Region until the finding or resource ages out.

Trends data is based on findings and resources that are present within the Region that the trend is for. Trends data in a home Region reflects the current state of findings and resources that have been synced to the home Region.

Cross-Region aggregation does not add to the cost of Security Hub. You are not charged when Security Hub replicates new data or updates.

In the home Region, the Summary page provides a view of your active findings and resources across linked Regions.

Security Hub only aggregates data from Regions where an account has Security Hub enabled. Security Hub is not automatically enabled for an account based on the cross-Region aggregation configuration.

It's possible to have cross-Region aggregation enabled without any linked Regions selected. In this case, no data replication occurs.

Aggregation for administrator and member accounts

Standalone accounts and administrator accounts can configure cross-Region aggregation. If configured by an administrator, the presence of the administrator account is essential for cross-Region aggregation to work in administered accounts. If the administrator account is removed or disassociated from a member account, cross-Region aggregation stops for that member account. However, if the member account had its own cross-Region aggregation configuration before being associated with an administrator, that configuration goes back into effect.

When an administrator account enables cross-Region aggregation, Security Hub replicates the data that the administrator account generates in all linked Regions to the home Region. In addition, Security Hub identifies the member accounts that are associated with that administrator, and each member account inherits the cross-Region aggregation settings of the administrator. Security Hub replicates the data that a member account generates in all linked Regions to the home Region.

The administrator can access and manage security findings from all member accounts within the administered Regions. Additionally, the administrator can view resource inventory from all member accounts within the administered Regions.

As a Security Hub member account, you must be signed in to the home Region to view aggregated data from your account from all linked Regions. Member accounts do not have permissions to view data from other member accounts and are not permitted to call the `CreateAggregatorV2`, `DeleteAggregatorV2`, and `GetAggregatorV2` APIs.

Automation rules and cross-Region aggregation

When cross-Region aggregation is enabled automation rules can only be created in the defined home Region. Any rule that you define applies to all linked Regions unless your rule criteria applies to specific regions. You must create separate automation rules for any region that is not a linked Region.

Any rules that were created in the home Region, prior to enabling cross-Region aggregation, automatically become applicable in linked Regions. Rules previously created in linked Regions will no longer apply once an aggregator is created. Rules defined in linked Regions resume applying after the aggregator is deleted or the Region is no longer linked.

Enabling cross-Region aggregation

You must enable cross-Region aggregation from the AWS Region that you want to designate as the home Region.

To enable cross-Region aggregation, you create a Security Hub resource called a finding aggregator. The finding aggregator resource specifies your home Region and linked Regions (if any).

You cannot use an AWS Region that is disabled by default as your home Region. For a list of Regions that are disabled by default, see Enabling a Region in the AWS General Reference.

When you enable cross-Region aggregation, you choose to specify one or more linked Regions if you wish. Enabling cross-Region aggregation does not enable Security Hub in that Region. To enable Security Hub in a region refer to Creating a policy as the delegated administrator to manage member accounts in the Security Hub user guide.

To enable cross-Region aggregation (console)

1. From the administrator account or in a standalone account, open the AWS Security Hub console at https://console.aws.amazon.com/securityhub/v2/home
2. Using the AWS Region selector, sign in to the Region that you want to use as the aggregation Region.
3. In the Security Hub navigation menu, choose **Settings** and then **General**.
4. In the **Cross-Region aggregation** section choose **Configure**.
5. By default, the home Region is set to **No aggregation Region**.
6. Under **Home Region**, select the option to designate the current Region as the home Region.
7. Optionally, for **Linked Regions**, select the Regions to aggregate data from.
8. Choose **Save**.

Reviewing cross-Region aggregation settings

You can view the current cross-Region aggregation configuration in AWS Security Hub from any AWS Region in the administrator account or in a standalone account. Member accounts cannot view cross-Region aggregation configuration. The configuration includes the home Region, and the linked Regions (if any).

Follow the steps to view your current cross-Region aggregation settings

To view cross-Region aggregation settings (console)

1. Open the AWS Security Hub console at https://console.aws.amazon.com/securityhub/v2/home.

2. On the navigation pane, choose **Settings** and then the **General**.
3. If cross-Region aggregation is not enabled, then the General page displays the option to enable cross-Region aggregation. Only administrator accounts and standalone accounts can enable cross-Region aggregation.
4. If cross-Region aggregation is enabled, then the Regions tab displays the following information:

   - The home Region
   - Whether to automatically aggregate findings, resources, and trends from new Regions that Security Hub supports and that you opt into
   - The list of linked Regions (if any are selected)

Updating cross-Region aggregation settings

You can update your current cross-Region aggregation settings in AWS Security Hub by changing the linked Regions or the current home Region.

Changes to cross-Region aggregation are not implemented for an opt-in Region until you enable the Region in your AWS account. Regions that AWS introduced on or after March 20, 2019 are opt-in Regions.

When you stop aggregating data from a linked Region, AWS Security Hub does not remove any existing aggregated data from that Region that is accessible in the home Region.

You cannot use the update procedures in this section to change the home Region. To change the home Region, you must do the following:

1. Delete the current cross-Region aggregation configuration. For instructions, see the section called “Deleting aggregation”.
2. Change to the Region that you want to be the new home Region.
3. Enable cross-Region aggregation. For instructions, see the section called “Enabling aggregation”.

You must update the cross-Region aggregation configuration from the current home Region.

To change the linked Regions (console)

1. From the administrator account or in a standalone account, open the AWS Security Hub console at https://console.aws.amazon.com/securityhub/v2/home.
2. Sign in to the current aggregation Region.
3. In the Security Hub navigation menu, choose **Settings**, then choose **General**.
4. For **Cross-Region aggregation**, choose **Edit**.
5. For **Linked Regions**, update the selected linked Regions.
6. Choose **Save**.

Deleting cross-Region aggregation

If you do not want AWS Security Hub to aggregate data, you can delete your finding aggregator. Alternatively, you can keep your finding aggregator but not link any AWS Regions to the home Region by updating the existing aggregator to have no linked Regions selected.

To change your home Region, you must delete your current finding aggregator and create a new one.

When you delete your finding aggregator, Security Hub stops aggregating data. It does not remove any existing aggregated data from the home Region.

Deleting the finding aggregator (console)

You can delete your finding aggregator from the current home Region only.

In Regions other than the home Region, the Finding aggregation panel on the Security Hub console displays a message that you must edit the configuration in the home Region. Choose this message to display a link to switch to the home Region.

To stop cross-Region aggregation (console)

1. Open the AWS Security Hub console at https://console.aws.amazon.com/securityhub/v2/home.
2. Ensure that you are signed in to your current home Region.
3. In the Security Hub navigation menu, choose **Settings**, then choose **General**.
4. Under **Cross-Region aggregation**, choose **Edit**.
5. Under **Aggregation Region**, choose **No aggregation Region**.

6. Choose **Save**.
7. On the confirmation dialog, in the confirmation field, type **`Confirm`**.
8. Choose **Confirm**.

Integrating Security Hub with Microsoft Azure

To monitor your Microsoft Azure resources, you can integrate Microsoft Azure with AWS Security Hub. Security Hub then automatically enables posture management and vulnerability management for your Azure environment and generates findings and other data about your environment. You do not need to turn on any Azure security services—all functionality is performed by AWS. More specifically, the service provides you with the following:

CIS Microsoft Azure Foundations Benchmark v4.0 and Azure Foundational Best Practices

Automated compliance checks against the CIS Azure v4.0 standard and the Azure Foundational Best Practices standard. These standards cover identity, networking, storage, logging, and database controls.

Vulnerability management

Amazon Inspector automatically scans your Azure VMs, Function Apps, and Azure Container Registry (ACR) container images for software vulnerabilities through the service-linked connector.

> **Note**
>
> VM scanning requires Amazon EC2 Systems Manager to be configured in the same Region. For setup details, see the Amazon Inspector documentation for Azure integration.

Exposure correlation

Automated detection of exposed Azure resources based on network reachability, public access, and misconfiguration combinations.

Microsoft Defender for Cloud threat detection alerts

If you configure Azure Defender continuous export to the Event Hub, Security Hub ingests Defender for Cloud threat detection alerts and maps them to Open Cybersecurity Schema

Framework (OCSF) format. These appear alongside your posture management and vulnerability findings in the Security Hub console.

Asset inventory

A complete inventory of your Azure resources discovered through the integration, visible in the Security Hub console alongside your AWS resources.

OCSF format

Security Hub generates all findings in the Open Cybersecurity Schema Framework (OCSF) format, providing a consistent schema across AWS and Azure findings.

To create the integration, you connect your Azure environment to Security Hub through the following process:

1. You configure your Azure environment with an application registration, federated identity credentials, Azure role assignments, and Event Hub infrastructure.
2. By using the Security Hub console, you create a connector for the integration. You specify your Azure tenant ID, application client ID, monitoring scope, and Event Hub region.
3. Security Hub creates the necessary service-linked roles and resources in your AWS account.
4. AWS Config collects resource configuration data from your Azure environment.

   AWS Config is used internally to collect resource configuration data. Unlike AWS posture management, where you must explicitly enable AWS Config and pay for recording, Azure posture management handles AWS Config automatically. You do not need to enable AWS Config separately, configure a recorder, or pay separately for AWS Config usage. These costs are included in your Security Hub pricing.
5. Security Hub begins receiving resource configuration data and Activity Log events from your Azure environment.
6. Security Hub generates posture management and vulnerability findings about your Azure environment.

How AWS Config is used

AWS Config is used internally to collect resource configuration data and detect changes in your Azure environment. The connector handles this automatically. You do not need to enable AWS

Config separately, configure a recorder, or pay for AWS Config usage. These costs are included in your Security Hub pricing for Azure resources.

Additional information

When you create the integration, Security Hub also creates corresponding service-linked integrations in Security Hub CSPM and Amazon Inspector automatically. These service-linked integrations ensure that the scope of your CSPM checks and your Inspector vulnerability scans match the scope that you define in Security Hub. If you want to change the scope, you have to make the changes in the Security Hub. You cannot modify a service-linked integration directly in Security Hub CSPM or Inspector.

You can also create an Azure integration directly in Security Hub CSPM and specify independent scope settings. The CSPM integration then operates independently from the Security Hub integration and can have different Azure Subscription and Azure Region scope.

For information about estimating and calculating costs for integrating Security Hub with Azure, see AWS Security Hub pricing.

Topics

- Prerequisites for integrating Security Hub with Microsoft Azure
- Configuring Microsoft Azure to integrate with Security Hub
- Configuring Security Hub to integrate with Microsoft Azure
- Deleting a Microsoft Azure connector in Security Hub

Prerequisites for integrating Security Hub with Microsoft Azure

Before you integrate Microsoft Azure with AWS Security Hub, complete the following tasks in your AWS and Azure environments. This helps ensure that you and Security Hub have the resources and permissions that you need to monitor your Azure resources.

Topics

- Prerequisites for AWS
- Prerequisites for Microsoft Azure

Prerequisites for AWS

Verify that you have the following in your AWS account:

AWS Security Hub enabled

Security Hub must be enabled in the AWS account and AWS Region where you want to create the connector. You must enable Security Hub before creating an Azure connector.

AWS Security Hub CSPM enabled

Security Hub CSPM must be enabled in the same AWS account and AWS Region. The Azure integration relies on Security Hub CSPM for resource configuration evaluation.

Console IAM permissions

The IAM principal creating the connector must have the following permissions:

- `config:GetConnector`
- `config:ListConnectors`
- `config:PutConnector`

IAM Outbound Identity Federation enabled

You must enable IAM Outbound Identity Federation in your AWS account. This feature allows AWS services to authenticate to external identity providers (such as Microsoft Entra ID) using federated credentials rather than long-lived secrets.

After enabling Outbound Identity Federation, note the **Token Issuer URL**. This URL follows the format:

```
https://uuid.tokens.sts.global.api.aws
```

You will need this URL when configuring federated identity credentials in Azure.

Prerequisites for Microsoft Azure

Verify that you have the following in your Azure environment:

Azure tenant

You must have an Azure tenant in the Azure commercial cloud. Azure Government and Azure China are not supported.

Microsoft Entra ID log availability

Resource recording requires Microsoft Graph audit logs and sign-in logs from your Microsoft Entra ID tenant. Some Microsoft Entra ID logs require Microsoft Entra ID P1 or P2 licensing.

If the tenant lacks required logs, resource recording might report partial failures. The app registration and Azure role assignments do not supply missing log data.

Global Administrator role

You must have the **Global Administrator** role in Microsoft Entra ID to configure the Azure environment. This role is required to register applications, grant admin consent for Microsoft Graph API permissions, assign RBAC roles at the tenant root management group scope, and configure diagnostic settings for Entra ID Audit Logs.

In addition to Global Administrator, you need the following Azure RBAC roles to create the resources that the integration requires:

- **User Access Administrator** (or Owner) at the root scope (/) – to assign RBAC roles at the tenant root management group scope.
- **Resource Policy Contributor** (or Owner) at the tenant root management group scope – to create the Azure Policy definitions and assignments that automate diagnostic settings and remediation.
- **Contributor** (or Owner) at the subscription scope that hosts the Event Hub – to create the Event Hub namespace and related resources.

> **Note**
>
> In many organizations, the Azure Global Administrator and the AWS security administrator are different people. The Azure setup can be completed independently using the generated setup script.

After you complete these tasks, you are ready to configure your Azure environment.

Configuring Microsoft Azure to integrate with Security Hub

After you complete the prerequisite tasks, you can configure your Microsoft Azure environment to support integration with AWS Security Hub. To help you do this, the Security Hub console generates a setup script that is customized for your configuration.

To generate the setup script

1. Open the AWS Security Hub console at https://console.aws.amazon.com/securityhub/advanced/home?region=us-east-1..
2. In the navigation pane, choose **Integrations**.
3. Choose **Create Azure connector**.
4. Complete the connector configuration (tenant ID, scope, and name), and then copy the generated setup script.

To run the script, use the Azure CLI and authenticate with a Global Administrator account (`az login`).

When you run the script, it performs a series of tasks. The following sections describe each task that the script performs. If your organization restricts script execution, you can perform these tasks manually, using this topic as a guide. After you configure your Azure environment, you can configure Security Hub to integrate with Azure.

Steps 1–7 configure the shared foundation that all Security Hub capabilities use: the application registration, federated credentials, Azure role assignments, Microsoft Graph permissions, Event Hub, and log export. Steps 8–10 configure the additional Azure resources for specific capabilities:

- **Vulnerability management (Amazon Inspector)** – Configures Azure Container Registry (ACR) repository-event export and a system-assigned managed identity on your Azure VMs.
- **Threat detection (Microsoft Defender for Cloud)** – Configures Microsoft Defender for Cloud to continuously export security alerts to the Event Hub.

> **Note**
>
> A single Azure app registration is shared across AWS security services. If you also use Security Hub CSPM or Amazon Inspector for Azure, they use the same app registration. You do not need to create separate registrations for each AWS service.

Tasks

- Step 1: Register an Azure application
- Step 2: Create a service principal

- Step 3: Configure federated identity credentials
- Step 4: Assign RBAC roles
- Step 5: Configure Microsoft Graph API permissions
- Step 6: Set up Azure Event Hub
- Step 7: Configure Activity Log and Entra ID Audit Log export
- Step 8: Configure Azure Container Registry export
- Step 9: Enable a managed identity on Azure VMs
- Step 10: Export Microsoft Defender for Cloud alerts

Step 1: Register an Azure application

Register a new application in Microsoft Entra ID. This application serves as the identity that AWS uses to authenticate to your Azure environment using federated credentials. No client secrets are required.

```
$ az ad app create --display-name "AWSSecurityHubIntegration"
```

Note the **Application (client) ID** from the output (the `appId` attribute). You will provide this value when creating the connector in the Security Hub console.

Step 2: Create a service principal

Create a service principal for the registered application. You use Azure role assignments to grant permissions to the service principal. The service principal performs actions in your Azure environment.

```
$ az ad sp create --id application-client-id
```

Where *`application-client-id`* is the Application (client) ID from the previous step.

Set the Application ID URI on the registration to `api://`*`application-client-id`*. AWS requires this identifier to exchange federated tokens with the application. Without this URI, AWS cannot produce a valid federated-token audience, and every capability fails to authenticate to Azure.

```
$ az ad app update \
  --id application-client-id \
  --identifier-uris "api://application-client-id"
```

Step 3: Configure federated identity credentials

Configure federated identity credentials on the application to enable AWS to authenticate without client secrets. This establishes an OIDC trust between AWS and Azure. No long-lived secrets or credentials are stored.

The Security Hub Azure integration authenticates using one AWS IAM role per capability: resource configuration discovery, vulnerability management, and threat detection. Add a federated identity credential for each role so that every capability can authenticate to Azure. AWS creates the service-linked roles automatically when you create the connector. The `Inspector2SSMFederationRole` used for VM scanning is not a service-linked role; you create it as part of Amazon Inspector VM scanning setup, described in Step 9.

Capability	Subject (IAM role ARN)
Resource configuration discovery (AWS Config)	`arn:aws:iam:: account-id :role/aws-service-role/thirdparty.config.amazonaws.com/AWSServiceRoleForConfigThirdParty`
Vulnerability management (Inspector)	`arn:aws:iam:: account-id :role/aws-service-role/thirdparty.inspector2.amazonaws.com/AWSServiceRoleForAmazonInspector2ThirdPa rty`
Vulnerability management – VM scanning (Amazon EC2 Systems Manager)	`arn:aws:iam:: account-id :role/Inspector2SS MFederationRole- tenant-id`
Threat detection (Security Hub)	`arn:aws:iam:: account-id :role/aws-service-role/securityhubv2.amazonaws.com/AWS ServiceRoleForSecurityHubV2`

Run the following command once for each subject in the preceding table, changing the `name` and `subject` values each time. The `issuer` and `audiences` values are the same for every credential.

```
$ az ad app federated-credential create \
  --id application-client-id \
  --parameters '{
```

```
    "name": "credential-name",
    "issuer": "token-issuer-url",
    "subject": "service-linked-role-arn",
    "audiences": ["api://AzureADTokenExchange"],
    "description": "AWS federation for Security Hub Azure integration"
  }'
```

Key values:

- **Issuer** – Your Token Issuer URL from IAM Outbound Identity Federation. This follows the format `https://uuid.tokens.sts.global.api.aws`.
- **Subject** – An IAM role ARN from the preceding table. The *tenant-id* in the Amazon EC2 Systems Manager role is your Azure tenant ID.
- **Audience** – `api://AzureADTokenExchange` (standard value for workload identity federation).
- **Name** – Any name that is unique within the application.

Step 4: Assign RBAC roles

Assign the following built-in roles to the service principal:

- **Reader** – Grants read-only access to all Azure resources, so Security Hub can discover and evaluate your resource configurations. Assign this role at the root scope (/).
- **Contributor** – Grants the write access that Amazon Inspector requires to scan your Azure virtual machines, Function Apps, and container images for vulnerabilities. Assign this role at the tenant root management group scope, which propagates it to every subscription in the tenant.
- **Azure Event Hubs Data Receiver** – Allows AWS to read events from the Event Hub. Assign this role at the tenant root management group scope.

> **⚠ Assign Reader at the root scope**
>
> Make sure to assign the **Reader** role at the **root scope** (/), not the tenant root management group scope. Security Hub reads Azure role-assignment resources at every scope, including assignments scoped at the tenant root. A Reader assignment at the root management group does not cover assignments whose scope is /, so without it those reads fail with an authorization error and the connector can enter a degraded state.

Contributor grants tenant-wide write access

The **Contributor** role at the tenant root management group scope grants highly privileged, tenant-wide write access to your Azure resources. Security Hub requires this access so that Amazon Inspector can scan your compute resources for vulnerabilities. For example, Inspector uses the virtual machine run-command permissions that Contributor provides. Through Amazon EC2 Systems Manager Automation, Inspector runs commands on your Azure VMs to install and operate the VM Scanner agent.

```
$ az role assignment create \
  --assignee application-client-id \
  --role "Contributor" \
  --scope "/providers/Microsoft.Management/managementGroups/tenant-id"

$ az role assignment create \
  --assignee application-client-id \
  --role "Azure Event Hubs Data Receiver" \
  --scope "/providers/Microsoft.Management/managementGroups/tenant-id"

$ az role assignment create \
  --assignee application-client-id \
  --role "Reader" \
  --scope "/"
```

Root-scope assignment requires elevated access

Assigning a role at the root scope (/) requires elevated access. If a role assignment fails, verify that *Access management for Azure resources* is set to **Yes** in Microsoft Entra ID > Properties. Then sign out and sign back in to refresh your token.

Remove the temporary root elevation

Enabling *Access management for Azure resources* grants the signed-in administrator the User Access Administrator role at the root scope (/), which can manage access across every subscription and management group in the tenant. After onboarding is complete, set

Access management for Azure resources back to **No** in Microsoft Entra ID > Properties, save, and sign out so that this elevation does not remain active.

Step 5: Configure Microsoft Graph API permissions

Grant the following Microsoft Graph API permissions (Application type) to the application, and then grant admin consent:

- `Application.Read.All`
- `AuditLog.Read.All`
- `DelegatedPermissionGrant.Read.All`
- `Device.Read.All`
- `Group.Read.All`
- `GroupMember.Read.All`
- `GroupSettings.Read.All`
- `Organization.Read.All`
- `Policy.Read.All`
- `RoleManagement.Read.Directory`
- `User.Read.All`
- `UserAuthenticationMethod.Read.All`

```
$ az ad app permission admin-consent --id application-client-id
```

Step 6: Set up Azure Event Hub

AWS Config uses an Azure Event Hub to receive near real-time notifications of resource configuration changes in your Azure environment. The setup script creates the Event Hub infrastructure and tags it for discovery. Event Hub discovery uses tag-based resolution: Security Hub looks for a tag on the Event Hub namespace with the format `AWSConfig-account-id-region` to identify the correct Event Hub instance for your integration.

```
$ az group create \
  --name "aws-securityhub-integration" \
```

```
  --location event-hub-region

$ az eventhubs namespace create \
  --resource-group "aws-securityhub-integration" \
  --name "aws-securityhub-account-id" \
  --location event-hub-region \
  --sku Standard

$ az eventhubs eventhub create \
  --resource-group "aws-securityhub-integration" \
  --namespace-name "aws-securityhub-account-id" \
  --name "activitylog" \
  --message-retention 3 \
  --partition-count 4

$ az eventhubs eventhub consumer-group create \
  --resource-group "aws-securityhub-integration" \
  --namespace-name "aws-securityhub-account-id" \
  --eventhub-name "activitylog" \
  --name "AWSConfig"
```

After creating the Event Hub, tag the namespace for discovery and assign the Data Receiver role. Use `az tag update` with `--operation merge` so that you preserve any other tags on the namespace (such as the threat detection discovery tag from Step 10):

```
$ az tag update \
  --resource-id namespace-resource-id \
  --operation merge \
  --tags "AWSConfig-account-id-region=activitylog"

$ az role assignment create \
  --assignee application-client-id \
  --role "Azure Event Hubs Data Receiver" \
  --scope namespace-resource-id
```

Note

In the tag format `AWSConfig-`*`account-id`*`-`*`region`*, *`account-id`* is your 12-digit AWS account ID and *`region`* is the AWS Region where you are creating the connector (for example, `us-east-1`). These values identify which AWS account and Region own this Event Hub integration.

Key configuration:

- **Namespace SKU** – Standard (required for consumer groups).
- **Event Hub name** – `activitylog`.
- **Consumer group** – `AWSConfig`.
- **Tag** – `AWSConfig-account-id-region` with value `activitylog`. This tag enables AWS Config to discover the Event Hub automatically.
- **Role assignment** – Azure Event Hubs Data Receiver on the namespace.

For threat detection, the setup also creates a separate `defender-alerts` Event Hub with an `AWSSecurityHub` consumer group, and adds a second discovery tag in the format `AWSSecurityHub-account-id-region` that identifies the hubs Security Hub reads directly. For more information, see Step 10.

Step 7: Configure Activity Log and Entra ID Audit Log export

Configure Azure to export Activity Logs and Microsoft Entra ID logs to the Event Hub.

Activity Log export:

Configure diagnostic settings on each subscription to export Activity Logs to the Event Hub. The setup script configures this automatically for all monitored subscriptions. Activity Logs capture subscription-level activity including role assignments and resource changes.

Microsoft Entra ID log export:

Configure diagnostic settings on Microsoft Entra ID to export logs to the same Event Hub. Navigate to *Microsoft Entra ID > Monitoring > Diagnostic settings > Add diagnostic setting*. Enable **AuditLogs**, **SignInLogs**, and **NonInteractiveUserSignInLogs**, and route them to your Event Hub.

Step 8: Configure Azure Container Registry export

Security Hub scans your Azure Container Registry (ACR) container images for vulnerabilities through Amazon Inspector. To do this, Inspector needs ACR repository events exported to an Event Hub in the same Azure region as the registry. For the ACR export setup, see Configuring Amazon Inspector to integrate with Microsoft Azure in the *Amazon Inspector User Guide*.

Step 9: Enable a managed identity on Azure VMs

Security Hub scans your Azure virtual machines through Inspector. Each target Azure VM must have a system-assigned managed identity enabled. To add this identity to your VMs automatically, assign two Azure Policies that use the `modify` effect at the tenant root management group scope:

- For a VM that has no identity, the policy adds a system-assigned managed identity.
- For a VM that has only a user-assigned identity, the policy adds a system-assigned managed identity while preserving the existing user-assigned identities.

A VM that already has a system-assigned managed identity is left unchanged. Because the policies use the `modify` effect, they adjust the identity in place without redeploying the VM.

Inspector uses Amazon EC2 Systems Manager Automation to deploy and manage the Inspector VM Scanner agent on your Azure VMs. This requires additional AWS-side setup, including an IAM OIDC identity provider for Microsoft Entra ID and several IAM roles. For the complete VM scanning setup, see Configuring Amazon Inspector to integrate with Microsoft Azure in the *Amazon Inspector User Guide*.

Step 10: Export Microsoft Defender for Cloud alerts

Security Hub ingests Microsoft Defender for Cloud threat detection alerts and maps them to the Open Cybersecurity Schema Framework (OCSF) format. To deliver these alerts, create a dedicated `defender-alerts` Event Hub and configure Microsoft Defender for Cloud to continuously export security alerts to it.

In the Event Hub namespace from Step 6, create the `defender-alerts` Event Hub, an `AWSSecurityHub` consumer group for Security Hub to read from, and a hub-scoped shared access signature (SAS) authorization rule with **Send** permission that Microsoft Defender for Cloud uses to send alerts:

```
$ az eventhubs eventhub create \
  --resource-group "aws-securityhub-integration" \
  --namespace-name "aws-securityhub-account-id" \
  --name "defender-alerts" \
  --message-retention 3 \
  --partition-count 4

$ az eventhubs eventhub consumer-group create \
```

```
  --resource-group "aws-securityhub-integration" \
  --namespace-name "aws-securityhub-account-id" \
  --eventhub-name "defender-alerts" \
  --name "AWSSecurityHub"

$ az eventhubs eventhub authorization-rule create \
  --resource-group "aws-securityhub-integration" \
  --namespace-name "aws-securityhub-account-id" \
  --eventhub-name "defender-alerts" \
  --name "DefenderExportSend" \
  --rights Send
```

Then, merge a second discovery tag onto the namespace so that Security Hub discovers the `defender-alerts` hub. Use `az tag update` with `--operation merge` so that you preserve the `AWSConfig` discovery tag from Step 6:

```
$ az tag update \
  --resource-id namespace-resource-id \
  --operation merge \
  --tags "AWSSecurityHub-account-id-region=defender-alerts"
```

Finally, configure Microsoft Defender for Cloud continuous export of the **Security alerts** data type to the `defender-alerts` Event Hub. In the Azure portal, go to *Microsoft Defender for Cloud > Environment settings*, select the subscription, choose *Continuous export > Event Hub*, select **Security alerts**, and choose the `defender-alerts` Event Hub and the `DefenderExportSend` SAS rule.

> **Note**
>
> If you configure continuous export programmatically (through the Azure Resource Manager API, an ARM template, or Azure Policy) rather than in the portal, authenticate the export to the Event Hub with the `DefenderExportSend` SAS connection string. Retrieve it with `az eventhubs eventhub authorization-rule keys list` for the `DefenderExportSend` rule, and set it as the export action's connection string. For more information, see Set up continuous export in the Microsoft Azure documentation.

> **Note**
>
> After you complete these tasks, wait approximately 15–30 minutes for the configuration to take effect. Then, verify that your Event Hub is receiving messages (the *IncomingMessages* metric) before you create the connector in Security Hub.

Configuring Security Hub to integrate with Microsoft Azure

After you complete the prerequisite tasks and configure your Microsoft Azure environment, you can configure AWS Security Hub to integrate with Azure. To configure Security Hub to integrate with Azure, you create a connector. You can create the connector from a delegated administrator account or the management account. After you create the connector, the following events occur:

1. Security Hub validates the Azure credentials and connectivity to your Azure environment. This process can take several minutes.
2. Security Hub creates service-linked connectors in Security Hub CSPM and Amazon Inspector. These connectors ensure that posture management checks and vulnerability scanning match the scope you defined in Security Hub.
3. AWS Config begins discovering Azure resources using the federated identity credentials.
4. Security Hub automatically enables the CIS Microsoft Azure Foundations Benchmark v4.0 standard and the Azure Foundational Best Practices standard in CSPM for your Azure resources.
5. Initial findings begin appearing within 15–30 minutes for resources with Activity Log events. Full evaluation of all existing resources can take up to 24 hours.

Topics

- Create an Azure connector
- Adjust the scope of an Azure connector
- Verify the health of an Azure connector
- Troubleshoot an Azure connector
- How Security Hub handles resource and finding identifiers

Create an Azure connector

To create an Microsoft Azure connector for your environment, complete the following steps by using the AWS Security Hub console or the API.

1. Open the AWS Security Hub console at https://console.aws.amazon.com/securityhub/advanced/home?region=us-east-1..
2. In the navigation pane, choose **Integrations**.
3. Choose **Create Azure connector**.
4. In the **Security capabilities** section, choose whether you want the **Network scanning** feature enabled. This feature is enabled by default for the account where you are enabling the Azure integration, and can be unchecked before completing your connector setup. If an organization policy is blocking this feature for your account, it does not appear as an option. For more information, see Network scanning in Security Hub.
5. For **Azure Tenant ID**, enter your Microsoft Entra ID tenant identifier. You can find this in the Azure portal under *Microsoft Entra ID > Properties > Tenant ID*.
6. For **Application (client) ID**, enter the application ID for the Azure application that you registered during the Azure environment setup.
7. Configure additional settings and the scope of the connector by doing the following:

   - For **Name**, enter a unique name for the connector. The name can contain up to 50 alphanumeric characters and it can include hyphens.

     > **Note**
     >
     > The connector name cannot be changed after creation.

   - For **Description**, optionally enter a brief description of the connector. The description can contain up to 200 characters.

     > **Important**
     >
     > Names and descriptions are used to identify your content. Do not include sensitive, confidential, or personally identifiable information (PII) in them.

- For **Subscriptions**, choose **All subscriptions** to monitor all current and future subscriptions in the tenant, or **Specific subscriptions** to monitor only the subscriptions that you specify. If you choose to monitor only specific subscriptions, enter the ID for each one.
- For **Regions**, choose **All regions** to monitor resources in all Azure regions, or **Specific regions** to monitor only the Regions that you specify.

> **Note**
>
> If you already created a connector in Security Hub CSPM or Amazon Inspector for the same Azure tenant, the scope of the connector in Security Hub must include the same subscriptions and Regions as the connector in Security Hub CSPM or Amazon Inspector.

> **Note**
>
> Controls that evaluate Microsoft Entra ID and Microsoft Graph resources require the global Region scope to be included in your integration configuration. If you select specific Azure Regions only, these controls do not generate findings.

8. Review the connector configuration.

> **Note**
>
> If you plan to use Amazon Inspector for Azure VM scanning, you must create the required IAM roles. For details, see the section called “IAM roles for VM scanning”.

9. When you finish entering and reviewing the settings, choose **Create connector**.

IAM roles for Azure VM scanning through Amazon Inspector

To enable vulnerability scanning through Amazon Inspector, you must create the following IAM resources in your AWS account.

IAM OIDC identity provider

Create an IAM OIDC identity provider for Microsoft Entra ID with the following configuration:

- **Issuer URL:** `https://sts.windows.net/tenant-id/`
- **Client ID list:** `api://app-id`, `api://AzureADTokenExchange`
- **Thumbprint:** A 40-character string of all zeros (`0` repeated 40 times). AWS STS validates tokens via the JWKS endpoint rather than the thumbprint value.

Inspector2VmScannerRole-*tenant-id*

Used by the Amazon Inspector VM Scanner agent running on Azure VMs to send scan telemetry to Amazon Inspector. This role uses OIDC web identity federation through the Microsoft Entra ID identity provider.

Trust policy:

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Principal": {
                "Federated": "arn:aws:iam::account-id:oidc-provider/
sts.windows.net/tenant-id/"
            },
            "Action": "sts:AssumeRoleWithWebIdentity",
            "Condition": {
                "StringEquals": {
                    "sts.windows.net/tenant-id/:aud": "api://app-id"
                }
            }
        }
    ]
}
```

Prerequisites for VM scanning

The Azure app registration must have its Application ID URI set to `api://app-id`.

Each Azure VM that you want to scan must have a system-assigned managed identity enabled. To automatically assign managed identity to new VMs, use a DeployIfNotExists policy in your Azure environment.

After you create the connector, Security Hub begins monitoring your Azure environment. You can check the status of the connector on the **Integrations** page.

Adjust the scope of an Azure connector

After you create an Microsoft Azure connector, you can adjust the scope of the connector by changing the Azure Subscriptions or Azure Regions that it monitors. Scope changes typically take effect within 15–30 minutes for resources with Activity Log events. Full evaluation of newly added Azure Subscriptions can take up to 24 hours.

Before you adjust the scope of a connector, note the following:

- When you change the scope of a connector in Security Hub, the associated service-linked connectors in Security Hub CSPM and Amazon Inspector are automatically updated to match.
- The scope of a Security Hub connector can never be less than any existing customer-managed connector in Security Hub CSPM or Amazon Inspector for the same Azure tenant.
- If you add a Region to the connector scope, you must re-run the setup script to provision Event Hub infrastructure in the new Region. Your existing Event Hub configuration is not affected.

Verify the health of an Azure connector

You can check the health of an Microsoft Azure connector at any time to confirm that Security Hub is receiving data from your Azure environment.

To verify the health of a connector

1. Open the AWS Security Hub console at https://console.aws.amazon.com/securityhub/advanced/home?region=us-east-1..
2. In the navigation pane, choose **Integrations** and select your Azure connector.
3. Verify that the connector status shows **Active**. If the connector shows Active, verification is complete. If it shows a different status, see the section called “Troubleshoot a connector”.
4. Navigate to **Findings** and filter by `ResourceCloudProviders = Azure` to confirm findings are being generated for your Azure resources.
5. Check the **Security standards** page to confirm the CIS Azure v4.0 standard shows controls in PASSED or FAILED status (not all NO_DATA).

Note

Connector health status is eventually consistent. When a permission or configuration issue occurs, the connector status changes to **Degraded** quickly with an actionable message. However, after you fix the issue, the status can take up to 24 hours to return to **Connected**.

- A **Degraded** status after a recent fix does not necessarily indicate an ongoing problem.
- For real-time visibility into recording failures, check the CloudWatch metrics in the namespace.

Troubleshoot an Azure connector

If you experience issues with your connector, review the following common issues and resolutions.

Connector status is Unhealthy

This issue typically occurs if federated credentials are not configured correctly in Azure.

To address this issue, verify that the Token Issuer URL and subject ARN in your Azure federated credentials match your AWS account.

No findings after 30 minutes

This issue can occur if the Event Hub is not receiving Activity Logs.

To address this issue, check that diagnostic settings are configured on your Azure subscriptions and that the Event Hub namespace is tagged correctly with `AWSConfig-`*`account-id`*`-`*`region`*.

All controls show NO_DATA

This issue can occur if the connector is disabled or if AWS Config cannot reach your Azure environment.

To address this issue, verify that the connector is enabled and that the service principal has the Reader role at the tenant root management group scope.

Unable to record some Azure resources

The error can occur for any of the following reasons:

- The Azure environment does not meet the prerequisites for resource recording.
- The app registration does not have admin consent for Microsoft Graph API permissions.

- The Reader role assignment does not cover all required scopes.
- The Microsoft Entra ID tenant does not have required log data.

To address the error, do the following:

1. To confirm that your environment meets all requirements, review Prerequisites for Microsoft Azure.
2. Confirm that the app registration has the required Microsoft Graph API permissions with admin consent.
3. Verify that the service principal has the Reader role at the tenant root management group scope.

Findings appear for some subscriptions only

This issue can occur if Activity Log export is not configured for all target subscriptions.

To address this issue, confirm that the diagnostic settings cover all subscriptions included in the connector scope.

How Security Hub handles resource and finding identifiers

By enabling your Azure integration for AWS Security Hub, resource and security finding identifiers from other cloud providers are stored in AWS Config, Security Hub, and other AWS services (as needed) as metadata related to the management of the corresponding resource configuration and security finding data collected from the other cloud providers. Such identifiers do not constitute Your Content. Do not include sensitive, confidential, or personally identifiable information in them.

The following identifiers from your connected cloud environment are stored and used by AWS to provide multicloud security capabilities:

- **Resource identifiers:** Azure Tenant ID, Subscription ID, Location (region), Resource ID (Resource Group IDs or Names, Resource Provider, Resource Type)
- **Security Finding identifiers:** the unique identifiers assigned to each security finding generated by the detecting service.

Relationships among these identifiers - including how resources relate to one another and how findings relate to resources - are also stored as service metadata. AWS uses these identifiers for resource correlation, associating findings to resources, service operational logging, and de-duplication.

Deleting a Microsoft Azure connector in Security Hub

After you create a Microsoft Azure connector in AWS Security Hub, you can delete it at any time. If you delete a connector, Security Hub stops performing posture management checks and vulnerability monitoring for your Azure environment. Security Hub also stops generating new findings and other data about your environment. Your existing findings are retained for 90 days. Resource inventory remains as it was when the connector was deleted and is removed after 90 days.

When you delete a connector, Security Hub automatically deletes the associated service-linked connectors in AWS Security Hub CSPM and Amazon Inspector. Security Hub does not delete the Azure application registration and Event Hub infrastructure in your Azure environment. You must delete these manually, directly in Microsoft Azure. To learn how, see Remove an application in the Microsoft Azure documentation.

To delete an Azure connector

1. Open the AWS Security Hub console at https://console.aws.amazon.com/securityhub/advanced/home?region=us-east-1..
2. In the navigation pane, choose **Integrations**.
3. Select the connector that you want to delete.
4. Choose **Delete**.
5. When prompted, confirm that you want to delete the connector.

> **Important**
>
> If you delete a connector and create a new one within 6 hours, resource detection may take up to 6 hours. Plan connector deletion and recreation accordingly.

Working in the summary dashboard in Security Hub

The **Summary** dashboard in the Security Hub console displays an overview of your exposures, threats, resources, and security coverage across security widgets. You can customize the dashboard by adding and removing widgets and by creating and applying filter sets to retrieve data in each widget.

Considerations

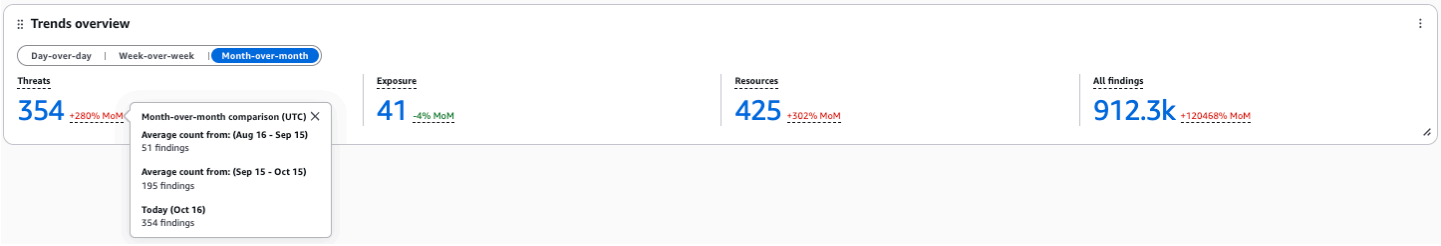
Consider the following before interacting with the dashboard:

- Customizations like saved filter sets or changes to the layout of widgets are saved automatically.
- Data automatically refreshes every time you open the dashboard.
- If you configure cross-Region aggregation, the dashboard includes findings from all of your linked Regions (when viewing the dashboard in your home Region).

Consider the following if your account is a delegated administrator account for an organization, member account in an organization, or standalone account.

- Customizations made by a delegated administrator account will be saved independently from customizations made by member accounts. Customizations might include saved filter sets or changes to the layout of widgets.
- If your account is the delegated administrator account for an organization, data includes findings for your account and member accounts.
- If your account is a member account in an organization or a standalone account, data includes findings only for your account.

As a best practice, do not include confidential, sensitive, or personally identifiable information (PII) in saved filter sets, custom widgets, or other related free-form text fields.



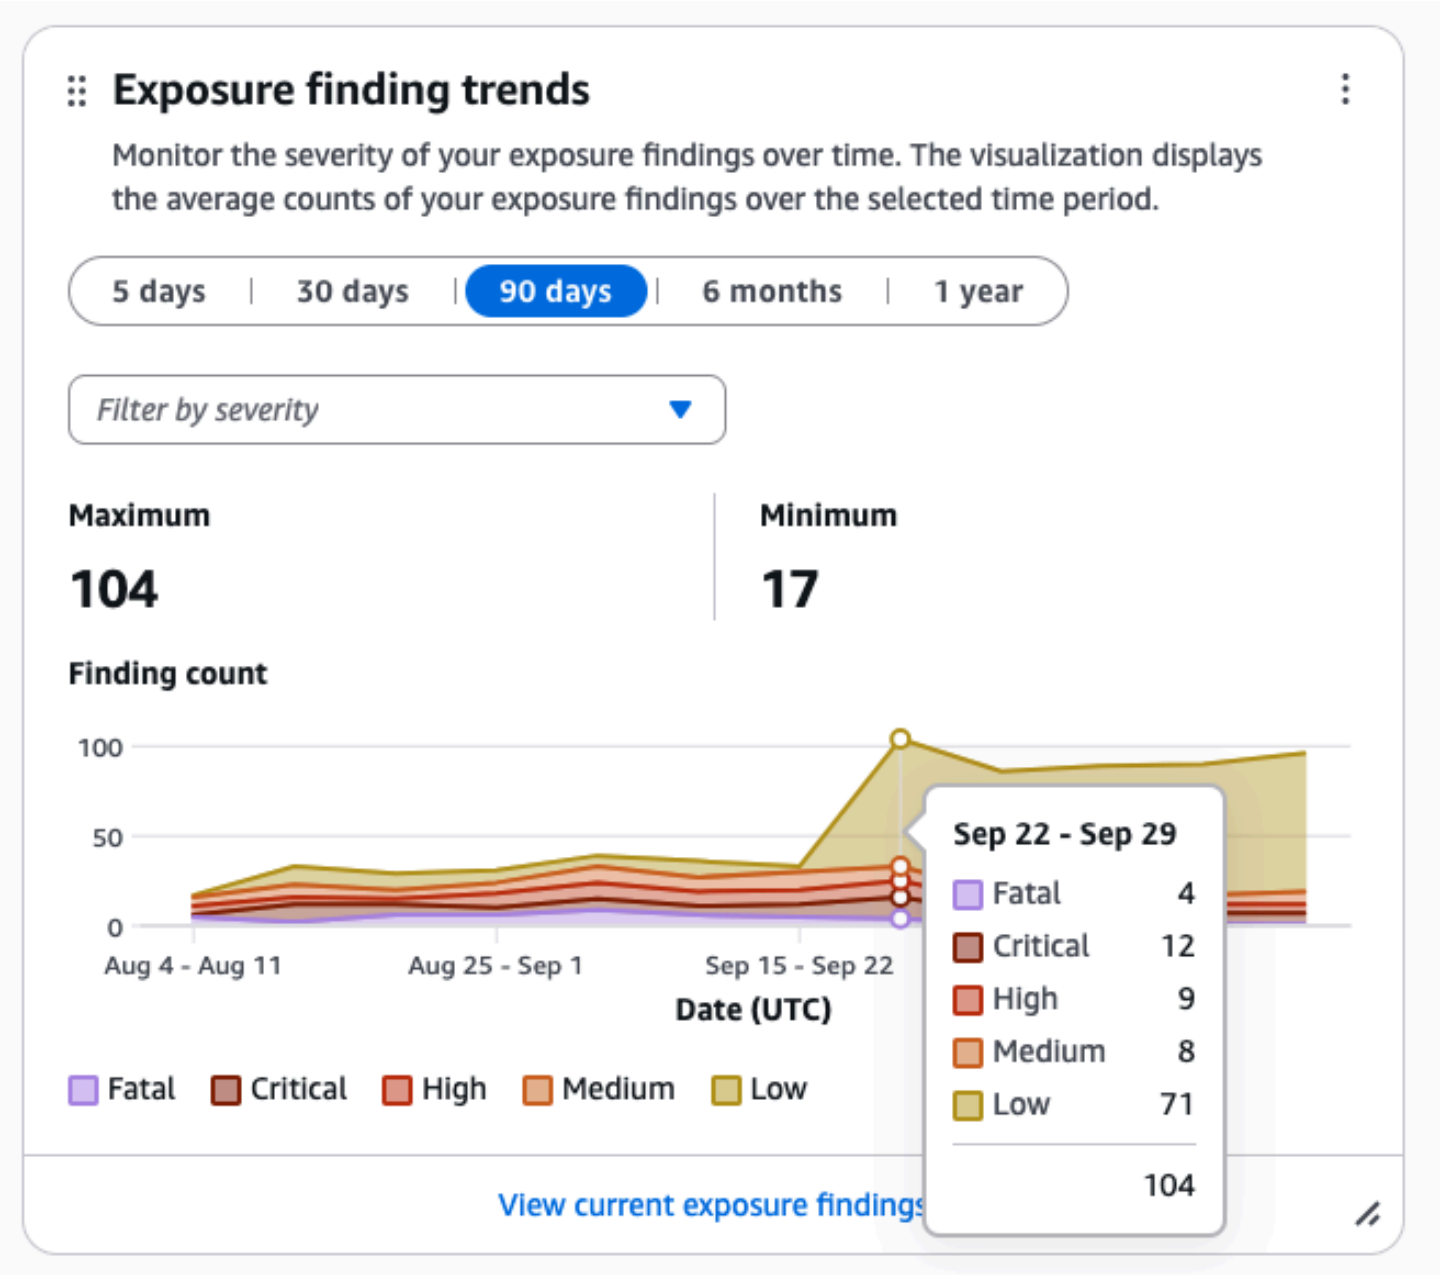
Available widgets

You can interact with different widgets in the **Executive** and **Triage** tabs of the **Summary** dashboard. The **Executive** tab includes widgets that display trends data for your exposures, threats, and resources and the **Security Coverage** widget to help track your account coverage across different security capabilities. The **Triage** tab includes widgets that display a summary of your exposures, threats, and resources. However, you can add widgets, remove widgets, and manage the position of each widget in both tabs to customize your experience.

Trends widgets

The following widgets display trends data for your exposures, threats, and resources, so you can analyze them over time.

Trends overview widget



This widget displays an overview of your exposures, threats, resources, and findings in the following time periods:

- **Month-over-month** reflects the period-over-period count for the last two months.
- **Week-over-week** reflects the period-over-period count for the past two weeks.
- **Day-over-day** reflects the period-over-period count for the past 2 days.

The number next to the percentage reflects the average period-over-period count to date. Choosing this number directs you to its corresponding dashboard in the console. If you navigate to another dashboard that displays trends data, the dashboard only displays trends data for the last 90 days or in a best-fit time period if your account does not contain findings or resources older than 30 days.

> **Note**
>
> To receive data in this widget, you must enable the following security services:
>
> - **AWS Security Hub CSPM** – To receive data about exposures
> - **Amazon Inspector** – To receive data about exposures
> - **GuardDuty** – To receive data about threats

Exposure finding trends widget

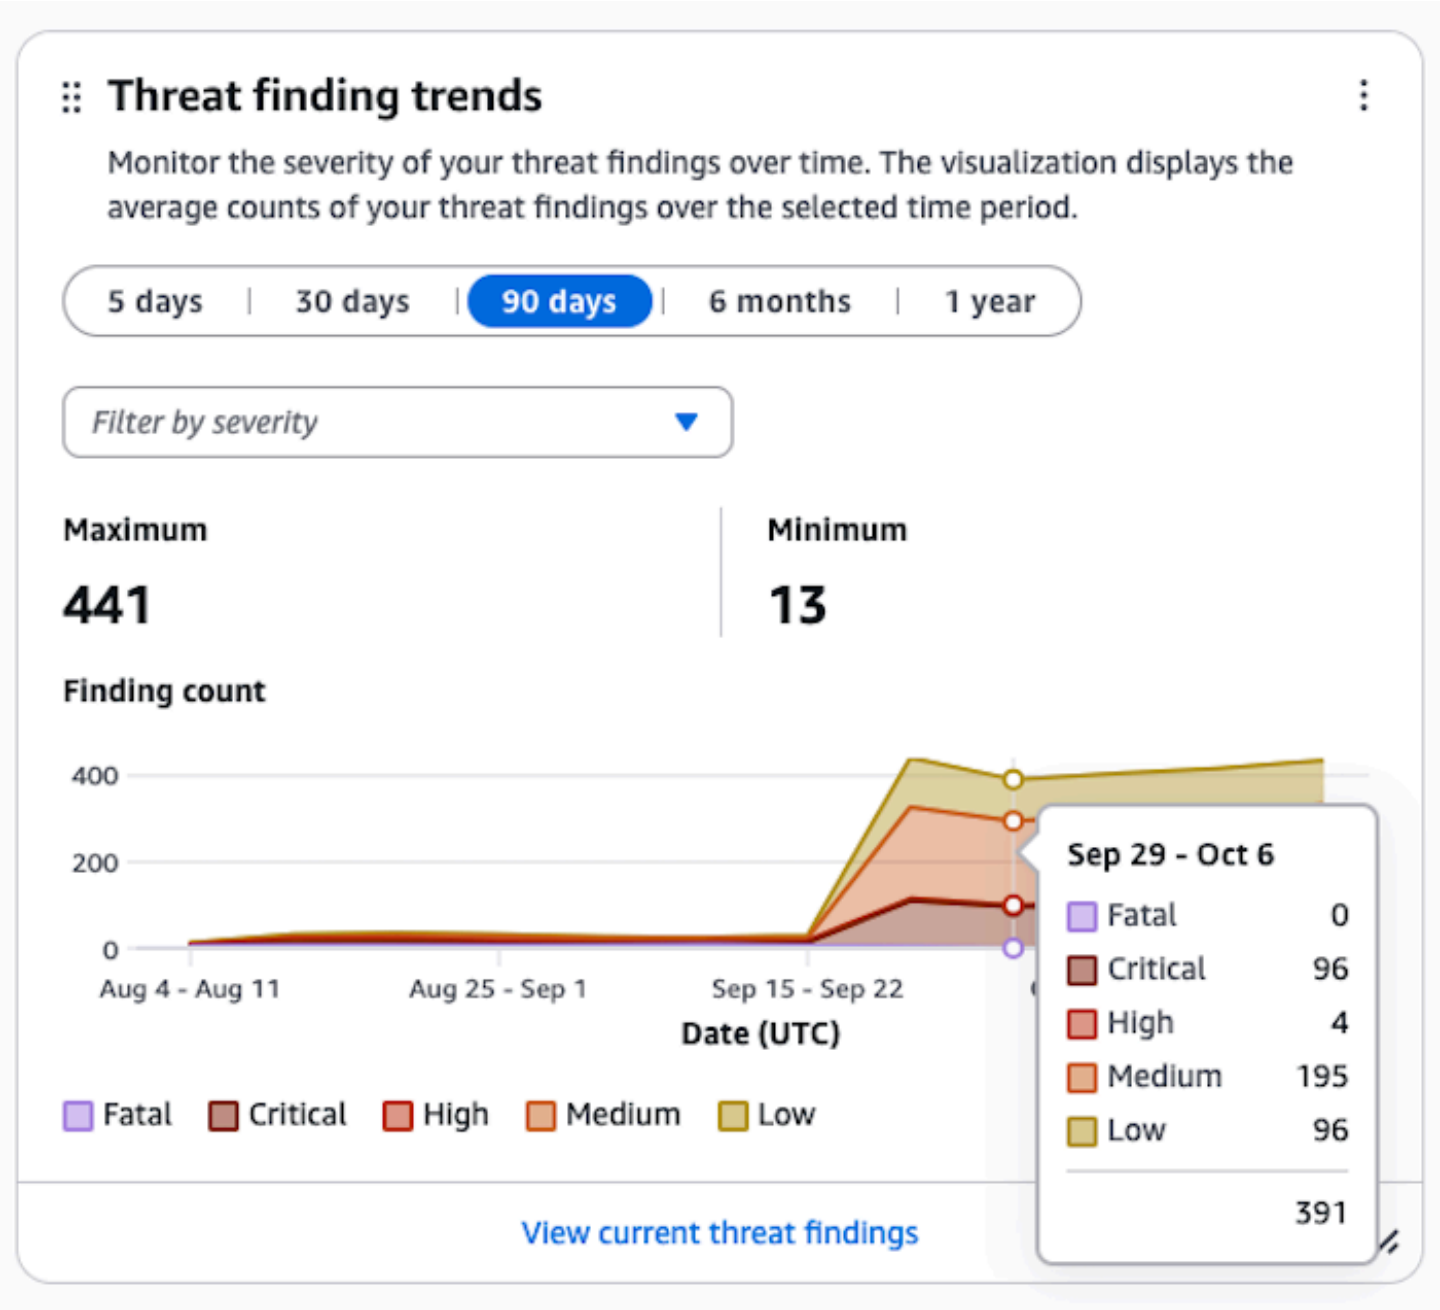
This widget displays the severity of your exposure findings in the following time periods:

- **5 days**
- **30 days**
- **90 days**
- **6 months**
- **1 year**

The visualization displays the average count of your findings over the selected time period.

Severity filters

You can update the graph by including or excluding the following severity filters:



- **Fatal**
- **Critical**
- **High**
- **Medium**
- **Low**
- **Informational**
- **Other**
- **Unknown**

Applied severity filters show at the bottom of the visualization in different boxes. You can hover over the visualization to review the average count of findings for specific points in time. You can also review the average count of findings that match each applied severity filter.

You can choose **View all current exposure findings** to be directed to the **Exposure** dashboard. By default, the **Exposure** dashboard only displays trends data for the last 90 days. If your account does not contain exposure findings older than 30 days, the dashboard displays trends data based on a best-fit time period.

> **Note**
>
> To receive data in this widget, you must enable Amazon Inspector and Security Hub CSPM.

Threat finding trends widget

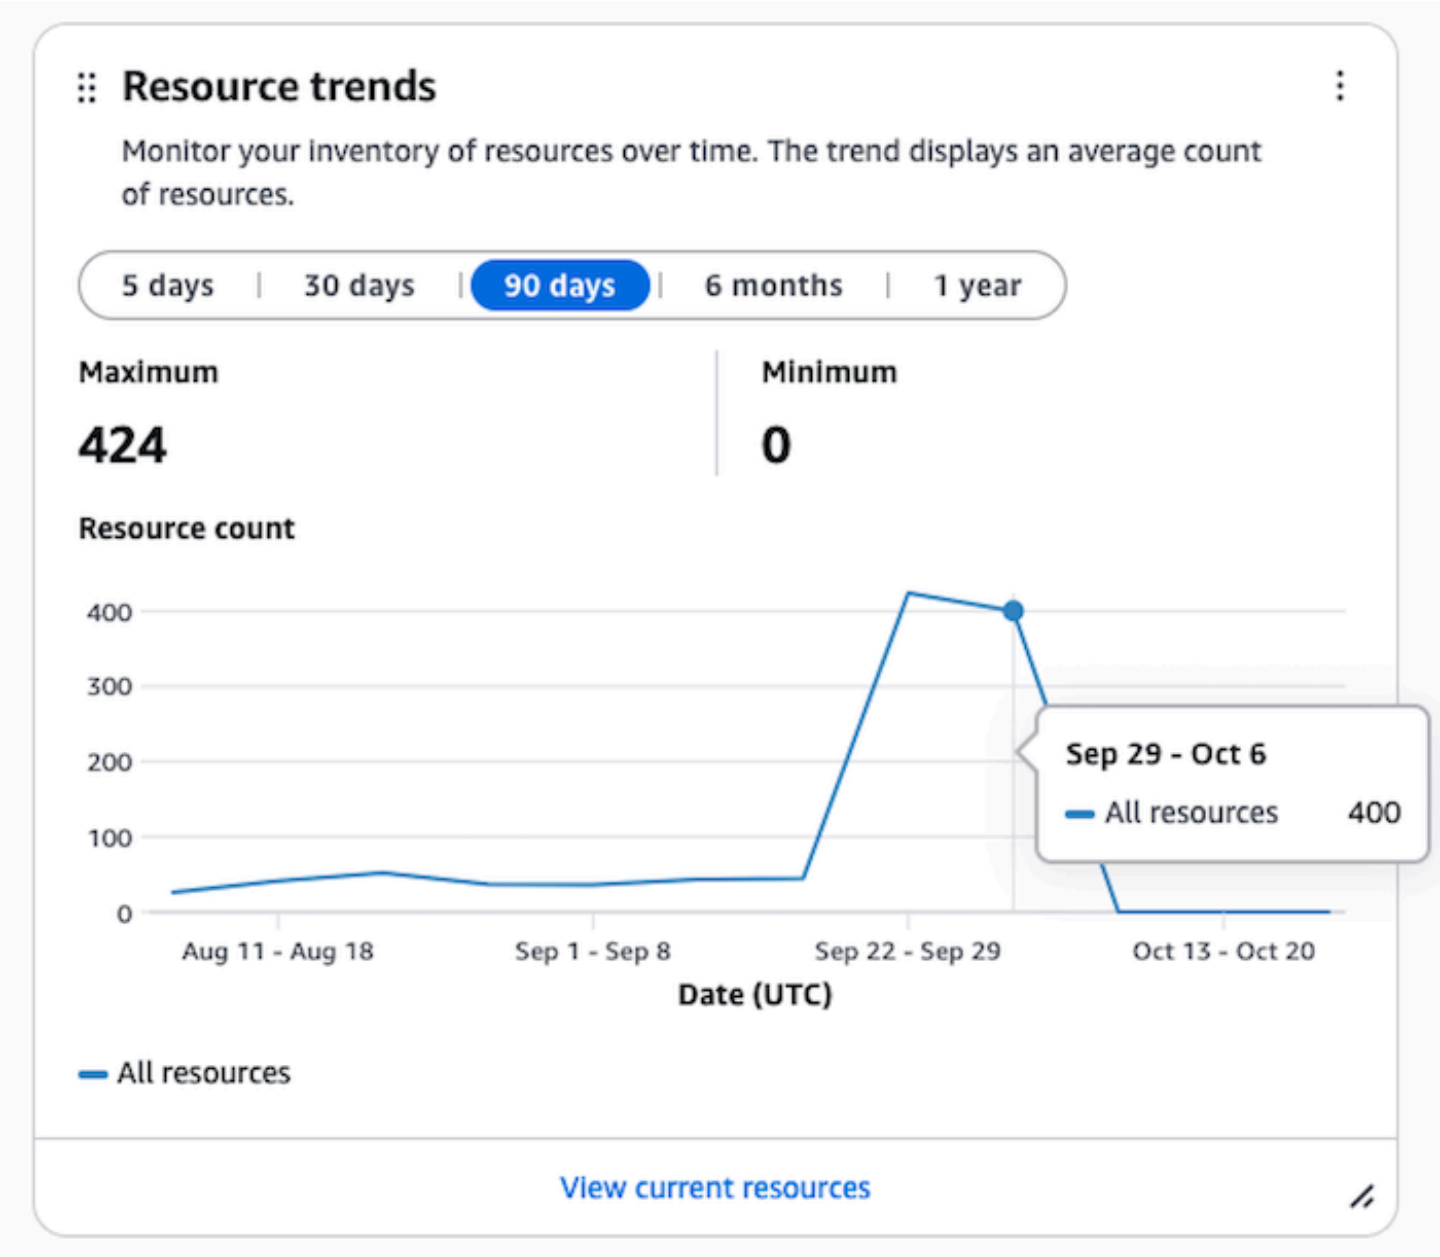
This widget displays the severity of your threat findings in the following time periods:

- **5 days**
- **30 days**
- **90 days**
- **6 months**
- **1 year**

The visualization displays the average count of your findings over the selected time period.

Severity filters

You can update the graph by including or excluding the following severity filters:



- **Fatal**
- **Critical**
- **High**
- **Medium**
- **Low**
- **Informational**
- **Other**
- **Unknown**

Applied severity filters show at the bottom of the visualization in different boxes. You can hover over the visualization to review the average count of findings for specific points in time. You can also review the average count of findings that match each applied severity filter.

You can choose **View all current threat findings** to be directed to the **Exposure** dashboard. By default, the **Threats** dashboard only displays trends data for the last 90 days. If your account does not contain threat findings older than 30 days, the dashboard displays trends data based on a best-fit time period.

> **Note**
>
> To receive data in this widget, you must enable GuardDuty.

Resource trends widget

This widget displays an inventory of your resources in the following time periods:

- **5 days**
- **30 days**
- **90 days**
- **6 months**
- **1 year**

The visualization displays the average count of your resources over the selected time period. You can hover over the visualization to review the average count of resources for specific points in time.

You can choose **View current resources** to be directed to the **Resources** dashboard. By default, the **Resources** dashboard only displays trends data for the last 90 days. If your account does not contain resources older than 30 days, the dashboard displays trends data based on a best-fit time period.

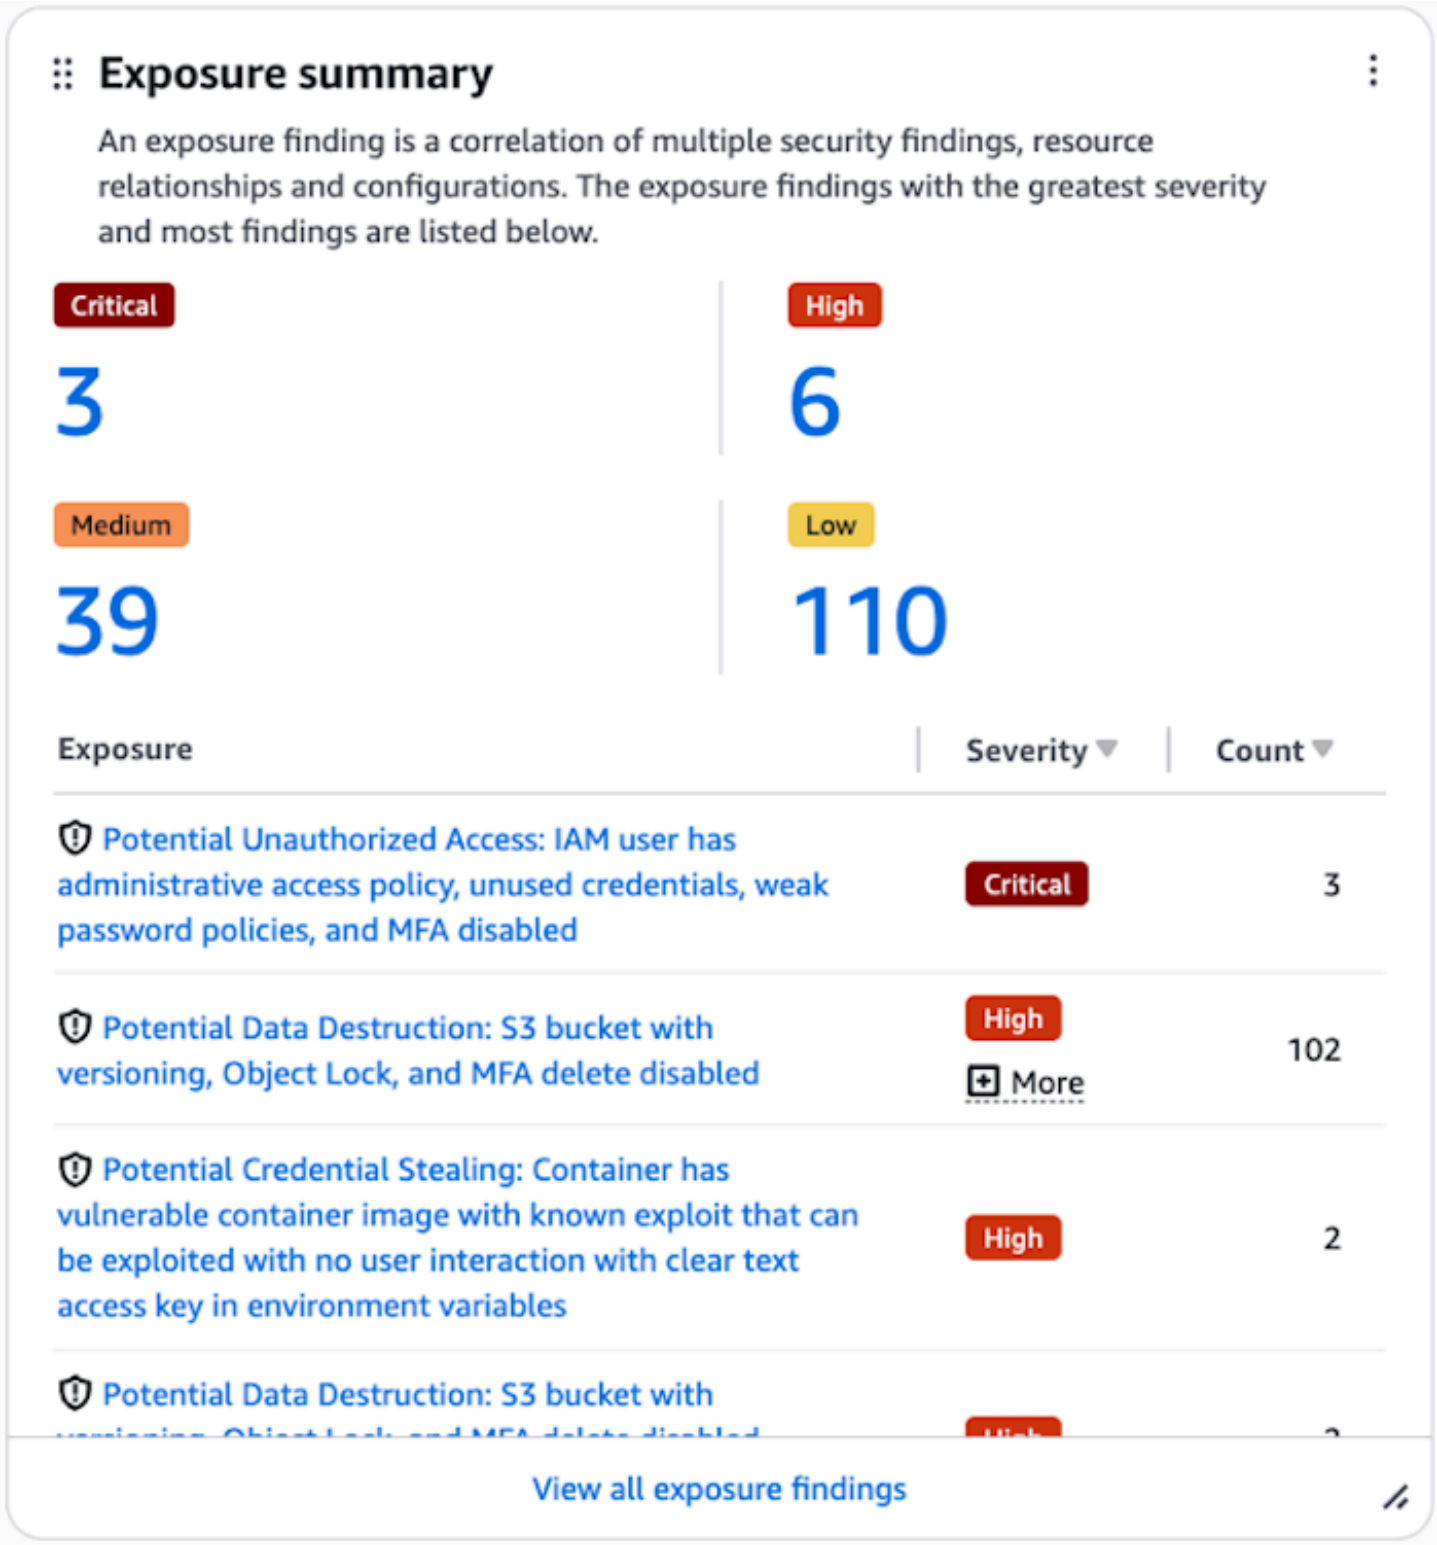
This widget displays an inventory of your resources in the following time periods:

- **5 days**
- **30 days**
- **90 days**
- **6 months**
- **1 year**

Data retention for trends

Security Hub retains trends data for one year for all AWS accounts where Security Hub is enabled. After trends data has been retained for one year, it is deleted from Security Hub.

Trends data for delegated administrator and standalone accounts is deleted after Security Hub is disabled, or if the accounts are terminated.



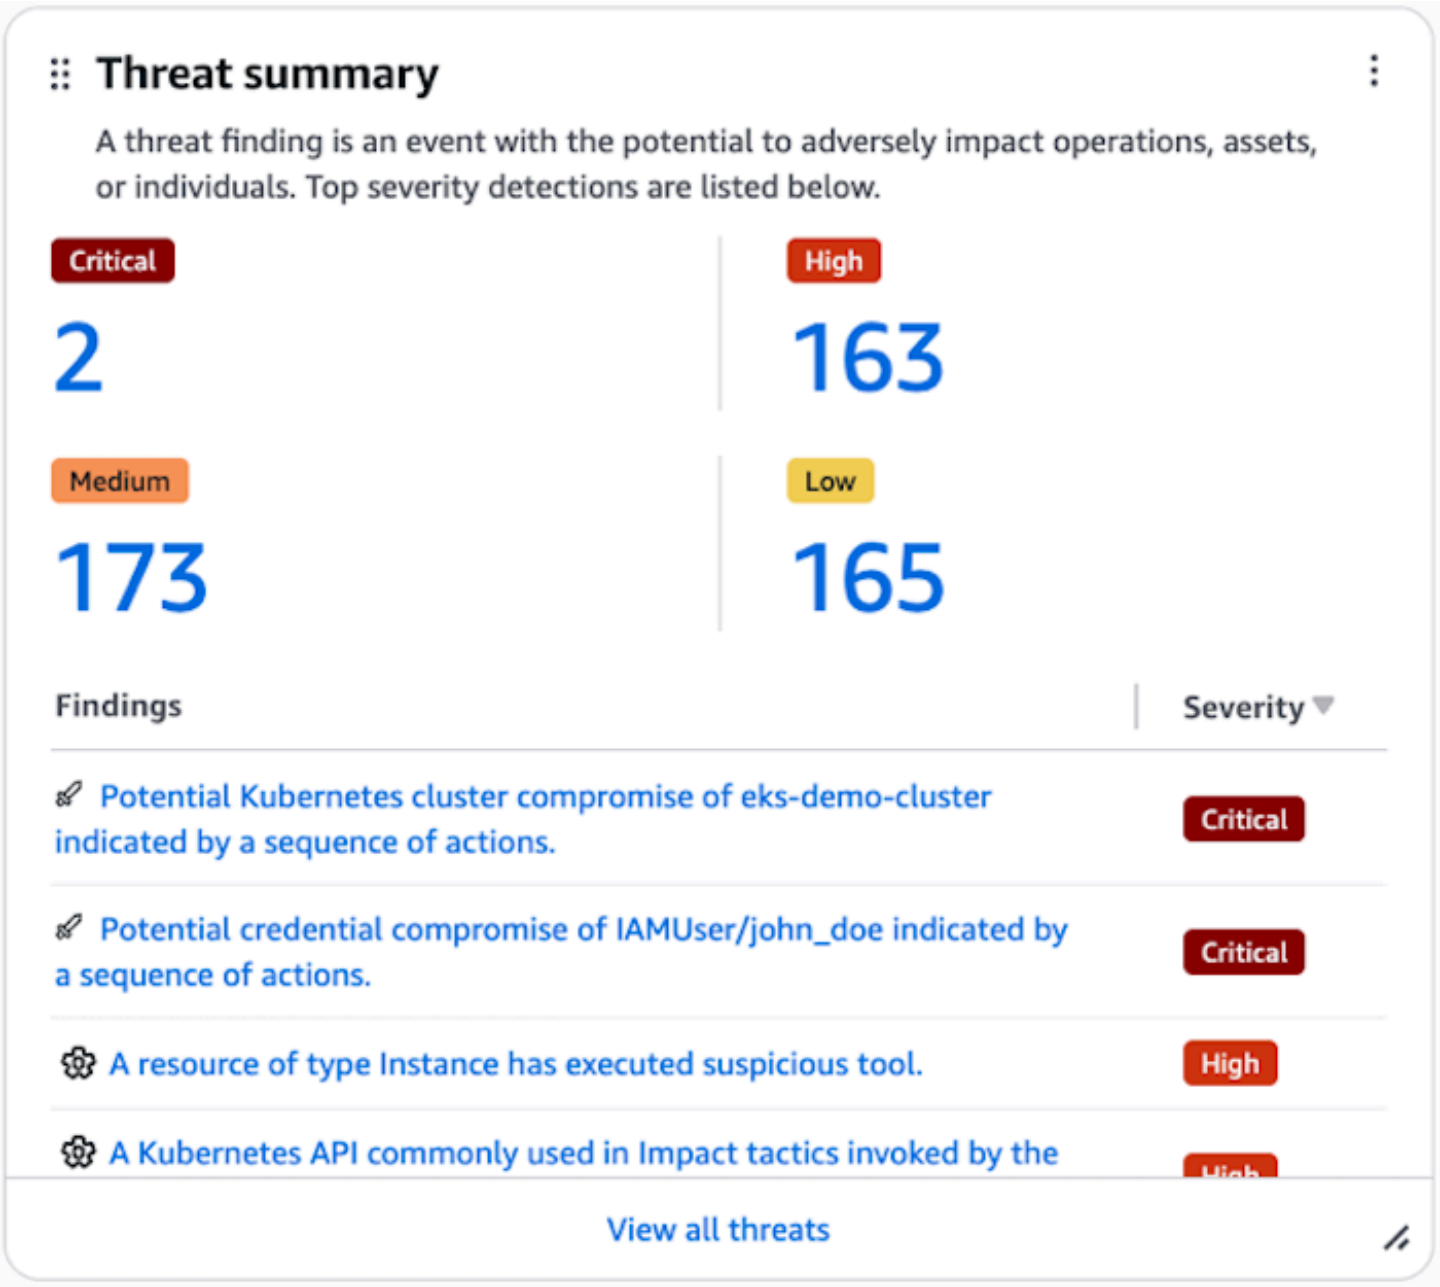
Trends data retention scenarios for member accounts with Security Hub enabled:

- If a member account leaves its organization, Security Hub still stores the trends data, up to when the account left the organization, for a year.
- If Security Hub is disabled for a member account, Security Hub retains the trends data, up to when the account was disabled, for a year.
- If a member account is terminated, Security Hub disassociates the trends data from the terminated account (for example, scrubbing the terminated account ID) and retains the rest of the trends data for one year.

Summary widgets

The following widgets display a summary of your exposures, threats, and resources.

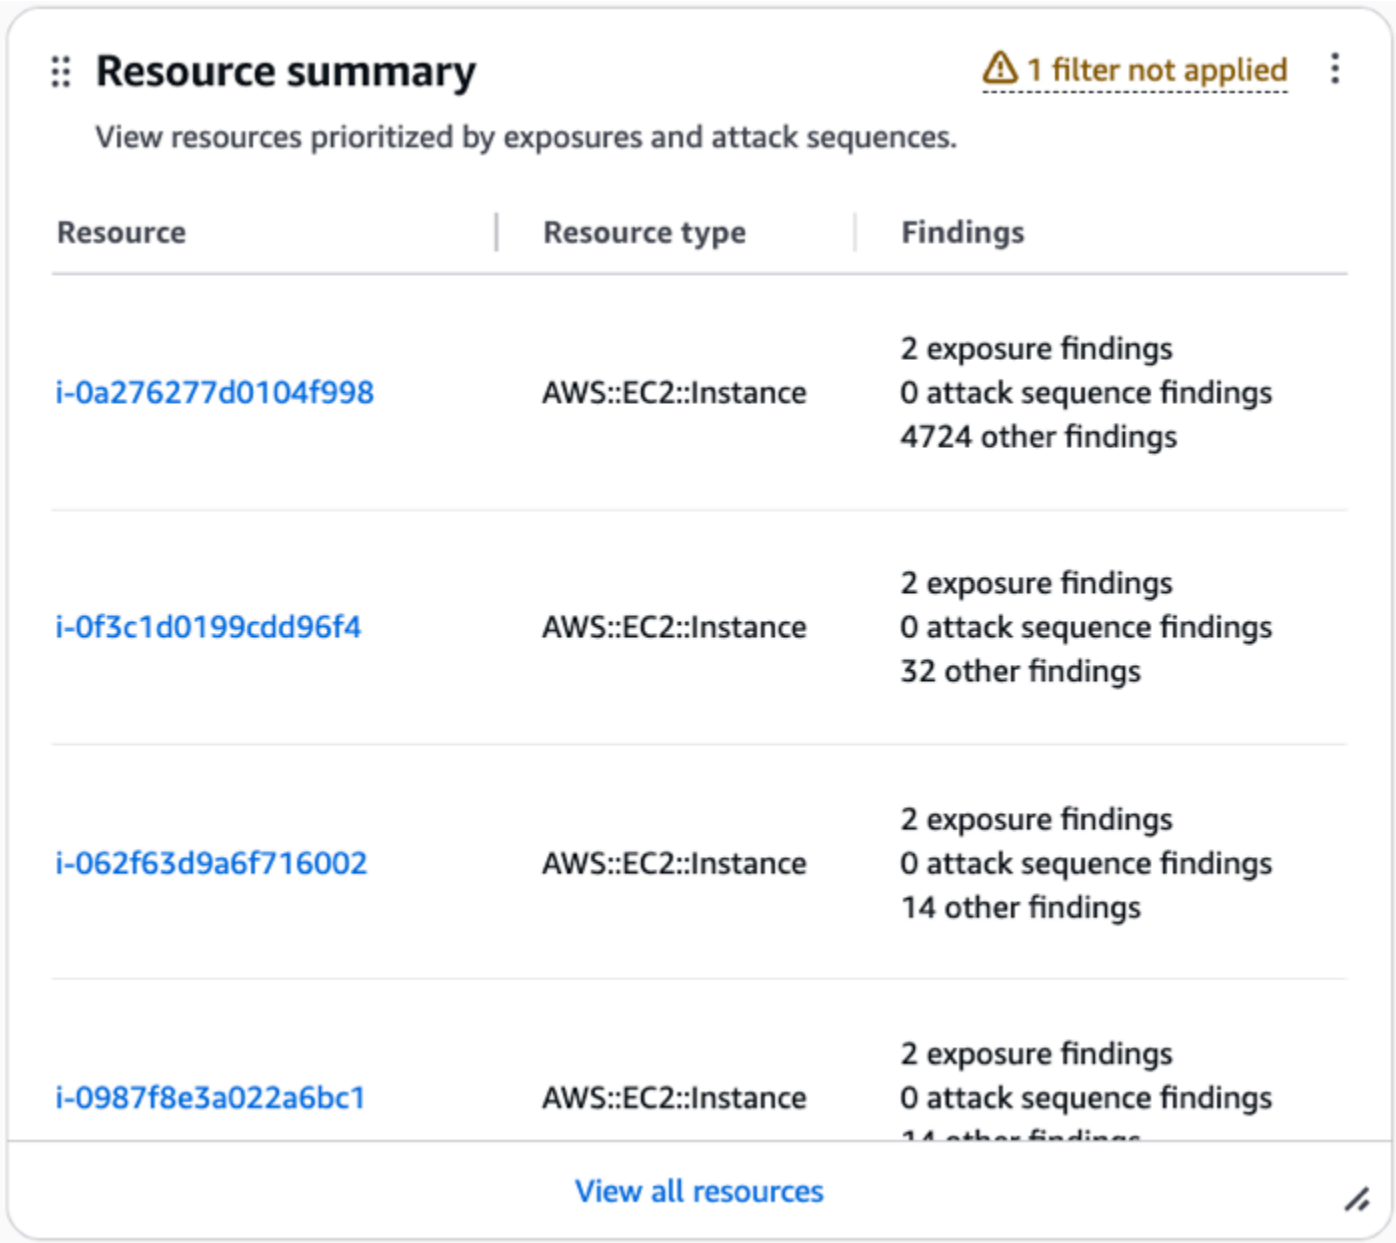
Exposure summary widget



This widget displays your exposures by severity. An exposure is based on an analysis of findings and traits from Security Hub and other AWS security services, such as Amazon Inspector. The list

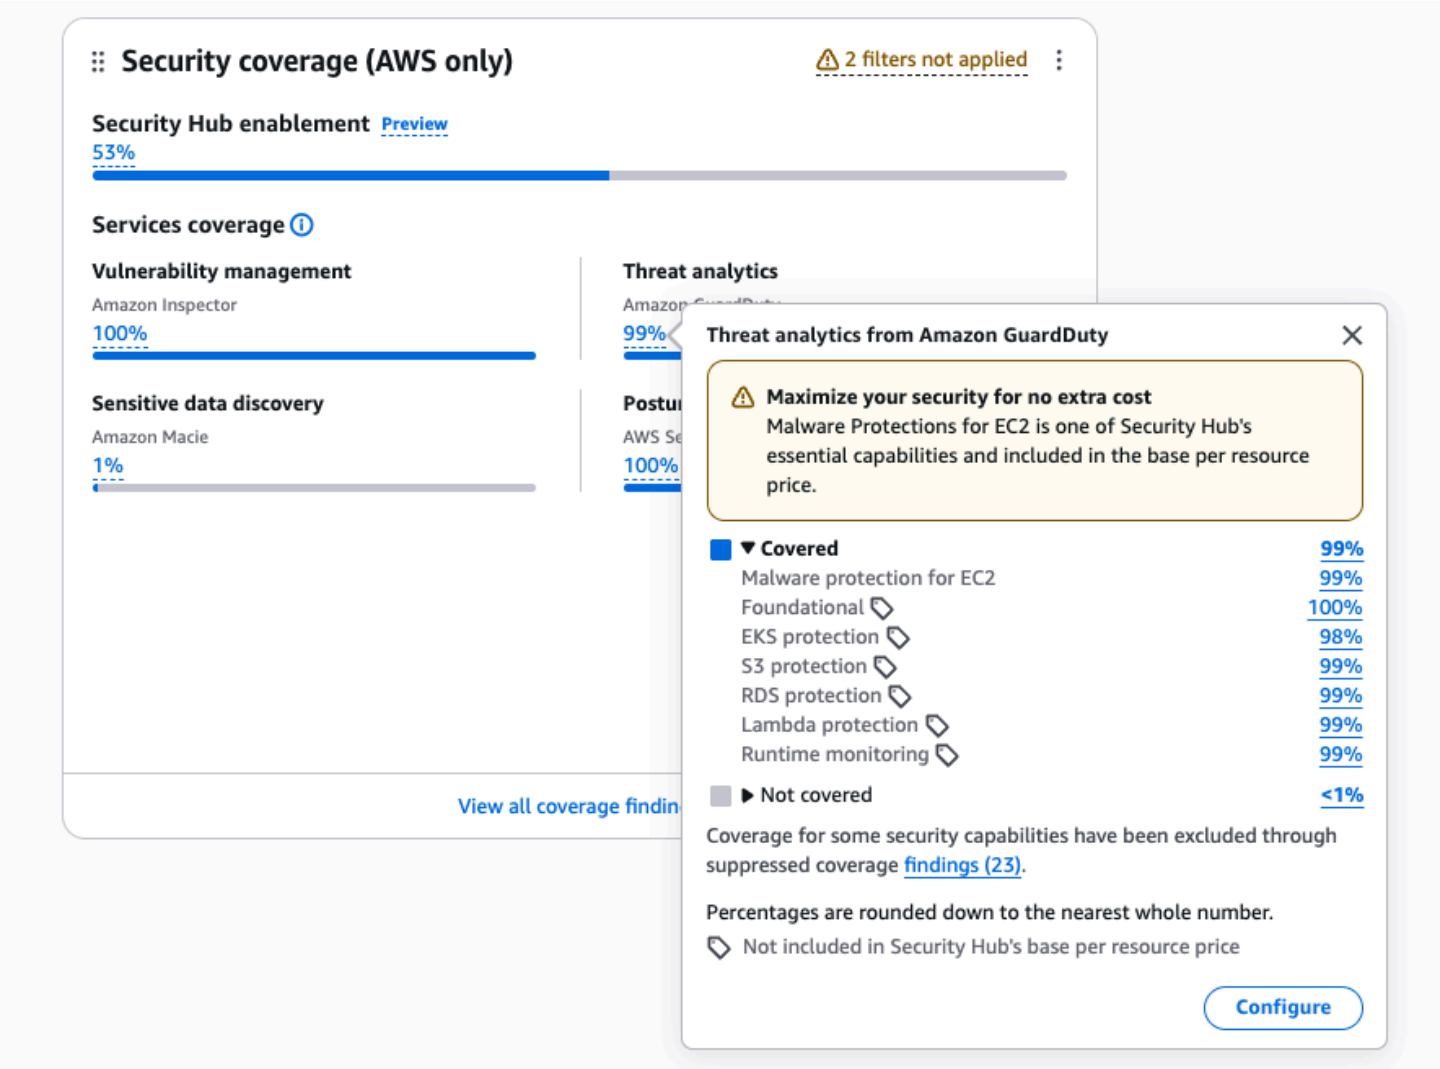
of exposures in this widget is limited to the eight exposures with the highest severity. Exposures with greater severity appear first in the list. If two or more exposures are of equal severity, the list automatically groups those exposures behind more recent exposures. Choosing **View all exposures** directs you to the **Exposure** dashboard.

> **Note**
>
> To receive data in this widget, you must enable Amazon Inspector and Security Hub CSPM.



Threat summary widget

This widget displays your threats by severity. A threat refers to malicious activity or suspicious activity that can compromise the security of your environment. The list of threats in this widget is limited to the eight threats with the highest severity. Threats with greater severity appear first in the list. If two or more threats are of equal severity, the list automatically groups those threats behind more recent threats. Choosing **View all threats** directs you to the **Threats** dashboard.



> **Note**
>
> To receive data in this widget, you must enable GuardDuty.

Resource summary widget

This widget displays resources by type and findings associated with resources. Resources are prioritized by exposures and attack sequences. Choosing **View all resources** directs you to the **Resource** dashboard.

Security coverage widget

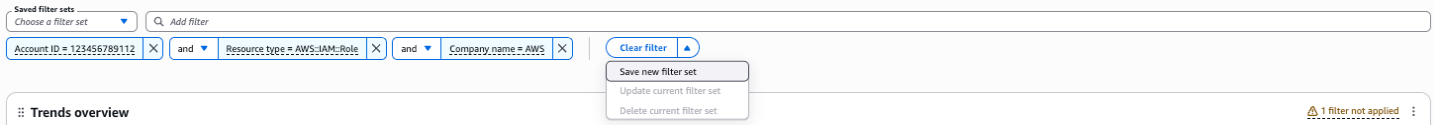
The widget displays a summary of your account coverage for the following security capabilities:

- Vulnerability management by Amazon Inspector
- Threat detection by Amazon GuardDuty
- Sensitive data discovery by Amazon Macie
- Posture management by AWS Security Hub CSPM

In delegated administrator accounts, the widget also displays account coverage for Security Hub enablement.

Each coverage item shows a percentage representing that capability's enablement across your accounts. Choosing a percentage displays details about coverage for that capability. Choosing the

Security Hub enablement percentage displays a side panel. The panel shows how many accounts are enabled in each Region across your organization.



In the **Services coverage** section, percentages represent the proportion of coverage checks that passed for each security capability. These checks span the accounts and Regions where Security Hub is enabled. Choosing a coverage percentage displays a popover that breaks down each feature as **Covered** (check passed) or **Not covered** (check failed). Percentages are rounded down to the nearest whole number. Choosing any percentage in the popover opens the coverage findings page with details about the findings that make up that percentage. Choose **Configure** to open the individual service where you can manage the configuration for that capability, or to open the Security Hub configurations page where you can update your configurations for security services.

If any of your coverage findings in Security Hub are suppressed, the widget displays a message informing you that coverage has been excluded: *Coverage for security capabilities has been excluded through suppressed coverage findings*.

For more information about viewing and suppressing coverage findings, see Coverage findings in Security Hub.

Available filters

You can apply filters to security widgets using the **Add filter bar**.

Filters are organized in the following categories:

- **Shared filters** – applies to all security widgets
- **Finding filters** – applies to security widgets that display finding data
- **Resource filters** – applies to security widgets that display resource data

You can create a filter set by connecting filters using the **and/or** operators and then choosing **Save new filter set** in the dropdown.

Filters applied to the Exposure finding trends widget and Threat finding trends widget

Currently, the filters supported for these widgets include the following:

- **Account ID**
- **Finding class name**
- **Finding type**
- **Product name**
- **Region**
- **Status**

Filters applied to the Resource trends widget

Currently, the filters supported for this widget include the following:

- **Account ID**
- **Region**
- **Resource category**
- **Resource type**

Filters not applied to widgets

If a widget does not support a filter, the filter is not applied to the widget. In this case, the widget displays a warning message letting you know how many filters were not applied and lists the names of which filters it does not support.

Viewing details about resources in Security Hub

The **Resources** page tracks common resources across your account and organization. You can access the **Resources** page in the Security Hub console by choosing **Resources** in the navigation pane. The benefit of the **Resources** page is that it helps you monitor your security posture, organize your resources, and review details about your resources. When you choose a resource type, you can review all of the resources associated with the resource type. You can review any findings associated with a resource. The resource types available in the **Resources** page include any resources in your accounts covered by AWS security services contributing findings to Security Hub.

> **Note**
>
> The delegated administrator can view all resources associated with member accounts. If you configured a home AWS Region, you can view all of your resources in your home AWS Region from linked AWS Regions.

If you choose a resource, you can review details for that resource. These details include the resource name, ID, ARN, type, and category. You can review the account ID associated with the resource, when the resource was created (timestamp), and where the resource was created (AWS Region). You also can review additional configuration details about the resource. These details can be found in a JSON snippet that you can copy.

If you switch from the **Overview** tab to the **Findings** tab, you can review any findings associated with the resource. The **Findings** tab shows the name of each finding, type of each finding, and severity of each finding. You can group findings by different fields and search for findings using filters. If you choose a finding, you can review an overview of the finding, which includes information about compliance and how to remediate issues associated with the finding. The **Traits** tab shows each trait that has been identified about the resource. You can view contributing traits that were used to create an exposure finding for the resource. You can also see contextual traits, which are other security items identified for the resource but did not directly contribute to any exposure findings. If you go back to the resource, you can choose **Open resource** to review the resource in the console for its resource type. For example, if the resource is an IAM resource, you can open the resource in the IAM console.

The resources page provides you with different ways to organize and search for resources. You can group resources by type. For example, you can group resources by account ID, finding type, AWS Region, resource category, resource name, and resource type. Quick filters help you review resources by category, accounts, and finding types.

Security Hub and the Open Cybersecurity Schema Framework (OCSF)

Security Hub uses the Open Cybersecurity Schema Framework (OCSF) as the standard format for all security findings. This topic describes OCSF and how Security Hub implements it.

OCSF overview

Security Hub findings are formatted using OCSF (Open Cybersecurity Schema Framework). OCSF is an open-source project that delivers an extensible framework for developing schemas, along with a vendor-agnostic core security schema. Vendors and other data producers can adopt and extend the schema for their specific domains. Data producers can map differing schemas to help security teams simplify data ingestion and normalization, so that data scientists and analysts can work with a common language for threat detection and investigation. The goal is to provide an open standard, adopted in any environment, application, or solution, while complementing existing security standards and processes.

The framework consists of data types, an attribute dictionary, and a taxonomy. Although not limited to cybersecurity or events, the initial focus is on cybersecurity event schemas. OCSF is independent of storage format, data collection methods, and ETL processes.

Security Hub currently supports findings in OCSF schema version 1.6.

- OCSF Extensions Registry

AWS extension for OCSF

OCSF schemas can be extended by adding new attributes, objects, categories, profiles and event classes. A schema is the aggregation of core schema entities and extensions.

Extensions to OCSF allow a particular vendor or customer to augment an existing schema by adding attributes to provide domain-specific customization, improve data interoperability, and add more detailed context for security analysis.

The AWS Extension for Open Cybersecurity Schema Framework (OCSF) provides attribute definitions for cloud resources within OCSF events. This extension adds a `cloud_resources`

profile that extends the OCSF `resource_details` object with cloud-specific resource attributes. With these attributes, security teams can analyze resource configurations, potential vulnerabilities, and threat detection metadata.

Extended `resource_details` object

The AWS Extension extends the `resource_details` object with attributes mentioned in the list of attribute references below. These attributes ensure proper identification and classification of cloud resources across different providers within standardized event frameworks.

AWS Extension for OCSF attribute reference

The Basic attributes and Resource specific objects sections provide examples of each of the attributes that are part of the AWS OCSF extension to resource_details.

Each of the attribute definitions contains an OCSF status outlining its current relationship to the public OCSF schema:

- **Existing**: This attribute was already in standard OCSF resource_details and is now part of the AWS extension.
- **New**: The attribute is not part of OCSF and was introduced as part of the AWS extension. It does not exist in the core OCSF schema.
- **Added to resource_details**: The attribute is defined in OCSF but not part of resource_details.

Basic attributes

These are fundamental attributes used for resource identification, location, and basic metadata. They consist of simple data types such as strings, timestamps, and arrays.

Cloud partition

The cloud partition where the resource exists.

Requirement

Recommended

Type

String

OCSF status

Existing

Example

```
{
  "resources": [
    {
      "cloud_partition": "aws"
    }
  ]
}
```

Owner account ID

A 12-digit account identifier that the resource belongs to.

Requirement

Recommended

Type

String

OCSF status

Existing

Example

```
{
  "resources": [
    {
      "owner": {
        "account": {
          "uid": "123456789012"
        }
      }
    }
  ]
```

```
}
```

Resource type

The AWS CloudFormation resource type that identifies the specific service and resource.

Requirement

Required

Type

String

Format

Must follow AWS CloudFormation resource type naming convention: `AWS::<Service>::<ResourceType>`

OCSF status

Existing

Example

```
{
  "resources": [
    {
      "type": "AWS::EC2::Instance"
    }
  ]
}
```

Resource identifier

The unique identifier for the cloud resource (for example, i-1234567890abcdef0).

Requirement

Recommended

Type

String

Format

Must be a valid resource identifier. Minimum length of 1. Maximum length of 768.

OCSF status

Existing

Example

```
{
  "resources": [
    {
      "uid": "i-1234567890abcdef0"
    }
  ]
}
```

Alternate resource identifier

The unique identifier for the cloud resource, typically the Amazon Resource Name (ARN).

Requirement

Recommended

Type

String

Format

Should be a valid AWS ARN. Common patterns include:

- `"arn:partition:service:region:account-id:resource-id"`
- `"arn:partition:service:region:account-id:resource-type/resource-id"`
- `"arn:partition:service:region:account-id:resource-type:resource-id"`

Note: Some services like S3 use variations such as arn:aws:s3:::bucket-name (without region or account-id).

OCSF status

Existing

Examples

```
{
  "resources": [
    {
      "uid_alt": "arn:aws:ec2:us-east-1:123456789012:instance/i-1234567890abcdef0"
    }
  ]
}
```

```
{
  "resources": [
    {
      "uid_alt": "arn:aws:s3:::my-bucket-name"
    }
  ]
}
```

Resource name

The unique name for the cloud resource.

Requirement

Recommended

Type

String

Format

User-created names whose values will depend on the environment.

OCSF status

Existing

Example

```
{
  "resources": [
    {
      "name": "My-Server-1"
```

```
    }
  ]
}
```

Cloud region

The AWS region where the resource is located.

Requirement

Recommended

Type

String

Format

Valid cloud region identifier (for example, us-east-1, eu-west-1, ap-southeast-2)

OCSF status

Existing

Example

```
{
  "resources": [
    {
      "region": "us-west-2"
    }
  ]
}
```

Resource creation time

The time when the resource was created.

Requirement

Recommended

Type

Timestamp

Format

Unix timestamp in milliseconds since epoch (January 1, 1970, 00:00:00 UTC)

OCSF status

Existing

Example

```
{
  "resources": [
    {
      "created_time": 1762019193000
    }
  ]
}
```

Tags

Key-value pairs for resource metadata and organization.

Requirement

Recommended

Type

Array of key:value objects

Format

A generic object allowing to define a key:value pair.

OCSF status

Existing

Example

```
{
  "resources": [
    {
```

```
      "tags": [
        {
          "name": "Environment",
          "value": "Production"
        },
        {
          "name": "Owner",
          "value": "SecurityTeam"
        }
      ]
    }
  ]
}
```

IP address

The IP address associated with the instance in either IPv4 or IPv6 format.

Requirement

Optional

Type

String

Format

Valid IPv4 or IPv6 address

OCSF status

Existing

Example

```
{
  "resources": [
    {
      "ip": "10.0.1.25"
    }
  ]
}
```

IP addresses

An array of IP addresses (IPv4 or IPv6) associated with the device. These may include both public and private IP addresses.

Requirement

Optional

Type

Array of IP addresses

OCSF status

New

Example

```
{
  "resources": [
    {
      "ip_addresses": ["10.0.1.25", "52.12.34.56"]
    }
  ]
}
```

VPC UID

The VPC ID where the resource is located.

Requirement

Optional

Type

String

Format

VPC identifier (for example, vpc-12345678900)

OCSF status

Added to `resource_details`

Example

```
{
  "resources": [
    {
      "vpc_uid": "vpc-0a1b2c3d4e5f6g7h8"
    }
  ]
}
```

Example resource object with basic attributes

```
{
  "resources": [
    {
      "cloud_partition": "aws",
      "owner": {
        "account": {
          "uid": "123456789012"
        }
      },
      "region": "us-east-1",
      "type": "AWS::EC2::NetworkInterface",
      "uid": "eni-03e6c892dd45e836c",
      "uid_alt": "arn:aws:ec2:us-east-1:123456789012:network-interface/
eni-03e6c892dd45e836c",
      "zone": "us-east-1f",
      "vpc_uid": "vpc-0ef6045717b0362f6"
    }
  ]
}
```

Resource specific objects

These are complex nested objects that provide detailed information for specific resource types and services. Each object contains multiple fields and sub-objects with service-specific configuration and metadata.

Device

Enhanced cloud instance attributes for compute resources including encryption details, image information, instance profile, and launch time.

Requirement

Optional

Type

Object

OCSF status

Added to `resource_details`. See the OCSF Device object definition.

AWS Extension adds the following attributes to this object:

- `encryption_details` - The encryption details of resource
- `image` - Image information
- `instance_profile` - The IAM instance profile to associate with the instance
- `launch_time` - The time the instance was launched
- `uid_alt` - Amazon Resource Name (ARN) of the resource

Example

```
{
  "device": {
    "image": {
      "uid": "ami-99999999",
      "name": "LoadTestAMI-Current"
    },
    "instance_profile": {
      "uid": "LoadTestingInstanceProfileId",
      "uid_alt": "arn:aws:iam::012345678999:instance-profile/generated"
    },
    "launch_time": 1762019193000,
    "launch_time_dt": "2025-08-02T02:05:06Z",
    "model": "m3.xlarge",
    "network_interfaces": [
      {
        "ip": "198.51.100.0",
        "security_groups": [
          {
            "name": "LoadTestingSecurityGroupName",
            "uid": "LoadTestingSecurityId"
```

```
          }
        ],
        "uid": "eni-abcdef12"
      }
    ],
    "type": "Virtual",
    "type_id": 6,
    "uid": "i-99999999"
  }
}
```

Network interface

Network interface details and configuration including attachments and security groups.

Requirement

Optional

Type

Object

OCSF status

Added to `resource_details`. See the OCSF Network Interface object definition.

AWS Extension adds the following attributes to this object:

- `attachments` - Information about the network interface attachments
- `security_groups` - Array of security group unique identifiers
- `uid_alt` - Amazon Resource Name (ARN) of the resource

Example

```
{
  "network_interface": {
    "uid": "eni-0a1b2c3d4e5f6g7h8",
    "uid_alt": "arn:aws:ec2:us-east-1:123456789012:network-interface/
eni-0a1b2c3d4e5f6g7h8",
    "name": "prod-web-server-eni",
    "attachments": [
```

```
      {
        "uid": "eni-attach-0abcd1234efgh5678",
        "instance_uid": "i-0123456789abcdef0",
        "name": "/dev/eth0",
        "state": "attached",
        "attach_time": 1762019193000
      }
    ],
    "security_groups": [
      {
        "uid": "sg-0a1b2c3d4e5f6g7h8",
        "name": "web-server-sg"
      },
      {
        "uid": "sg-9i8h7g6f5e4d3c2b1",
        "name": "ssh-access-sg"
      }
    ]
  }
}
```

Storage device

Storage device details including attachments, encryption, and snapshot information.

Requirement

Optional

Type

Object

OCSF status

New

The storage device object includes the following attributes:

- `name` - The name of the storage device
- `uid` - The unique identifier of the storage device
- `attachments` - The storage device attachments

- `encryption_details` - The storage device encryption key
- `is_encrypted` - Whether the storage device is encrypted (required)
- `snapshot_id` - The storage device snapshot identifier
- `uid_alt` - Amazon Resource Name (ARN) of the resource

Example

```
{
  "storage_device": {
    "is_encrypted": false,
    "name": "LocalVolumeDeviceName1",
    "snapshot_id": "snap-12345678901234567",
    "uid": "vol-09d5050dea915943d",
    "uid_alt": "arn:aws:ec2:us-west-2:123456789000:volume/vol-09d5050dea915943d"
  }
}
```

Database

Database instance attributes including engine type, endpoint, and user information.

Requirement

Optional

Type

Object

OCSF status

Added to `resource_details`. See the OCSF Database object definition.

AWS Extension adds the following attributes to this object:

- `cluster_uid` - The database cluster identifier
- `db_endpoint` - The database endpoint
- `encryption_details` - The database encryption details
- `engine` - The database engine name (for example, mysql)

- `is_encrypted` - Whether the database is encrypted
- `is_iam_authentication` - Whether IAM authentication is enabled
- `is_public` - Whether the database is publicly accessible
- `port` - The database port number
- `security_groups` - Array of VPC security groups associated with the database instance
- `snapshot_details` - The database snapshot details
- `status` - The database status (for example, available)
- `subnet_group` - A database subnet group is a collection of subnets in a VPC
- `uid_alt` - Amazon Resource Name (ARN) of the resource
- `user` - The database user
- `version` - The database version

Example

```
{
  "database": {
    "cluster_uid": "SampleDBClusterId",
    "engine": "mysql",
    "is_iam_authentication": true,
    "is_public": false,
    "type": "Relational",
    "type_id": 1,
    "uid": "SampleDBId",
    "version": "13.6"
  }
}
```

Database cluster

Database instance attributes including engine type, endpoint, and user information.

Requirement

Optional

Type

Object

OCSF status

New

The database object includes the following attributes:

- `uid` - The unique identifier of the database cluster
- `uid_alt` - Amazon Resource Name (ARN) of the resource
- `name` - The name of the database cluster
- `status` - The database cluster status
- `engine` - The engine associated with the cluster
- `version` - The database cluster version
- `cluster_members` - List of database instances that are part of the cluster
- `security_groups` - Array of security groups associated with the cluster
- `is_encrypted` - Whether the database cluster is encrypted
- `is_iam_authentication` - Whether IAM authentication is enabled
- `encryption_details` - The database cluster encryption details
- `subnet_group` - The subnet group associated with the cluster
- `port` - The database cluster port number
- `zones` - List of availability zones
- `db_endpoint` - The database cluster endpoint
- `snapshot_details` - Details of the database snapshot

Example

```
{
  "db_cluster": {
    "uid": "production-aurora-cluster",
    "uid_alt": "arn:aws:rds:us-east-1:123456789012:cluster:production-aurora-cluster",
    "name": "production-aurora-cluster",
    "status": "available",
    "engine": "aurora-mysql",
    "version": "8.0.mysql_aurora.3.04.0",
    "cluster_members": [
      "instance-1",
```

```
      "instance-2"
    ],
    "security_groups": [
      {
        "uid": "sg-0a1b2c3d4e5f6g7h8",
        "name": "db-security-group"
      }
    ],
    "is_encrypted": true,
    "is_iam_authentication": true,
    "encryption_details": {
      "key_uid": "arn:aws:kms:us-
east-1:123456789012:key/12345678-1234-1234-1234-123456789012"
    },
    "subnet_group": {
      "uid": "production-db-subnet-group"
    },
    "port": 3306,
    "zones": [
      "us-east-1a",
      "us-east-1b",
      "us-east-1c"
    ],
    "db_endpoint": {
      "name": "production-aurora-cluster.cluster-abc123xyz.us-
east-1.rds.amazonaws.com",
      "port": 3306
    }
  }
}
```

Cloud function

Cloud function attributes for serverless functions including handler, layers, and runtime configuration.

Requirement

Optional

Type

Object

OCSF status

New

The cloud function object includes the following attributes:

- `name` - The name of the cloud function
- `uid` - The unique identifier of the cloud function
- `uid_alt` - Amazon Resource Name (ARN) of the resource
- `encryption_details` - The cloud function encryption details
- `handler` - The method in the function code that processes events
- `layers` - The list of cloud function layers that contain supplementary code or data
- `runtime` - The cloud function language-specific environment
- `security_groups` - Array of security groups associated with the cloud function
- `subnet_info_list` - Details about subnets associated with the cloud function
- `user` - Details about the IAM entity that grants the cloud_function permission to access services
- `version` - The cloud function version
- `vpc_uid` - The unique identifier of the VPC if the cloud function is in a VPC

Example

```
{
  "cloud_function": {
    "name": "my-lambda-function",
    "uid": "my-lambda-function",
    "uid_alt": "arn:aws:lambda:us-east-1:123456789012:function:my-lambda-function",
    "handler": "index.handler",
    "runtime": "python3.11",
    "version": "$LATEST",
    "layers": [
      {
        "name": "my-layer",
        "uid_alt": "arn:aws:lambda:us-east-1:123456789012:layer:my-layer:1",
        "version": "1"
      }
    ],
    "security_groups": [
```

```
      {
        "name": "lambda-security-group",
        "uid": "sg-0123456789abcdef0"
      }
    ],
    "subnet_info_list": [
      {
        "uid": "subnet-0a1b2c3d4e5f6g7h8"
      }
    ],
    "vpc_uid": "vpc-0ef6045717b0362f6"
  }
}
```

Databucket

S3 bucket or data storage attributes.

Requirement

Optional

Type

Object

OCSF status

Added to `resource_details`. See the OCSF Databucket object definition.

Note: This object is added to resource_details by the AWS Extension. The core OCSF Databucket object is used without additional attributes.

Example

```
{
  "databucket": {
    "type": "S3",
    "type_id": 1,
    "uid": "my-bucket-name"
  }
}
```

Image

Image information for compute resources including platform and usage details.

Requirement

Optional

Type

Object

OCSF status

Added to `resource_details`. See the OCSF Image object definition.

AWS Extension adds the following attributes to this object:

- `platform` - The operating system platform of the image
- `in_use_count` - Count of resources using this image

Example

```
{
  "image": {
    "uid": "ami-0abcdef1234567890",
    "uid_alt": "arn:aws:ec2:us-east-1:123456789012:image/ami-0abcdef1234567890",
    "name": "my-custom-ami",
    "platform": "AMAZON_LINUX_2",
    "in_use_count": 2
  }
}
```

Subnet info

Details about the subnet where the resource is located.

Requirement

Optional

Type

Object

OCSF status

New

The subnet info object includes the following attributes:

- `uid` - The unique identifier of the subnet
- `uid_alt` - Amazon Resource Name (ARN) of the resource
- `name` - The name of the subnet
- `zone` - The availability zone
- `ip_count` - The number of IP addresses in the subnet
- `cidr_block` - The CIDR block of the subnet
- `is_default` - Whether this is the default subnet
- `is_public` - Whether the subnet is publicly accessible
- `state` - The state of the subnet
- `vpc_uid` - The VPC ID where the subnet is located

Example

```
{
  "subnet_info": {
    "uid": "subnet-0a1b2c3d4e5f6g7h8",
    "uid_alt": "arn:aws:ec2:us-east-1:123456789012:subnet/subnet-0a1b2c3d4e5f6g7h8",
    "name": "production-web-subnet-1a",
    "zone": "us-east-1a",
    "ip_count": 251,
    "cidr_block": "10.0.1.0/24",
    "is_default": false,
    "is_public": true,
    "state": "available",
    "vpc_uid": "vpc-0123456789abcdef0"
  }
}
```

User

IAM user attributes including instance profiles and policies.

Requirement

Optional

Type

Object

OCSF status

Added to `resource_details`. See the OCSF User object definition.

The user object includes the following attributes:

- `instance_profiles` - List of instance profiles attached to an cloud instance
- `policies` - Policies that assign permissions for users, groups, roles, and resources

Example

```
{
  "user": {
    "type_id": 1,
    "uid": "AIDACKCEVSQ6C2EXAMPLE",
    "uid_alt": "arn:aws:iam::123456789012:user/developers/john.doe",
    "name": "john.doe",
    "type": "User",
    "groups": [
      {
        "name": "Developers"
      },
      {
        "name": "ReadOnlyAccess"
      }
    ],
    "policies": [
      {
        "name": "AmazonS3ReadOnlyAccess"
      },
      {
```

```
        "name": "AmazonEC2ReadOnlyAccess"
      }
    ]
  }
}
```

Coverage findings in Security Hub

Coverage findings for Security Hub provide visibility into which AWS security features are enabled and where there might be gaps in coverage in a standalone account or across an organization's member accounts. Coverage findings currently support reporting which services and features are enabled for Amazon GuardDuty, Amazon Inspector, Amazon Macie, and AWS Security Hub CSPM. These findings appear in the Security Coverage widget on the Security Hub dashboard with the ability to drill down into more detailed views by specific security capability.

Limitations

- For member accounts, coverage information is aggregated across linked AWS Regions, but only for that member account.
- Coverage information is not shown for accounts not onboarded to Security Hub.

Coverage findings for AWS Security Hub CSPM

Security Hub CSPM coverage findings assess whether a qualified posture management security standard is enabled in an account. Enabling any Security Hub CSPM Standard will qualify, with the exception of AWS Control Tower and Resource Tagging standards.

It can take up to 24 hours to detect standards enabled by default when enabling Security Hub CSPM.

Coverage findings for Amazon GuardDuty

GuardDuty coverage findings assess whether GuardDuty is enabled and which GuardDuty features are enabled in an AWS account:

- GuardDuty Malware Protection for Amazon EC2 – Scans Amazon EC2 instances for potential malware.

- GuardDuty Amazon EKS Protection – Monitors Kubernetes audit logs for threats in Amazon EKS clusters.
- GuardDuty Lambda Protection – Analyzes Lambda function invocations for potential threats.
- GuardDuty Amazon S3 Protection – Analyzes data events for potential threats to Amazon S3 buckets.
- GuardDuty Amazon RDS Protection – Monitors for threats to Amazon RDS databases.
- GuardDuty Runtime Monitoring – Provides real-time monitoring of runtime behavior in Amazon EC2 instances.
- GuardDuty Foundational Coverage – Baseline GuardDuty features which are automatically turned on when GuardDuty is enabled.

> **Note**
>
> For GuardDuty Foundational Coverage, coverage findings that indicate the feature is turned off mean GuardDuty is not enabled in the account for the coverage finding.

It can take up to 24 hours for updates to GuardDuty coverage to reflect across all member accounts in an organization.

Coverage findings for Amazon Inspector

Amazon Inspector coverage findings assess whether Amazon Inspector is enabled and which features are enabled in an account:

- Inspector EC2 Scanning – Scans Amazon EC2 instances for vulnerabilities.
- Inspector ECR Scanning – Scans Amazon ECR container images for vulnerabilities.
- Inspector Lambda Standard Scanning – Scans Lambda functions for vulnerabilities.
- Inspector Lambda Code Scanning – Scans Lambda code functions for code vulnerabilities.

Coverage findings for Amazon Macie

Macie coverage findings assess whether Macie is enabled across AWS accounts:

- Macie Automated Sensitive Data Discovery Coverage – Continuously evaluates your Amazon S3 data estate for sensitive data.

It can take up to 24 hours for updates to Macie automated sensitive data discovery for coverage findings to reflect across all member accounts in an organization.

Suppressing coverage findings

By default, security coverage findings evaluate which Amazon GuardDuty, Amazon Inspector, Amazon Macie, and AWS Security Hub CSPM features are enabled for an account and Region. If certain security capabilities are not applicable for you or are an accepted risk, you can use the suppression feature to suppress coverage findings similar to all other findings. When a coverage finding is suppressed, it is not included in the coverage calculations within the security coverage widget. The widget displays the following message: *Coverage for security capabilities has been excluded through suppressed coverage findings*. The message includes a count of suppressed findings.

To suppress a coverage finding in Security Hub

1. When viewing the security coverage widget choose the **percent covered** link.
2. From the coverage popup choose **View coverage findings**. Each finding with a status of **New** outlines an observed coverage gap.
3. Select the check box next to each finding that you want to suppress.
4. At the top of the page, choose **Update status**, and then choose **Suppressed**.
5. In the **Set status to Suppressed** dialog box, optionally enter a note that details the reason for changing the status. Then choose **Set status**.

AI Inventory in Security Hub

The AI inventory in AWS Security Hub provides a unified view of your artificial intelligence (AI) and machine learning (ML) resources across your AWS environment. Use the AI inventory to identify unsanctioned AI workloads, understand where AI is running and how it was discovered, and prioritize the resources that require closer security review. Security Hub organizes AI resources into two discovery types:

- **Managed** – AI resources that AWS provides as a managed service. Security Hub discovers these resources from AWS Config configuration items. Managed resource types include a supported subset of Amazon Bedrock, Amazon Bedrock AgentCore, and Amazon SageMaker.
- **Self-hosted** – AI resources that aren't provided as a managed service. Examples include open source models, agents, and inference servers that run on your own compute. Security Hub

detects these resources from contributing signals on Amazon Elastic Compute Cloud (Amazon EC2) instances and Amazon Elastic Container Registry (Amazon ECR) images. The signals include Amazon Inspector software bill of materials (SBOM) findings and Amazon GuardDuty DNS activity.

Administrator accounts can view AI resources from all enabled accounts in their organization. Member accounts can view only the AI resources within their own account.

Prerequisites for self-hosted AI discovery

Discovery of managed AI resources requires no additional configuration beyond enabling Security Hub. To discover self-hosted AI resources, you must also enable the AWS services that provide the contributing signals:

- **Amazon Inspector** – Enable Amazon Inspector (with Security Hub essentials) to generate SBOMs. Security Hub uses these SBOMs to detect self-hosted models, inference endpoints, and agents. For Amazon EC2 instances, enable agent-based scanning with enhanced scanning mode, agentless scanning, or hybrid scanning. Agent-based scanning without enhanced scanning mode doesn't produce the deep software inventory that AI resource detection requires. For Amazon ECR images, Amazon Inspector provides SBOMs through container image scanning.
- **Amazon GuardDuty** – Enable GuardDuty so that Security Hub can use DNS activity to detect external AI endpoints that your Amazon EC2 instances call.

Supported AI resource types

At general availability, Security Hub supports the following self-hosted AI resource types. Security Hub uses a confidence-based detection system for self-hosted AI resources. Each detection is anchored to a primary signal, such as an SBOM component. Security Hub then correlates additional signals to establish confidence before a resource appears in your inventory. Security Hub shows only the resources that meet the confidence threshold, which helps minimize false positives. Each resource uses a `ResourceType` with the `SelfHosted::AI::` prefix.

- **Models** (`SelfHosted::AI::Model`) – Hugging Face and Ollama models. Security Hub detects models only in the default model-cache directories (such as the Hugging Face and Ollama caches) and in custom paths that you configure for Amazon Inspector scanning.

- **Inference endpoints** (`SelfHosted::AI::InferenceEndpoint`) – Supported model-serving software, such as vLLM, Ollama, TorchServe, Triton, Text Generation Inference (TGI), SGLang, llama.cpp, LocalAI, BentoML, Xinference, Ray Serve, and GPT4All.
- **Agents** (`SelfHosted::AI::Agent`) – OpenClaw agents.
- **External endpoints** (`SelfHosted::AI::ExternalEndpoint`) – External AI service domains that your Amazon EC2 instances call. Security Hub maintains an allow list of known AI service domains, such as OpenAI, Anthropic, Cohere, Mistral, and other major AI providers, and detects when your instances make DNS requests to them. External endpoints are detected from GuardDuty DNS activity on Amazon EC2 only.

Managed AI resources are a supported subset of Amazon Bedrock, Amazon Bedrock AgentCore, and Amazon SageMaker configuration item types, each with the `AI/ML` resource category.

Finding AI resources from the Resources page

The **Resources** page lists all of the resources in your environment. For AI resources, you can use the following capabilities to identify AI workloads and the hosts that run them:

- Managed AI/ML resources display an AI icon next to the resource. Choose the icon to view a description.
- Host resources that run self-hosted AI resources, such as Amazon EC2 instances, display a self-hosted AI count badge. Hosts with no self-hosted AI resources don't display a badge.
- Use the quick filter toggle to show only the hosts that contain self-hosted AI resources.
- To drill down into a host, choose the host to open its detail panel, choose the **AI assets** tab, and then choose **View all** to see the self-hosted AI resources detected on that host.

Using the AI inventory page

The AI inventory page focuses on the AI resources in your organization. Every resource on this page belongs to the `AI/ML` resource category. This page shows managed AWS AI resources and self-hosted AI resources in your environment. The following sections describe the main components of the page.

Summary bar

The summary bar displays the total number of AI assets and a breakdown by discovery type, either self-hosted or managed. It also displays a breakdown by sub-category, such as model or agent. Choose the value for a statistic to display the supporting details in the table.

Grouping, filtering, and searching

The AI inventory table groups resources by resource type by default. You can modify the grouping or remove it for a flat view of all resources. Available grouping fields include canonical ID, host resource type, discovery type, account ID, and resource type.

The canonical ID identifies what a resource is, independent of where it runs. For example, two Amazon EC2 instances that run the same Hugging Face model share the same canonical ID, so that you can find all deployments of a specific model across your organization.

> **Note**
>
> The canonical ID and host resource type groupings apply only to self-hosted resources. When you group by these fields, managed AI resources don't appear in the results because they don't have these attributes. Use the discovery type or resource type groupings to see both managed and self-hosted resources together.

Quick filters enable filtering by resource sub-category or discovery type. **Property filters** support additional fields, including host resource type and canonical ID for self-hosted resources.

Resource detail and contributing signals

Choose a resource row to open the detail panel. For managed resources, the panel displays the resource configuration as JSON. For self-hosted resources, the panel displays the contributing signals that Security Hub used to detect the resource. These signals include the detection source and individual signal details, such as the SBOM components and supporting inference software for a model, or the DNS domain for an external endpoint.

Rolling up to the host resource

For a self-hosted AI resource, the detail panel displays the host resource where Security Hub detected the resource. To see all of the self-hosted AI resources on the same host, filter the table

by the host resource. With this view, you can drill up from an individual self-hosted resource to its host and review the adjacent AI resources on that host.

Considerations

The AI inventory has the following limitations at general availability:

- Self-hosted AI resources don't have findings in this release. Security Hub shows finding counts for managed AI resources only.
- Self-hosted AI detection is supported on Amazon EC2 instances and Amazon ECR images only. AWS Lambda functions and other compute types aren't supported.
- Security Hub doesn't attribute Amazon ECR images to a parent host in this release, so the host AI counts don't include them.
- Security Hub detects external endpoints from GuardDuty DNS activity on Amazon EC2 only. In this release, Security Hub doesn't attribute calls from AWS Fargate, AWS Lambda, Amazon SageMaker, Amazon EKS, or other service-managed compute.

Accessing the AI inventory with the API

You can retrieve AI inventory data programmatically with the GetResourcesV2 and GetResourcesStatisticsV2 operations.

For AI/ML resources, the `GetResourcesV2` response includes the `ResourceSubCategory` and `DiscoveryType` fields. The `DiscoveryType` field indicates whether a resource is `Managed` or `SelfHosted`. For self-hosted AI resources and their host resources, the response also includes `ResourceInfo` with an `AIDetails` structure.

Self-hosted AI resources use a `ResourceType` with the `SelfHosted::AI::` prefix. Supported types include the following:

- `SelfHosted::AI::Model`
- `SelfHosted::AI::Agent`
- `SelfHosted::AI::InferenceEndpoint`
- `SelfHosted::AI::ExternalEndpoint`

The `AIDetails` structure links a self-hosted AI resource to its host with the `HostResourceGuid` and `HostResourceType` fields. The `CanonicalId` field identifies what a resource is, independent

of where it's deployed, so that you can aggregate identical resources across multiple hosts. The canonical ID uses a `type/identifier` format:

- For ML models: `model/<purl>` (for example, `model/pkg:huggingface/meta-llama/llama-3-8b`)
- For inference endpoints and agents: a `type/asset-identifier-name` format
- For external endpoints: the normalized domain (for example, `api.*.openai.com`)

On a host resource, such as an Amazon EC2 instance, the `SelfHostedAI*ResourceCount` fields and the `SelfHostedTotalAIResourceCount` field contain the counts of the self-hosted AI resources detected on the host.

Note

When you use `GetResourcesV2` and filter by `ResourceSubCategory`, you must also include a `ResourceCategory` filter. Set the comparison to `EQUALS` and the value to `AI/ML`. This requirement also applies when you group by `ResourceSubCategory`, `ResourceInfo.AIDetails.HostResourceType`, or `ResourceInfo.AIDetails.CanonicalId` in `GetResourcesStatisticsV2`. Otherwise, the operation returns a `ValidationException`.
The following example shows a valid filter combination:

```
{
    "Filters": {
        "CompositeFilters": [
            {
                "Operator": "AND",
                "StringFilters": [
                    {
                        "FieldName": "ResourceCategory",
                        "Filter": {
                            "Comparison": "EQUALS",
                            "Value": "AI/ML"
                        }
                    },
                    {
                        "FieldName": "ResourceSubCategory",
                        "Filter": {
                            "Comparison": "EQUALS",
```

```
                            "Value": "Model"
                        }
                    }
                ]
            }
        ]
    }
}
```

Software bill of materials

A software bill of materials (SBOM) is a list of the software packages installed on a compute resource. AWS Security Hub builds an organization-wide SBOM inventory from the SBOMs that Amazon Inspector generates for the compute resources it scans. Security Hub keeps the inventory current as Amazon Inspector scans new and changed resources, so you don't need to export and reconcile SBOM files yourself.

The inventory covers the following types of compute resources, in AWS and in other cloud providers that you connect to Security Hub:

- **Virtual machines** – For example, Amazon Elastic Compute Cloud (Amazon EC2) instances and Microsoft Azure virtual machines.
- **Container images** – For example, Amazon Elastic Container Registry (Amazon ECR) container images and Azure Container Registry container images.
- **Serverless functions** – For example, AWS Lambda functions.

Use the SBOM inventory to find every resource that contains a specific package when a new vulnerability is disclosed, to understand what a resource does when you triage a finding on it, and to keep a current record of your software supply chain for compliance programs.

Administrator accounts can view software from all enabled accounts in their organization. Member accounts can view only the software on resources in their own account.

How the SBOM inventory works

When Amazon Inspector scans a supported resource, it generates an SBOM that lists the packages it found on that resource. Amazon Inspector sends each new SBOM to Security Hub, and Security

Hub stores the latest SBOM for each resource. When a resource is terminated, deleted, or leaves Amazon Inspector coverage, Security Hub removes its software from the inventory. Security Hub also reconciles the inventory against Amazon Inspector on a schedule so that the two stay in sync.

Security Hub organizes the inventory by package. A package is a single software component, such as `openssl` version `3.1.4`.

A package appears once in the inventory no matter how many resources it is installed on. The **Resources** count tells you how widely it is deployed. In the summary charts, Security Hub counts one installation for each resource a package is on, so the chart totals can be higher than the number of rows in the table. For example, `openssl 3.1.4` installed on three resources is one row in the table and three installations in the chart.

After Amazon Inspector generates a new SBOM, it can take a few hours for the change to appear in the SBOM inventory.

Prerequisites

The SBOM inventory requires no setup in Security Hub. It populates automatically when the following conditions are met:

- Security Hub is enabled in the AWS account and AWS Region.
- Amazon Inspector is enabled for the compute resource types that you want to inventory, such as Amazon EC2 instances, Amazon ECR container images, or Lambda functions. Security Hub shows software only for the resource types that Amazon Inspector scans. For example, if Amazon Inspector scans Amazon EC2 instances but not Lambda functions, the inventory contains software from your Amazon EC2 instances only. For resources in other cloud providers, Amazon Inspector scanning is set up when you connect the provider to Security Hub. For more information, see Integrating Security Hub with Microsoft Azure.

If Amazon Inspector isn't enabled, the SBOM page shows an **Amazon Inspector is not enabled** message with an **Enable Inspector** button that opens the Security Hub configuration settings. For more information about enabling Amazon Inspector through Security Hub, see Security Hub configuration catalog.

Viewing the SBOM page

The SBOM page lists every package in the inventory for the accounts you can view.

To open the SBOM page

1. Open the Security Hub console at https://console.aws.amazon.com/securityhub/.
2. In the navigation pane, under **Inventory**, choose **SBOM**.

The SBOM page shows the following information:

- **Distribution and footprint** – Two charts that summarize the inventory. **Packages by type** shows how installations are distributed across package types, with the total number of installations in the center. **Most common packages** shows the packages that are installed on the largest number of resources. Choose a chart value to filter the package table to that value.
- **Package table** – One row for each package and version, with the **Package**, **Version**, **Package type**, and **Resources** columns. The table is sorted by package name by default. Choose a column header to sort by that column.
- **Filters and grouping** – Filter the table by package, version, package type, account, Region, resource type, or cloud provider, and group it by package type, account, Region, or resource type. Quick filters show the most common values for each of these properties. You can save a set of filters as a filter set and reuse it later.

Pivoting between packages and resources

The SBOM inventory connects packages to the resources they are installed on, so you can move between the two views in either direction.

From the SBOM page, choose a package name or its **Resources** count to list the resources that contain that package. From that list, choose a resource to open its resource detail panel, where you can review the resource's criticality, its findings, and all of its installed software.

From the **Resources** page, or from any finding, open a compute resource and choose the **Installed software** tab to see every package installed on that resource, with its version and package type. You can filter the list to find a specific package.

Resources in Security Hub

Security Hub assigns a **criticality** level to each resource in your environment. Criticality indicates how important a resource is to your business, and it helps you prioritize security work. Criticality is one of `Very High`, `High`, `Medium`, `Low`, or `Unknown`.

How Security Hub infers criticality

By default, Security Hub **infers** criticality from signals on the resource:

- **Resource name** – Security Hub matches patterns in the resource name. For example, a resource with `pci` or `prod` in its name is treated as more critical than a resource named `sandbox`.
- **Tags** – Security Hub matches patterns in resource tags. For example, a resource tagged with `environment=production` is treated as more critical than one tagged `environment=dev`.

Overriding criticality with an automation rule

You can override the inferred criticality by creating an automation rule that sets criticality explicitly on resources that match the rule's criteria. An automation rule always takes precedence over inferred criticality. For more information, see Resource rule actions and criteria.

How criticality affects exposure finding severity

Security Hub uses resource criticality as an input when it calculates the impact and severity of an exposure finding. Resources with a criticality of `Unknown` do not influence exposure finding severity. For more information, see Impact.

Exposure findings in Security Hub

An exposure finding in Security Hub represents the correlation of multiple security signals that identify potential security risks in your AWS environment. Exposure findings help you understand and prioritize security risks. They automatically analyze combinations of vulnerabilities, configurations, threats, and resource relationships. An exposure finding includes traits and signals. A signal can include one or more types of exposure traits. Security Hub generates an exposure finding when signals from Security Hub CSPM, Amazon Inspector, GuardDuty, Macie, or other AWS services indicate the presence of an exposure. A resource can be the primary resource in, at most, one exposure finding. If a resource does not have any exposure traits or has insufficient traits, Security Hub does not generate an exposure finding for that resource.

How exposure findings work

Security Hub generates exposure findings by:

Analyzing signals from multiple AWS security services

Security Hub continuously collects and analyzes security signals from multiple AWS security services. It ingests findings from GuardDuty for threat detection, Amazon Inspector for vulnerability assessment, Security Hub CSPM for configuration checks, and Macie for sensitive data exposure. These signals are processed through advanced correlation engines to identify potential security risks.

Evaluating resource configurations and relationships

The system performs detailed evaluation of resource configurations against security best practices. It examines service-specific settings, compliance requirements, and security controls. This analysis helps identify misconfigurations that could lead to security vulnerabilities when combined with other factors.

Assessing network reachability

A crucial component of exposure findings is the assessment of network reachability. The system evaluates both internet exposure and internal network access paths. It analyzes security group configurations and network ACL settings to determine potential attack vectors. This analysis helps identify resources that might be inadvertently exposed to unauthorized access.

Correlating related security issues

The correlation engine maps relationships between AWS resources, analyzing how they interact and identifying potential security implications. It examines IAM permissions, roles, and resource access patterns to understand the broader security context. This process helps identify security risks that might exist due to the combination of seemingly innocent individual configurations.

Components of an exposure finding

Each exposure finding includes:

Title and description of the potential security risk

Each exposure finding includes a clear, descriptive title that immediately conveys the nature of the security risk. The description provides detailed information about the potential security impact, affected resources, and the broader context of the exposure. This information helps security teams quickly understand and assess the risk.

Severity classification (Critical, High, Medium, Low)

- **Critical severity** indicates immediate attention is required due to high likelihood of exploit and significant potential impact. These findings typically represent easily discoverable and exploitable vulnerabilities.
- **High severity** suggests priority attention is needed, with moderate to high exploit likelihood and substantial potential impact. These findings might be relatively easy to exploit but might require specific conditions.
- **Medium severity** indicates scheduled attention is required, with lower exploit likelihood and moderate potential impact. These findings typically require more complex exploitation methods.
- **Low severity** suggests routine attention is needed, with limited exploit potential and minor impact. These findings are typically difficult to exploit and present minimal risk.

Contributing traits that led to the exposure

Contributing traits represent the primary factors that led to the exposure finding. Contributing traits include the following:

- Direct security vulnerabilities
- Configuration issues
- Network exposure conditions
- Resource permission settings
- Resource criticality (the importance of a resource to the business)

Each trait provides specific details about how it contributes to the overall security risk.

Potential attack path and blast radius visualization

The potential attack path and blast radius visualization provides an interactive diagram showing how potential attackers could exploit the identified exposure. It maps resource relationships, network paths, and privilege escalation paths to downstream resources that are potentially accessible by an attacker if the exposure is exploited.

Detailed remediation guidance

Each exposure finding includes detailed remediation guidance with specific, actionable steps to address the identified risks. This guidance includes best practice recommendations, configuration correction steps, and prioritized action items. The guidance is tailored to the specific exposure scenario and considers the AWS services involved.

Resource configuration details

Configuration of the resource at the time the finding was created as well as current configuration of the resource in the Security Hub resource inventory dashboard.

Contextual traits providing additional security context

Contextual traits are additional security markers that were identified by Security Hub but were not used to create an exposure finding.

Unused access information from IAM Access Analyzer can appear as contextual traits in exposure findings. When an IAM role attached to a resource has unused permissions, Security Hub includes this information as a contextual trait in the exposure detail view. For example, if an Amazon EC2 instance has a software vulnerability and its attached IAM role has 47 unused permissions across 5 services, the exposure finding shows the unused permissions as supplementary context. This helps you understand the potential blast radius — a vulnerable resource with an over-privileged IAM role presents a higher risk than one with least-privilege permissions, because a compromised resource could use those unused permissions to escalate access.

The following resource types can display unused access contextual traits in their exposure findings:

- Amazon Elastic Compute Cloud instances
- AWS Lambda functions
- Amazon Elastic Container Service services
- Amazon Elastic Kubernetes Service clusters
- IAM users (directly)

Severity classification

Exposure findings are classified based on:

- Ease of discovery
- Ease of exploit
- Likelihood of exploit
- Public awareness
- Potential impact

- Primary resource criticality

For more information, see Exposure findings severity classification.

Benefits of exposure findings

- **Reduced manual analysis through automated correlation**: Exposure findings significantly reduce the time and effort required for security analysis through automated correlation and intelligent risk prioritization. Security Hub continuously monitors your AWS environment, automatically identifying and correlating security risks that might be missed through manual review.
- **Prioritized view of security risks**: Security Hub employs sophisticated risk assessment algorithms to prioritize exposures based on severity, impact, resource criticality, and exploit likelihood. This helps security teams focus their efforts on the most significant risks first, improving the efficiency of security operations.

Sources of exposure findings

Exposure findings incorporate data from:

- **Amazon GuardDuty integration** provides continuous threat detection capabilities within exposure findings. It monitors for malicious activities, potential account compromises, and behavioral anomalies. The system incorporates these threat findings into the broader exposure analysis, helping identify when threats combine with other security issues to create significant risks.
- **Amazon Inspector** contributes crucial vulnerability assessment data to exposure findings. It provides detailed information about network reachability, software vulnerabilities, and security best practice violations. This integration helps understand how vulnerabilities might be exploited through identified attack paths.
- **AWS Security Hub CSPM** ensures that configuration compliance and security standards are considered in exposure analysis. It evaluates resources against established security controls and best practices, providing a foundation for understanding configuration-based risks.
- **Amazon Macie** enhances exposure findings with sensitive data discovery and classification capabilities. It identifies where sensitive data exists within your AWS environment and evaluates potential privacy risks, helping understand the potential impact of identified exposures.

Best practices

- **Regularly review exposure findings**: Effective exposure management requires structured review processes. Organizations should implement daily reviews of critical exposures, weekly assessments of overall exposure status, monthly trend analysis, and quarterly security posture evaluations. This layered approach ensures appropriate attention to both immediate risks and long-term security trends.
- **Prioritize critical and high-severity exposures**: Successful exposure management depends on effective risk prioritization. Organizations should focus first on critical exposures while considering resource criticality and business impact. This risk-based approach helps ensure security efforts align with business priorities and maximize risk reduction.
- **Implement recommended remediation steps**: Exposure remediation should follow a systematic approach. Organizations should carefully implement recommended remediation steps, maintain detailed documentation of changes, conduct thorough testing of modifications, and validate the effectiveness of implemented fixes. This methodical approach helps ensure successful risk mitigation while avoiding unintended consequences.
- **Configure automated response rules**: Maximizing the value of exposure findings requires effective automation. Organizations should implement automated response rules, configure appropriate notifications, establish efficient workflows, and maintain comprehensive audit trails. This automation helps ensure consistent and timely response to identified exposures while reducing manual effort.

Supported resource types for exposure findings in Security Hub

AWS Security Hub generates exposure findings for the following types of AWS resources:

- `AWS::DynamoDB::Table`
- `AWS::EC2::Instance`
- `AWS::ECS::Service`
- `AWS::EKS::Cluster`
- `AWS::IAM::User`
- `AWS::Lambda::Function`
- `AWS::RDS::DBInstance`
- `AWS::S3::Bucket`

- `AWS::SageMaker::NotebookInstance`

If you have an Azure connector, Security Hub also generates exposure findings for the following types of Azure resources:

- `microsoft.app/containerapps`
- `microsoft.compute/virtualmachines`
- `microsoft.containerservice/managedclusters`
- `microsoft.documentdb/databaseaccounts`
- `microsoft.graph/user`
- `microsoft.sql/servers/databases`
- `microsoft.storage/storageaccounts/blobservices/containers`
- `microsoft.web/sites`

Security Hub generates one exposure finding per primary resource. If a resource does not have any exposure traits or has insufficient traits, Security Hub does not generate an exposure finding for that resource.

Supported trait types in Security Hub

AWS Security Hub generates an exposure finding when AWS Security Hub CSPM control findings and findings generated by other supported AWS services, such as Amazon Inspector, contain exposure traits for a resource. The following table provides information about the supported trait types.

Trait type	Description	Source	Impacted resources
Assumability	Indicates a resource with vended AWS Identity and Access Management permissions	Resource configuration from AWS Config	AWS resources with associated AWS Identity and Access Management roles

Trait type	Description	Source	Impacted resources
Impact	Indicates the potential blast radius if the resource is compromised, based on the effective permissions of associated AWS Identity and Access Management principals, including the ability to create and modify resources, the criticality of downstream resources, and the criticality of the primary resource.	• Effective permissions analysis of associated AWS Identity and Access Management principals. • Criticality of resources accessible by a given AWS Identity and Access Management principal. Criticality can be set by automation rules, or it will be inferred based on the name and tags of the resource.	AWS resources with associated AWS Identity and Access Management identities

Trait type	Description	Source	Impacted resources
Misconfiguration	Indicates a misconfigured resource	AWS Security Hub CSPM control findings, Amazon GuardDuty threat findings, and information about resource confirmation in AWS Config.	All resource types
Reachability	Indicates open network paths to a resource	AWS Security Hub CSPM control findings, Amazon GuardDuty threat findings, and Amazon Inspector network reachability findings.	Amazon EC2 instances, Amazon EKS clusters, Lambda functions, and Amazon S3 buckets
Sensitive Data	Indicates that a resource contains sensitive data	Macie sensitive data findings	Amazon S3 buckets

Trait type	Description	Source	Impacted resources
Vulnerability	Indicates that a resource has a weakness which could be exploited by a threat source.	Amazon Inspector package vulnerability findings and Amazon GuardDuty Amazon EC2 Malware findings.	Amazon EC2 instances, Amazon ECS services, Amazon EKS clusters, and Lambda functions
Criticality	Indicates the importance of a resource to the business	Assigned via automation rules. If criticality isn't set by an automation rule, Security Hub infers it from the resource name and tags. For more information, see Resources in Security Hub.	All resource types

Each trait can be associated with multiple titles that provide details about the exposure affecting the resource. For example, you might see an **Exploit Available** title for the **Vulnerability** trait in the details for an EC2 exposure finding.

Impact and effective permissions

The **Impact** trait describes the potential blast radius of an exposure — the downstream resources an attacker could reach and compromise if the primary resource in the exposure finding is compromised. To determine impact, Security Hub analyzes the *effective permissions* of the AWS

Identity and Access Management (IAM) principals associated with the resource, as well as the criticality of the resources.

Effective permissions are the permissions a principal actually has after Security Hub evaluates its identity-based policies together with the resource-based policies of the resources it can access, and any AWS Organizations service control policies (SCPs) and resource control policies (RCPs) that apply to the account. Because effective permissions account for what a principal is granted, what target resources allow, and the organization-level guardrails that constrain the account, they more accurately reflect the actions a principal can perform than the identity-based policies alone.

Using effective permissions, Security Hub traces the privilege escalation paths from the primary resource to other resources in your environment. Each path is a chain of resources connected by the permissions that allow an attacker to move from one resource to the next. When Security Hub identifies a concrete path to an existing resource, it surfaces that path as part of the **Impact** trait. Impact also accounts for permissions beyond these paths, such as the ability to invoke AWS services that can create or modify other resources and the criticality of the primary resource. You can review these paths in the potential attack path graph and reduce your blast radius by removing unnecessary permissions. For more information, see Viewing exposures in Security Hub with the potential attack path graph.

Generating exposure findings

Security Hub generates exposure findings in near real-time. As new security findings are ingested and existing findings are updated, Security Hub generates or updates exposure findings in near real time. Security Hub generates one exposure finding per resource ID.

Security Hub does not publish exposure findings for resource types not supported by exposure findings. When a resource has a significant number and combination of traits, Security Hub generates an exposure finding. The number and combination of traits also determine the severity level of the exposure finding.

Sample exposure finding

AWS Security Hub normalizes exposure findings in the Open Cybersecurity Schema Framework (OCSF).

Sample exposure finding

In the following sample exposure finding, the `related_events` parameter contains details unique to the exposure finding, such as contributing findings. Contributing findings are the traits

and signals associated with an exposure finding. A single contributing finding can include one or more traits. The `observables` parameter identifies the resource associated with the contributing finding. This can be different from the `resources` parameter, which identifies the resource associated with the exposure finding.

Determining the severity level of an exposure finding

AWS Security Hub assigns each exposure finding a default severity of `CRITICAL`, `HIGH`, `MEDIUM`, or `LOW`. Exposure findings with a severity of `INFORMATIONAL` are not published. Security Hub determines the severity of an exposure finding by combining two dimensions, **likelihood** and **impact**, on a risk matrix. Likelihood reflects how easily the exposure can be exploited, and impact reflects the magnitude of harm if it is exploited.

In cases where impact cannot be determined for a resource, the severity is based purely on likelihood.

Risk matrix

The following table shows how likelihood and impact combine to produce the final severity of an exposure finding. Likelihood establishes a baseline severity, and impact adjusts it: high impact increases severity by one level (capped at `CRITICAL`), medium impact leaves severity unchanged, and low impact decreases severity by one level (floored at `INFORMATIONAL`). Impact only adjusts the severity that likelihood establishes. Impact alone doesn't generate an exposure finding.

Severity risk matrix

Likelihood ↓ / Impact →	Low	Medium	High
Very High	HIGH	CRITICAL	CRITICAL
High	MEDIUM	HIGH	CRITICAL
Moderate	LOW	MEDIUM	HIGH
Low	INFORMATIONAL	LOW	MEDIUM

> **Note**
>
> Low likelihood combined with low impact results in a severity of `INFORMATIONAL`. Security Hub doesn't publish exposure findings with this severity, so they don't appear on the **Exposures** page or in GetFindingsV2 results.

Likelihood

Likelihood measures how easily an exposure can be exploited, based on the contributing traits present on the resource, such as **Assumability**, **Misconfiguration**, **Reachability**, **Sensitive Data**, and **Vulnerability**. Security Hub uses several characteristics to assess likelihood, including the following:

- **Awareness** – The extent at which the exposure is not theoretical, but has publicly available or automated exploits.
- **Ease of discovery** – Whether automated tools, such as a port scan or internet search, are available to discover the resource at risk.
- **Ease of exploit** – The ease at which a threat actor can exploit the exposure. For example, if open network paths or misconfigured metadata exists, a threat actor can more easily exploit the exposure.
- **Likelihood of exploit** – The likelihood the exposure will be exploited in the next 30 days. This factor corresponds to the Exploit Prediction Scoring System (EPSS).

Impact

Impact measures the magnitude of harm to your environment if the exposure is exploited. For example, an exposure could lead to loss of accountability, loss of availability, loss of confidentiality from data exposure, or loss of integrity from data corruption.

To assess impact, Security Hub analyzes the effective permissions of the AWS Identity and Access Management principals associated with the resource to determine the actions and AWS services an attacker could invoke. It also identifies the existing resources an attacker could reach and compromise through privilege escalation. For more information, see Impact and effective permissions.

Reviewing exposure findings

You can review all of your exposure findings in the Security Hub console and with the GetFindingsV2 API. The **Exposures** page in the Security Hub console shows all active exposure findings. Exposure findings are listed by decreasing severity. You can filter your exposure findings by adding and removing filters with the **Add filter** search bar. You can group your exposure findings with the **Group by** dropdown. You can also filter your exposure findings with the **Quick filters** menu.

Details for exposure findings

You can view many details for an exposure finding. These details are divided among tabs in the Security Hub console. The **Overview** tab provides key details about the exposure finding. The **Traits** tab lists the traits and signals associated with an exposure finding. The **Resources** tab provides details about the resource and resource tags associated with an exposure finding. The following list provides descriptions for exposure finding details.

- **Finding title** – The title of the exposure finding.
- **Severity level** – The severity level of the exposure finding. Security Hub uses the number and combination of traits for a resource to determine the severity level of an exposure finding. The severity level can be `CRITICAL`, `HIGH`, `MEDIUM`, or `LOW`. Security Hub does not publish exposure findings with a severity of `INFORMATIONAL`. You can update the `Severity` through the Security Hub console or with the BatchUpdateFindingsV2 API operation.
- **Description** – The description of the exposure finding.
- **Type** – The name of the exposure finding type. For example, the name might resemble `Exposure/Potential Impact/Resource Hijacking`.
- **Account** – The ID of the AWS account where the exposure finding was generated.
- **Age** – Indicates how long the exposure finding has been active.
- **Created time** – A timestamp that indicates when the exposure finding was created.
- **Modified time** – A timestamp that indicates when the exposure finding was last updated.
- **Region** – The AWS Region where the exposure finding was generated.
- **Product name** – The name of the product that generated the exposure finding. This will always be **Security Hub Exposure Detection**.
- **Company name** – The name of the company that generated the exposure finding. This will always be **AWS**.
- **Activity name** – The name of the activity last performed against the finding.
- **Status** – The status of this exposure finding.
- **Finding ID** – A unique identifier associated with the exposure finding.
- **Potential attack path (console only)** – An interactive visualization showing how potential attackers can access and take control of resources associated with an exposure finding. For more information, see Viewing exposures in Security Hub with the potential attack path graph.

- **Traits** – Identifies trait types and trait titles associated with the exposure finding. In the Security Hub console, you can view traits by trait type or signal. This helps you analyze contributing findings in the context of the related exposure.
- **Remediation** – Links to remediation documentation specific to traits identified in the exposure.
- **Resources** – Identifies the resource associated with the exposure finding.

Reviewing details for exposure findings

This topic describes how to review details about exposure findings in the AWS Security Hub console and with the API.

Reviewing details for an exposure finding in the Security Hub console

To view details for an exposure finding in the Security Hub console

1. Sign in using your credentials, and open the Security Hub console at https://console.aws.amazon.com/securityhub/v2/home.
2. From the navigation pane, choose **Exposures**.
3. Choose an exposure finding that you want to view details.

Reviewing details for an exposure finding with the API

You can review exposure findings with the GetFindingsV2 API or with the AWS CLI. You can filter all exposure findings with the `metadata.product.feature.uid` field with the `security-hub/Exposure` value. For more information, see GetFindingsV2.

Example command

The following is an AWS CLI example that retrieves the 10 most recently generated exposure findings in your account. This example is formatted for Linux, macOS, or Unix, and it uses the backslash (\) line-continuation character to improve readability.

```
aws securityhub get-findings-v2 \
--max-results '10' \
--filter '{"CompositeFilters": [{"StringFilters":
 [{"FieldName":"metadata.product.feature.uid","Filter": {"Value":"security-hub/
Exposure","Comparison":"EQUALS"}} ]}]}'
```

Viewing exposures in Security Hub with the potential attack path graph

The potential attack path graph is an interactive visualization that shows how potential attackers can access and take control of resources associated with an exposure finding. You can access this graph only in the Security Hub console from the **Exposures** page. When you view details for an exposure finding, the **Overview** tab includes a section called **Potential attack path and Blast radius**.

The attack path graph shows the primary resource where the exposure was generated, the network path (if applicable), and the downstream resources that an attacker could reach by escalating permissions. When Security Hub identifies concrete privilege escalation paths from the primary resource to other resources in your environment, it displays them as the blast radius portion of the graph. Each node represents a resource, and the connections between nodes show the permissions that enable an attacker to move from one resource to the next.

In this section of the **Overview** tab, you can choose and drag AWS resources in the potential attack path graph. You can focus on specific areas of the attack path graph with the zoom-in and zoom-out icons. You can expand the attack path graph in and out of fullscreen mode through the fullscreen icon. The legend codes the primary resource, involved resource, blast radius resources, and contributing trait count by color and shows the trait categories and number of traits in the attack path graph. You can view details for a resource by choosing a resource and choosing **View resource details**. You can also copy the ID and AWS account number associated with a resource. Exposure findings with a reachability trait show the public internet and collapsed network path in the attack path graph. You can view this detail by choosing the collapsed network path node.

To view the downstream resources and the privilege escalation paths that connect them, choose the **Impact assessment** tab. Each path shows the chain of resources an attacker could traverse and the specific permissions at each step. For more information about impact traits and effective permissions, see Impact and effective permissions.

Remediating exposure findings

The topics in this section describe remediation steps for exposure findings across different AWS services.

The `Remediation` field of the OCSF format contains two fields: `remediation` and `references`.

```
"Remediation": {
    "Recommendation": {
        "remediation":{"desc":"String",
```

```
        "references":["string array"]}
    }
},
```

> **Note**
>
> The remediation guidance provided in the following sections might require additional consultation in other AWS resources.

Remediating exposures for DynamoDB tables

AWS Security Hub can generate exposure findings for DynamoDB tables.

On the Security Hub console, the DynamoDB table involved in an exposure finding and its identifying information are listed in the **Resources** section of the finding details. Programmatically, you can retrieve resource details with the GetFindingsV2 operation of the Security Hub CSPM API.

After identifying the resource involved in an exposure finding, you can delete the resource if you don't need it. Deleting a nonessential resource can reduce your exposure profile and AWS costs. If the resource is essential, follow these recommended remediation steps to help mitigate the risk. The remediation topics are divided based on the type of trait.

A single exposure finding contains issues identified in multiple remediation topics. Conversely, you can address an exposure finding and bring down its severity level by addressing just one remediation topic. Your approach to risk remediation depends on your organizational requirements and workloads.

> **Note**
>
> The remediation guidance provided in this topic might require additional consultation in other AWS resources.

Contents

- Misconfiguration traits in DynamoDB
  - The DynamoDB table has point-in-time recovery disabled
  - The DynamoDB table is not covered by a backup plan
  - The DynamoDB table has deletion protection disabled

Misconfiguration traits in DynamoDB

The following describes the misconfiguration traits and remediation steps for DynamoDB tables.

The DynamoDB table has point-in-time recovery disabled

Remediation: Enable DynamoDB point-in-time recovery

DynamoDB point-in-time recovery provides continuous automated backups for your DynamoDB table data. For information about how to restore a DynamoDB table to a point in time, see Restoring a DynamoDB table to a point in time in the *Amazon DynamoDB Developer Guide*.

The DynamoDB table is not covered by a backup plan

AWS Backup provides a centralized service to configure, manage, and automate backups across AWS services, including DynamoDB. Without a backup plan, your table lacks scheduled, automated backups with customizable retention periods, creating significant security risks. An attacker could maliciously corrupt or delete your table data. Without proper backups, you may have no recovery option beyond the Point-in-Time Recovery window (if enabled), potentially resulting in permanent data loss. Following data protection best practices, cover your DynamoDB tables with a backup plan.

Remediation: Create a backup plan

Before creating a backup plan, determine an appropriate backup frequency and retention periods for your data. For information about how to create a backup plan, see Assign resources to a backup plan in the *AWS Backup Developer Guide*.

The DynamoDB table has deletion protection disabled

Deletion protection prevents the accidental deletion of DynamoDB tables. When deletion protection is disabled, DynamoDB tables are vulnerable to unintended deletion through console actions, API calls, CLI commands, or automated processes. This can expose your AWS environment to data loss, as an unauthorized entity with access to your AWS environment could intentionally delete tables, resulting in service disruption and permanent data loss. Following data protection best practices, enable data protection for DynamoDB tables.

Remediation: Enable deletion protection

If you manage multiple tables, consider using CloudFormation to update table properties in bulk. You can modify your CloudFormation templates to include `DeletionProtectionEnabled`

property and update your stacks. After completing remediation, verify deletion protection is enabled in the **Additional** info dropdown in the table **Settings** tab.

Remediating exposures for EC2 instances

AWS Security Hub can generate exposure findings for Amazon Elastic Compute Cloud (EC2) instances.

On the Security Hub console, the EC2 instance involved in an exposure finding and its identifying information are listed in the **Resources** section of the finding details. Programmatically, you can retrieve resource details with the GetFindingsV2 operation of the Security Hub CSPM API.

After identifying the resource involved in an exposure finding, you can delete the resource if you don't need it. Deleting a nonessential resource can reduce your exposure profile and AWS costs. If the resource is essential, follow these recommended remediation steps to help mitigate the risk. The remediation topics are divided based on the type of trait.

A single exposure finding contains issues identified in multiple remediation topics. Conversely, you can address an exposure finding and bring down its severity level by addressing just one remediation topic. Your approach to risk remediation depends on your organizational requirements and workloads.

> **Note**
>
> The remediation guidance provided in this topic might require additional consultation in other AWS resources.

Contents

- Misconfiguration traits for EC2 instances
  - The EC2 instance allows access to IMDS using version 1
  - The Amazon EC2 instance has a security group or network ACL that allows SSH or RDP access
  - The Amazon EC2 instance has an open security group
- Reachability traits for EC2 instances
  - The EC2 instance is reachable over the internet
- Vulnerability traits for EC2 instances
  - The Amazon EC2 instance has software vulnerabilities which are notable

- EC2 instance has network-exploitable software vulnerabilities with a high likelihood of exploitation
- The Amazon EC2 instance has software vulnerabilities
- The EC2 instance has an End-Of-Life operating system
- The EC2 instance has malicious software packages
- The EC2 instance has malicious files
- Impact traits for EC2 instances
  - Has full control privileged executor path
  - Has direct policy escalation path
  - Has trust policy hijack path
  - Has data ransomware path

  - Business criticality

Misconfiguration traits for EC2 instances

Here are misconfiguration traits for EC2 instances and suggested remediation steps.

The EC2 instance allows access to IMDS using version 1

Instance metadata is data about your Amazon EC2 instance that applications can use to configure or manage the running instance. The instance metadata service (IMDS) is an on-instance

component that code on the instance uses to securely access instance metadata. If IMDS is not properly secured, it can become a potential attack vector, as it provides access to temporary credentials and other sensitive configuration data. IMDSv2 provides stronger protection against exploitation through session-oriented authentication, requiring a session token for metadata requests and limiting session duration. Following standard security principles, configure Amazon EC2 instances to use IMDSv2 and disable IMDSv1.

Remediation

Take one or more of the following actions to address this exposure:

Test application compatibility

Before implementing IMDSv2, test your instance to ensure its compatibility with IMDSv2. Some applications or scripts may require IMDSv1 for core functionality and require additional configuration. For more information about tools and recommended paths for testing application compatibility, Transition to using Instance Metadata Service Version 2 in the *Amazon Elastic Compute Cloud User Guide*.

Update instance to use IMDSv2

Modify existing instances to use IMDSv2. For more information, see Modify instance metadata options for existing instances in the *Amazon Elastic Compute Cloud User Guide*.

Apply updates to instances in an Auto Scaling group

If your instance is part of an Auto Scaling group, update your launch template or launch configuration with a new configuration, and perform an instance refresh.

The Amazon EC2 instance has a security group or network ACL that allows SSH or RDP access

Remote access protocols like SSH and RDP allow users to connect to and manage Amazon EC2 instances from external locations. When security groups permit unrestricted access to these protocols from the internet, they increase the attack surface of your Amazon EC2 instances by allowing internet access to your instance. Following standard security principles, limit remote access to specific, trusted IP addresses or ranges.

Remediation: Modify security group rules

Restrict access to your Amazon EC2 instances to specific trusted IP addresses. Limit SSH and RDP access to specific trusted IP addresses, or use CIDR notation to specify IP ranges (for example,

192.168.1.0/24). To modify security group rules, see Configure security group rules in the *Amazon Elastic Compute Cloud User Guide*.

The Amazon EC2 instance has an open security group

Security groups act as virtual firewalls for your Amazon EC2 instances to control inbound and outbound traffic. Open security groups, which allow unrestricted access from any IP address, may expose your instances to unauthorized access. Following standard security principles, restrict security group access to specific IP addresses and ports.

Remediation

Take one or more of the following actions to address this exposure:

Review security group rules and assess current configuration

Evaluate which ports are open and accessible from broad IP ranges, such as `(0.0.0.0/0 or ::/0)`. For instructions on viewing security group details, see DescribeSecurityGroups in the *Porting Assistant for .NET API Reference*.

Modify security group rules

Modify your security group rules to restrict access to specific trusted IP addresses or ranges. When updating your security group rules, consider separating access requirements for different network segments by creating rules for each required source IP range or restricting access to specific ports. To modify security group rules, see Configure security group rules in the *Amazon EC2 User Guide*.

Reachability traits for EC2 instances

Here are reachability traits for EC2 instances and suggested remediation steps.

The EC2 instance is reachable over the internet

Amazon EC2 instances with ports that are reachable from the internet may expose your instance. Reachability can occur through an internet gateway (including instances behind Application Load Balancers or Classic Load Balancers), a VPC peering connection, or a VPN virtual gateway. Following standard security principles, implement least-privilege network access controls by restricting inbound traffic to only necessary sources and ports.

Remediation

Take one or more of the following actions to address this exposure:

Modify or remove security group rules

In the **Resources** tab, open the resource for the Amazon EC2 Security Group. Review whether internet access is required for the instance to function. Modify or remove inbound security group rules that allow unrestricted access (`0.0.0.0/0` or `::/0`). Implement more restrictive rules based on specific IP ranges or security groups. If limited public access is necessary, restrict access to specific ports and protocols required for the instance's function. For instructions on managing security group rules, see Configure security group rules in the *Amazon EC2 User Guide*.

Update network ACLs

Review and modify network access control lists (ACLs) associated with the instance's subnet. Verify that the ACL settings align with the security group changes and do not unintentionally allow public access. For instructions on modifying network ACLs, see Work with network ACLs in the *Amazon VPC User Guide*.

Alternative access methods

Consider the following options for alternative access methods:

- **Use NAT Gateway for outbound internet connectivity** – For instances in private subnets that require access to the internet (for example, to download updates), consider using a NAT Gateway instead of assigning a public IP address. A NAT Gateway allows instances in private subnets to initiate outbound connections to the internet while preventing inbound connections from the internet.
- **Use Systems Manager Session Manager** – Session Manager provides secure shell access to your Amazon EC2 instances without the need for inbound ports, managing SSH keys, or maintaining bastion hosts.
- **Use WAF and Elastic Load Balancing or Application Load Balancer** – For instances that are running web applications, consider using an LB combined with AWS Web Application Firewall (WAF). LBs can be configured to allow your instances to run in private subnets while the LB runs in a public subnet and handles internet traffic. Adding a WAF to your load balancer provides additional protection against web exploits and bots.

Vulnerability traits for EC2 instances

Here are vulnerability traits for EC2 instances and suggested remediation steps.

The Amazon EC2 instance has software vulnerabilities which are notable

A *notable vulnerability* is a Common Vulnerabilities and Exposures (CVE) entry that Security Hub tracks on a curated list because of active exploitation in the wild or significant potential impact. Security Hub prioritizes these CVEs regardless of their CVSS score, so a notable vulnerability on this resource represents an immediate security threat. Patch these vulnerabilities first.

The curated list currently includes the following vulnerabilities in the PHP runtime. With either vulnerability, a remote, unauthenticated party can run code on the server through a crafted multipart request. Both affect PHP versions 5.4 through 8.5, regardless of the application code that runs on them:

- `CVE-2026-109618`: PHP can corrupt its memory state when it runs out of memory as it processes a crafted multipart request.
- `CVE-2026-109619`: The issue is in the session upload progress feature (`session.upload_progress`), which PHP turns on by default.

PHP versions 8.5.12, 8.4.27, 8.3.36, and 8.2.35 address these issues. PHP 8.1 and earlier have no update, so migrate those workloads to a supported PHP branch. For more information about these issues, see AWS Security Bulletin 2026-143 on the AWS website.

Remediation: Update affected instances

Review the **References** section in the **Vulnerability** tab of the trait, and follow the remediation advice in the finding. Use Systems Manager Patch Manager to update the affected package on the instance, or update the application to a version that is not affected. If the instance is part of an Auto Scaling group, update the AMI that the group uses so that new instances are not affected. For more information about patching instances in an Auto Scaling group, see AMI updates patching (using patched AMIs for Auto Scaling groups).

Distribution packages can include the fix under an older version number, so check the package changelog for the CVE IDs. After you update, restart the web server and PHP processes, such as Apache and PHP-FPM, so that the update takes effect.

EC2 instance has network-exploitable software vulnerabilities with a high likelihood of exploitation

Software packages that are installed on EC2 instances can be exposed to Common Vulnerabilities and Exposures (CVEs). Critical CVEs pose significant security risks to your AWS environment.

Unauthorized principals can exploit these unpatched vulnerabilities to compromise the confidentiality, integrity, or availability of data, or to access other systems. Critical vulnerabilities with high exploitation likelihood represent immediate security threats, as exploit code may already be publicly available and actively used by attackers or automated scanning tools. Patch these vulnerabilities to protect your instance.

Remediation: Update affected instances

Review the **References** section in the **Vulnerability** tab of the trait. Vendor documentation may include specific remediation guidance. Follow the appropriate remediation using these general guidelines:

Use Systems Manager Patch Manager to apply patches for both operating systems and applications. Patch Manager helps you select and deploy operating system and software patches automatically on large groups of instances. If you do not have Patch Manager configured, manually update the operating system on each affected instance.

Update the affected applications to their latest secure versions following the vendor's recommended procedures. To manage application updates across multiple instances, consider using Systems Manager State Manager to keep your software in a consistent state. If updates are not available, consider removing or disabling the vulnerable application until a patch is released or other mitigations, such as restricting network access to the application or disabling vulnerable features.

Follow the specific remediation advice provided in the Amazon Inspector finding. This could involve changing security group rules, modifying instance configurations, or adjusting application settings.

Check if the instance is part of Auto Scaling Group. AMI-replacement patching is done on immutable infrastructures by updating the AMI ID that is configured to deploy new Amazon EC2 instances in an Auto Scaling group. If you are using a custom/golden AMI, create an instance with the new AMI, and then customize the instance and create a new golden AMI For more information, see AMI updates patching (using patched AMIs for Auto Scaling groups).

Future considerations

To prevent future occurrences, consider implementing a vulnerability management program. Amazon Inspector can be configured to automatically scan for CVEs on your instances. Amazon Inspector can also be integrated with Security Hub for automatic remediations. Consider implementing a regular patching schedule using Systems Manager Maintenance Windows to minimize disruption to your instances.

The Amazon EC2 instance has software vulnerabilities

Software packages that are installed on Amazon EC2 instances can be exposed to Common Vulnerabilities and Exposures (CVEs). Noncritical CVEs represent security weaknesses with lower severity or exploitability compared to critical CVEs. While these vulnerabilities pose less immediate risk, attackers can still exploit these unpatched vulnerabilities to compromise the confidentiality, integrity, or availability of data, or to access other systems. Following security best practices, patch these vulnerabilities to protect your instance from attack.

Remediation: Update affected instances

Use AWS Systems Manager Patch Manager to apply patches for operating systems. Patch Manager helps you select and deploy operating system and software patches automatically on large groups of instances. If you do not have Patch Manager configured, manually update the operating system on each affected instance.

Update the affected applications to their latest secure versions following the vendor's recommended procedures. To manage application updates across multiple instances, consider using AWS Systems Manager State Manager to keep your software in a consistent state. If updates are not available, consider removing or disabling the vulnerable application until a patch is released or other mitigations, such as restricting network access to the application or disabling vulnerable features.

Follow the specific remediation advice provided in the Amazon Inspector finding. This could involve changing security group rules, modifying instance configurations, or adjusting application setting.

Check if the instance is part of Auto Scaling Group. AMI-replacement patching is done on immutable infrastructures by updating the AMI ID that is configured to deploy new Amazon EC2 instances in an Auto Scaling group. If you are using a custom/golden AMI, create an instance with the new AMI, and then customize the instance and create a new golden AMI For more information, see AMI updates patching (using patched AMIs for Auto Scaling groups).

Future considerations

To prevent future occurrences, consider implementing a vulnerability management program. Amazon Inspector can be configured to automatically scan for CVEs on your instances. Amazon Inspector can also be integrated with Security Hub for automatic remediations. Consider implementing a regular patching schedule using Systems Manager Maintenance Windows to minimize disruption to your instances.

The EC2 instance has an End-Of-Life operating system

The EC2 instance runs an end-of-life operating system that is no longer supported or maintained by the original developer. This exposes the instance to security vulnerabilities and potential attacks. When operating systems reach end-of-life, vendors typically stop releasing new security advisories. Existing security advisories may also be removed from vendor feeds. As a result, Amazon Inspector could potentially stop generating findings for known CVEs, creating further gaps in security coverage.

See Discontinued operating systems in the *Amazon Inspector User Guide* for information about operating systems that have reached end of life that can be detected by Amazon Inspector.

Remediation: Update to a supported operating system version

Update to a supported version of the operating system. In the exposure finding, open the resource to access the affected resource. Before updating the operating system version on your instance, create a snapshot or AMI backup in case you need to roll back. Then, review available versions in Supported Operating Systems in the *Amazon Inspector User Guide* for a list of currently supported OS versions.

The EC2 instance has malicious software packages

Malicious packages are software components that contain harmful code designed to compromise the confidentiality, integrity, and availability of your systems and data. Malicious packages pose an active and critical threat to your instance, as attackers can execute malicious code automatically without exploiting a vulnerability. Following security best practices, remove malicious packages to protect your instance from potential attacks.

Remediation: Remove malicious packages

Review the malicious package details in the **References** section of the **Vulnerability** tab of the trait to understand the threat. Remove the identified malicious packages using the appropriate package manager. See Package management tool in the *Amazon Linux 2023 User Guide* for an example. After removing the malicious packages, consider performing a scan to ensure that all packages that may have been installed by the malicious code have been removed. For more information, see Starting On-demand malware scan in GuardDuty in the .

The EC2 instance has malicious files

Malicious files contain harmful code designed to compromise the confidentiality, integrity, and availability of your systems and data. Malicious files pose an active and critical threat to your

instance, as attackers can execute malicious code automatically without exploiting a vulnerability. Following security best practices, remove malicious files to protect your instance from potential attacks.

Remediation: Remove malicious files

To identify the specific Amazon Elastic Block Store (Amazon EBS) volume that has malicious files, review the **Resources** section of the trait's finding details. After you have identified the volume with the malicious file, create a snapshot of the volume before making changes, then remove the identified malicious files. After removing the malicious files, consider performing a scan to ensure that all files that may have been installed by the malicious file have been removed. For more information, see Starting On-demand malware scan in GuardDuty in the .

Impact traits for EC2 instances

Impact traits describe the potential blast radius of an exposure. Security Hub analyzes the effective permissions of the AWS Identity and Access Management principal associated with the EC2 instance to determine the downstream resources an attacker could reach if the instance is compromised, as well as the business criticality of those resources. Each impact trait identifies a specific privilege escalation pattern. To reduce your blast radius, review the permission paths described in each trait and remove any unnecessary privileges.

Following standard security principles, grant least privilege by providing only the permissions required to perform a task. Replace broad policies with scoped-down policies that grant only the specific actions and resources needed. To identify unused permissions to remove, use IAM Access Analyzer to generate recommendations based on access history. For more information, see Findings for external and unused access and Apply least-privilege permissions in the *IAM User Guide*.

Has full control privileged executor path

The associated principal can pass a role to and inject code into a compute resource that already has elevated permissions. This allows the principal to gain full control over the executor and perform any action that the executor's role permits.

Has direct policy escalation path

The associated principal can directly modify IAM policies to grant itself additional permissions, escalating its own privileges without intermediate resources.

Has trust policy hijack path

The associated principal can modify the trust policy of an IAM role to allow itself to assume that role, gaining the role's permissions.

Has data ransomware path

The associated principal can encrypt or delete data in a way that could be used for ransomware, such as encrypting Amazon S3 objects with a customer-managed AWS KMS key and then modifying the key policy.

Has remove restriction path

The associated principal can remove security restrictions such as permission boundaries, service control policies, or resource-based policy deny statements, expanding what other principals or the resource itself can do.

Has pass role create executor path

The associated principal can create a new compute resource (such as a Lambda function or Amazon EC2 instance) and pass it a privileged role, effectively laundering its own permissions through the new resource.

Has swap role existing executor path

The associated principal can change the IAM role attached to an existing compute resource, replacing it with a more privileged role to escalate access.

Has role chain escalation path

The associated principal can assume a sequence of roles, where each role in the chain has progressively broader permissions, ultimately reaching a highly privileged role.

Has inject code privileged executor path

The associated principal can inject code into a running compute resource that has elevated permissions, executing arbitrary operations under that resource's privileged role.

Has disable audit trail path

The associated principal can disable logging or monitoring services such as CloudTrail, effectively covering its tracks during or after an escalation.

Has access existing executor path

The associated principal can invoke or connect to an existing compute resource and use its attached role to perform privileged actions.

Has credential minting path

The associated principal can create new long-term credentials (such as access keys or login profiles) for other principals, establishing persistent access paths that survive password rotations or session expirations.

Has pass role data access path

The associated principal can create a service resource and pass it a role that has access to sensitive data, gaining indirect access to that data through the new resource.

Has pass role task hijack path

The associated principal can pass a role to a scheduled or event-driven task (such as a Lambda function triggered by an event), allowing it to execute arbitrary code with that role's permissions.

Has single hop data access path

The associated principal can directly access sensitive data resources (such as Amazon S3 buckets or DynamoDB tables) through its existing permissions, without needing intermediate escalation steps.

Has capability advancing path

The associated principal has a privilege escalation path that advances its overall capabilities beyond what its directly assigned permissions would suggest. This is a general classification for paths that do not match a more specific pattern.

Business criticality

The business criticality of the primary resource, set either by automation rules or by inference from the name and tags.

Remediating exposures for Amazon ECS services

AWS Security Hub can generate exposure findings for Amazon Elastic Container Service (Amazon ECS) services.

The Amazon ECS service involved in an exposure finding and its identifying information are listed in the **Resource** section of the finding details. You can retrieve these resource details on the Security Hub console or programmatically with the GetFindingsV2 operation of the Security Hub CSPM API.

After identifying the resource involved in an exposure finding, you can delete the resource if you don't need it. Deleting a nonessential resource can reduce your exposure profile and AWS costs. If the resource is essential, follow these recommended remediation steps to help mitigate the risk. The remediation topics are divided based on the type of trait.

A single exposure finding contains issues identified in multiple remediation topics. Conversely, you can address an exposure finding and bring down its severity level by addressing just one remediation topic. Your approach to risk remediation depends on your organizational requirements and workloads.

> **Note**
>
> The remediation guidance provided in this topic might require additional consultation in other AWS resources.

Misconfiguration traits for Amazon ECS services

Here are misconfiguration traits for Amazon ECS services and suggested remediation steps.

The Amazon ECS service uses a task definition that allows containers to access the root file systems

Amazon ECS containers with access to the host root filesystem can potentially read, modify, or execute critical files on the host system. This configuration increases the risk that a compromised

container could be used to access or modify resources outside its intended scope, potentially exposing sensitive data on the host filesystem. Following standard security principles, grant least privileges, which means that you grant only the permissions required to perform a task.

Remediation: Review and modify containers with host filesystem access

In the exposure finding, identify the task definition ARN. Open the task definition in the Amazon ECS console. Look for the volumes section in the task definition that defines host path mappings.

Review the task definition to determine if the host filesystem access is required for container functionality. If host filesystem access is not required, create a new task definition revision and remove any volume definitions that use host paths. If host filesystem access is required, consider configuring the container to use a read-only file system to prevent unauthorized modifications.

The Amazon ECS service uses a task definition configured to share a host's process namespace

Amazon ECS containers running with exposed namespaces can potentially access host system resources and other container namespaces. This configuration could allow a compromised container to escape its isolation boundary, accessing processes, network interfaces, or other resources outside of its intended scope.

A process ID (PID) namespace provides separation between processes. It prevents system processes from being visible, and allows PIDs to be reused, including PID 1. If the host PID namespace is shared with containers, containers can see all processes on the host system, reducing process-level isolation. This could lead to unauthorized access to host processes, including the ability to manipulate and terminate them. Following standard security principles, maintain proper namespace isolation for containers.

Remediation: Update task definitions with exposed namespaces

Open the **Resources** tab of the exposure, identify the task definition with the exposed namespace. Open the task definition in the Amazon ECS console. Look for the pidMode settings with a value of host, which would share the process ID namespaces with the host. Remove the pidMode: host settings from your task definitions to ensure containers run with proper namespace isolation.

The Amazon ECS service uses a task definition configured with cleartext credentials in the environment variables

Amazon ECS containers with cleartext credentials in environment variables expose sensitive authentication information that could be compromised if an attacker gains access to the task

definition, container environment, or container logs. This creates a significant security risk, as leaked credentials could be used to access other AWS services or resources.

Remediation

Take one or more of the following actions to address this exposure:

Replace cleartext credentials

In the exposure finding, identify the task definition with cleartext credentials. Open the task definition in the Amazon ECS console. Look for environment variables in the container definition that contain sensitive values such as AWS access keys, database passwords, or API tokens.

Consider the following alternatives to pass credentials:

- Instead of using AWS access keys, use IAM task execution roles and task roles to grant permissions to your containers.
- Store credentials as secrets in AWS Secrets Manager and reference them in your task definition.

Update task definitions

Create a new revision of your task definition that securely handles credentials. Then update your Amazon ECS service to use the new task definition revision.

The Amazon ECS service has an open security group

Security groups act as virtual firewalls for your Amazon ECS tasks to control inbound and outbound traffic. Open security groups, which allow unrestricted access from any IP address, may expose your containers to unauthorized access, increasing the risk of exposure to automated scanning tools and targeted attacks. Following standard security principles, restrict security group access to specific IP addresses and ports.

Remediation

Take one or more of the following actions to address this exposure:

Review security group rules and assess current configuration

Open the resource for the Amazon ECS Security Group. Evaluate which ports are open and accessible from broad IP ranges, such as (`0.0.0.0/0 or ::/0`).

Modify security group rules

Modify your security group rules to restrict access to specific trusted IP addresses or ranges. When updating your security group rules, consider separating access requirements for different network segments by creating rules for each required source IP range or restricting access to specific ports.

Modify security group rules

Consider the following options for alternative access methods:

- Session Manager provides secure shell access to your Amazon EC2 instances without the need for inbound ports, managing SSH keys, or maintaining bastion hosts.
- NACLs provide an additional layer of security at the subnet level. Unlike security groups, NACLs are stateless and require both inbound and outbound rules to be explicitly defined.

The Amazon ECS service has public IP addresses

Amazon ECS services with public IP addresses assigned to their tasks are directly accessible from the internet. While this may be necessary for services that need to be publicly available, it increases the attack surface and potential for unauthorized access.

Remediation

Take one or more of the following actions to address this exposure:

Identify services with public IP addresses

In the exposure finding, identify the Amazon ECS service that has public IP addresses assigned to its tasks. Look for the `assignPublicIp` setting with a value of `ENABLED` in the service configuration.

Update task definitions

Create a new revision of your task definition that disables public IP addresses. Then update your Amazon ECS service to use the new task definition revision.

Implement private network access patterns

For instances that are running web applications, consider using a Load Balancer (LB). LBs can be configured to allow your instances to run in private subnets while the LB runs in a public subnet and handles internet traffic.

The Amazon ECS service uses a task definition that is configured with host networking mode enabled

Amazon ECS containers running with host networking mode share the network namespace with the host, allowing direct access to the host's network interfaces, ports, and routing tables. This configuration bypasses the network isolation provided by containers, potentially exposing services running on the container directly to external networks and allowing containers to modify host network settings. Following standard security principles, maintain proper network isolation for containers.

Remediation

Take one or more of the following actions to address this exposure:

Disable host networking mode

In the exposure finding, identify the task definition with host networking mode. Open the task definition in the Amazon ECS console. Look for the networkMode setting with a value of host in the task definition.

Consider the following options to disable host networking mode:

- The `awsvpc` network mode provides the strongest level of network isolation by giving each task its own elastic network interface.
- The `bridge` network mode provides isolation while allowing port mappings to expose specific container ports to the host.

Update task definitions

Create a new revision of your task definition with the updated network mode configuration. Then update your Amazon ECS service to use the new task definition revision.

Reachability traits for Amazon ECS services

Here are reachability traits for Amazon ECS services and suggested remediation steps.

The Amazon ECS service is reachable over the internet

An Amazon ECS service that runs tasks on a public subnet is directly accessible from the internet. This increases the attack surface and the risk of unauthorized access. Following standard security

principles, run tasks on private subnets and allow only the internet access that your service requires.

Remediation

Take one or more of the following actions to address this exposure:

Run tasks on a private subnet

To move your tasks off a public subnet, update the network configuration for your launch type:

- For Fargate, specify private subnets in the network configuration of your Amazon ECS service and set `assignPublicIp` to `DISABLED`. Amazon ECS hosts each task on a private subnet and routes its outbound traffic through a NAT gateway that you associate with the subnet.
- For EC2, launch the container instances that provide your cluster capacity on private subnets. Tasks use the private networking of the host and route outbound traffic through a NAT gateway.

Use a NAT gateway for outbound access

For tasks on a private subnet that require outbound internet access, use a NAT gateway. You can use a NAT gateway to let tasks start outbound connections to the internet and prevent inbound connections from the internet. For more information, see Connect Amazon ECS applications to the internet in the Amazon ECS Developer Guide.

Use a load balancer for inbound access

For services that need to accept internet traffic, run your tasks on private subnets behind a load balancer that runs on a public subnet. To add protection against web exploits and bots, associate AWS Web Application Firewall (WAF) with your load balancer. For more information, see Use load balancing to distribute Amazon ECS service traffic in the Amazon ECS Developer Guide.

Vulnerability traits for Amazon ECS services

Here are vulnerability traits for Amazon ECS and suggested remediation steps.

The Amazon ECS service has a container with software vulnerabilities which are notable

A *notable vulnerability* is a Common Vulnerabilities and Exposures (CVE) entry that Security Hub tracks on a curated list because of active exploitation in the wild or significant potential impact.

Security Hub prioritizes these CVEs regardless of their CVSS score, so a notable vulnerability on this resource represents an immediate security threat. Patch these vulnerabilities first.

The curated list currently includes the following vulnerabilities in the PHP runtime. With either vulnerability, a remote, unauthenticated party can run code on the server through a crafted multipart request. Both affect PHP versions 5.4 through 8.5, regardless of the application code that runs on them:

- `CVE-2026-109618`: PHP can corrupt its memory state when it runs out of memory as it processes a crafted multipart request.
- `CVE-2026-109619`: The issue is in the session upload progress feature (`session.upload_progress`), which PHP turns on by default.

PHP versions 8.5.12, 8.4.27, 8.3.36, and 8.2.35 address these issues. PHP 8.1 and earlier have no update, so migrate those workloads to a supported PHP branch. For more information about these issues, see AWS Security Bulletin 2026-143 on the AWS website.

Remediation: Update affected container images

Review the **References** section in the **Vulnerability** tab of the trait, and follow the remediation advice in the finding. Update the package version in the ECR container image as suggested by Amazon Inspector. Rebuild the image, push it to ECR, update the task definition to use the new image, and redeploy the service. For more information about Amazon Inspector finding details, see Viewing details for your Amazon Inspector findings in the *Amazon Inspector User Guide*.

The Amazon ECS service has a container with network-exploitable software vulnerabilities with a high likelihood of exploitation

1. **Understand the exposure**

   Package vulnerability findings identify software packages in your AWS environment that are exposed to Common Vulnerabilities and Exposures (CVEs). Attackers can exploit these unpatched vulnerabilities to compromise the confidentiality, integrity, or availability of data, or to access other systems. ECR container images can have package vulnerability findings.

2. **Remediate the exposure**

   a. **Update package version**

      Review the package vulnerability finding for your ECR container image. Update the package version as suggested by Amazon Inspector. For more information, see Viewing details for your

Amazon Inspector findings in the *Amazon Inspector User Guide*. The **Remediation** section of the finding details in the Amazon Inspector console tells you which commands you can run to update the package.

b. **Update base container images**

Rebuild and update base container images regularly to keep your containers up to date. When rebuilding an image, do not include unnecessary components to reduce the attack surface. For instructions on rebuilding a container image, see Rebuild your images often.

The Amazon ECS service has a container with software vulnerabilities

Software packages that are installed on Amazon ECS containers can be exposed to Common Vulnerabilities and Exposures (CVEs). Low priority vulnerabilities represent security weaknesses with lower severity or exploitability compared to high priority vulnerabilities. Although these vulnerabilities pose less immediate risk, attackers can still exploit these unpatched vulnerabilities to compromise the confidentiality, integrity, or availability of data, or to access other systems.

Remediation

Take one or more of the following actions to address this exposure:

Update affected container images

Review the **References** section in the **Vulnerability** tab of the trait. Vendor documentation may include specific remediation guidance.

Apply the appropriate remediation by following these general guidelines:

- Update your container images to use patched versions of the affected packages.
- Update the affected dependencies in your application to their latest secure versions.

After updating your container image, push it to your container registry and update your Amazon ECS task definition to use the new image.

Future considerations

To further strengthen the security posture of your container images, consider following Amazon ECS task and container security best practices. Amazon Inspector can be configured to automatically scan for CVEs on your containers. Amazon Inspector can also be integrated with

Security Hub for automatic remediations. Consider implementing a regular patching schedule using Systems Manager Maintenance Windows to minimize disruption to your containers.

The Amazon ECS service has a container with an End-Of-Life operating system

The Amazon ECS container relies on an end-of-life operating system that is no longer supported or maintained by the original developer. This exposes the container to security vulnerabilities and potential attacks. When operating systems reach end-of-life, vendors typically stop releasing new security advisories. Existing security advisories may also be removed from vendor feeds. As a result, Amazon Inspector could potentially stop generating findings for known CVEs, creating further gaps in security coverage.

See Discontinued operating systems in the *Amazon Inspector User Guide* for information about operating systems that have reached end of life that can be detected by Amazon Inspector.

Remediation: Update to a supported operating system version

Update to a supported version of the operating system. In the exposure finding, open the resource to access the affected resource. Before updating the operating system version in your container image, review available versions in Supported Operating Systems in the *Amazon Inspector User Guide* for a list of currently supported OS versions. After updating your container image, push it to your container registry and update your Amazon ECS task definition to use the new image.

The Amazon ECS service has a container with malicious software packages

Malicious packages are software components that contain harmful code designed to compromise the confidentiality, integrity, and availability of your systems and data. Malicious packages pose an active and critical threat to your Amazon ECS container images, as attackers can execute malicious code automatically without exploiting a vulnerability. Following security best practices, remove malicious packages to protect your containers from potential attacks.

Remediation: Remove malicious packages

Review the malicious package details in the **References** section of the **Vulnerability** tab of the trait to understand the threat. Remove the identified malicious packages from your container images then rebuild them. For more information, see ContainerDependency in the *AWS Amazon ECS API Reference*.

After updating your container image, push it to your container registry and update your Amazon ECS task definition to use the new image. For more information, see Updating an Amazon ECS task definition using the console in the *AWS Amazon ECS Developer Guide*.

Impact traits for Amazon ECS services

Impact traits describe the potential blast radius of an exposure. Security Hub analyzes the effective permissions of the AWS Identity and Access Management principal associated with the Amazon ECS service to determine the downstream resources an attacker could reach if the service is compromised, as well as the business criticality of those resources. Each impact trait identifies a specific privilege escalation pattern. To reduce your blast radius, review the permission paths described in each trait and remove any unnecessary privileges.

Following standard security principles, grant least privilege by providing only the permissions required to perform a task. Replace broad policies with scoped-down policies that grant only the specific actions and resources needed. To identify unused permissions to remove, use IAM Access Analyzer to generate recommendations based on access history. For more information, see Findings for external and unused access and Apply least-privilege permissions in the *IAM User Guide*.

Has full control privileged executor path

The associated principal can pass a role to and inject code into a compute resource that already has elevated permissions. This allows the principal to gain full control over the executor and perform any action that the executor's role permits.

Has direct policy escalation path

The associated principal can directly modify IAM policies to grant itself additional permissions, escalating its own privileges without intermediate resources.

Has trust policy hijack path

The associated principal can modify the trust policy of an IAM role to allow itself to assume that role, gaining the role's permissions.

Has data ransomware path

The associated principal can encrypt or delete data in a way that could be used for ransomware, such as encrypting Amazon S3 objects with a customer-managed AWS KMS key and then modifying the key policy.

Has remove restriction path

The associated principal can remove security restrictions such as permission boundaries, service control policies, or resource-based policy deny statements, expanding what other principals or the resource itself can do.

Has pass role create executor path

The associated principal can create a new compute resource (such as a Lambda function or Amazon EC2 instance) and pass it a privileged role, effectively laundering its own permissions through the new resource.

Has swap role existing executor path

The associated principal can change the IAM role attached to an existing compute resource, replacing it with a more privileged role to escalate access.

Has role chain escalation path

The associated principal can assume a sequence of roles, where each role in the chain has progressively broader permissions, ultimately reaching a highly privileged role.

Has inject code privileged executor path

The associated principal can inject code into a running compute resource that has elevated permissions, executing arbitrary operations under that resource's privileged role.

Has disable audit trail path

The associated principal can disable logging or monitoring services such as CloudTrail, effectively covering its tracks during or after an escalation.

Has access existing executor path

The associated principal can invoke or connect to an existing compute resource and use its attached role to perform privileged actions.

Has credential minting path

The associated principal can create new long-term credentials (such as access keys or login profiles) for other principals, establishing persistent access paths that survive password rotations or session expirations.

Has pass role data access path

The associated principal can create a service resource and pass it a role that has access to sensitive data, gaining indirect access to that data through the new resource.

Has pass role task hijack path

The associated principal can pass a role to a scheduled or event-driven task (such as a Lambda function triggered by an event), allowing it to execute arbitrary code with that role's permissions.

Has single hop data access path

The associated principal can directly access sensitive data resources (such as Amazon S3 buckets or DynamoDB tables) through its existing permissions, without needing intermediate escalation steps.

Has capability advancing path

The associated principal has a privilege escalation path that advances its overall capabilities beyond what its directly assigned permissions would suggest. This is a general classification for paths that do not match a more specific pattern.

Business criticality

The business criticality of the primary resource, set either by automation rules or by inference from the name and tags.

Remediating exposures for Amazon EKS clusters

AWS Security Hub can generate exposure findings for Amazon Elastic Kubernetes Service (Amazon EKS) clusters.

The Amazon EKS cluster involved in an exposure finding and its identifying information are listed in the **Resource** section of the finding details. You can retrieve these resource details on the Security Hub console or programmatically with the GetFindingsV2 operation of the Security Hub CSPM API.

After identifying the resource involved in an exposure finding, you can delete the resource if you don't need it. Deleting a nonessential resource can reduce your exposure profile and AWS costs. If the resource is essential, follow these recommended remediation steps to help mitigate the risk. The remediation topics are divided based on the type of trait.

A single exposure finding contains issues identified in multiple remediation topics. Conversely, you can address an exposure finding and bring down its severity level by addressing just one

remediation topic. Your approach to risk remediation depends on your organizational requirements and workloads.

> **Note**
>
> The remediation guidance provided in this topic might require additional consultation in other AWS resources.

  - The Amazon EKS cluster has malicious files

Misconfiguration traits for Amazon EKS clusters

Here are misconfiguration traits for Amazon EKS clusters and suggested remediation steps.

The Amazon EKS cluster allows public access

The Amazon EKS cluster endpoint is the endpoint that you use to communicate with your cluster's Kubernetes API server. By default, this endpoint is public to the internet. Public endpoints increase your attack surface area and the risk of unauthorized access to your Kubernetes API server, potentially allowing attackers to access or modify cluster resources or access sensitive data. Following security best practices, restrict access to your Amazon EKS cluster endpoint to only necessary IP ranges.

Remediation

Take one or more of the following actions to address this exposure:

Modify endpoint access

In the exposure finding, open the resource. This opens the affected Amazon EKS cluster. You can configure your cluster to use private access, public access, or both.

With private access, Kubernetes API requests that originate within your cluster's VPC use the private VPC endpoint. With public access, Kubernetes API requests that originate from outside your cluster's VPC use the public endpoint.

Modify or remove public access to the cluster

To modify endpoint access for an existing cluster, see Modifying cluster endpoint access in the *Amazon Elastic Kubernetes Service User Guide*. Implement more restrictive rules based on specific IP ranges or security groups. If limited public access is necessary, restrict access to specific CIDR block ranges or use prefix lists.

The Amazon EKS cluster uses an unsupported Kubernetes version

Amazon EKS supports each Kubernetes version for a limited period of time. Running clusters with unsupported Kubernetes versions can expose your environment to security vulnerabilities, as CVE patches will stop being released for outdated versions. Unsupported versions may contain known security vulnerabilities that can be exploited by attackers and lack security features that may be available in newer versions. Following security best practices, keep your Kubernetes version updated.

Remediation: Update Kubernetes version

In the exposure finding, open the resource. This opens the affected Amazon EKS cluster. Before updating your cluster, review Available versions on standard support in the *Amazon Elastic Kubernetes Service User Guide* for a list of currently supported Kubernetes versions.

The Amazon EKS cluster uses unencrypted Kubernetes secrets

Kubernetes secrets are, by default, stored unencrypted in the API server's underlying data store (etcd). Anyone with API access or with access to etcd can retrieve or modify a secret. To prevent this, you should encrypt Kubernetes secrets at rest. If Kubernetes Secrets are unencrypted, they are vulnerable to unauthorized access if etcd is compromised. Since secrets often contain sensitive

information like passwords and API tokens, their exposure could lead to unauthorized access to other applications and data. Following security best practices, encrypt all sensitive information stored in Kubernetes secrets.

Remediation: Encrypt Kubernetes secrets

Amazon EKS supports the encryption of Kubernetes secrets using KMS keys through envelope encryption. To enable encryption of Kubernetes secrets for your EKS cluster, see Encrypt Kubernetes secrets with KMS on existing clusters in the *Amazon EKS User Guide*.

Vulnerability traits for Amazon EKS clusters

Here are the vulnerability traits for Amazon EKS clusters.

The Amazon EKS cluster has a container with software vulnerabilities which are notable

A *notable vulnerability* is a Common Vulnerabilities and Exposures (CVE) entry that Security Hub tracks on a curated list because of active exploitation in the wild or significant potential impact. Security Hub prioritizes these CVEs regardless of their CVSS score, so a notable vulnerability on this resource represents an immediate security threat. Patch these vulnerabilities first.

The curated list currently includes the following vulnerabilities in the PHP runtime. With either vulnerability, a remote, unauthenticated party can run code on the server through a crafted multipart request. Both affect PHP versions 5.4 through 8.5, regardless of the application code that runs on them:

- `CVE-2026-109618`: PHP can corrupt its memory state when it runs out of memory as it processes a crafted multipart request.
- `CVE-2026-109619`: The issue is in the session upload progress feature (`session.upload_progress`), which PHP turns on by default.

PHP versions 8.5.12, 8.4.27, 8.3.36, and 8.2.35 address these issues. PHP 8.1 and earlier have no update, so migrate those workloads to a supported PHP branch. For more information about these issues, see AWS Security Bulletin 2026-143 on the AWS website.

Remediation: Update affected container images

Review the **References** section in the **Vulnerability** tab of the trait, and follow the remediation advice in the finding. Rebuild the affected container images with an updated base image or dependency that is not affected, then deploy the new images to your Amazon EKS cluster. For

more information about Amazon Inspector finding details, see Viewing details for your Amazon Inspector findings in the *Amazon Inspector User Guide*.

The Amazon EKS cluster has a container with network-exploitable software vulnerabilities with a high likelihood of exploitation

Software packages that are installed on Amazon EKS clusters can be exposed to Common Vulnerabilities and Exposures (CVEs). Critical CVEs pose significant security risks to your AWS environment. Unauthorized users can exploit these unpatched vulnerabilities to compromise the confidentiality, integrity, or availability of data, or to access other systems. Critical vulnerabilities with high exploitation likelihood represent immediate security threats, as exploit code may already be publicly available and actively used by attackers or automated scanning tools. Following security best practices, patch these vulnerabilities to protect your instance from attack.

Remediation: Update affected instances

Update your container images to newer versions that include security fixes for the identified vulnerabilities. This typically involves rebuilding your container images with updated base images or dependencies, then deploying the new images to your Amazon EKS cluster.

The Amazon EKS cluster has a container with software vulnerabilities

Software packages that are installed on Amazon EKS clusters can be exposed to Common Vulnerabilities and Exposures (CVEs). Noncritical CVEs represent security weaknesses with lower severity or exploitability compared to critical CVEs. Although these vulnerabilities pose less immediate risk, attackers can still exploit these unpatched vulnerabilities to compromise the confidentiality, integrity, or availability of data, or to access other systems. Following security best practices, patch these vulnerabilities to protect your instance from attack.

Remediation: Update affected instances

Update your container images to newer versions that include security fixes for the identified vulnerabilities. This typically involves rebuilding your container images with updated base images or dependencies, then deploying the new images to your Amazon EKS cluster.

The Amazon EKS cluster has a container with an End-Of-Life operating system

The Amazon EKS container image relies on an end-of-life operating system that is no longer supported or maintained by the original developer. This exposes the container to security vulnerabilities and potential attacks. When operating systems reach end-of-life, vendors typically

stop releasing new security advisories. Existing security advisories may also be removed from vendor feeds. As a result, Amazon Inspector could potentially stop generating findings for known CVEs, creating further gaps in security coverage.

See Discontinued operating systems in the *Amazon Inspector User Guide* for information about operating systems that have reached end of life that can be detected by Amazon Inspector.

Remediation: Update to a supported operating system version

Update to a supported version of the operating system. In the exposure finding, open the resource to access the affected resource. Before updating the operating system version in your container image, review available versions in Supported Operating Systems in the *Amazon Inspector User Guide* for a list of currently supported OS versions. After updating your container image, rebuild and redeploy your containers to the Amazon EKS cluster.

The Amazon EKS cluster has a container with malicious software packages

Malicious packages are software components that contain harmful code designed to compromise the confidentiality, integrity, and availability of your systems and data. Malicious packages pose an active and critical threat to your Amazon EKS cluster, as attackers can execute malicious code automatically without exploiting a vulnerability. Following security best practices, remove malicious packages to protect your cluster from potential attacks.

Remediation: Remove malicious packages

Review the malicious package details in the **References** section of the **Vulnerability** tab of the trait to understand the threat. Remove the identified malicious packages from your container images. Then, delete the pods with the compromised image.

Update your Kubernetes deployments to use the updated container images. Then, deploy your changes and redeploy your pods.

The Amazon EKS cluster has malicious files

Malicious files contain harmful code designed to compromise the confidentiality, integrity, and availability of your systems and data. Malicious files pose an active and critical threat to your cluster, as attackers can execute malicious code automatically without exploiting a vulnerability. Following security best practices, remove malicious files to protect your cluster from potential attacks.

Remediation: Remove malicious files

To identify the specific Amazon Elastic Block Store (Amazon EBS) volume that has malicious files, review the **Resources** section of the trait's finding details. After you have identified the volume with the malicious file, remove the identified malicious files. After removing the malicious files, consider performing a scan to ensure that all files that may have been installed by the malicious file have been removed. For more information, see Starting On-demand malware scan in GuardDuty in the .

Remediating exposures for IAM users

AWS Security Hub can generate exposure findings for AWS Identity and Access Management (IAM) users.

On the Security Hub console, the IAM user involved in an exposure finding and its identifying information are listed in the **Resources** section of the finding details. Programmatically, you can retrieve resource details with the GetFindingsV2 operation of the Security Hub CSPM API.

After identifying the resource involved in an exposure finding, you can delete the resource if you don't need it. Deleting a nonessential resource can reduce your exposure profile and AWS costs. If the resource is essential, follow these recommended remediation steps to help mitigate the risk. The remediation topics are divided based on the type of trait.

A single exposure finding contains issues identified in multiple remediation topics. Conversely, you can address an exposure finding and bring down its severity level by addressing just one remediation topic. Your approach to risk remediation depends on your organizational requirements and workloads.

> **Note**
>
> The remediation guidance provided in this topic might require additional consultation in other AWS resources.

IAM best practices recommend that you create IAM roles or use federation with an identity provider to access AWS using temporary credentials instead of creating individual IAM users. If that is an option for your organization and use case, switch to roles or federation instead of using IAM users. For more information, see IAM users in the *IAM User Guide*.

Contents

- Misconfiguration traits for IAM users

- The IAM user does not have MFA enabled

  - Business criticality

Misconfiguration traits for IAM users

Here are misconfiguration traits for IAM users and suggested remediation steps.

The IAM user does not have MFA enabled

Multi-factor authentication (MFA) adds an extra layer of protection on top of a user name and password. When MFA is enabled and an IAM user signs in to an AWS website, they are prompted for their user name, password, and an authentication code from their AWS MFA device. The

authenticating principal must possess a device that emits a time-sensitive key and must have knowledge of a credential. Without MFA, if a user's password is compromised, an attacker gains full access to the user's AWS permissions. Following standard security principles, enable MFA for all accounts and users that have AWS Management Console access.

Remediation

Take one or more of the following actions to address this exposure:

Review MFA types

AWS supports the following MFA types:

- Passkeys and security keys
- Virtual authenticator applications
- Hardware TOTP tokens

Although authentication with a physical device typically provides more stringent security protection, using any type of MFA is more secure than having MFA disabled.

Enable MFA

To enable the MFA type that suits your requirements, see AWS multi-factor authentication in IAM in the *IAM User Guide*. Follow the steps for the specific MFA type you want to implement. For organizations managing many users, you may want to enforce MFA usage by requiring MFA to access sensitive resources.

The AWS account for the IAM user has weak password policies

Password policies help protect against unauthorized access by enforcing minimum complexity requirements for IAM user passwords. Without strong password policies, there's an increased risk that user accounts could be compromised through password guessing or brute force attacks. Following standard security principles, implement a strong password policy to ensure users create complex passwords that are difficult to guess.

Remediation

Take one or more of the following actions to address this exposure:

Configure a strong password policy

Go to the IAM dashboard and navigate to Account settings. Review the current password policy settings for your account, including minimum length, character types required, and password expiration settings.

At a minimum, follow these best practices when setting your password policy:

- Require at least one uppercase character.
- Require at least one lowercase character.
- Require at least one symbol.
- Require at least one number.
- Require at least eight characters.

Additional security considerations

Consider these additional security measures in addition to a strong password policy:

- MFA adds an additional security layer by requiring an additional form of authentication. This helps prevent unauthorized access even if credentials are compromised.
- Setting up condition elements to restrict when and how administrative permissions can be used based on factors like source IP or MFA age.

The IAM user has unrotated access keys

Access keys consist of an access key ID and a secret access key that enable programmatic access to AWS resources. When access keys remain unchanged for extended periods of time, they increase the risk of unauthorized access if they are compromised. Following security best practices, rotate access keys every 90 days to minimize the window of opportunity for attackers to use compromised credentials.

Remediation: Rotate access keys

In the exposure finding, open the resource. This opens the user details window. To rotate access keys, see Manage access keys for IAM users in the *IAM User Guide*.

The IAM user has a policy that allows unrestricted access to KMS key decryption

AWS KMS enables you to create and manage cryptographic keys that are used to protect your data. IAM policies that allow unrestricted AWS KMS decryption permissions (for example, `kms:Decrypt`

or `kms:ReEncryptFrom`) on all KMS keys can lead to unauthorized data access if an IAM user's credentials are compromised. If an attacker gains access to these credentials, they could potentially decrypt any encrypted data in your environment, which could include sensitive data. Following security best practices, implement least privilege by limiting AWS KMS decryption permissions to only specific keys that users need for their job functions.

Remediation

Take one or more of the following actions to address this exposure:

Implement least-privilege access

In the exposure finding, open the resource. This opens the IAM Policy window. Look for permissions in KMS that allow kms:Decrypt or `kms:ReEncryptFrom` or `KMS:*` with a resource specification of `"*"`.

Update the policy to restrict AWS KMS decryption permissions to only the specific keys needed. Modify the policy to replace the `"*"` resource with the specific ARNs of required AWS KMS keys.

Secure configuration considerations

Consider adding conditions to further restrict when these permissions can be used. For example, you can limit decryption operations to specific VPC endpoints or source IP ranges. You can also configure key policies to further restrict who can use specific KMS keys.

Unused access traits for IAM users

When an IAM user has unused permissions, access keys, or passwords, Security Hub may include these as contextual traits in exposure findings for that user. These traits are generated by the service-managed IAM Access Analyzer and provide additional context about the user's security posture. Unused access traits are not the primary cause of the exposure finding, but they indicate that the user has more permissions than needed, which increases the potential impact if the user's credentials are compromised.

For unused permissions specifically, you can generate a least-privilege policy recommendation that shows you a scoped-down replacement policy. For more information, see the section called "Policy recommendations".

Impact traits for IAM users

Impact traits describe the potential blast radius of an exposure. Security Hub analyzes the effective permissions of the AWS Identity and Access Management principal associated with the IAM user

to determine the downstream resources an attacker could reach if the IAM user is compromised, as well as the business criticality of those resources. Each impact trait identifies a specific privilege escalation pattern. To reduce your blast radius, review the permission paths described in each trait and remove any unnecessary privileges.

Following standard security principles, grant least privilege by providing only the permissions required to perform a task. Replace broad policies with scoped-down policies that grant only the specific actions and resources needed. To identify unused permissions to remove, use IAM Access Analyzer to generate recommendations based on access history. For more information, see Findings for external and unused access and Apply least-privilege permissions in the *IAM User Guide*.

Has full control privileged executor path

The associated principal can pass a role to and inject code into a compute resource that already has elevated permissions. This allows the principal to gain full control over the executor and perform any action that the executor's role permits.

Has direct policy escalation path

The associated principal can directly modify IAM policies to grant itself additional permissions, escalating its own privileges without intermediate resources.

Has trust policy hijack path

The associated principal can modify the trust policy of an IAM role to allow itself to assume that role, gaining the role's permissions.

Has data ransomware path

The associated principal can encrypt or delete data in a way that could be used for ransomware, such as encrypting Amazon S3 objects with a customer-managed AWS KMS key and then modifying the key policy.

Has remove restriction path

The associated principal can remove security restrictions such as permission boundaries, service control policies, or resource-based policy deny statements, expanding what other principals or the resource itself can do.

Has pass role create executor path

The associated principal can create a new compute resource (such as a Lambda function or Amazon EC2 instance) and pass it a privileged role, effectively laundering its own permissions through the new resource.

Has swap role existing executor path

The associated principal can change the IAM role attached to an existing compute resource, replacing it with a more privileged role to escalate access.

Has role chain escalation path

The associated principal can assume a sequence of roles, where each role in the chain has progressively broader permissions, ultimately reaching a highly privileged role.

Has inject code privileged executor path

The associated principal can inject code into a running compute resource that has elevated permissions, executing arbitrary operations under that resource's privileged role.

Has disable audit trail path

The associated principal can disable logging or monitoring services such as CloudTrail, effectively covering its tracks during or after an escalation.

Has access existing executor path

The associated principal can invoke or connect to an existing compute resource and use its attached role to perform privileged actions.

Has credential minting path

The associated principal can create new long-term credentials (such as access keys or login profiles) for other principals, establishing persistent access paths that survive password rotations or session expirations.

Has pass role data access path

The associated principal can create a service resource and pass it a role that has access to sensitive data, gaining indirect access to that data through the new resource.

Has pass role task hijack path

The associated principal can pass a role to a scheduled or event-driven task (such as a Lambda function triggered by an event), allowing it to execute arbitrary code with that role's permissions.

Has single hop data access path

The associated principal can directly access sensitive data resources (such as Amazon S3 buckets or DynamoDB tables) through its existing permissions, without needing intermediate escalation steps.

Has capability advancing path

The associated principal has a privilege escalation path that advances its overall capabilities beyond what its directly assigned permissions would suggest. This is a general classification for paths that do not match a more specific pattern.

Business criticality

The business criticality of the primary resource, set either by automation rules or by inference from the name and tags.

Remediating exposures for AWS Lambda functions

AWS Security Hub can generate exposure findings for AWS Lambda functions.

On the Security Hub console, the Lambda function involved in an exposure finding and its identifying information are listed in the **Resources** section of the finding details. Programmatically, you can retrieve resource details with the GetFindingsV2 operation of the Security Hub CSPM API.

After identifying the resource involved in an exposure finding, you can delete the resource if you don't need it. Deleting a nonessential resource can reduce your exposure profile and AWS costs. If the resource is essential, follow these recommended remediation steps to help mitigate the risk. The remediation topics are divided based on the type of trait.

A single exposure finding contains issues identified in multiple remediation topics. Conversely, you can address an exposure finding and bring down its severity level by addressing just one remediation topic. Your approach to risk remediation depends on your organizational requirements and workloads.

> **Note**
>
> The remediation guidance provided in this topic might require additional consultation in other AWS resources.

Misconfiguration traits for Lambda functions

Here are misconfiguration traits for Lambda functions and suggested remediation steps.

Lambda function is deployed outside of an Amazon VPC

Lambda functions by default are deployed with access to the public internet. This default configuration gives Lambda functions the ability to reach AWS service endpoints and external APIs, but it also exposes them to potential security risks. Functions with internet access could be used to exfiltrate data, communicate with unauthorized servers, or become entry points for external actors if compromised. Amazon VPC provides network isolation by restricting your Lambda functions to communicate only with resources within your defined private network. Following standard security principles, deploy Lambda functions within a VPC to improve security through network isolation.

Remediation: Attach function to VPC

In the exposure finding, choose the resource link. This opens the Lambda function in the Lambda console. To secure your Lambda function by restricting its network access, attach it to a VPC that has the appropriate network controls in place.

Before attaching your function to a VPC, plan for any AWS service access it may need, as functions in private subnets without NAT gateways or VPC endpoints cannot reach AWS service APIs. For information about how to attach a Lambda function to an Amazon VPC in your account, see Attaching Lambda functions to an Amazon VPC in your AWS account. Consider using VPC endpoints for service connectivity without internet access if your function requires to access AWS services from within a private subnet. Configure a NAT Gateway if you require outbound internet connectivity from private subnets.

The Lambda function is accessible through API Gateway without authorization

API Gateway methods without authorization allow any caller with access to the API Gateway to invoke the integrated Lambda function without identity verification. This configuration creates security risks, as callers can invoke the Lambda function without proper authorization, potentially leading to abuse of function capabilities, resource consumption, access to sensitive data, or unauthorized operations. While API Gateway may have network-level access controls, the lack of method-level authorization could allow free invocation of the function by any caller with network access to the API Gateway. Following security best practices, implement appropriate authorization mechanisms for API Gateway methods that integrate with Lambda functions.

Remediation: Configure API Gateway authentication

In the **Resources** tab of the exposure, choose the resource link to access the API Gateway method. Review the current authorization configuration and implement appropriate authentication mechanisms.

API Gateway supports several authentication options including AWS IAM, Amazon Cognito User Pools, Lambda authorizers, and API keys. Choose the authentication method that best fits your security requirements and use case. For detailed instructions on configuring authentication, see Controlling and managing access to a REST API in API Gateway in the *API Gateway Developer Guide*.

The Lambda function is exposed through an Amazon Bedrock AgentCore gateway with no authorizer configured

Amazon Bedrock AgentCore gateways expose Lambda functions as tools that AI agents can discover and invoke. A gateway without an authorizer accepts requests without verifying the identity of the caller. Any caller who obtains the gateway endpoint can list the tools the gateway exposes and invoke the integrated Lambda function without authentication. This creates security risks, because unauthenticated invocations could lead to abuse of function capabilities, access to sensitive data, or unauthorized operations in your environment. Following security best practices, configure inbound authorization on Amazon Bedrock AgentCore gateways that front Lambda functions.

Remediation: Configure gateway inbound authorization

In the **Resources** section of the exposure finding, note the gateway identifier. Open the Amazon Bedrock AgentCore console, choose the gateway, and review its inbound authorization configuration.

Amazon Bedrock AgentCore gateways support inbound authorization with a JSON Web Token (JWT) authorizer through an OAuth-compliant identity provider such as Amazon Cognito. Configure an authorizer so that the gateway validates the caller's token before it serves tool requests. For detailed instructions, see Prerequisites for using the Amazon Bedrock AgentCore gateway service in the *Amazon Bedrock AgentCore Developer Guide*.

The Lambda function is exposed through an Amazon Bedrock AgentCore gateway that allows unauthenticated public access

Amazon Bedrock AgentCore gateways can carry a resource-based policy that controls which principals can invoke the gateway. A gateway policy that includes "*" as the principal allows any caller to invoke the tools the gateway exposes, including the integrated Lambda function. This configuration bypasses identity-based access controls and creates significant risk because unauthenticated callers can invoke the function. This could lead to abuse of function capabilities, access to sensitive data, or unauthorized operations. Following security best practices, restrict gateway access to only authorized principals.

Remediation: Restrict the gateway resource-based policy

Open the gateway identified in the **Resources** section of the exposure finding and review its resource-based policy. Remove statements that allow "*" as the principal. Grant access only to the specific AWS account IDs or IAM principals that need to invoke the gateway.

For more information about restricting access to Amazon Bedrock AgentCore gateways, see Fine-grained access control for Amazon Bedrock AgentCore Gateway in the *Amazon Bedrock AgentCore Developer Guide*.

Reachability traits for Lambda functions

Here are reachability traits for Lambda functions and suggested remediation steps.

The Lambda function can be publicly invoked

Lambda resource-based policies determine who can invoke your functions. A function with a resource policy that includes "*" as the principal (or no principal at all) allows any authenticated AWS users to invoke it. This creates significant risk, especially for functions that process sensitive data, modify resources, or have elevated permissions. Unauthorized users could exploit this configuration to perform unwanted operations, potentially exposing data, manipulating resources, or abusing function capabilities. Following security best practices, restrict Lambda function access to only authorized principals.

Remediation: Modify the function's resource-based policy

In the **Resources** tab of the exposure, open the resource with the hyperlink. This opens the Lambda function in the Lambda console. Restrict access to your Lambda function by specifying only authorized AWS account IDs or specific IAM principals (users, roles, or services) in the resource-based policy. You can only modify resource-based policies programmatically.

Vulnerability traits for Lambda functions

Here are vulnerability traits for Lambda functions and suggested remediation steps.

The Lambda function has software vulnerabilities which are notable

A *notable vulnerability* is a Common Vulnerabilities and Exposures (CVE) entry that Security Hub tracks on a curated list because of active exploitation in the wild or significant potential impact. Security Hub prioritizes these CVEs regardless of their CVSS score, so a notable vulnerability on this resource represents an immediate security threat. Patch these vulnerabilities first.

The curated list currently includes the following vulnerabilities in the PHP runtime. With either vulnerability, a remote, unauthenticated party can run code on the server through a crafted multipart request. Both affect PHP versions 5.4 through 8.5, regardless of the application code that runs on them:

- `CVE-2026-109618`: PHP can corrupt its memory state when it runs out of memory as it processes a crafted multipart request.
- `CVE-2026-109619`: The issue is in the session upload progress feature (`session.upload_progress`), which PHP turns on by default.

PHP versions 8.5.12, 8.4.27, 8.3.36, and 8.2.35 address these issues. PHP 8.1 and earlier have no update, so migrate those workloads to a supported PHP branch. For more information about these issues, see AWS Security Bulletin 2026-143 on the AWS website.

Remediation: Update affected functions

Review the **References** section in the **Vulnerability** tab of the trait, and follow the remediation advice in the finding. Update the affected libraries to a version that is not affected, update the function code or container image to use it, and deploy the updated version. For more information about Amazon Inspector finding details, see Viewing details for your Amazon Inspector findings in the *Amazon Inspector User Guide*.

The Lambda function has network-exploitable software vulnerabilities

Software packages used in Lambda function code can contain Common Vulnerabilities and Exposures (CVEs) that have a high chance of being exploited. Critical CVEs pose significant security risks to your AWS environment. Attackers can exploit these unpatched vulnerabilities to compromise the confidentiality, integrity, or availability of data, or to access other systems. Critical vulnerabilities with high exploitation likelihood represent immediate security threats, as exploit code may already be publicly available and actively used by attackers or automated scanning tools. Following security best practices, patch these vulnerabilities to protect your function from attack.

Remediation: Update affected functions

Review the **References** section in the **Vulnerability** tab for the trait. Vendor documentation might include specific remediation guidance. Update the vulnerable libraries to their latest secure versions following the vendor recommended procedures.

Typically, the remediation workflow depends on whether you deployed the Lambda package by uploading a zip file or by creating a Lambda function with a container image. After updating the libraries, update the Lambda function code to use the fixed version. Afterwards, deploy the updated version.

The Lambda function has software vulnerabilities

Lambda functions often use third-party libraries and dependencies that may contain security vulnerabilities with lower severity or exploitability compared to critical CVEs. While these non-critical vulnerabilities might not be as immediately exploitable, they still represent security weaknesses that could be chained together with other vulnerabilities to compromise your function. Over time, new exploit techniques might also emerge that elevate the risk of these vulnerabilities. Following standard security principles, patch these vulnerabilities to maintain a secure environment.

Remediation: Update affected functions

Review the **References** section in the **Vulnerability** tab for the trait. Vendor documentation might include specific remediation guidance. Update the vulnerable libraries to their latest secure versions following the vendor recommended procedures.

Typically, the remediation workflow depends on whether you deployed the Lambda package by uploading a zip file or by creating a Lambda function with a container image. After updating

the libraries, update the Lambda function code to use the fixed version. Afterwards, deploy the updated version.

The Lambda function has malicious software packages

Malicious packages are software components that contain harmful code designed to compromise the confidentiality, integrity, and availability of your systems and data. Malicious packages pose an active and critical threat to your Lambda function, as attackers can execute malicious code automatically without exploiting a vulnerability. Following security best practices, remove malicious packages to protect your Lambda function from potential attacks.

Remediation: Remove malicious packages

Review the malicious package details in the **References** section of the **Vulnerability** tab of the trait to understand the threat. Remove the identified malicious packages from your function code and dependencies. For functions using layers, check if the malicious packages are installed in any layers and remove them.

Update your deployment package or container image to exclude the malicious packages, then deploy the updated version. For instructions, see Deploying Lambda functions as .zip file archives for .zip file archives or Create a Lambda function using a container image for container images.

The Lambda function has code vulnerabilities

Lambda function application code contains security vulnerabilities that could be exploited by threat actors. Code vulnerabilities include data leaks, injection flaws, missing encryption, and weak cryptography that are identified through automated code analysis. These vulnerabilities pose security risks to your AWS environment, as attackers can exploit them to compromise the confidentiality, integrity, or availability of data, or to access other systems. Code vulnerabilities represent security weaknesses that could be chained together with other attack vectors to compromise your function. Following security best practices, address these code vulnerabilities to protect your function from attack.

Remediation: Update affected functions

Review the **References** section in the **Vulnerability** tab of the trait. Amazon Inspector findings may include specific remediation guidance and code snippets showing the vulnerable code locations. Address the identified security issues in your function code using the provided plug-and-play code blocks or by implementing secure coding practices.

Always review code remediation suggestions before adopting them, as you might need to edit them to ensure your code performs as intended. After fixing the vulnerabilities, update the Lambda function code to use the corrected version. For instructions, see Updating function code in the *AWS Lambda Developer Guide*.

Afterwards, deploy the updated version. For instructions, see Deploying Lambda functions as .zip file archives for .zip file archives or Create a Lambda function using a container image for container images. For more information about Amazon Inspector code scanning, see Amazon Inspector Lambda code scanning in the *Amazon Inspector User Guide*.

Impact traits for Lambda functions

Impact traits describe the potential blast radius of an exposure. Security Hub analyzes the effective permissions of the AWS Identity and Access Management principal associated with the Lambda function to determine the downstream resources an attacker could reach if the function is compromised, as well as the business criticality of those resources. Each impact trait identifies a specific privilege escalation pattern. To reduce your blast radius, review the permission paths described in each trait and remove any unnecessary privileges.

Following standard security principles, grant least privilege by providing only the permissions required to perform a task. Replace broad policies with scoped-down policies that grant only the specific actions and resources needed. To identify unused permissions to remove, use IAM Access Analyzer to generate recommendations based on access history. For more information, see Findings for external and unused access and Apply least-privilege permissions in the *IAM User Guide*.

Has full control privileged executor path

The associated principal can pass a role to and inject code into a compute resource that already has elevated permissions. This allows the principal to gain full control over the executor and perform any action that the executor's role permits.

Has direct policy escalation path

The associated principal can directly modify IAM policies to grant itself additional permissions, escalating its own privileges without intermediate resources.

Has trust policy hijack path

The associated principal can modify the trust policy of an IAM role to allow itself to assume that role, gaining the role's permissions.

Has data ransomware path

The associated principal can encrypt or delete data in a way that could be used for ransomware, such as encrypting Amazon S3 objects with a customer-managed AWS KMS key and then modifying the key policy.

Has remove restriction path

The associated principal can remove security restrictions such as permission boundaries, service control policies, or resource-based policy deny statements, expanding what other principals or the resource itself can do.

Has pass role create executor path

The associated principal can create a new compute resource (such as a Lambda function or Amazon EC2 instance) and pass it a privileged role, effectively laundering its own permissions through the new resource.

Has swap role existing executor path

The associated principal can change the IAM role attached to an existing compute resource, replacing it with a more privileged role to escalate access.

Has role chain escalation path

The associated principal can assume a sequence of roles, where each role in the chain has progressively broader permissions, ultimately reaching a highly privileged role.

Has inject code privileged executor path

The associated principal can inject code into a running compute resource that has elevated permissions, executing arbitrary operations under that resource's privileged role.

Has disable audit trail path

The associated principal can disable logging or monitoring services such as CloudTrail, effectively covering its tracks during or after an escalation.

Has access existing executor path

The associated principal can invoke or connect to an existing compute resource and use its attached role to perform privileged actions.

Has credential minting path

The associated principal can create new long-term credentials (such as access keys or login profiles) for other principals, establishing persistent access paths that survive password rotations or session expirations.

Has pass role data access path

The associated principal can create a service resource and pass it a role that has access to sensitive data, gaining indirect access to that data through the new resource.

Has pass role task hijack path

The associated principal can pass a role to a scheduled or event-driven task (such as a Lambda function triggered by an event), allowing it to execute arbitrary code with that role's permissions.

Has single hop data access path

The associated principal can directly access sensitive data resources (such as Amazon S3 buckets or DynamoDB tables) through its existing permissions, without needing intermediate escalation steps.

Has capability advancing path

The associated principal has a privilege escalation path that advances its overall capabilities beyond what its directly assigned permissions would suggest. This is a general classification for paths that do not match a more specific pattern.

Business criticality

The business criticality of the primary resource, set either by automation rules or by inference from the name and tags.

Remediating exposures for Amazon RDS instances and clusters

AWS Security Hub can generate exposure findings for Amazon RDS instances and clusters.

On the Security Hub console, the Amazon RDS instance or cluster involved in an exposure finding and its identifying information are listed in the **Resources** section of the finding details. Programmatically, you can retrieve resource details with the GetFindingsV2 operation of the Security Hub CSPM API.

After identifying the resource involved in an exposure finding, you can delete the resource if you don't need it. Deleting a nonessential resource can reduce your exposure profile and AWS costs. If the resource is essential, follow these recommended remediation steps to help mitigate the risk. The remediation topics are divided based on the type of trait.

A single exposure finding contains issues identified in multiple remediation topics. Conversely, you can address an exposure finding and bring down its severity level by addressing just one remediation topic. Your approach to risk remediation depends on your organizational requirements and workloads.

> **Note**
>
> The remediation guidance provided in this topic might require additional consultation in other AWS resources.

Misconfiguration traits for Amazon RDS instances and clusters

The following describes the misconfiguration traits and remediation steps for Amazon RDS instances and clusters.

The Amazon RDS DB instance is configured with public access

Amazon RDS instances with public access are potentially accessible over the internet through their endpoints. While public access is sometimes necessary for instance functionality, this configuration can be used as a potential attack vector for unauthorized users to attempt to access your database. Publicly accessible databases can be exposed to port scanning, brute force attacks, and exploitation attempts. Following standard security principles, limit public exposure of your database resources.

Remediation: Modify public access settings

In the exposure finding, choose the resource link. This opens the affected DB instance in the Amazon RDS console. Evaluate whether the DB instance requires public accessibility based on your application architecture. For more information, see Setting up public or private access in Amazon RDS.

The Amazon RDS DB cluster has a snapshot that is shared publicly

Public snapshots can be accessed by any AWS account, potentially exposing sensitive data to unauthorized users. Any AWS account has permission to copy these public snapshots and create DB instances from them, which could lead to data breaches or unauthorized data access. Following security best practices, restrict access to your Amazon RDS snapshots to only trusted AWS accounts and organizations.

Remediation: Configure an Amazon RDS snapshot for private access

In the exposure finding, open the resource through the hyperlink. For information about how to modify snapshot sharing settings, see Sharing a snapshot in the *Amazon Aurora User Guide.* For information about how to stop sharing snapshots, see Stopping snapshot sharing in the *Amazon Aurora User Guide.*.

The Amazon RDS DB instance has a snapshot that is shared publicly

Public snapshots can be accessed by any AWS account, potentially exposing sensitive data to unauthorized users. Any AWS account has permission to copy these public snapshots and create DB instances from them, which could lead to data breaches or unauthorized data access. Following security best practices, restrict access to your Amazon RDS snapshots to only trusted AWS accounts and organizations.

Remediation: Configure an Amazon RDS snapshot for private access

In the exposure finding, open the resource through the hyperlink. For information about how to modify snapshot sharing settings, see Sharing a DB snapshot in the *Amazon RDS User Guide.* For information about how to stop sharing snapshots, see Stop sharing a DB snapshot in the *Amazon RDS User Guide.*.

The Amazon RDS DB instance has a snapshot that is not encrypted at rest

Unencrypted Amazon RDS DB instance snapshots may expose sensitive data if unauthorized access to the storage layer is obtained. Without encryption, data in snapshots could potentially be exposed through unauthorized access. This creates a risk of data breaches and compliance violations. Following security best practices, encrypt all database resources and their backups to maintain data confidentiality.

Remediation: Update affected resources

In the exposure finding, choose the resource link. This opens the affected snapshot in the Amazon RDS console. You cannot directly encrypt an existing unencrypted snapshot.

Instead, create an encrypted copy of the unencrypted snapshot. For detailed instructions, see DB cluster snapshot copying and Encrypting Amazon RDS resources in the *Amazon Aurora User Guide.*

The Amazon RDS DB cluster has a snapshot that is not encrypted at rest

Unencrypted Amazon RDS DB cluster snapshots may expose sensitive data if unauthorized access to the storage layer is obtained. Without encryption, data in snapshots could potentially be exposed through unauthorized access. This creates a risk of data breaches and compliance violations. Following security best practices, encrypt all database resources and their backups to maintain data confidentiality.

Remediation: Create an encrypted copy of the snapshot

In the exposure finding, choose the resource link. This opens the affected snapshot in the Amazon RDS console. You cannot directly encrypt an existing unencrypted snapshot.

Instead, create an encrypted copy of the unencrypted snapshot. For detailed instructions, see DB cluster snapshot copying and Encrypting Amazon RDS resources in the *Amazon Aurora User Guide.*

The Amazon RDS DB instance has an open security group

Security groups act as virtual firewalls for your Amazon RDS instances to control inbound and outbound traffic. Open security groups, which allow unrestricted access from any IP address, may expose your database instances to unauthorized access and potential attacks. Following standard security principles, restrict security group access to specific IP addresses and ports to maintain the principle of least privilege.

Remediation

Take one or more of the following actions to address this exposure:

Review security group rules and assess current configuration

In the exposure finding, open the resource for the DB instance Security Group. Evaluate which ports are open and accessible from broad IP ranges, such as (`0.0.0.0/0 or ::/0`). For information about viewing security group details, see DescribeSecurityGroups in the *Amazon Elastic Compute Cloud API Reference*.

Modify security group rules

Modify your security group rules to restrict access to specific trusted IP addresses or ranges. When updating your security group rules, consider separating access requirements for different network segments by creating rules for each required source IP range or restricting access to specific ports. To modify security group rules, see Configure security group rules in the *Amazon EC2 User Guide*. To modify the default port of an existing Amazon RDS database instance, see Modifying the DB cluster by using the console, CLI, and API in the *Amazon Aurora User Guide*.

The Amazon RDS DB instance has IAM database authentication disabled

IAM database authentication allows you to authenticate to your Amazon RDS database using IAM credentials instead of database passwords. This provides several security benefits, such as centralized access management, temporary credentials, and elimination of storing database passwords in application code. IAM database authentication allows authentication to database

instances with an authentication token instead of a password. As a result, network traffic to and from the database instance is encrypted using SSL. Without IAM authentication, databases typically rely on password-based authentication, which can lead to password reuse and weak passwords. Following security best practices, enable IAM database authentication.

Remediation: Enable IAM database authentication

In the exposure finding, choose the resource link. This opens the affected DB instance in the Amazon RDS console. You can enable IAM database authentication in the Database options.

For more information, see Enabling and disabling IAM database authentication in the *Amazon RDS User Guide*. After enabling IAM authentication, update your DB instances to use IAM authentication instead of password based authentication.

The Amazon RDS DB instance uses the default admin username

Using default usernames (for example, “admin”, “root”) for DB instances increases security risk as these are widely known and commonly targeted in brute force attacks. Default usernames are predictable and make it easier for unauthorized users to attempt to gain access to your database. With default usernames, attackers only need to obtain passwords rather than needing both to gain access to your database. Following security best practices, use unique administrator usernames for your database instance to enhance security through obscurity and reduce the risk of unauthorized access attempts.

Remediation: Configure a unique administrator username

In the exposure finding, choose the resource link. This opens the affected DB instance in the Amazon RDS console. You cannot change the administrator username of an existing Amazon RDS DB instance. To create a unique administrator name, you need to create a new DB instance with a custom username and migrate your data.

The Amazon RDS DB cluster uses the default admin username

Using default usernames (for example, “admin”, “root”) for DB instances increases security risk as these are widely known and commonly targeted in brute force attacks. Default usernames are predictable and make it easier for unauthorized users to attempt to gain access to your database. With default usernames, attackers only need to obtain passwords rather than needing both to gain access to your database. Following security best practices, use unique administrator usernames for your database instance to enhance security through obscurity and reduce the risk of unauthorized access attempts.

Remediation: Configure a unique administrator username

In the exposure finding, choose the resource link. This opens the affected DB instance in the Amazon RDS console. You cannot change the administrator username of an existing Amazon RDS DB instance. To create a unique administrator name, you need to create a new DB instance with a custom username and migrate your data.

The Amazon RDS DB instance has automatic minor version upgrades disabled

Automatic minor version upgrades ensure that your Amazon RDS instances automatically receive minor engine version upgrades when they become available. These upgrades often include important security patches and bug fixes that help maintain the security and stability of your database. Your database is at risk of running with known security vulnerabilities that have been fixed in newer minor versions. Without automatic updates, database instances can accumulate security vulnerabilities as new CVEs are discovered. Following security best practices, enable automatic minor version upgrades for all Amazon RDS instances.

Remediation: Enable automatic minor version upgrades

In the exposure finding, choose the resource link. This opens the affected DB instance in the Amazon RDS console. You can view automatic minor upgrade settings in the **Maintenance & backups** tab.

For more information, see Automatic minor version upgrades for Amazon RDS for MySQL. You can also configure your maintenance window to occur during periods of low database activity.

The Amazon RDS DB instance has automated backups disabled

Automated backups provide point-in-time recovery for your Amazon RDS instances, allowing you to restore your database to any point within your retention period. When automated backups are disabled, you risk losing data in case of malicious deletion, data corruption, or other data loss scenarios. In the event of malicious activity like ransomware attacks, database table deletion, or corruption, the ability to restore to a point in time before the incident reduces the time required to recover from an incident. Following security best practices, enable automated backups with an appropriate retention period for all production databases.

The Amazon RDS DB instance has deletion protection disabled

Database deletion protection is a feature that helps prevent the deletion of your database instances. When deletion protection is disabled, your database can be deleted by any user with

sufficient permissions, potentially resulting in data loss or application downtime. Attackers can delete your database, leading to service disruption, data loss, and increased recovery time. Following security best practices, enable deletion protection for your RDS DB instances to prevent malicious deletion.

Remediation: Enable delete protection for your Amazon RDS DB cluster

In the exposure finding, choose the resource link. This opens the affected DB cluster.

The Amazon RDS DB cluster has deletion protection disabled

Database deletion protection is a feature that helps prevent the deletion of your database instances. When deletion protection is disabled, your database can be deleted by any user with sufficient permissions, potentially resulting in data loss or application downtime. Attackers can delete your database, leading to service disruption, data loss, and increased recovery time. Following security best practices, enable deletion protection for your RDS DB clusters to prevent malicious deletion.

Remediation: Enable delete protection for your Amazon RDS DB cluster

In the exposure finding, choose the resource link. This opens the affected DB cluster.

The Amazon RDS DB instance uses the default port for the database engine

Amazon RDS instances that use default ports for database engines may face increased security risks, as these default ports are widely known and are often targeted by automated scanning tools. Modifying your DB instance to use non-default ports adds an additional layer of security through obscurity, making it more difficult for unauthorized users to perform automated or targeted attacks on your database. Default ports are commonly scanned for by unauthorized persons, and may cause your DB instance to be targeted. Following security best practices, change the default port to a custom port to reduce the risk of automated or targeted attacks.

Remediation

Take one or more of the following actions to address this exposure:

Update affected resources

In the exposure finding, choose the resource link. This opens the affected DB instance in the Amazon RDS console.

Update application connection strings

After changing the port, update all applications and services that connect to your Amazon RDS instance to use the new port number.

The Amazon RDS DB instance is not covered by a backup plan

AWS Backup is a fully managed backup service that centralizes and automates the backup of data across AWS services. If your DB instance is not covered by a backup plan, you risk losing data in case of malicious deletion, data corruption, or other data loss scenarios. In the event of malicious activity like ransomware attacks, database table deletion, or corruption, the ability to restore to a point in time before the incident reduces the time required to recover from an incident. Following security best practices, include your Amazon RDS instances in a backup plan to ensure data protection.

Remediation: Create and assign a backup plan for your DB instance

In the exposure finding, choose the resource link. This opens the affected DB instance in the Amazon RDS console. Consider what backup frequency, retention period, and lifecycle rules are best for your applications.

Reachability traits for Amazon RDS DB instances

Here are the reachability traits for Amazon RDS DB instances and suggested remediation steps.

The Amazon RDS DB instance is reachable from the public internet

A network scan from the internet confirmed that the database port on the Amazon RDS DB instance endpoint accepts connections. Unlike a configuration check, this trait shows you whether the endpoint is actually reachable. The DB instance allows public access, and its security groups and network access control lists permit inbound traffic on the database port.

A reachable database endpoint is exposed to port scanning, credential brute forcing, and exploitation attempts against the database engine. Following standard security principles, keep databases off the public internet and restrict access to only the networks that require it.

Remediation

Take one or more of the following actions to address this exposure:

Disable public access

In the exposure finding, choose the resource link to open the affected DB instance in the Amazon RDS console. If you don't need to reach the DB instance from the internet, modify the DB instance so that it isn't publicly accessible. This removes the public endpoint and closes the reachable port. For more information, see Setting up public or private access in Amazon RDS.

Restrict inbound security group rules

If you need the DB instance to remain publicly accessible, restrict the security groups that are associated with it. Remove inbound rules that permit traffic on the database port from any address (`0.0.0.0/0` or `::/0`), and add rules for trusted sources only. For instructions on configuring security group rules, see Configure security group rules in the *Amazon EC2 User Guide*.

Use private connectivity

To connect from outside the VPC, use private connectivity instead of a public endpoint. For example, use a VPN connection, AWS Direct Connect, or a bastion host in a public subnet that connects to the DB instance over the private network.

Sensitive data traits for Amazon RDS DB instances

Here are the sensitive data traits for Amazon RDS DB instances and suggested remediation steps.

The Amazon RDS DB instance contains sensitive data

A data security scan has confirmed that sensitive records are present on the Amazon RDS DB instance. An integrated data security product sets this trait when it inspects the contents of the DB instance and identifies records that require protection.

The presence of sensitive data raises the impact of every other weakness on the same DB instance. A network path or a permissive access configuration that would otherwise expose application data instead exposes regulated or confidential records. A threat actor who reaches the DB instance can query and copy those records in bulk and retain them outside your environment. The threat actor can also use any recovered credentials to authenticate to other systems. Following security best practices, we recommend restricting network and identity access to Amazon RDS DB instances that store sensitive records, and encrypting those records at rest and in transit.

Sensitive data can include:

- Credentials – such as passwords, access keys, and connection strings
- Personally identifiable information
- Financial information – such as account numbers and payment card data

- Confidential content requiring protection

Removing the sensitive records is the only way to clear this trait. If your workload requires the DB instance to store sensitive data, the following security best practices reduce the risk of exposure.

Review the sensitive data on the DB instance

In the exposure finding, open the resource with the hyperlink. This opens the affected DB instance. Note the DB instance identifier, and record the VPC security groups listed under **Connectivity & security**. Review the data security finding that reported the sensitive records to determine which databases, schemas, and tables contain them.

Based on the type of sensitive data discovered, implement the appropriate security controls:

- **Restrict inbound network access** – In the Amazon RDS console, choose **Databases**, select the DB instance, and choose **Connectivity & security**. Open each attached VPC security group and review its inbound rules. Replace any rule that allows the database port from `0.0.0.0/0` or `::/0` with the specific CIDR ranges or security group IDs that your applications use. For more information, see Controlling access with security groups in the *Amazon RDS User Guide*.
- **Remove public accessibility** – In the Amazon RDS console, select the DB instance, choose **Modify**, and under **Connectivity** set **Public access** to **Not publicly accessible**. Place the DB instance in private subnets that have no route to an internet gateway. Reach it from your applications through the VPC, AWS Direct Connect, or a VPN connection. For more information, see Working with a DB instance in a VPC in the *Amazon RDS User Guide*.
- **Limit who can authenticate to the database** – Grant each application and user only the database privileges required for its function. Revoke read access to the tables that contain sensitive records from any database user that does not need it. Use IAM database authentication so that IAM identities and short-lived tokens control access instead of long-lived database passwords. For more information, see IAM database authentication in the *Amazon RDS User Guide*.
- **Encrypt the sensitive records at rest** – In the Amazon RDS console, select the DB instance and choose the **Configuration** tab to see whether the DB instance uses encryption. You cannot enable encryption at rest on an existing unencrypted DB instance. To encrypt its data, create a snapshot of the DB instance. Copy the snapshot and select an AWS KMS key for the copy, then restore the encrypted snapshot copy to a new DB instance. Repoint your applications at the new endpoint, and delete the unencrypted DB instance and its snapshots. For more information, see Encrypting Amazon RDS resources in the *Amazon RDS User Guide*.

- **Require encryption in transit** – Configure your database clients to connect with SSL/TLS using the Amazon RDS certificate bundle. Enforce encrypted connections on the DB instance through the parameter that your database engine provides for that purpose. For more information, see Using SSL/TLS to encrypt a connection to a DB instance or cluster in the *Amazon RDS User Guide*.
- **Monitor access to the DB instance** – Publish the database engine logs to Amazon CloudWatch Logs, and review them for connections from unexpected sources and for queries against the tables that contain sensitive records. For more information, see Monitoring Amazon RDS log files in the *Amazon RDS User Guide*.

Remediating exposures for Amazon S3 buckets

AWS Security Hub can generate exposure findings for Amazon Simple Storage Service (Amazon S3) buckets.

On the Security Hub console, the Amazon S3 bucket involved in an exposure finding and its identifying information are listed in the **Resources** section of the finding details. Programmatically, you can retrieve resource details with the GetFindingsV2 operation of the Security Hub CSPM API.

After identifying the resource involved in an exposure finding, you can delete the resource if you don't need it. Deleting a nonessential resource can reduce your exposure profile and AWS costs. If the resource is essential, follow these recommended remediation steps to help mitigate the risk. The remediation topics are divided based on the type of trait.

A single exposure finding contains issues identified in multiple remediation topics. Conversely, you can address an exposure finding and bring down its severity level by addressing just one remediation topic. Your approach to risk remediation depends on your organizational requirements and workloads.

> **Note**
>
> The remediation guidance provided in this topic might require additional consultation in other AWS resources.

  - The Amazon S3 bucket has public write access
- Sensitive data traits for Amazon S3 buckets
  - The Amazon S3 bucket contains sensitive data

Misconfiguration traits for Amazon S3 buckets

Here are misconfiguration traits for Amazon S3 buckets and suggested remediation steps.

The Amazon S3 bucket has versioning disabled

Amazon S3 Versioning helps you keep multiple variants of an object in the same bucket. When versioning is disabled, Amazon S3 stores only the most recent version of each object, meaning that if objects are accidentally or maliciously deleted or overwritten, they cannot be recovered. Versioning-enabled buckets provide protection against accidental deletion, application failures, and security incidents like ransomware attacks, where unauthorized modification or deletion of data could occur. Following security best practices, enable versioning for buckets containing important data that would be difficult or impossible to recreate if lost.

Remediation: Enable versioning

To enable Amazon S3 Versioning on a bucket, see Enabling versioning on buckets in the *Amazon S3 User Guide*. When enabling versioning, consider implementing lifecycle rules to manage storage, as versioning will maintain multiple copies of objects.

The Amazon S3 bucket has Object Lock disabled

Amazon S3 Object Lock provides a write-once-read-many (WORM) model for Amazon S3 objects, preventing them from being deleted or overwritten for a fixed period or indefinitely. When Object Lock is disabled, your objects could be vulnerable to accidental or malicious deletion, modification, or encryption by ransomware. Object Lock is especially important for compliance with regulatory

requirements that demand immutable data storage and for protection against sophisticated threats like ransomware that may attempt to encrypt your data. By enabling Object Lock, you can enforce retention policies as an added layer of data protection and create an immutable backup strategy for your critical data. Following security best practices, enable Object Lock to prevent malicious modification of your objects.

Remediation: Configure S3 Object Lock

Note that Object Lock can only be enabled when creating a new bucket, so you will need to create a new bucket with Object Lock enabled. For large migrations, consider using Batch Operations to copy objects to the new bucket. Before you lock any objects, you must also enable Amazon S3 Versioning and Object Lock on a bucket. Since Object Lock can only be enabled on new buckets, you'll need to migrate existing data to a new bucket with Object Lock enabled. For information about how to configure Object Lock on a bucket, see Configuring Amazon S3 Object Lock in the *Amazon S3 User Guide*. After setting up Object Lock, choose an appropriate retention mode according to your environment.

Amazon S3 bucket is not encrypted at rest with AWS KMS keys

Amazon S3 applies server-side encryption with Amazon S3 managed keys as the default level of encryption for all new buckets. While Amazon S3 managed keys provides strong encryption protection, it does not offer the same level of access control and audit capabilities as AWS Key Management Service keys. When using KMS keys, access to objects requires permissions to both the Amazon S3 bucket and the KMS key that encrypted the object. This is particularly important for sensitive data where you need granular control over who can access the encrypted objects and comprehensive audit logging of encryption key usage. Following security best practices, use KMS keys to encrypt buckets containing sensitive data or for environments with strict compliance requirements.

Remediation: Configure S3 bucket key

To configure a bucket to use an Amazon S3 bucket key for new objects, see Configuring your bucket to use an Amazon S3 Bucket Key with SSE-KMS for new objects in the *Amazon S3 User Guide*. For information about how to encrypt an existing object, see Encrypting objects with Amazon S3 Batch Operations in the AWS Storage Blog.

When implementing AWS KMS encryption, consider the following:

- **Key management** – Decide on whether to use an AWS managed key or a customer managed key (CMK). CMKs offer customers full control over the lifecycle and usage of their keys. For more

information on the difference between these two types of keys, see AWS KMS keys in the *AWS Key Management Service Developer Guide*.

- **Key rotation** – For additional security measures, enable automatic key rotation for your KMS keys. For more information, see Enable automatic key rotation in the *AWS Key Management Service Developer Guide*.

Multi-factor authentication (MFA) delete is disabled on a versioned Amazon S3 bucket

Multi-factor authentication (MFA) delete provides an additional layer of security for your Amazon S3 bucket. It requires multi-factor authentication for destructive Amazon S3 operations. When MFA delete is disabled, users with appropriate permissions can permanently delete object versions or suspend versioning on your bucket without additional authentication challenges. Enabling MFA delete helps protect against unauthorized or accidental deletion of your data, providing enhanced protection against ransomware attacks, insider threats, and operational errors. MFA delete is particularly valuable for buckets containing critical or compliance-sensitive data that must be protected from unauthorized deletion. Following security best practices, enable MFA for your Amazon S3 buckets.

Remediation

Take one or more of the following actions to address this exposure:

Review MFA types

AWS supports the following MFA types. Although authentication with a physical device typically provides more stringent security protection, using any type of MFA is more secure than having MFA disabled.

Enforce MFA at the resource policy level

Use the `aws:MultiFactorAuthAge` condition key in a bucket policy to require MFA for sensitive operations. For more information, see Requiring MFA in the *Amazon S3 User Guide*.

Enable MFA

To enable MFA delete, first, ensure that versioning is enabled on your Amazon S3 bucket. MFA delete is only supported on buckets that have versioning enabled. For information about how to enable Amazon S3 versioning, see Enabling versioning on buckets in the *Amazon S3 User Guide*. MFA delete cannot be enabled through the Amazon S3 console. You must use the Amazon S3 API or the AWS CLI. For more information, see Configuring MFA delete in the *Amazon S3 User Guide*.

The Amazon S3 bucket allows principals from other AWS accounts to modify bucket permissions

Amazon S3 bucket policies control access to buckets and objects. When bucket policies allow principals from other AWS accounts to modify bucket permissions, unauthorized users can reconfigure your bucket. If external principal credentials are compromised, unauthorized users can gain control over your bucket, leading to data breaches or service disruptions. Following standard security principles, restrict permission management actions to trusted principals only.

Remediation

Take one or more of the following actions to address this exposure:

Review and identify bucket policies

In the exposure, identify the Amazon S3 bucket in the ARN field. In the Amazon S3 console, select the bucket, and navigate to the **Permissions** tab to review the bucket policy. Review the permissions policy attached to the bucket. Look for policy statements that grant actions like `s3:PutBucketPolicy, s3:PutBucketAcl, s3:DeleteBucketPolicy, s3:*` or policy statements that allow access to principals outside your account, as denoted in the principal statement.

Modify the bucket policy

Modify the bucket policy to remove or restrict actions granted to other AWS accounts:

- Remove policy statements that grant external accounts permission management actions.
- If cross-account access is required, replace broad permissions (`s3:*`) with specific actions that do not include bucket permission management.

For information about modifying a bucket policy, see Adding a bucket policy by using the Amazon S3 console in the *Amazon S3 User Guide*.

Reachability traits for Amazon S3 buckets

Here are reachability traits for Amazon S3 buckets and suggested remediation steps.

The Amazon S3 bucket has public read access

Amazon S3 buckets with public read access allow anyone on the internet to view the contents of your bucket. While this may be necessary for publicly accessible websites or shared resources,

it can create security risks if the bucket contains sensitive data. Public read access can lead to unauthorized viewing and downloading, which can lead to data breaches if sensitive data is stored in those buckets. Following standard security principles, restrict access to Amazon S3 buckets to necessary users and systems.

Remediation

Take one or more of the following actions to address this exposure:

Block public access at the bucket level

Amazon S3 provides Block Public Access settings that can be configured at both the bucket and account levels to prevent public access regardless of bucket policies or ACLs. For more information, see Blocking public access to your Amazon S3 storage in the *Amazon S3 User Guide*. After blocking public access, review your bucket access control configuration to make sure it aligns with your access requirements. Then review your Amazon S3 bucket policy to explicitly define who can access your bucket. For examples of bucket policies see Examples of Amazon S3 bucket policies in the *Amazon S3 User Guide*.

Alternative access methods

If public read access is required, consider these more secure alternatives:

- **Amazon CloudFront** – Use CloudFront with an Origin Access Identity (OAI) or Origin Access Control (OAC) to allow read access from a private Amazon S3 bucket. This alternative restricts direct access to your Amazon S3 bucket while allowing content to be publicly accessible through CloudFront. For more information, see Restricting access to an Amazon S3 origin in the *Amazon CloudFront Developer Guide*.
- **Presigned URLs** – Use presigned URLs for temporary access to specific objects. For more information, see Sharing objects with presigned URLs in the *Amazon S3 User Guide*.

The Amazon S3 bucket has public write access

Amazon S3 buckets with public write access allow anyone on the internet to upload, modify, or delete objects in your bucket. This creates significant security risks, including the potential for someone to upload malicious files, modify existing files, and delete data. Public write access creates security vulnerabilities that can be exploited by attackers. Following standard security principles, restrict write access to your Amazon S3 buckets to only necessary users and systems.

Remediation

Take one or more of the following actions to address this exposure:

Block public access at the account and bucket level

Amazon S3 provides block public access settings that can be configured at both the bucket and account levels to prevent public access regardless of bucket policies or ACLs. For more information, see Blocking public access to your Amazon S3 storage in the *Amazon S3 User Guide*.

Modify bucket policies

For a more granular approach to remove public write access, review the bucket policy. You can look for `s3:PutObject`, `s3:DeleteObject`, or `s3:*`. For more information on managing bucket policies, see Bucket policies for Amazon S3 in the *Amazon S3 User Guide*.

Alternative access methods

If public write access is required, consider these more secure alternatives:

- **Presigned URLs** – Use presigned URLs for temporary access to specific objects. For more information, see Sharing objects with presigned URLs in the *Amazon S3 User Guide*.
- **Amazon API Gateway proxy** – Use an intermediary such as API Gateway with AWS Lambda to validate and authorize requests before writing to your Amazon S3 bucket. This approach ensures that clients never write to the bucket directly. For more information, see Tutorial: Create a REST API as an Amazon S3 proxy in the *API Gateway Developer Guide*.
- **Amazon CloudFront** – Use CloudFront with an Origin Access Control (OAC) configured to always sign requests. Enable the PUT and POST methods to allow authenticated writes without exposing your Amazon S3 bucket directly. Configure your bucket policy to restrict `s3:DeleteObject` permissions to authorized principals only, so that unauthorized users cannot delete objects you want to keep. For more information, see Restrict access to an Amazon S3 origin in the *Amazon CloudFront Developer Guide*.

Sensitive data traits for Amazon S3 buckets

Here are the sensitive data traits for Amazon S3 buckets and suggested remediation steps.

The Amazon S3 bucket contains sensitive data

A data security scan has confirmed that sensitive data is present in the Amazon S3 bucket. An integrated data security product sets this trait when it inspects the objects in the bucket and

identifies content that requires protection. Security Hub reports the trait the same way regardless of which product performed the inspection.

Sensitive data can include:

- Credentials
- Personally identifiable information
- Financial information
- Confidential content requiring protection

If sensitive data is exposed through misconfiguration or unauthorized access, it could lead to compliance violations, data breaches, identity theft, or financial loss. Following security best practices, ensure proper classification of data and continuous monitoring of sensitive data in your Amazon S3 buckets.

Remediation

To clear this trait, remove the sensitive data from the bucket. If your workload requires the bucket to store sensitive data, implement the following security controls to reduce the risk of exposure.

Review the sensitive data in the bucket

In the exposure finding, choose **Open resource**. Review the data security finding that reported the sensitive data to determine which objects or prefixes contain it. If the detection came from Macie, the finding type describes the category of sensitive data. For more information, see Types of Macie findings in the *Amazon Macie User Guide*.

Based on the type of sensitive data discovered, implement the appropriate security controls:

- **Restrict access to the bucket** – Review bucket permissions to make sure they follow the principle of least privilege. Use IAM policies, bucket policies, and ACLs to restrict access. For more information, see Identity and Access Management for Amazon S3 in the *Amazon S3 User Guide*.
- **Enable server-side encryption** – Enable server-side encryption with KMS keys keys for additional protection. For more information, see Using server-side encryption with AWS KMS keys (SSE-KMS) in the *Amazon S3 User Guide*.
- **Redact or transform the sensitive data** – If the objects do not need to retain sensitive values, use AWS Glue DataBrew to prepare the data. Apply the masking, replacement, or hashing transformations that remove those values before downstream systems consume the data. Write

the prepared output to a separate bucket that has its own access controls. For more information, see What is AWS Glue DataBrew in the *AWS Glue DataBrew Developer Guide*.

Remediating exposures for Amazon SageMaker notebook instances

AWS Security Hub can generate exposure findings for Amazon SageMaker notebook instances.

On the Security Hub console, the notebook instance involved in an exposure finding and its identifying information are listed in the **Resources** section of the finding details. Programmatically, you can retrieve resource details with the GetFindingsV2 operation of the Security Hub CSPM API.

After identifying the resource involved in an exposure finding, you can delete the resource if you don't need it. Deleting a nonessential resource can reduce your exposure profile and AWS costs. If the resource is essential, follow these recommended remediation steps to help mitigate the risk. The remediation topics are divided based on the type of trait.

A single exposure finding contains issues identified in multiple remediation topics. Conversely, you can address an exposure finding and bring down its severity level by addressing just one remediation topic. Your approach to risk remediation depends on your organizational requirements and workloads.

> **Note**
>
> The remediation guidance provided in this topic might require additional consultation in other AWS resources.

Misconfiguration traits for Amazon SageMaker notebook instances

Here are misconfiguration traits for Amazon SageMaker notebook instances and suggested remediation steps.

The Amazon SageMaker notebook instance has direct internet access enabled

When `DirectInternetAccess` is enabled on an Amazon SageMaker notebook instance, outbound traffic is routed through a SageMaker-managed network address translation (NAT) gateway to the internet. This provides an egress path that can be used for data exfiltration or as a command-and-control channel if the notebook is compromised. Following security best practices, disable direct internet access and place notebook instances in a VPC with VPC endpoints for required AWS services.

Remediation

Take one or more of the following actions to address this exposure:

Disable direct internet access

The `DirectInternetAccess` setting cannot be changed after a notebook instance is created. To disable it, create a new notebook instance with `DirectInternetAccess` set to `Disabled` in a private subnet within a VPC, then migrate your notebooks and data from the existing instance. For instructions, see Connect a notebook instance in a VPC to external resources in the *Amazon SageMaker Developer Guide*.

Configure VPC endpoints

When direct internet access is disabled, the notebook instance requires VPC endpoints to access AWS services such as Amazon S3 and the Amazon SageMaker API. Create interface VPC endpoints for the services your notebook needs. For information on VPC endpoints, see What is AWS PrivateLink? in the *AWS PrivateLink Guide*.

The Amazon SageMaker notebook instance has root access enabled

When `RootAccess` is enabled on an Amazon SageMaker notebook instance, users have full OS-level root privileges. Root access allows arbitrary system modifications, persistent backdoors, and unrestricted package installation. Following security best practices, disable root access for notebook instances unless it is explicitly required for your workflow.

Remediation: Disable root access

You cannot change the `RootAccess` setting on a running notebook instance. To disable it, stop the instance, then update the instance configuration to set `RootAccess` to `Disabled`. Most notebook workflows, including installing packages with `pip` and running lifecycle configurations, continue to work without root access. For instructions, see Control root access to a Amazon SageMaker notebook instance in the *Amazon SageMaker Developer Guide*.

Additional considerations

If root access is required for specific tasks, consider using Amazon SageMaker Studio notebooks instead, which provide isolated container-based environments with more granular access controls. You can also use lifecycle configurations to pre-install required packages at instance creation time, reducing the need for root access during normal use.

Sensitive data traits for Amazon SageMaker notebook instances

Here are the sensitive data traits for Amazon SageMaker notebook instances and suggested remediation steps.

The Amazon SageMaker notebook instance contains sensitive data

A data security scan has confirmed that sensitive data is present on the Amazon SageMaker notebook instance. An integrated data security product sets this trait. The product inspects the notebook files, outputs, and attached storage, and identifies content that requires protection. We report this trait in Security Hub consistently, regardless of which integrated product performed the inspection.

Sensitive data raises the impact of every other weakness on the same notebook instance. A permissive execution role, a direct internet egress path, or overly broad access exposes regulated or confidential content. A threat actor who reaches the notebook can read and copy those records from the notebook files, output cells, and saved checkpoints. The threat actor can then retain those records outside your environment. They can also use any credentials found in the notebook to authenticate to other systems.

Following security best practices, we recommend restricting access to notebook instances that hold sensitive data, and encrypting the attached storage at rest.

Sensitive data can include:

- Credentials – such as passwords, access keys, and connection strings
- Personally identifiable information
- Financial information – such as account numbers and payment card data
- Confidential content requiring protection

Removing the sensitive data from the notebook is the only way to clear this trait. If the notebook must reference sensitive data, the following security best practices reduce the risk of exposure.

Review the sensitive data on the notebook instance

In the exposure finding, open the resource with the hyperlink. This opens the affected notebook instance. Note the notebook instance name, the AWS account, and the AWS Region. Review the data security finding that reported the sensitive data to determine which notebook files, output cells, or checkpoints contain it.

Based on the type of sensitive data discovered, implement the appropriate security controls:

- **Remove the sensitive values from the notebook** – Delete sensitive values from the notebook code and clear the output cells that contain them. Delete any saved checkpoints and exported

copies that retain the values. Where a value must remain referenced, replace it with a tokenized or masked placeholder. For more information, see Use Amazon SageMaker notebook instances in the *Amazon SageMaker Developer Guide*.

- **Rotate any exposed credentials** – If the notebook contained credentials, treat them as compromised. Disable and rotate the credentials, then review the audit logs of the affected system for use of the exposed values. Retrieve secrets at run time from AWS Secrets Manager through a narrowly scoped execution role instead of embedding them in notebook content. For more information, see Rotate AWS Secrets Manager secrets in the *AWS Secrets Manager User Guide*.
- **Restrict who can open the notebook instance** – Grant access only to the IAM identities that need it. Scope the execution role to the specific actions and resources that the notebook uses. Control who can open the notebook by restricting the `sagemaker:CreatePresignedNotebookInstanceUrl` permission. For more information, see Amazon SageMaker identity-based policy examples in the *Amazon SageMaker Developer Guide*.
- **Encrypt the notebook storage at rest** – Attach an AWS KMS key to the notebook instance so that the storage volume holding the notebook files and checkpoints is encrypted at rest. Use a customer managed key so that you control the key policy. Grant `kms:Decrypt` on that key only to the identities that need to read the notebook. For more information, see Protect data at rest using encryption in the *Amazon SageMaker Developer Guide*.
- **Monitor access to the notebook instance** – Review AWS CloudTrail for `sagemaker:CreatePresignedNotebookInstanceUrl` calls and for access from unexpected identities or sources. For more information, see Log Amazon SageMaker API calls with AWS CloudTrail in the *Amazon SageMaker Developer Guide*.

Impact traits for Amazon SageMaker notebook instances

Impact traits describe the potential blast radius of an exposure. Security Hub analyzes the effective permissions of the AWS Identity and Access Management principal associated with the SageMaker notebook instance to determine the downstream resources an attacker could reach if the notebook instance is compromised, as well as the business criticality of those resources. Each impact trait identifies a specific privilege escalation pattern. To reduce your blast radius, review the permission paths described in each trait and remove any unnecessary privileges.

Following standard security principles, grant least privilege by providing only the permissions required to perform a task. Replace broad policies with scoped-down policies that grant only the specific actions and resources needed. To identify unused permissions to remove, use IAM

Access Analyzer to generate recommendations based on access history. For more information, see Findings for external and unused access and Apply least-privilege permissions in the *IAM User Guide*.

Has full control privileged executor path

The associated principal can pass a role to and inject code into a compute resource that already has elevated permissions. This allows the principal to gain full control over the executor and perform any action that the executor's role permits.

Has direct policy escalation path

The associated principal can directly modify IAM policies to grant itself additional permissions, escalating its own privileges without intermediate resources.

Has trust policy hijack path

The associated principal can modify the trust policy of an IAM role to allow itself to assume that role, gaining the role's permissions.

Has data ransomware path

The associated principal can encrypt or delete data in a way that could be used for ransomware, such as encrypting Amazon S3 objects with a customer-managed AWS KMS key and then modifying the key policy.

Has remove restriction path

The associated principal can remove security restrictions such as permission boundaries, service control policies, or resource-based policy deny statements, expanding what other principals or the resource itself can do.

Has pass role create executor path

The associated principal can create a new compute resource (such as a Lambda function or Amazon EC2 instance) and pass it a privileged role, effectively laundering its own permissions through the new resource.

Has swap role existing executor path

The associated principal can change the IAM role attached to an existing compute resource, replacing it with a more privileged role to escalate access.

Has role chain escalation path

The associated principal can assume a sequence of roles, where each role in the chain has progressively broader permissions, ultimately reaching a highly privileged role.

Has inject code privileged executor path

The associated principal can inject code into a running compute resource that has elevated permissions, executing arbitrary operations under that resource's privileged role.

Has disable audit trail path

The associated principal can disable logging or monitoring services such as CloudTrail, effectively covering its tracks during or after an escalation.

Has access existing executor path

The associated principal can invoke or connect to an existing compute resource and use its attached role to perform privileged actions.

Has credential minting path

The associated principal can create new long-term credentials (such as access keys or login profiles) for other principals, establishing persistent access paths that survive password rotations or session expirations.

Has pass role data access path

The associated principal can create a service resource and pass it a role that has access to sensitive data, gaining indirect access to that data through the new resource.

Has pass role task hijack path

The associated principal can pass a role to a scheduled or event-driven task (such as a Lambda function triggered by an event), allowing it to execute arbitrary code with that role's permissions.

Has single hop data access path

The associated principal can directly access sensitive data resources (such as Amazon S3 buckets or DynamoDB tables) through its existing permissions, without needing intermediate escalation steps.

Has capability advancing path

The associated principal has a privilege escalation path that advances its overall capabilities beyond what its directly assigned permissions would suggest. This is a general classification for paths that do not match a more specific pattern.

Business criticality

The business criticality of the primary resource, set either by automation rules or by inference from the name and tags.

Remediating exposures for Amazon SageMaker models

AWS Security Hub can generate exposure findings for Amazon SageMaker models. A model whose artifact runs malicious code when it loads can act with the permissions of the model's execution role. Remediate these findings before you deploy or continue to serve the model.

On the Security Hub console, the model involved in an exposure finding and its identifying information are listed in the **Resources** section of the finding details. Programmatically, you can retrieve resource details with the GetFindingsV2 operation of the Security Hub CSPM API.

After identifying the resource involved in an exposure finding, you can delete the resource if you don't need it. Deleting a nonessential resource can reduce your exposure profile and AWS costs. If the resource is essential, follow these recommended remediation steps to help mitigate the risk. The remediation topics are divided based on the type of trait.

A single exposure finding contains issues identified in multiple remediation topics. Conversely, you can address an exposure finding and bring down its severity level by addressing just one remediation topic. Your approach to risk remediation depends on your organizational requirements and workloads.

> **Note**

Vulnerability traits for Amazon SageMaker models

Here are the vulnerability traits for Amazon SageMaker models and suggested remediation steps.

The Amazon SageMaker model has a potentially malicious artifact

An integrated AI security product flags the artifact that backs the Amazon SageMaker model as potentially malicious. For example, the product found a serialized callable in the model artifact that runs code when the model is loaded, outside of an approved set of runtime libraries. Security Hub reports this trait consistently, regardless of which integrated product performed the inspection.

When SageMaker loads the artifact to serve the model, that code runs inside the inference container with the permissions of the model's execution role. A threat actor who controls the

artifact can use those permissions to read or modify the data that the role can reach. The threat actor can also take the role's credentials, tamper with predictions, or open an outbound connection to a command-and-control server. The impact traits in this finding show which downstream resources the execution role can reach.

Replace or delete the flagged artifact to resolve this trait. Until you do, the following security best practices reduce the risk of the artifact running.

To identify the model artifact, do the following:

1. To open the affected model, choose the resource hyperlink in the exposure finding.
2. Note the model name, the AWS account, and the AWS Region.
3. In the model details, note the location of the model artifact in Amazon S3 (`ModelDataUrl`) and the container image.
4. Review the finding from the AI security product to determine what it detected in the artifact.

Based on how the model is used, implement the appropriate security controls:

- **Stop serving the model** – If any of your endpoint configurations reference the model, update the endpoint to use a verified model, or delete the endpoint. Then delete the model so that no one can deploy it again. For instructions on deleting endpoints and resources, see Delete endpoints and resources in the *Amazon SageMaker Developer Guide*.
- **Quarantine and replace the artifact** – Restrict access to the artifact in Amazon S3 so that it can't be loaded again, and keep a copy for investigation. Verify where the artifact came from, then rebuild the model from trusted code and dependencies. Where your framework supports it, save model weights in a format that doesn't run code when it's loaded.
- **Require approval before deployment** – Register model versions in the SageMaker Model Registry, and deploy only versions with an approval status of `Approved`. For instructions on updating the approval status of a model, see Update the approval status of a model in the *Amazon SageMaker Developer Guide*.
- **Enable network isolation** – Create the model with `EnableNetworkIsolation` set to `True`. With network isolation, the inference container can't make outbound network calls and doesn't receive any AWS credentials. You set network isolation when you create a model, so to enable it, create a new model and update the endpoint to use it. For instructions on enabling network isolation, see Run training and inference containers in internet-free mode in the *Amazon SageMaker Developer Guide*.

- **Scope the execution role** – Grant the model's execution role only the permissions that inference requires, such as read access to the artifact and the container image. For more information, see How to use SageMaker execution roles in the *Amazon SageMaker Developer Guide*.
- **Monitor model and endpoint changes** – Review AWS CloudTrail for `CreateModel`, `CreateEndpointConfig`, and `UpdateEndpoint` calls from unexpected identities, and for writes to the Amazon S3 location of your model artifacts. For more information, see Logging Amazon SageMaker API calls using AWS CloudTrail in the *Amazon SageMaker Developer Guide*.

Impact traits for Amazon SageMaker models

Impact traits describe the potential blast radius of an exposure. Security Hub analyzes the effective permissions of the execution role associated with the SageMaker model. From these permissions, it determines the downstream resources that an attacker could reach if the model artifact runs malicious code, and the business criticality of those resources. Each impact trait identifies a specific privilege escalation pattern. To reduce your blast radius, review the permission paths described in each trait and remove any unnecessary privileges.

Following standard security principles, grant least privilege by providing only the permissions required to perform a task. Replace broad policies with scoped-down policies that grant only the specific actions and resources needed. To identify unused permissions to remove, use IAM Access Analyzer to generate recommendations based on access history. For more information, see Findings for external and unused access and Apply least-privilege permissions in the *IAM User Guide*.

Has full control privileged executor path

The associated principal can pass a role to and inject code into a compute resource that already has elevated permissions. This allows the principal to gain full control over the executor and perform any action that the executor's role permits.

Has direct policy escalation path

The associated principal can directly modify IAM policies to grant itself additional permissions, escalating its own privileges without intermediate resources.

Has trust policy hijack path

The associated principal can modify the trust policy of an IAM role to allow itself to assume that role, gaining the role's permissions.

Has data ransomware path

The associated principal can encrypt or delete data in a way that could be used for ransomware, such as encrypting Amazon S3 objects with a customer-managed AWS KMS key and then modifying the key policy.

Has remove restriction path

The associated principal can remove security restrictions such as permission boundaries, service control policies, or resource-based policy deny statements, expanding what other principals or the resource itself can do.

Has pass role create executor path

The associated principal can create a new compute resource (such as a Lambda function or Amazon EC2 instance) and pass it a privileged role, effectively laundering its own permissions through the new resource.

Has swap role existing executor path

The associated principal can change the IAM role attached to an existing compute resource, replacing it with a more privileged role to escalate access.

Has role chain escalation path

The associated principal can assume a sequence of roles, where each role in the chain has progressively broader permissions, ultimately reaching a highly privileged role.

Has inject code privileged executor path

The associated principal can inject code into a running compute resource that has elevated permissions, executing arbitrary operations under that resource's privileged role.

Has disable audit trail path

The associated principal can disable logging or monitoring services such as CloudTrail, effectively covering its tracks during or after an escalation.

Has access existing executor path

The associated principal can invoke or connect to an existing compute resource and use its attached role to perform privileged actions.

Has credential minting path

The associated principal can create new long-term credentials (such as access keys or login profiles) for other principals, establishing persistent access paths that survive password rotations or session expirations.

Has pass role data access path

The associated principal can create a service resource and pass it a role that has access to sensitive data, gaining indirect access to that data through the new resource.

Has pass role task hijack path

The associated principal can pass a role to a scheduled or event-driven task (such as a Lambda function triggered by an event), allowing it to execute arbitrary code with that role's permissions.

Has single hop data access path

The associated principal can directly access sensitive data resources (such as Amazon S3 buckets or DynamoDB tables) through its existing permissions, without needing intermediate escalation steps.

Has capability advancing path

The associated principal has a privilege escalation path that advances its overall capabilities beyond what its directly assigned permissions would suggest. This is a general classification for paths that do not match a more specific pattern.

Business criticality

The business criticality of the primary resource, set either by automation rules or by inference from the name and tags.

Remediating exposures for Azure virtual machines

AWS Security Hub can generate exposure findings for Azure virtual machines.

On the Security Hub console, the Azure virtual machine involved in an exposure finding and its identifying information are listed in the **Resources** section of the finding details. Programmatically, you can retrieve resource details with the GetFindingsV2 operation of the Security Hub CSPM API.

After identifying the resource involved in an exposure finding, you can delete the resource if you don't need it. Deleting a nonessential resource can reduce your exposure profile and AWS costs. If

the resource is essential, follow these recommended remediation steps to help mitigate the risk. The remediation topics are divided based on the type of trait.

A single exposure finding contains issues identified in multiple remediation topics. Conversely, you can address an exposure finding and bring down its severity level by addressing just one remediation topic. Your approach to risk remediation depends on your organizational requirements and workloads.

> **Note**
>
> The remediation guidance provided in this topic might require additional consultation in other Microsoft Azure resources.

  - The Azure virtual machine has network-exploitable software vulnerabilities with a high likelihood of exploitation
  - The Azure virtual machine has software vulnerabilities
  - The Azure virtual machine has malicious software packages

Misconfiguration traits for Azure virtual machines

Here are misconfiguration traits for Azure virtual machines and suggested remediation steps.

The Azure virtual machine has an open network security group

A network security group (NSG) acts as a virtual firewall for your Azure virtual machine, filtering inbound and outbound traffic with a set of prioritized security rules. An open network security group contains rules that allow unrestricted access from any source (for example, a source of Any or `0.0.0.0/0`). These rules can expose your virtual machine to unauthorized access from the internet. Following standard security principles, restrict network security group rules to only the specific IP addresses, ports, and protocols that your workload requires.

Remediation

Take one or more of the following actions to address this exposure:

Review network security group rules and assess current configuration

Identify the network security group associated with the virtual machine's network interface or subnet, and review its inbound security rules. Evaluate which ports allow traffic from broad source ranges, such as Any or `0.0.0.0/0`. Rules are processed in priority order, so confirm that a permissive rule is not taking precedence over a more restrictive one. For more information, see Network security groups in the Microsoft Azure documentation.

Restrict network security group rules

Modify or remove rules that allow unrestricted access. Replace a broad source such as Any with the specific trusted IP addresses, CIDR ranges, service tags, or application security groups that require access. Limit the destination port range to only the ports your workload uses. For more information, see Manage network security groups in the Microsoft Azure documentation.

The Azure virtual machine has a security rule that allows SSH or RDP access

Remote management protocols such as SSH (port 22) and RDP (port 3389) let users connect to and manage Azure virtual machines from remote locations. When a network security group rule permits these ports from the internet (a source of Any or `0.0.0.0/0`), your virtual machine's attack surface increases significantly and it becomes exposed to brute-force and credential-based attacks. Following standard security principles, limit remote access to specific, trusted IP addresses, or remove direct internet access to these ports entirely.

Remediation

Take one or more of the following actions to address this exposure:

Restrict the network security group rule

Limit SSH and RDP access to specific trusted IP addresses or CIDR ranges instead of `Any`, or remove the inbound rule if remote access from the internet is not required. For more information, see Manage network security groups in the Microsoft Azure documentation.

Use Azure Bastion for secure connectivity

Instead of exposing SSH or RDP ports to the internet, use Azure Bastion to connect to your virtual machine over TLS without a public IP address or open inbound ports. For more information, see Azure Bastion in the Microsoft Azure documentation.

Use just-in-time virtual machine access

Enable just-in-time (JIT) virtual machine access in Microsoft Defender for Cloud so that management ports such as SSH and RDP stay closed by default and open only for approved, time-bound requests from a specified source IP address. For more information, see Enable just-in-time access in the Microsoft Azure documentation.

The role associated with the Azure virtual machine has an administrative access role assignment

You can assign a managed identity to an Azure virtual machine and grant it Azure role-based access control (Azure RBAC) role assignments to access other Azure resources. When the associated identity has an administrative role assignment (such as `Owner` or `Contributor`) at a broad scope, it typically grants permissions far beyond what the workload requires. If the virtual machine is compromised, an attacker can use these excessive permissions to move laterally across your environment, access data, or manipulate resources. Following standard security principles, grant least privilege by assigning only the permissions the workload needs.

Remediation

Take one or more of the following actions to address this exposure:

Review and identify administrative role assignments

In the Azure portal, review the role assignments for the identity associated with the virtual machine. Look for privileged administrator roles such as `Owner`, `Contributor`, or `User Access Administrator`, and for custom roles that use a wildcard (`*`) in their `Actions`. For more information, see List Azure role assignments in the Microsoft Azure documentation.

Implement least privilege access

Replace administrative role assignments with the least-privileged built-in role that grants only the permissions the workload requires. Assign it at the narrowest scope (resource or resource group) that meets your needs. When creating custom roles, specify `Actions` and `DataActions` explicitly instead of using a wildcard. For more information, see Best practices for Azure RBAC in the Microsoft Azure documentation.

The Azure virtual machine has an end-of-life operating system

The Azure virtual machine runs an end-of-life operating system that is no longer supported or maintained by its vendor. When an operating system reaches end of life, the vendor stops releasing security updates and advisories, which leaves known vulnerabilities permanently unpatched and exposes the virtual machine to attack. Following security best practices, upgrade to a supported operating system version.

Remediation: Upgrade to a supported operating system version

Plan an in-place upgrade or migrate the workload to a virtual machine running a supported operating system version. Before upgrading, confirm application compatibility and take a backup or snapshot so that you can roll back if needed. For Windows, follow the in-place upgrade guidance; for Linux, follow the upgrade guidance from your distribution vendor. For more information, see Perform an in-place upgrade of a Windows Server VM in the Microsoft Azure documentation.

Reachability traits for Azure virtual machines

Here are reachability traits for Azure virtual machines and suggested remediation steps.

The Azure virtual machine is reachable over the internet

An Azure virtual machine with ports that are reachable from the internet might be exposed to attack. A virtual machine becomes reachable when it has a public IP address. It can also become reachable when a load balancer, application gateway, or other network path permits inbound traffic from the internet. Following standard security principles, implement least-privilege network access controls by restricting inbound traffic to only necessary sources and ports.

Remediation

Take one or more of the following actions to address this exposure:

Restrict or remove internet exposure

Review whether the virtual machine requires a public IP address. If it does not, disassociate the public IP address from the network interface and use a private IP address instead. If outbound internet connectivity is still required, use a NAT gateway.

If inbound access is required, place the virtual machine behind a load balancer, Azure Firewall, or application gateway rather than exposing it directly. For more information, see Public IP addresses in the Microsoft Azure documentation.

Tighten inbound network security group rules

Modify or remove inbound network security group rules that allow unrestricted access (`Any` or `0.0.0.0/0`), and restrict access to the specific source ranges, ports, and protocols your workload requires. For more information, see Network security groups in the Microsoft Azure documentation.

Use Azure Bastion for management access

For management connectivity, use Azure Bastion to reach the virtual machine over TLS without a public IP address or open SSH/RDP ports. For more information, see Azure Bastion in the Microsoft Azure documentation.

Vulnerability traits for Azure virtual machines

Here are vulnerability traits for Azure virtual machines and suggested remediation steps.

The Azure virtual machine has software vulnerabilities which are notable

A *notable vulnerability* is a Common Vulnerabilities and Exposures (CVE) entry that Security Hub tracks on a curated list because of active exploitation in the wild or significant potential impact. Security Hub prioritizes these CVEs regardless of their CVSS score, so a notable vulnerability on this resource represents an immediate security threat. Patch these vulnerabilities first.

The curated list currently includes the following vulnerabilities in the PHP runtime. With either vulnerability, a remote, unauthenticated party can run code on the server through a crafted multipart request. Both affect PHP versions 5.4 through 8.5, regardless of the application code that runs on them:

- `CVE-2026-109618`: PHP can corrupt its memory state when it runs out of memory as it processes a crafted multipart request.

- `CVE-2026-109619`: The issue is in the session upload progress feature (`session.upload_progress`), which PHP turns on by default.

PHP versions 8.5.12, 8.4.27, 8.3.36, and 8.2.35 address these issues. PHP 8.1 and earlier have no update, so migrate those workloads to a supported PHP branch. For more information about these issues, see AWS Security Bulletin 2026-143 on the AWS website.

Remediation: Update affected virtual machines

Review the **References** section in the **Vulnerability** tab of the trait, and follow the remediation advice in the finding. Use Microsoft Defender for Cloud vulnerability assessment to review the affected CVEs, then use Azure Update Manager to deploy the update for the affected software. If an update is not available, remove or disable the vulnerable software, or restrict network access to it, until a patch is released. For more information about deploying updates, see Azure Update Manager on the Microsoft Learn website.

Distribution packages can include the fix under an older version number, so check the package changelog for the CVE IDs. After you update, restart the web server and PHP processes, such as Apache and PHP-FPM, so that the update takes effect.

The Azure virtual machine has network-exploitable software vulnerabilities with a high likelihood of exploitation

Common Vulnerabilities and Exposures (CVEs) can affect software packages installed on Azure virtual machines. A high-priority vulnerability is network-exploitable with a high likelihood of exploitation. This represents an immediate security threat because exploit code might already be publicly available and actively used by attackers or automated scanning tools. Patch these vulnerabilities promptly to protect your virtual machine.

Remediation

Take one or more of the following actions to address this exposure:

Review and remediate the finding

Use Microsoft Defender for Cloud vulnerability assessment to review the affected CVEs and the remediation steps for the virtual machine. The details pane for each finding includes the relevant CVEs and recommended remediation. For more information, see Remediate machine vulnerabilities in the Microsoft Azure documentation.

Apply updates

Use Azure Update Manager to assess and deploy operating system and software updates across your virtual machines on a schedule. If an update is not available, consider removing or disabling the vulnerable software, or restricting network access to it, until a patch is released. For more information, see Azure Update Manager in the Microsoft Azure documentation.

Future considerations

To prevent future occurrences, enable Microsoft Defender for Servers to continuously scan your virtual machines for vulnerabilities, and establish a regular patching schedule with Azure Update Manager. For more information, see Microsoft Defender for Servers in the Microsoft Azure documentation.

The Azure virtual machine has software vulnerabilities

Common Vulnerabilities and Exposures (CVEs) can affect software packages installed on Azure virtual machines. Noncritical vulnerabilities represent security weaknesses with lower severity or exploitability than high-priority vulnerabilities. Although they pose less immediate risk, attackers can still exploit unpatched vulnerabilities to compromise the confidentiality, integrity, or availability of data, or to access other systems. Following security best practices, patch these vulnerabilities to protect your virtual machine from attack.

Remediation

Take one or more of the following actions to address this exposure:

Review and remediate the finding

Use Microsoft Defender for Cloud vulnerability assessment to review the affected CVEs and follow the remediation steps in the finding details pane. For more information, see Remediate machine vulnerabilities in the Microsoft Azure documentation.

Apply updates

Use Azure Update Manager to assess and deploy operating system and software updates across your virtual machines. To manage updates consistently at scale, configure scheduled patching. For more information, see Azure Update Manager in the Microsoft Azure documentation.

The Azure virtual machine has malicious software packages

Malicious packages are software components that contain harmful code designed to compromise the confidentiality, integrity, and availability of your systems and data. Malicious packages pose an

active and critical threat to your virtual machine, because attackers can execute the malicious code automatically without exploiting a separate vulnerability. Following security best practices, remove malicious packages to protect your virtual machine from potential attacks.

Remediation: Investigate and remove malicious packages

Review the finding details to understand the threat and identify the affected packages, then remove the identified packages using the appropriate package manager for the operating system. After removal, run a scan to confirm that no related malicious components remain. For more information, see Microsoft Defender for Servers in the Microsoft Azure documentation.

Remediating exposures for Azure Storage blob containers

AWS Security Hub can generate exposure findings for Azure Storage blob containers.

On the Security Hub console, the Azure Storage blob container involved in an exposure finding and its identifying information are listed in the **Resources** section of the finding details. Programmatically, you can retrieve resource details with the GetFindingsV2 operation of the Security Hub CSPM API.

After identifying the resource involved in an exposure finding, you can delete the resource if you don't need it. Deleting a nonessential resource can reduce your exposure profile and AWS costs. If the resource is essential, follow these recommended remediation steps to help mitigate the risk. The remediation topics are divided based on the type of trait.

A single exposure finding contains issues identified in multiple remediation topics. Conversely, you can address an exposure finding and bring down its severity level by addressing just one remediation topic. Your approach to risk remediation depends on your organizational requirements and workloads.

> **Note**
>
> The remediation guidance provided in this topic might require additional consultation in other Microsoft Azure resources.

  - The storage account allows permanent deletion of soft-deleted blobs
  - The Azure Storage blob container has blob versioning disabled
  - The storage container does not have an immutability policy

Reachability traits for Azure Storage blob containers

Here are reachability traits for Azure Storage blob containers and suggested remediation steps.

The storage account allows anonymous blob access

When anonymous read access is enabled, unauthenticated clients can read blob data without authorization. When the storage account permits anonymous (public) blob access and a container's access level allows it, anyone on the public internet can read the data in that container. Following standard security principles, disallow anonymous access at the account level and require every request to be authorized, unless your scenario explicitly depends on public read access.

Remediation

Take one or more of the following actions to address this exposure:

Disallow anonymous access for the storage account

Set the storage account's `AllowBlobPublicAccess` property to `false`. Disallowing anonymous access at the account level overrides the access settings of all containers in the account and blocks future anonymous requests. For more information, see Prevent anonymous read access in the Microsoft Azure documentation.

Set the container access level to private

If individual containers were configured for public access, set each container's anonymous access level to `Private` so that all requests require authorization. Before changing the setting, review any client applications that might depend on anonymous access. For more information, see Configure anonymous read access in the Microsoft Azure documentation.

Misconfiguration traits for Azure Storage blob containers

Here are misconfiguration traits for Azure Storage blob containers and suggested remediation steps.

The storage account does not require HTTPS for transfer operations

When a storage account does not require secure transfer, it accepts requests over unencrypted HTTP. Data and credentials sent over HTTP can be intercepted or modified in transit by an attacker on the network path. Following standard security principles, require secure transfer so that the account accepts requests only over HTTPS.

Remediation

Take one or more of the following actions to address this exposure:

Require secure transfer

Enable the **Secure transfer required** property on the storage account (the `enableHttpsTrafficOnly` property). When secure transfer is required, any request made over HTTP is rejected. For more information, see Require secure transfer in the Microsoft Azure documentation.

Enforce a minimum TLS version

Set the storage account's minimum TLS version to 1.2 (the `minimumTlsVersion` property) so that requests that use older, less secure protocol versions are rejected. Confirm that your clients support TLS 1.2 before you enforce this setting. For more information, see Configure the minimum TLS version for a storage account in the Microsoft Azure documentation.

The storage account is not encrypted with customer-managed keys

By default, Azure Storage encrypts data at rest with Microsoft-managed keys. Customer-managed keys (CMK) give you control over the key that protects your data, including the ability to rotate, revoke, and audit access to the key. If your organization's compliance requirements call for control over encryption keys, the absence of customer-managed keys is a gap. Following data protection best practices, configure the storage account to use customer-managed keys stored in Azure Key Vault or a managed HSM.

Remediation: Configure customer-managed keys

Store a key in Azure Key Vault or Azure Key Vault Managed HSM, with soft delete and purge protection enabled. Grant a managed identity the `get`, `wrapkey`, and `unwrapkey` permissions, and then configure the storage account to use that key for encryption. You can switch between customer-managed and Microsoft-managed keys at any time. For more information, see Customer-managed keys for storage encryption in the Microsoft Azure documentation.

The storage account allows cross-tenant access

Cross-tenant access settings, such as cross-tenant object replication or cross-tenant shared access signature (SAS) delegation, can cause data to leave the Microsoft Entra tenant that owns the storage account. If your workload does not require sharing data across tenants, leaving these settings enabled increases the risk of data leaving your tenant boundary. Following standard security principles, disable cross-tenant access unless it is explicitly required.

Remediation: Disable cross-tenant access settings

On the storage account, disable cross-tenant object replication (set `allowCrossTenantReplication` to `false`) and, where supported, restrict cross-tenant SAS delegation. Review your replication and sharing requirements before making the change. For more information, see Azure Storage account overview in the Microsoft Azure documentation.

The storage account has blob soft delete disabled

Blob soft delete protects individual blobs, snapshots, and versions from accidental or malicious deletion and overwrite. It retains the deleted data for a configurable retention period, during which you can restore it. When soft delete is disabled, deleted or overwritten blob data cannot be recovered, which exposes your account to permanent data loss. Following data protection best practices, enable blob soft delete with an appropriate retention period.

Remediation: Enable blob soft delete

Enable blob soft delete on the storage account and set a retention period (1 to 365 days) that meets your recovery requirements. For more complete protection, enable container soft delete and blob versioning as well. For more information, see Soft delete for blobs in the Microsoft Azure documentation.

The storage account allows permanent deletion of soft-deleted blobs

When permanent delete is allowed (the `allowPermanentDelete` property is `true`), soft-deleted blobs and snapshots can be removed before the soft delete retention period expires. This

undermines the protection that soft delete provides, because a user or a compromised principal can permanently destroy recoverable data before the retention period expires. Following data protection best practices, do not allow permanent deletion of soft-deleted blobs unless you have a specific, well-understood requirement.

Remediation: Disable permanent delete

Set the storage account's `allowPermanentDelete` property to `false` so that soft-deleted blobs and snapshots remain recoverable for the full retention period. For more information, see Soft delete for blobs in the Microsoft Azure documentation.

The Azure Storage blob container has blob versioning disabled

Blob versioning automatically maintains previous versions of a blob. When a blob is modified or deleted, the prior state is preserved as a previous version that you can restore. When versioning is disabled, overwrites and deletes cannot be rolled back to an earlier state, which increases the risk of unrecoverable data loss or corruption. Following data protection best practices, enable blob versioning, together with soft delete, for optimal data protection.

Remediation: Enable blob versioning

Enable versioning on the storage account's blob service. To control the cost of retaining many versions, use a lifecycle management policy to delete old versions automatically. For more information, see Blob versioning in the Microsoft Azure documentation.

The storage container does not have an immutability policy

An immutability policy stores blob data in a WORM (Write Once, Read Many) state. In this state, data cannot be modified or deleted for a specified interval (a time-based retention policy) or until a legal hold is cleared. Without an immutability policy, business-critical or compliance-relevant data in the container can be overwritten or deleted, including by privileged users. Where regulatory or data-integrity requirements apply, configure an immutability policy for the container.

Remediation: Configure an immutability policy

Configure a time-based retention policy or a legal hold on the container. Lock the time-based policy when testing is complete so that the data is fully protected in a WORM state. Enable soft delete before applying immutability policies for additional protection. For more information, see Immutable storage for blob data in the Microsoft Azure documentation.

Remediating exposures for Azure SQL databases

AWS Security Hub can generate exposure findings for Azure SQL databases.

On the Security Hub console, the Azure SQL database involved in an exposure finding and its identifying information are listed in the **Resources** section of the finding details. Programmatically, you can retrieve resource details with the GetFindingsV2 operation of the Security Hub CSPM API.

After identifying the resource involved in an exposure finding, you can delete the resource if you don't need it. Deleting a nonessential resource can reduce your exposure profile and AWS costs. If the resource is essential, follow these recommended remediation steps to help mitigate the risk. The remediation topics are divided based on the type of trait.

A single exposure finding contains issues identified in multiple remediation topics. Conversely, you can address an exposure finding and bring down its severity level by addressing just one remediation topic. Your approach to risk remediation depends on your organizational requirements and workloads.

> **Note**
>
> The remediation guidance provided in this topic might require additional consultation in other Microsoft Azure resources.

Contents

- Misconfiguration traits for Azure SQL databases
  - The Azure SQL database has public network access enabled
  - The Azure SQL database does not enforce Azure AD-only authentication
  - The Azure SQL database uses a default or common admin username
  - The Azure SQL database has geo-redundant backup disabled

Misconfiguration traits for Azure SQL databases

Here are misconfiguration traits for Azure SQL databases and suggested remediation steps.

The Azure SQL database has public network access enabled

When public network access is enabled on the logical server, the database is reachable through a public endpoint and can accept connections from the public internet (subject to firewall rules).

A public endpoint increases the attack surface of your database and exposes it to unauthorized connection attempts. Following standard security principles, disable public network access and connect to the database privately, or tightly restrict the server firewall rules.

Remediation

Take one or more of the following actions to address this exposure:

Disable public network access and use Private Link

Set the logical server's public network access to `Disabled` and connect to the database through a private endpoint (Azure Private Link) within your virtual network. This keeps database traffic on the Azure backbone and off the public internet. For more information, see Network access controls for Azure SQL Database in the Microsoft Azure documentation.

Restrict firewall rules if public access is required

If you must keep public access enabled, remove any rule that allows the full internet range, and disable **Allow Azure services and resources to access this server** when it is not needed. Limit server-level firewall rules to the specific trusted IP addresses your workload requires. For more information, see Network access controls for Azure SQL Database in the Microsoft Azure documentation.

Enforce a minimum TLS version

Set the logical server's minimum TLS version to 1.2 so that connections that use older, less secure protocol versions are rejected. Confirm that your clients support TLS 1.2 before you enforce this setting. For more information, see Connectivity settings for Azure SQL Database in the Microsoft Azure documentation.

The Azure SQL database does not enforce Azure AD-only authentication

When Microsoft Entra-only authentication (formerly Azure AD-only authentication) is not enforced, the logical server also accepts SQL authentication, which relies on passwords stored and managed within the database. SQL authentication is more susceptible to credential theft and brute-force attacks and does not benefit from centralized Microsoft Entra controls such as Conditional Access and multifactor authentication. Following standard security principles, enforce Microsoft Entra-only authentication so that only Microsoft Entra identities can connect.

Remediation: Enforce Microsoft Entra-only authentication

Set a Microsoft Entra admin for the logical server, then enable Microsoft Entra-only authentication. This disables SQL authentication so that only Microsoft Entra identities can connect to the server and its databases. Confirm that your applications support Microsoft Entra authentication before enforcing this setting. For more information, see Microsoft Entra-only authentication in the Microsoft Azure documentation.

The Azure SQL database uses a default or common admin username

The logical server's administrator login uses a well-known or common username, such as `sqladmin`, `admin`, or `sa`. Common administrator usernames are predictable, which makes the server an easier target for brute-force and credential-stuffing attacks because an attacker needs to guess only the password. Following standard security principles, avoid default or common administrator usernames and centralize administrative access through Microsoft Entra ID.

Remediation: Use a non-default administrator and Microsoft Entra authentication

Avoid predictable administrator login names. Where possible, enforce Microsoft Entra-only authentication and manage administrative access through Microsoft Entra identities and groups rather than a SQL administrator login. Follow the Azure SQL security best practices for managing logins and least-privilege access. For more information, see Azure SQL Database security best practices in the Microsoft Azure documentation.

The Azure SQL database has geo-redundant backup disabled

Azure SQL Database stores automated backups in geo-redundant storage by default, which replicates backups to a paired region and enables geo-restore during a regional outage. When backup storage redundancy is set to locally redundant or zone-redundant storage instead, geo-restore is unavailable. You cannot recover the database in another region if the primary region becomes unavailable. Following data protection best practices, use geo-redundant backup storage for databases that require resilience to regional outages.

Remediation

Take one or more of the following actions to address this exposure:

Configure geo-redundant backup storage

Set the database's backup storage redundancy to geo-redundant storage (GRS) or geo-zone-redundant storage (GZRS) so that geo-restore is available. Changes apply to future backups and can take up to 48 hours to take effect. For more information, see Automated backups in Azure SQL Database in the Microsoft Azure documentation.

Configure long-term retention

For databases with compliance or long-term recovery requirements, configure a long-term retention (LTR) policy. LTR retains full backups for up to 10 years, in addition to the default short-term retention. For more information, see Long-term retention in Azure SQL Database in the Microsoft Azure documentation.

Remediating exposures for Azure Cosmos DB accounts

AWS Security Hub can generate exposure findings for Azure Cosmos DB accounts.

On the Security Hub console, the Azure Cosmos DB account involved in an exposure finding and its identifying information are listed in the **Resources** section of the finding details. Programmatically, you can retrieve resource details with the GetFindingsV2 operation of the Security Hub CSPM API.

After identifying the resource involved in an exposure finding, you can delete the resource if you don't need it. Deleting a nonessential resource can reduce your exposure profile and AWS costs. If the resource is essential, follow these recommended remediation steps to help mitigate the risk. The remediation topics are divided based on the type of trait.

A single exposure finding contains issues identified in multiple remediation topics. Conversely, you can address an exposure finding and bring down its severity level by addressing just one remediation topic. Your approach to risk remediation depends on your organizational requirements and workloads.

> **Note**
>
> The remediation guidance provided in this topic might require additional consultation in other Microsoft Azure resources.

Contents

- Misconfiguration traits for Azure Cosmos DB accounts
  - The Azure Cosmos DB account has public network access enabled
  - The Azure Cosmos DB account does not use continuous backup

Misconfiguration traits for Azure Cosmos DB accounts

Here are misconfiguration traits for Azure Cosmos DB accounts and suggested remediation steps.

The Azure Cosmos DB account has public network access enabled

When public network access is enabled, the Azure Cosmos DB account is reachable through a public endpoint. It can accept connections from the public internet, subject to firewall and virtual network rules. A public endpoint increases the attack surface of your account and exposes it to unauthorized connection attempts and potential data exfiltration. Following standard security principles, disable public network access and connect to the account privately, or tightly restrict the account firewall rules.

Remediation

Take one or more of the following actions to address this exposure:

Disable public network access and use Private Link

Set the account's `publicNetworkAccess` property to `Disabled` and connect through a private endpoint (Azure Private Link) within your virtual network. When combined with restrictive network security group policies, private endpoints help reduce the risk of data exfiltration. For more information, see Configure Azure Private Link in the Microsoft Azure documentation.

Restrict firewall rules if public access is required

If you must keep public access enabled, configure IP firewall rules and virtual network rules to allow only the specific trusted sources your workload requires, instead of allowing all networks. For more information, see Configure IP firewall in the Microsoft Azure documentation.

The Azure Cosmos DB account does not use continuous backup

With continuous backup mode, you can use point-in-time restore to recover from an accidental write or delete. You can also restore a deleted database or container to any timestamp within the retention period. When the account uses periodic backup mode instead of continuous backup, you cannot perform self-service point-in-time restore. This limitation increases recovery time and the risk of data loss after an accidental or malicious change. Following data protection best practices, enable continuous backup mode where your workload supports it.

Remediation: Enable continuous backup mode

Configure the account to use continuous backup mode (7-day or 30-day tier) so that point-in-time restore is available. Review the current limitations and supported APIs before migrating from periodic to continuous backup. For more information, see Continuous backup with point-in-time restore in the Microsoft Azure documentation.

Remediating exposures for Azure Function apps

AWS Security Hub can generate exposure findings for Azure Function apps.

On the Security Hub console, the Azure Function app involved in an exposure finding and its identifying information are listed in the **Resources** section of the finding details. Programmatically, you can retrieve resource details with the GetFindingsV2 operation of the Security Hub CSPM API.

After identifying the resource involved in an exposure finding, you can delete the resource if you don't need it. Deleting a nonessential resource can reduce your exposure profile and AWS costs. If the resource is essential, follow these recommended remediation steps to help mitigate the risk. The remediation topics are divided based on the type of trait.

A single exposure finding contains issues identified in multiple remediation topics. Conversely, you can address an exposure finding and bring down its severity level by addressing just one remediation topic. Your approach to risk remediation depends on your organizational requirements and workloads.

> **Note**
>
> The remediation guidance provided in this topic might require additional consultation in other Microsoft Azure resources.

Contents

- Misconfiguration traits for Azure Function apps
  - The Azure Function app is deployed outside a VNet
  - The role associated with the Azure Function app has an administrative access role assignment
- Reachability traits for Azure Function apps
  - The Azure Function app allows anonymous HTTP trigger invocation
- Vulnerability traits for Azure Function apps
  - The Azure Function app has software vulnerabilities which are notable
  - The Azure Function app has network-exploitable software vulnerabilities with a high likelihood of exploitation
  - The Azure Function app has software vulnerabilities
  - The Azure Function app has malicious software packages

Misconfiguration traits for Azure Function apps

Here are misconfiguration traits for Azure Function apps and suggested remediation steps.

The Azure Function app is deployed outside a VNet

When a Function app is not integrated with a virtual network, its endpoints and outbound traffic traverse the public network rather than your private network boundary. When the Function app is not integrated with a virtual network, you cannot apply network-level controls such as private endpoints, network security groups, and restricted outbound access. This gap increases the app's exposure. Following standard security principles, integrate the Function app with a virtual network and use private endpoints where your hosting plan supports it.

Remediation

Take one or more of the following actions to address this exposure:

Integrate the Function app with a virtual network

Enable virtual network integration for the Function app. Where supported by your hosting plan (Flex Consumption, Elastic Premium, or Dedicated), use private endpoints so the app is reachable only from within your network. For more information, see Azure Functions networking options in the Microsoft Azure documentation.

Restrict inbound access

On hosting plans that do not support private endpoints, use access restrictions to allow inbound traffic only from trusted IP address ranges, and disable public network access where it is not required. For more information, see Set up access restrictions in the Microsoft Azure documentation.

The role associated with the Azure Function app has an administrative access role assignment

You can assign a managed identity to an Azure Function app and grant it Azure role-based access control (Azure RBAC) role assignments to access other Azure resources. When the associated identity has an administrative role assignment (such as `Owner` or `Contributor`) at a broad scope, it typically grants permissions far beyond what the app requires. If the Function app is compromised, an attacker can use these excessive permissions to move laterally across your environment, access data, or manipulate resources. Following standard security principles, grant least privilege by assigning only the permissions the app needs.

Remediation

Take one or more of the following actions to address this exposure:

Review and identify administrative role assignments

In the Azure portal, review the role assignments for the identity associated with the Function app. Look for privileged administrator roles such as `Owner`, `Contributor`, or `User Access Administrator`, and for custom roles that use a wildcard (`*`) in their `Actions`. For more information, see List Azure role assignments in the Microsoft Azure documentation.

Implement least privilege access

Replace administrative role assignments with the least-privileged built-in role that grants only the permissions the app requires, and assign it at the narrowest scope that meets your needs. Use a managed identity instead of stored secrets for connections to other Azure services. For more information, see Best practices for Azure RBAC in the Microsoft Azure documentation.

Reachability traits for Azure Function apps

Here are reachability traits for Azure Function apps and suggested remediation steps.

The Azure Function app allows anonymous HTTP trigger invocation

An HTTP-triggered function whose authorization level is set to `anonymous` can be invoked over the internet without any access key or authentication. Anonymous HTTP triggers expose your function logic to unauthenticated callers, which can lead to abuse, data exposure, or denial-of-wallet through uncontrolled invocation. Following standard security principles, require authentication or access keys for HTTP-triggered functions unless anonymous access is explicitly required.

Remediation

Take one or more of the following actions to address this exposure:

Require authorization for HTTP triggers

Raise the HTTP trigger authorization level from `anonymous` to `function` or `admin` so that requests must include a valid access key, and require HTTPS. For stronger protection, enable App Service Authentication/Authorization or front the app with Azure API Management. For more information, see Securing Azure Functions in the Microsoft Azure documentation.

Require authentication with a managed identity provider

Because access keys are an authorization control rather than authentication, enable App Service Authentication (Easy Auth) with Microsoft Entra ID so that callers must present a valid identity.

Also disable the administrative endpoints (the `/admin` routes) when they are not needed. For more information, see Securing Azure Functions in the Microsoft Azure documentation.

Vulnerability traits for Azure Function apps

Here are vulnerability traits for Azure Function apps and suggested remediation steps.

The Azure Function app has software vulnerabilities which are notable

A *notable vulnerability* is a Common Vulnerabilities and Exposures (CVE) entry that Security Hub tracks on a curated list because of active exploitation in the wild or significant potential impact. Security Hub prioritizes these CVEs regardless of their CVSS score, so a notable vulnerability on this resource represents an immediate security threat. Patch these vulnerabilities first.

The curated list currently includes the following vulnerabilities in the PHP runtime. With either vulnerability, a remote, unauthenticated party can run code on the server through a crafted multipart request. Both affect PHP versions 5.4 through 8.5, regardless of the application code that runs on them:

- `CVE-2026-109618`: PHP can corrupt its memory state when it runs out of memory as it processes a crafted multipart request.
- `CVE-2026-109619`: The issue is in the session upload progress feature (`session.upload_progress`), which PHP turns on by default.

PHP versions 8.5.12, 8.4.27, 8.3.36, and 8.2.35 address these issues. PHP 8.1 and earlier have no update, so migrate those workloads to a supported PHP branch. For more information about these issues, see AWS Security Bulletin 2026-143 on the AWS website.

Remediation: Update affected dependencies

Review the **References** section in the **Vulnerability** tab of the trait, and follow the remediation advice in the finding. Update the vulnerable packages and dependencies to a version that is not affected, and redeploy the app. For more information about monitoring the app for vulnerabilities, see Microsoft Defender for App Service on the Microsoft Learn website.

The Azure Function app has network-exploitable software vulnerabilities with a high likelihood of exploitation

Common Vulnerabilities and Exposures (CVEs) can affect software packages and dependencies in your Function app. A high-priority vulnerability is network-exploitable with a high likelihood of

exploitation, which represents an immediate security threat because exploit code might already be publicly available and actively used by attackers. Patch these vulnerabilities promptly to protect your Function app.

Remediation

Take one or more of the following actions to address this exposure:

Update affected dependencies

Review the affected CVEs in the finding, then update the vulnerable packages and dependencies to their latest secure versions and redeploy the app. Keep the Function app on a supported runtime so that platform security updates continue to apply. For more information, see Microsoft Defender for App Service in the Microsoft Azure documentation.

Future considerations

To prevent future occurrences, integrate dependency and vulnerability scanning into your build and deployment pipeline, and use Microsoft Defender for Cloud to monitor your app for configuration and vulnerability findings. For more information, see Microsoft Defender for App Service in the Microsoft Azure documentation.

The Azure Function app has software vulnerabilities

Common Vulnerabilities and Exposures (CVEs) can affect software packages and dependencies in your Function app. Noncritical vulnerabilities represent security weaknesses with lower severity or exploitability than high-priority vulnerabilities. Although they pose less immediate risk, attackers can still exploit unpatched vulnerabilities to compromise the confidentiality, integrity, or availability of data, or to access other systems. Following security best practices, patch these vulnerabilities to protect your Function app.

Remediation: Update affected dependencies

Update the vulnerable packages and dependencies to their latest secure versions and redeploy the app. If an update is not available, consider removing or disabling the vulnerable component until a patch is released. For more information, see Microsoft Defender for App Service in the Microsoft Azure documentation.

The Azure Function app has malicious software packages

Malicious packages are software components that contain harmful code designed to compromise the confidentiality, integrity, and availability of your systems and data. Malicious packages pose an

active and critical threat to your Function app, because attackers can execute the malicious code automatically without exploiting a separate vulnerability. Following security best practices, remove malicious packages to protect your Function app from potential attacks.

Remediation: Investigate and remove malicious packages

Review the finding details to identify the affected packages, remove them from your project dependencies, rebuild from a trusted source, and redeploy the app. After remediation, audit your dependency supply chain to confirm no related malicious components remain. For more information, see Microsoft Defender for App Service in the Microsoft Azure documentation.

Remediating exposures for Azure Container apps

AWS Security Hub can generate exposure findings for Azure Container apps.

On the Security Hub console, the Azure Container app involved in an exposure finding and its identifying information are listed in the **Resources** section of the finding details. Programmatically, you can retrieve resource details with the GetFindingsV2 operation of the Security Hub CSPM API.

After identifying the resource involved in an exposure finding, you can delete the resource if you don't need it. Deleting a nonessential resource can reduce your exposure profile and AWS costs. If the resource is essential, follow these recommended remediation steps to help mitigate the risk. The remediation topics are divided based on the type of trait.

A single exposure finding contains issues identified in multiple remediation topics. Conversely, you can address an exposure finding and bring down its severity level by addressing just one remediation topic. Your approach to risk remediation depends on your organizational requirements and workloads.

> **Note**
>
> The remediation guidance provided in this topic might require additional consultation in other Microsoft Azure resources.

  - The Azure Container app is reachable over the internet

Misconfiguration traits for Azure Container apps

Here are misconfiguration traits for Azure Container apps and suggested remediation steps.

The Azure Container app has cleartext credentials in environment variables

The Container app passes secret data, such as connection strings, API keys, or passwords, to the container as plaintext environment variables. Configuration, logs, or a compromised container can expose cleartext credentials in environment variables, which lets an attacker reuse them to access other systems. Following standard security principles, store sensitive values as secrets and reference them rather than embedding them in plaintext.

Remediation

Take one or more of the following actions to address this exposure:

Move credentials to secrets

Replace plaintext environment variable values with Container app secrets, or reference secrets stored in Azure Key Vault. Update the container to read the values from those secret references. Rotate any credentials that were previously exposed in plaintext. For more information, see Manage secrets in Azure Container Apps in the Microsoft Azure documentation.

Use a managed identity where possible

For connections to Azure services that support it, use the Container app's managed identity instead of storing a secret at all. For more information, see Managed identities in Azure Container Apps in the Microsoft Azure documentation.

The Azure Container app has an open network security group

The network security group protecting the Container app's environment contains rules that allow unrestricted access from any source (for example, a source of Any or `0.0.0.0/0`). An open network security group exposes the Container app's environment to unauthorized access from the

internet. Following standard security principles, restrict network security group rules to only the specific IP addresses, ports, and protocols that your workload requires.

Remediation

Take one or more of the following actions to address this exposure:

Restrict network security group rules

Review the network security group associated with the Container app environment's subnet, and modify or remove rules that allow unrestricted access. Replace a broad source such as Any with the specific trusted ranges your workload requires. For more information, see Networking in Azure Container Apps in the Microsoft Azure documentation.

Set IP ingress restrictions

In addition to network security group rules on the environment subnet, configure IP ingress restrictions on the container app itself to allow or deny inbound traffic by IP address range. For more information, see Set up IP ingress restrictions in Azure Container Apps in the Microsoft Azure documentation.

The Azure Container app has a managed identity that does not follow least privilege

The Container app has a managed identity that is granted more access than the workload requires. An over-privileged managed identity widens the blast radius if the Container app is compromised, because an attacker can act with all of the identity's permissions. Following standard security principles, grant the identity only the permissions the workload needs, at the narrowest scope.

Remediation: Scope the managed identity to least privilege

Review the role assignments granted to the Container app's managed identity and remove any that are not required. Assign the least-privileged built-in role at the narrowest scope (resource or resource group) that meets your needs. For more information, see Best practices for Azure RBAC in the Microsoft Azure documentation.

The role associated with the Azure Container app has an administrative access role assignment

The managed identity associated with the Container app has an administrative role assignment (such as `Owner` or `Contributor`) at a broad scope. This assignment typically grants permissions far beyond what the workload requires. If the Container app is compromised, an attacker can use these excessive permissions to move laterally across your environment, access data, or manipulate

resources. Following standard security principles, grant least privilege by assigning only the permissions the app needs.

Remediation

Take one or more of the following actions to address this exposure:

Review and identify administrative role assignments

In the Azure portal, review the role assignments for the identity associated with the Container app. Look for privileged administrator roles such as `Owner`, `Contributor`, or `User Access Administrator`, and for custom roles that use a wildcard (`*`) in their `Actions`. For more information, see List Azure role assignments in the Microsoft Azure documentation.

Implement least privilege access

Replace administrative role assignments with the least-privileged built-in role that grants only the permissions the app requires, and assign it at the narrowest scope that meets your needs. For more information, see Best practices for Azure RBAC in the Microsoft Azure documentation.

Reachability traits for Azure Container apps

Here are reachability traits for Azure Container apps and suggested remediation steps.

The Azure Container app is reachable over the internet

The Container app is reachable from the public internet, either because external ingress is enabled (`ingress.external` is set to `true`) or because its environment has a public IP address. Public reachability increases the attack surface of the Container app and exposes it to unauthorized requests. Following standard security principles, disable external ingress where it is not required, use an internal environment, or place the app behind a controlled, authenticated ingress point.

Remediation

Take one or more of the following actions to address this exposure:

Restrict or remove external ingress

Set ingress to internal if the app only needs to be reached from within your virtual network or environment. If public access is required, restrict it with ingress IP restrictions. Front the app with a gateway such as Azure Application Gateway or Azure Front Door.

These gateways provide authentication and a web application firewall. For more information, see Ingress in Azure Container Apps in the Microsoft Azure documentation.

Use an internal environment

To avoid assigning a public IP address, deploy the Container app into an internal (virtual network–integrated) environment that uses a private IP address, and expose only the endpoints that must be public through a controlled ingress point. For more information, see Networking in Azure Container Apps in the Microsoft Azure documentation.

Require HTTPS and authentication for public ingress

When ingress must remain public, disable insecure connections (set `allowInsecure` to `false`) so that traffic is served only over HTTPS. Enable the built-in authentication feature with Microsoft Entra ID so that unauthenticated requests are rejected. For more information, see Authentication and authorization in Azure Container Apps in the Microsoft Azure documentation.

Remediating exposures for Azure Kubernetes Service clusters

AWS Security Hub can generate exposure findings for Azure Kubernetes Service (AKS) clusters.

On the Security Hub console, the AKS cluster involved in an exposure finding and its identifying information are listed in the **Resources** section of the finding details. Programmatically, you can retrieve resource details with the GetFindingsV2 operation of the Security Hub CSPM API.

After identifying the resource involved in an exposure finding, you can delete the resource if you don't need it. Deleting a nonessential resource can reduce your exposure profile and AWS costs. If the resource is essential, follow these recommended remediation steps to help mitigate the risk. The remediation topics are divided based on the type of trait.

A single exposure finding contains issues identified in multiple remediation topics. Conversely, you can address an exposure finding and bring down its severity level by addressing just one remediation topic. Your approach to risk remediation depends on your organizational requirements and workloads.

> **Note**
>
> The remediation guidance provided in this topic might require additional consultation in other Microsoft Azure resources.

  - The Azure Kubernetes Service cluster has unencrypted Kubernetes secrets
- Reachability traits for Azure Kubernetes Service clusters
  - The Azure Kubernetes Service cluster allows public access

Misconfiguration traits for Azure Kubernetes Service clusters

Here are misconfiguration traits for Azure Kubernetes Service clusters and suggested remediation steps.

The Azure Kubernetes Service cluster is running an unsupported Kubernetes version

The AKS cluster is running a Kubernetes version that is no longer supported by Microsoft. Unsupported Kubernetes versions stop receiving security patches and bug fixes, which leaves known vulnerabilities in the control plane and node components unaddressed and exposes the cluster to attack. Following security best practices, keep the cluster on a supported Kubernetes version.

Remediation: Upgrade to a supported Kubernetes version

Upgrade the cluster control plane and node pools to a supported Kubernetes version. Because minor versions cannot be skipped, upgrade sequentially through each minor version and apply the latest patch. Review the breaking changes for each version before upgrading.

Consider enabling automatic upgrades to stay current. For more information, see Supported Kubernetes versions in AKS in the Microsoft Azure documentation.

The Azure Kubernetes Service cluster has unencrypted Kubernetes secrets

By default, the cluster stores Kubernetes secrets in the etcd data store without encryption by a customer-controlled key. Without encryption at rest using a key management service, anyone who gains access to the underlying etcd data can read sensitive secret values such as credentials and tokens. Following data protection best practices, enable KMS etcd encryption so that Kubernetes secrets are encrypted at rest with a key in Azure Key Vault.

Remediation

Take one or more of the following actions to address this exposure:

Enable KMS etcd encryption

Configure the cluster to use Key Management Service (KMS) etcd encryption with a key stored in Azure Key Vault. Grant the cluster identity encrypt and decrypt permissions on the key. Re-encrypt existing secrets after you enable the feature. Enable soft delete and purge protection on the key vault so the key can't be lost. For more information, see KMS etcd encryption in AKS in the Microsoft Azure documentation.

Enable soft delete and purge protection on the key vault so the key cannot be lost. For more information, see KMS etcd encryption in AKS in the Microsoft Azure documentation.

Store secrets in Azure Key Vault

To avoid storing sensitive values as Kubernetes secrets in etcd at all, use the Azure Key Vault provider for the Secrets Store CSI Driver to mount secrets, keys, and certificates from Azure Key Vault into pods at runtime. For more information, see Azure Key Vault provider for Secrets Store CSI Driver in the Microsoft Azure documentation.

Reachability traits for Azure Kubernetes Service clusters

Here are reachability traits for Azure Kubernetes Service clusters and suggested remediation steps.

The Azure Kubernetes Service cluster allows public access

The API server is the endpoint that you use to communicate with your cluster's Kubernetes control plane. The cluster is reachable from the internet when the API server endpoint is public, or when workloads are exposed through a public load balancer or ingress. Public endpoints increase your attack surface and the risk of unauthorized access to your Kubernetes API server. Attackers can potentially access or modify cluster resources and read sensitive data. Following security best practices, restrict access to your cluster's API server and workloads to only necessary IP ranges.

Remediation

Take one or more of the following actions to address this exposure:

Restrict access to the API server

Use a private cluster so the API server is reachable only from within your virtual network, or configure authorized IP ranges to limit which source addresses can reach the public API server

endpoint. For more information, see Private Azure Kubernetes Service clusters in the Microsoft Azure documentation.

Limit public exposure of workloads

Review services exposed through public load balancers or ingress, and restrict or remove public exposure where it is not required. Use internal load balancers, network security group rules, and a web application firewall on a controlled ingress point for workloads that must be reached from the internet. For more information, see Networking concepts for AKS in the Microsoft Azure documentation.

Remediating exposures for Azure Graph users

AWS Security Hub can generate exposure findings for Azure Graph users.

On the Security Hub console, the Azure Graph user involved in an exposure finding and its identifying information are listed in the **Resources** section of the finding details. Programmatically, you can retrieve resource details with the GetFindingsV2 operation of the Security Hub CSPM API.

After identifying the resource involved in an exposure finding, you can delete the resource if you don't need it. Deleting a nonessential resource can reduce your exposure profile and AWS costs. If the resource is essential, follow these recommended remediation steps to help mitigate the risk. The remediation topics are divided based on the type of trait.

A single exposure finding contains issues identified in multiple remediation topics. Conversely, you can address an exposure finding and bring down its severity level by addressing just one remediation topic. Your approach to risk remediation depends on your organizational requirements and workloads.

> **Note**
>
> The remediation guidance provided in this topic might require additional consultation in other Microsoft Azure resources.

Contents

- Misconfiguration traits for Azure Graph users
  - The role associated with the Azure Graph user has an administrative access role assignment
  - The Azure Graph user does not have MFA enabled

Misconfiguration traits for Azure Graph users

Here are misconfiguration traits for Azure Graph users and suggested remediation steps.

The role associated with the Azure Graph user has an administrative access role assignment

The Azure Graph user has an administrative Azure role-based access control (Azure RBAC) role assignment, such as `Owner`, `Contributor`, or `User Access Administrator`. The assignment is often at a broad scope, such as a subscription or management group. Administrative role assignments grant broad permissions, so an attacker can use a compromised user account to move laterally, access data, or manipulate resources across your environment. Following standard security principles, grant least privilege and limit privileged administrator role assignments.

Remediation

Take one or more of the following actions to address this exposure:

Review and identify administrative role assignments

In the Azure portal, review the user's role assignments. Look for privileged administrator roles such as `Owner`, `Contributor`, or `User Access Administrator`, and for custom roles that use a wildcard (*) in their `Actions`. For more information, see List Azure role assignments in the Microsoft Azure documentation.

Implement least privilege access

Remove unnecessary privileged role assignments and replace them with the least-privileged built-in role, assigned at the narrowest scope. Prefer job-function roles over privileged administrator roles. Keep the number of subscription owners to a minimum — Microsoft recommends no more than three.

Assign roles to groups rather than individual users. Use Microsoft Entra Privileged Identity Management to make privileged roles eligible for just-in-time, time-bound activation instead of granting standing access. For more information, see Best practices for Azure RBAC in the Microsoft Azure documentation.

The Azure Graph user does not have MFA enabled

The Azure Graph user can sign in interactively without multifactor authentication (MFA). Without MFA, an account is protected only by a password, which leaves it vulnerable to phishing, password

spray, and credential-stuffing attacks. A single compromised password is enough for an attacker to sign in. Following standard security principles, require MFA for all users with interactive sign-in.

Remediation: Require multifactor authentication

Require MFA for the user through a Microsoft Entra Conditional Access policy. For broad coverage, enable security defaults or a Conditional Access policy that requires MFA for all users. Prioritize a dedicated policy for administrators.

Where possible, require phishing-resistant methods — such as FIDO2 security keys, passkeys, or Windows Hello for Business — through a Conditional Access authentication strength. Avoid permitting phishable methods such as SMS or voice. For more information, see Plan a multifactor authentication deployment in the Microsoft Azure documentation.

Understanding unused access findings in Security Hub

Security Hub uses IAM Access Analyzer to identify unused IAM permissions, roles, access keys, and passwords in your account. These findings help you implement the security best practice of least-privilege access by highlighting IAM principals and permissions that are not actively being used. This capability is provided to all Security Hub customers at no additional cost.

How unused access analysis works

When you enable Security Hub, the service automatically creates a service-linked IAM Access Analyzer in your account. This analyzer evaluates all IAM principals (roles and users) against AWS CloudTrail activity data to determine which principals and permissions have not been used within a 90-day lookback period. The lookback period is not configurable.

IAM Access Analyzer re-evaluates all active findings every 24 hours. When a previously unused principal or permission becomes active, the corresponding finding is automatically resolved.

The unused access analyzer runs in US East (N. Virginia) because IAM is a global service. Security Hub replicates findings to all Regions where you have enabled Security Hub. You do not need to enable Security Hub in US East (N. Virginia) for the analyzer to run.

Unused access finding types

Security Hub generates four types of unused access findings:

Finding type	Description	Resource evaluated
UnusedIAMRole	An IAM role that has not been assumed within the 90-day lookback period.	IAM role
UnusedIAMUserAccessKey	An IAM user access key that has not been used to sign API requests within the 90-day lookback period.	IAM user
UnusedIAMUserPassword	An IAM user password that has not been used for console sign-in within the 90-day lookback period.	IAM user
UnusedPermission	Specific IAM actions that are granted to a role or user but have not been invoked within the 90-day lookback period.	IAM role or IAM user

Service-linked analyzer

The IAM Access Analyzer that Security Hub creates is a service-linked analyzer. You can view it in the IAM Access Analyzer console, but you cannot modify or delete it while Security Hub is enabled.

When you disable Security Hub in all Regions, the service-linked analyzer is automatically deleted. If automatic deletion fails, you can delete the analyzer by calling the IAM Access Analyzer `DeleteServiceLinkedAnalyzer` API operation. This operation succeeds only after Security Hub is fully disabled for your account.

The service-linked analyzer is separate from any customer-managed analyzers you may have created independently in IAM Access Analyzer. Creating or deleting customer-managed analyzers does not affect the service-linked analyzer, and vice versa.

Viewing unused access findings

Unused access findings appear in the Security Hub console alongside other Security Hub findings. You can filter findings by type to view only unused access findings. Unused access findings are formatted in the Open Cybersecurity Schema Framework (OCSF), the same format used by all Security Hub findings.

For UnusedPermission findings, if you remove some unused permissions from the overly permissive policy, but not all, Security Hub closes the existing finding and creates a new finding for the revised policy if it is still overly permissive.

Unused access findings are also accessible from the IAM Access Analyzer console. Unused access findings in the IAM Access Analyzer console are read only and are only visible in the US East (N. Virginia) region.

Unused access in exposure findings

Unused access information can appear as contextual traits in Security Hub exposure findings. When an IAM role attached to a resource has unused permissions, the exposure finding includes this as supplementary context. This helps you understand the potential blast radius of a vulnerability — a resource with an over-privileged IAM role presents a higher risk than one with least-privilege permissions.

The following resource types can display unused access contextual traits in their exposure findings:

- Amazon Elastic Compute Cloud instances
- AWS Lambda functions
- Amazon Elastic Container Service services
- Amazon Elastic Kubernetes Service clusters
- IAM users (directly)

For more information about exposure findings, see Exposure findings in Security Hub.

Policy recommendations for unused permissions

For UnusedPermission findings, Security Hub can generate least-privilege policy recommendations. These recommendations show you a scoped-down replacement policy that retains only the permissions your principal actually uses. For more information, see Generating policy recommendations for unused access findings.

Pricing

The service-linked IAM Access Analyzer is provided to all Security Hub customers at no additional cost. You are not separately charged for the analyzer or for unused access findings.

Generating policy recommendations for unused access findings

For unused permissions findings, Security Hub can generate least-privilege policy recommendations that show you a scoped-down replacement policy. The recommendation evaluates each policy attached to the IAM principal and generates a replacement that retains only the permissions the principal has actually used. This capability is provided to all Security Hub customers at no additional cost.

How policy recommendations work

Policy recommendation generation is an asynchronous operation. To generate and retrieve a recommendation:

1. Retrieve the unused permissions finding from Security Hub using the `GetFindingsV2` API operation. Note the `metadata.uid` field from the finding.
2. Call `GenerateRecommendedPolicyV2` with the finding's `metadata.uid`. This initiates the recommendation generation, which typically completes within 20 seconds.
3. Poll `GetRecommendedPolicyV2` with the same `metadata.uid` until the `status` field returns `SUCCEEDED`.
4. The response contains one or more recommendation steps. Each step specifies a `recommendedAction` of either `CREATE_POLICY` (create and attach a scoped-down replacement policy) or `DETACH_POLICY` (detach the over-privileged original policy). For `CREATE_POLICY` steps, the response includes both the `existingPolicy` JSON and the `recommendedPolicy` JSON so you can compare them.

You must call `GenerateRecommendedPolicyV2` before calling `GetRecommendedPolicyV2` if a recommendation has not been previously generated for that finding.

Who can generate recommendations

Both the account owner and delegated administrators can call these API operations:

- **Account owners** can generate and view recommendations for unused permissions findings in their own account.
- **Delegated administrators** can generate and view recommendations for any member account's unused permissions findings within their organization.

If you are not a delegated administrator and the finding belongs to a different account, the API operation returns an `AccessDeniedException` error.

Recommendation lifecycle

- Recommendations are cached for 90 days and remain available as long as the finding is active (not Closed). However, calling `GenerateRecommendedPolicyV2` multiple times invalidates the cache and starts a new job that replaces the cached policy. Call `GenerateRecommendedPolicyV2` only once per finding.
- The recommendation follows a detach-and-attach pattern. It does not modify your existing IAM policies. You review the recommended policy and manually apply it in the IAM console or through the IAM API.
- If the finding is resolved (for example, because the previously unused permissions are now being used), the recommendation is no longer available.

Error cases

The API operations return errors in the following situations:

- The finding has been resolved — `InvalidInputException` (HTTP 400).
- The finding is not an unused permissions finding — `InvalidInputException` (HTTP 400).
- The IAM principal was created through IAM Identity Center permission set. Policies for permission set principals cannot be directly modified. The recommendation returns a `FAILED` status with an explanation.
- The caller is not a delegated administrator and the finding belongs to a different account — `AccessDeniedException` (HTTP 403).
- No recommendation has been generated yet and you call `GetRecommendedPolicyV2` without first calling `GenerateRecommendedPolicyV2` — `ResourceNotFoundException` (HTTP 404).

Using the console

In the Security Hub console, you can generate a policy recommendation by viewing an unused permissions finding and choosing the **Remediation** tab. The console displays a loading spinner while the recommendation is being created. When the recommendation is ready, you can choose **Preview** to see a side-by-side comparison of your current policy and the recommended least-privilege replacement. You can copy the recommended policy in JSON format.

API reference

- GenerateRecommendedPolicyV2 — Initiates asynchronous generation of a least-privilege policy recommendation for an unused permissions finding. Takes the finding's `metadata.uid` as input. Returns HTTP 200 with an empty body on success.
- GetRecommendedPolicyV2 — Retrieves the generated policy recommendation. Takes the finding's `metadata.uid` as input. Supports pagination with `maxResults` (1–100) and `nextToken` parameters. Returns the recommendation status (`IN_PROGRESS`, `SUCCEEDED`, or `FAILED`), recommendation steps, the resource ARN, and any errors.

For detailed API documentation, see the *Security Hub API Reference*.

Network Scanning in Security Hub

Network Scanning is an opt-in feature of Security Hub that performs active network reachability testing on your cloud resources. Control-plane analysis evaluates security groups, Network Access Control Lists (NACLs), and route tables to determine what *could* be reachable. Network Scanning goes further by detecting what is *actually* reachable. It probes your resources from outside your accounts to identify open ports and running services.

All scans originate from AWS-owned IP addresses and answer two questions: Is this resource reachable from the internet? If reachable, what is running? Network Scanning publishes results as standalone OCSF findings in Security Hub with scan evidence.

Supported resource types

Network Scanning supports the following resource types.

Cloud provider	Resource type
AWS	EC2 Instance (with public IP)
AWS	Elastic IP (EIP)
AWS	Network Load Balancer (NLB)
AWS	Application Load Balancer (ALB)

Cloud provider	Resource type
AWS	Classic Load Balancer (CLB)
Azure	Public IP Address

Note

Network Scanning scans each resource type independently. For load balancers, Network Scanning resolves and scans the DNS name. Network Scanning only scans individual EC2 instances behind a load balancer if they have their own public IP or EIP.

Enable Network Scanning

To enable Network Scanning, Security Hub must be enabled on your account. You can enable Network Scanning through a configuration policy or for individual accounts.

Organization accounts (recommended) – Enable Network Scanning across your organization's accounts and Regions by creating or editing a configuration policy. For more information about editing a configuration policy, see Editing a configuration policy. When Network Scanning is enabled through a configuration policy, member accounts cannot turn off the feature.

Individual accounts – For accounts that are not managed by a configuration policy, you can enable Network Scanning using one of the following methods.

Note

By enabling Network Scanning, you authorize Security Hub to perform active network scanning against resources in your AWS environments and Azure environments. This includes TCP port connection attempts, application and protocol identification, and collection of service banners, HTTP headers, and TLS certificate metadata.

Security Hub console

To enable Network Scanning

1. Open the Security Hub console at https://console.aws.amazon.com/securityhub/v2/home.

2. In the navigation pane, choose **General settings**.
3. Locate the **Network Scanning** section.
4. Choose **Enable**.
5. Confirm the authorization to proceed with active network scanning.

Security Hub API

Invoke the `EnableSecurityHubFeatureV2` API with the feature name `NETWORK_SCANNING`.

> **Note**
>
> Calling this API when Network Scanning is already enabled returns a 200 response. The service preserves the `UpdatedAt` timestamp from the original enablement.

AWS CLI

Run the following command to enable Network Scanning:

```
aws securityhub enable-security-hub-feature-v2 --feature-name NETWORK_SCANNING
```

How Network Scanning works

After you enable Network Scanning, the following occurs:

- Network Scanning scans existing resources within approximately 24 hours of enabling the feature.
- Network Scanning scans new resources shortly after Security Hub receives notification of the created resource.
- Network Scanning rescans resources when certain eligible control plane changes are made to a scan-eligible resource.
- Network Scanning rescans active resources roughly every 12 hours to detect reachability changes.

Ephemeral or short-lived resources might not be scanned before they are terminated.

Network Scanning findings

Network Scanning publishes findings in Open Cybersecurity Schema Framework (OCSF) format, using the AWS OCSF Extension, and they appear alongside other Security Hub findings. Network Scanning creates findings whether or not a resource has reachable ports. If a finding does not exist for a supported resource type, Network Scanning has not scanned the resource yet.

Findings for reachable ports

Each finding represents a single reachable port on a specific resource and address combination. The `port_scan_result_list` section of an OCSF finding contains the scan results. The following examples show information returned for a reachable resource:

```
"port_scan_result_list": [
    {
      "port_info": {
        "port": 6379,
        "protocol_name": "tcp",
        "protocol_num": 6
      },
      "status": "Open",
      "status_id": 1,
      "svc_name": "redis"
    }
],
```

```
"port_scan_result_list": [
    {
      "http_response": {
        "code": 200,
        "content_type": "text/html; charset=UTF-8",
        "http_headers": [
          {
            "name": "Server",
            "value": "Apache/2.4.68 (Amazon Linux)"
          },
          {
            "name": "Content-Type",
            "value": "text/html; charset=UTF-8"
```

```
        }
      ],
      "latency": 124
    },
    "port_info": {
      "port": 8080,
      "protocol_name": "tcp",
      "protocol_num": 6
    },
    "status": "Open",
    "status_id": 1
  }
],
```

Informational findings for no open ports

Network Scanning creates a finding when it detects no open ports on a resource. This finding has a severity of `Informational` and requires no action. It confirms that Network Scanning scanned the resource.

The Informational finding remains open in Security Hub until you delete the resource or until Network Scanning detects open ports on the resource. When Network Scanning identifies open ports on a resource with an Informational finding, it closes the Informational finding. It then creates a finding for each open port.

Informational findings for no open ports cover the ports that Network Scanning currently supports. For a list of supported ports, see the section called “Supported ports”.

Finding lifecycle events

The following table describes the lifecycle for a Network Scanning finding.

Event	What happens
No open ports detected	Network Scanning creates an `Informational` finding that requires no action
Open ports detected on resource with Informational finding	Network Scanning closes the Informational finding and creates a finding for each open port

Event	What happens
Port first detected as reachable	Network Scanning creates and publishes a new finding
Port still reachable on rescan (no change)	Network Scanning periodically refreshes the finding
Port still reachable but evidence changed	Network Scanning republishes the finding with updated evidence
Port no longer reachable	Finding remains open until next rescan confirms port is unreachable
Resource terminated or deleted	Network Scanning closes all findings for the resource by setting the `activity_name` attribute to `Close`
IP address removed from resource	Network Scanning closes findings for that specific IP
Network Scanning disabled	Network Scanning produces no new findings; existing findings remain until they age out
Security Hub disabled	You no longer have access to findings

If a port is intermittently reachable, Network Scanning bases findings on positive evidence at scan time. After you fix an issue (for example, by closing a firewall rule or stopping a service), Network Scanning closes the finding on the next scan.

Disabling Network Scanning does not immediately close findings. Existing findings remain visible until they age out through the normal Security Hub finding lifecycle.

> **Note**
>
> When you attach an Elastic IP address (EIP) to an Amazon EC2 instance, Network Scanning produces findings on the EIP resource. The EIP is the top-level IP resource that owns the address. For Network Load Balancer (NLB) resources, the DNS name and attached EIPs are distinct network entry points, so Network Scanning produces separate findings for each.

Scan evidence

When Network Scanning detects that a port is reachable, the finding includes evidence about the reachable service. The following types of evidence can be collected:

TCP Banner

Initial bytes sent by the service upon connection, such as an SSH version string.

HTTP Metadata

Response headers and HTTP status code.

TLS Certificate

Common Name (CN), issuer, expiry date, and self-signed status.

Service Detection

Identified application or protocol running on the port.

Excluding resources from scanning

To exclude a resource from Network Scanning, add the tag key `SecurityHubNetworkScanExclusion` to the resource. The tag value can be any value or empty.

You must apply the tag to the actual resource with the scannable public IP:

- For an EIP attached to an EC2 instance – tag the EIP, not the EC2 instance.
- For an EC2 instance with only a public IP (no EIP) – tag the EC2 instance.
- For a load balancer – tag the load balancer and any targets with individual public IPs.

When you add the exclusion tag, Network Scanning stops future scans and closes active findings for that resource. Removing the tag makes the resource eligible for scanning again.

Supported ports

Network Scanning scans the following well-known TCP ports on eligible resources.

```
21, 22, 23, 25, 53, 80, 110, 143, 443, 445, 1433, 3306, 3389, 5432,
```

```
5900, 6379, 8080, 8443, 9200, 27017
```

Multi-cloud support

Network Scanning supports Azure Public IP Addresses. To scan Azure resources, create a Security Hub connector to your Azure environment. For more information about integrating with Microsoft Azure, see Integrating Security Hub with Microsoft Azure.

Scanning behavior, evidence, and findings for Azure resources are identical to AWS resources. Findings appear alongside AWS findings with appropriate cloud provider and region metadata.

Region availability

Network Scanning is available in commercial AWS Regions where Security Hub is available.

Disable Network Scanning

If your organization uses configuration policies, the delegated administrator can disable Network Scanning across specific accounts and Regions by editing the configuration policy. For more information about editing a configuration policy, see Editing a configuration policy. When editing the policy, select the Network Scanning capability, choose **Disable**, and then specify the accounts and Regions where you want to turn off scanning.

For accounts that are not managed by a configuration policy, you can disable Network Scanning using one of the following methods.

Security Hub console

To disable Network Scanning

1. Open the Security Hub console at https://console.aws.amazon.com/securityhub/v2/home.
2. In the navigation pane, choose **General settings**.
3. Locate the **Network Scanning** section.
4. Choose **Disable**.
5. Confirm that you want to disable Network Scanning.

Security Hub API

Invoke the `DisableSecurityHubFeatureV2` API with the feature name `NETWORK_SCANNING`.

AWS CLI

Run the following command to disable Network Scanning:

```
aws securityhub disable-security-hub-feature-v2 --feature-name NETWORK_SCANNING
```

When you disable Network Scanning:

- Network Scanning does not trigger new scans.
- Existing findings remain visible until they age out through the normal Security Hub finding lifecycle.
- Network Scanning completes any scans already in progress.

Remediation plans in Security Hub

A remediation plan in AWS Security Hub groups related exposure findings that share a root cause. Each plan targets a single resource in your AWS environment. When you fix that resource, you can resolve or reduce the severity of several exposures at once.

Related exposures often come from the same underlying problem, such as a misconfiguration or an overly permissive setting on one resource. Instead of listing a separate action for each exposure, a remediation plan groups these exposures by their shared cause. You address the source once, and you reduce the most risk with the fewest actions.

For more information about exposure findings, see Exposure findings in Security Hub.

How Security Hub creates remediation plans

Security Hub creates remediation plans from the exposure findings in your account. It generates a plan for each combination of target resource and exposure trait that it can address.

Security Hub prioritizes your plans so that the ones that reduce the most risk appear first. The priority helps you decide what to work on first.

When Security Hub detects a new exposure, a plan for it might not appear immediately.

Remediation plan details

Each remediation plan includes the following details.

- **Priority** – How urgently you should act on the plan. The value is **Critical**, **High**, **Medium**, or **Low**.
- **Status** – The current state of the plan. The value is **New**, **Updated**, or **Resolved**. For what each status means, see Remediation plan status.
- **Impact** – How the plan changes your exposures. A plan can fully resolve some exposures, reduce the severity of others, and address others without changing their severity. The value names the count in each case.
- **Rollout** – Whether the fix applies immediately or requires a deployment. The value is **Immediate** or **Requires deployment**.
- **Action** – The change that the plan recommends.
- **Trait** – The exposure trait that the plan addresses.
- **Target resource** – The resource that the plan fixes, and its resource type.
- **Account** and **Region** – The AWS account that owns the target resource, and its AWS Region.

A plan also shows an affected scope, a risk level, reversibility, automation level, and whether human review is required, when its guidance provides them.

Remediation plan status

Security Hub sets each plan's status. You can't change it directly.

New

Security Hub created the plan, and the plan hasn't changed since.

Updated

The plan changed after Security Hub created it. For example, its priority, impact, affected exposures, or guidance changed. The plan keeps this status until it's resolved.

Resolved

The plan no longer needs to be applied. Security Hub resolves a plan when it no longer generates the plan from your current exposures. This happens when the plan's exposures are resolved, suppressed, or archived, when their severity changes to **Informational**, or when they no longer have the trait that the plan addresses.

A resolved plan doesn't always mean that its exposure findings are resolved. For example, an exposure whose severity changes to **Informational** still exists.

A resolved plan stays in the list for about 14 days, then Security Hub removes it. If the plan needs to be applied again, its status changes to **New**.

Remediation guidance

Each remediation plan includes guidance that describes how to fix the problem. You open a plan to read its guidance in the **Guidance** section of the **Overview** tab.

> **Note**
>
> Security Hub describes the steps, and you apply them yourself. Security Hub doesn't change your resources for you.

Guidance groups the steps into phases, such as **Prerequisite**, **Snapshot**, **Fix**, **Verify**, and **Done**. The phases, and what each one contains, come from the guidance for the target resource.

A step can also include a rollback, which describes how to undo that step.

Guidance can include example commands in more than one format, such as AWS CLI, Azure CLI, Python, Terraform, CDK, CloudFormation, Bicep, and ARM template. The formats available come from the guidance for the target resource. If no guidance is available for the target resource, the section reports that instead.

Viewing remediation plans

You view your remediation plans on the **Remediation plans** page in the Security Hub console.

To view remediation plans

1. Open the Security Hub console at https://console.aws.amazon.com/securityhub/v2/home.
2. In the navigation pane, under **Response**, choose **Remediations**.

The **Remediation plans** page lists your remediation plans in a table. Each row shows the recommended action, the plan's priority, the target resource with its AWS Region and AWS account, and the plan's impact, status, and rollout. For what these mean, see Remediation plan details.

You can't sort the list by column.

Filtering remediation plans

To narrow the list, use the **Filter remediation plans** bar. You can filter by the following properties:

- **Priority**
- **Status**
- **Resource type**
- **Cloud provider**
- **Target resource ID**
- **Account**

These filters have the following limits:

- Each filter matches values by equality only. You can't use partial matches or ranges.
- You can apply up to two filters at a time. Security Hub combines them with `AND`, so a plan must match both filters to appear.
- Values are case sensitive. For **Resource type**, enter the full type as it appears in the list, such as `AWS::EC2::Instance`.

Viewing the exposures a plan affects

When you open a remediation plan, the detail panel includes an **Affected exposures** tab. This tab lists the exposure findings that the plan addresses. For each exposure, it shows the exposure title, how the plan changes it, and the resulting severity change.

An exposure that the plan addresses without lowering its severity shows a single severity value instead of a change.

If a plan affects more exposures than the tab shows, the tab reports how many it is showing.

Viewing remediation plans for an exposure

When you view an exposure finding, the detail panel includes a **Remediations** tab. This tab lists the remediation plans that address the exposure. An exposure can have more than one plan.

Each plan shows the recommended action, its priority, and the target resource with its resource type. Expand a plan to read its guidance.

Tracking remediation impact on the dashboard

The summary dashboard includes a **Remediation plans** widget. The widget lists up to five plans with a status of **New** or **Updated**, ordered by priority, so that you can act on the most urgent work without opening the full list.

For each plan, the widget shows the recommended action, the plan's priority, its impact, the target resource, and the AWS account that owns the resource. To see the exposures behind a plan, choose its impact.

The widget reports each plan's own impact. It doesn't combine impact across plans, so an exposure that more than one plan addresses is counted in each of those plans.

You can't apply filters to this widget.

Automations in Security Hub

Security Hub includes features that automatically modify and take action on findings based on your specifications.

Security Hub currently supports the following types of automations:

- **Automation rules** – Automatically update and suppress findings, as well as send findings to ticketing tools, in near real time based on defined criteria.
- **Automated response and remediation** – Create custom Amazon EventBridge rules that define automatic actions to take against specific findings and insights.

Automation rules are helpful when you want to automatically update finding fields in the Open Cybersecurity Schema Framework (OCSF). For example, you can use an automation rule to update the severity level of findings for resources with a specific tag. Using the automation rule eliminates the need to manually update the severity level of each finding related to the specific tag. You can configure automation rules to create tickets in tools like Jira Cloud and ServiceNow when findings match specific attributes. Tickets are created from findings as soon as they arrive in Security Hub.

EventBridge rules are helpful when you want to take actions outside of Security Hub for specific findings or send specific findings to third-party tools for remediation or additional investigation. The rules can be used to trigger supported actions, such as invoking an AWS Lambda function or notifying an Amazon Simple Notification Service (Amazon SNS) topic about a specific finding.

Automation rules take effect before EventBridge rules are applied. That is, automation rules are triggered and update a finding before EventBridge receives the finding. EventBridge rules then apply to the updated finding.

Automation rules in Security Hub

With Security Hub, you can automate tasks like updating finding details, updating the criticality of your resources, and creating tickets for third-party integrations.

Automation rules and AWS Regions

Automation rules can be created in one AWS Region and then applied in all configured AWS Regions. When using Region aggregation, you can only create rules in the home Region. When creating rules in the home Region, any rule you define is applied to all linked Regions, unless your rule criteria excludes a specific linked Region. You must create an automation rule for any Region that is not a linked Region.

Types of automation rules

Automation rules in Security Hub support two rule types: finding rules and resource rules. A finding rule matches findings and updates finding details or creates a ticket for a third-party integration. A resource rule matches resources and sets the criticality of those resources. A single rule uses either finding criteria or resource criteria, but not both. A resource rule pairs resource criteria with the resource action to set criticality, and it cannot update finding details or create a ticket.

Finding rules and resource rules share the same quota. You can create a maximum of 100 automation rules per account in each AWS Region, across both finding rules and resource rules.

Finding rule actions and criteria

Automation rules in Security Hub use criteria to reference OCSF attributes in Security Hub findings. For example, the filters supported for the `Criteria` parameter in CreateAutomationRuleV2 match the filters supported for the `Filters` parameter in GetFindingsV2. This means filters used in automation rules can be used to get findings. Security Hub supports the following OCSF fields for automation rule criteria.

OCSF field	Console filter value	Filter operators	Field type
`activity_id`	`Activity ID`	`Eq (equal-to), Gte (greater-`	`Number`

OCSF field	Console filter value	Filter operators	Field type
		than-equal), Lte (less-than-equal)	
activity_name	Provider status	EQUALS, PREFIX, CONTAINS, NOT_EQUALS, PREFIX_NOT_EQUALS	String
class_name	Finding class name	EQUALS, PREFIX, CONTAINS, NOT_EQUALS, PREFIX_NOT_EQUALS	String
cloud.account.name	Finding account name	EQUALS, PREFIX, CONTAINS, NOT_EQUALS, PREFIX_NOT_EQUALS	String
cloud.account.uid	Account ID	EQUALS, PREFIX, CONTAINS, NOT_EQUALS, PREFIX_NOT_EQUALS	String
cloud.provider	Cloud provider	EQUALS, PREFIX, CONTAINS, NOT_EQUALS, PREFIX_NOT_EQUALS	String

OCSF field	Console filter value	Filter operators	Field type
cloud.region	Region	EQUALS, PREFIX, CONTAINS, NOT_EQUALS, PREFIX_NOT_EQUALS	String
compliance.assessments.category	Assessment category	EQUALS, PREFIX, CONTAINS, NOT_EQUALS, PREFIX_NOT_EQUALS	String
compliance.assessments.meets_criteria	Compliance assessment meets criteria	True, False	Boolean
compliance.assessments.name	Assessment name	EQUALS, PREFIX, CONTAINS, NOT_EQUALS, PREFIX_NOT_EQUALS	String
compliance.control	Security control ID	EQUALS, PREFIX, CONTAINS, NOT_EQUALS, PREFIX_NOT_EQUALS	String
compliance.control_parameters	Control parameter name	EQUALS	Map

OCSF field	Console filter value	Filter operators	Field type
compliance.standards	Applicable standards	EQUALS, PREFIX, CONTAINS, NOT_EQUALS, PREFIX_NOT_EQUALS	String
compliance.status	Compliance status	EQUALS, PREFIX, CONTAINS, NOT_EQUALS, PREFIX_NOT_EQUALS	String
compliance.status_id	Compliance status ID	Eq (equal-to), Gte (greater-than-equal), Lte (less-than-equal)	Number
confidence_score	Confidence	Eq (equal-to), Gte (greater-than-equal), Lte (less-than-equal)	Number
finding_info.created_time_dt	Created at	Start, End, DateRange	Date (formatted as 2022-12-01T21:47:39.269Z)
finding_info.desc	Finding description	EQUALS, PREFIX, CONTAINS, NOT_EQUALS, PREFIX_NOT_EQUALS	String

OCSF field	Console filter value	Filter operators	Field type
finding_info.first_seen_time_dt	First observed at	Start, End, DateRange	Date (formatted as 2022-12-01T21:47:39.269Z)
finding_info.last_seen_time_dt	Last observed at	Start, End, DateRange	Date (formatted as 2022-12-01T21:47:39.269Z)
finding_info.modified_time_dt	Updated at	Start, End, DateRange	Date (formatted as 2022-12-01T21:47:39.269Z)
finding_info.related_events.product.uid	Related findings product ID	EQUALS, PREFIX, CONTAINS, NOT_EQUALS, PREFIX_NOT_EQUALS	String
finding_info.related_events.title	Related findings title	EQUALS, PREFIX, CONTAINS, NOT_EQUALS, PREFIX_NOT_EQUALS	String
finding_info.related_events.traits.category	Traits category	EQUALS, PREFIX, CONTAINS, NOT_EQUALS, PREFIX_NOT_EQUALS	String

OCSF field	Console filter value	Filter operators	Field type
finding_info.related_events.uid	Related findings ID	EQUALS, PREFIX, CONTAINS, NOT_EQUALS, PREFIX_NOT_EQUALS	String
finding_info.related_events_count	Related findings count	Eq (equal-to), Gte (greater-than-equal), Lte (less-than-equal)	Number
finding_info.src_url	Source URL	EQUALS, PREFIX, CONTAINS, NOT_EQUALS, PREFIX_NOT_EQUALS	String
finding_info.tags	Finding info tags	EQUALS	Map
finding_info.title	Finding title	EQUALS, PREFIX, CONTAINS, NOT_EQUALS, PREFIX_NOT_EQUALS	String
finding_info.types	Finding type	EQUALS, PREFIX, CONTAINS, NOT_EQUALS, PREFIX_NOT_EQUALS	String

OCSF field	Console filter value	Filter operators	Field type
finding_info.uid	Provider finding ID	EQUALS, PREFIX, CONTAINS, NOT_EQUALS, PREFIX_NOT_EQUALS	String
metadata.product.feature.uid	Generator ID	EQUALS, PREFIX, CONTAINS, NOT_EQUALS, PREFIX_NOT_EQUALS	String
metadata.product.name	Product name	EQUALS, PREFIX, CONTAINS, NOT_EQUALS, PREFIX_NOT_EQUALS	String
metadata.product.uid	Product ARN	EQUALS, PREFIX, CONTAINS, NOT_EQUALS, PREFIX_NOT_EQUALS	String
metadata.product.vendor_name	Company name	EQUALS, PREFIX, CONTAINS, NOT_EQUALS, PREFIX_NOT_EQUALS	String
remediation.desc	Recommendation text	EQUALS, PREFIX, CONTAINS, NOT_EQUALS, PREFIX_NOT_EQUALS	String

OCSF field	Console filter value	Filter operators	Field type
remediation.references	Recommendation URL	EQUALS, PREFIX, CONTAINS, NOT_EQUALS, PREFIX_NOT_EQUALS	String
resources.cloud_partition	Resource partition	EQUALS, PREFIX, CONTAINS, NOT_EQUALS, PREFIX_NOT_EQUALS	String
resources.modified_time_dt	Resource last modified time	Start, End, DateRange	Date (formatted as 2022-12-01T21:47:39.269Z)
resources.name	Resource name	EQUALS, PREFIX, CONTAINS, NOT_EQUALS, PREFIX_NOT_EQUALS	String
resources.owner.account.name	Account name	EQUALS, PREFIX, CONTAINS, NOT_EQUALS, PREFIX_NOT_EQUALS	String
resources.owner.account.uid	Account	EQUALS, PREFIX, CONTAINS, NOT_EQUALS, PREFIX_NOT_EQUALS	String

OCSF field	Console filter value	Filter operators	Field type
resources .owner.org.uid	Organization	EQUALS, PREFIX, CONTAINS, NOT_EQUAL S, PREFIX_NO T_EQUALS	String
resources .provider	Cloud provider	EQUALS, PREFIX, CONTAINS, NOT_EQUAL S, PREFIX_NO T_EQUALS	String
resources .region	Resource region	EQUALS, PREFIX, CONTAINS, NOT_EQUAL S, PREFIX_NO T_EQUALS	String
resources.tags	Resource tags	EQUALS	Map
resources.type	Resource type	EQUALS, PREFIX, CONTAINS, NOT_EQUAL S, PREFIX_NO T_EQUALS	String
resources.uid	Resource ID	EQUALS, PREFIX, CONTAINS, NOT_EQUAL S, PREFIX_NO T_EQUALS	String

OCSF field	Console filter value	Filter operators	Field type
vendor_attributes.severity	Provider severity	EQUALS, PREFIX, CONTAINS, NOT_EQUALS, PREFIX_NOT_EQUALS	String
vendor_attributes.severity_id	Provider severity ID	Eq (equal-to), Gte (greater-than-equal), Lte (less-than-equal)	Number
vulnerabilities.affected_code.file.path	Affected code file path	EQUALS, PREFIX, CONTAINS, NOT_EQUALS, PREFIX_NOT_EQUALS	String
vulnerabilities.affected_packages.name	Affected package name	EQUALS, PREFIX, CONTAINS, NOT_EQUALS, PREFIX_NOT_EQUALS	String
vulnerabilities.cve.cvss.base_score	CVE CVSS base score	Eq (equal-to), Gte (greater-than-equal), Lte (less-than-equal)	Number
vulnerabilities.cve.epss.score	Epss score	EQUALS, PREFIX, CONTAINS, NOT_EQUALS, PREFIX_NOT_EQUALS	String

OCSF field	Console filter value	Filter operators	Field type
vulnerabilities.cve.uid	Vulnerability ID	EQUALS, PREFIX, CONTAINS, NOT_EQUALS, PREFIX_NOT_EQUALS	String
vulnerabilities.fix_coverage	Software vulnerabilities coverage	EQUALS, PREFIX, CONTAINS, NOT_EQUALS, PREFIX_NOT_EQUALS	String
vulnerabilities.is_exploit_available	Software vulnerabilities with exploit available	True, False	Boolean
vulnerabilities.is_fix_available	Software vulnerabilities with fix available	True, False	Boolean
vulnerabilities.related_vulnerabilities	Related vulnerabilities	EQUALS, PREFIX, CONTAINS, NOT_EQUALS, PREFIX_NOT_EQUALS	String

For criteria labeled as string fields, using different filter operators on the same field affects the evaluation logic. For more information, see StringFilter in the *Security Hub API Reference*.

Each criterion supports a maximum number of values that can be used to filter matching findings. For the limits of each criterion, see OcsfFindingFilters in the *Security Hub API Reference*

OCSF fields that can be updated

The following are the OCSF fields that can be updated using automation rules.

- `Comment`
- `SeverityId`
- `StatusId`

Resource rule actions and criteria

Resource criteria reference resource attributes. The filters supported for resource criteria are a subset of the filters supported for the GetResourcesV2 operation. You can combine filters with `AND` and `OR` operators, and nest them up to three levels deep, with a maximum of 100 filters per rule.

Security Hub supports the following resource fields for resource criteria.

Resource field	Console filter value	Filter operators	Field type
`ResourceId`	`Resource ID`	`EQUALS, PREFIX, CONTAINS, NOT_CONTAINS, NOT_EQUALS, PREFIX_NOT_EQUALS`	`String`
`ResourceName`	`Resource name`	`EQUALS, PREFIX, CONTAINS, NOT_CONTAINS, NOT_EQUALS, PREFIX_NOT_EQUALS`	`String`
`ResourceType`	`Resource type`	`EQUALS, PREFIX, CONTAINS, NOT_CONTAINS, NOT_EQUALS, PREFIX_NOT_EQUALS`	`String`

Resource field	Console filter value	Filter operators	Field type
ResourceCategory	Resource category	EQUALS, PREFIX, CONTAINS, NOT_CONTAINS, NOT_EQUALS, PREFIX_NOT_EQUALS	String
ResourceSubCategory	Resource sub-category	EQUALS, PREFIX, CONTAINS, NOT_CONTAINS, NOT_EQUALS, PREFIX_NOT_EQUALS	String
ResourceProvider	Cloud provider	EQUALS, PREFIX, CONTAINS, NOT_CONTAINS, NOT_EQUALS, PREFIX_NOT_EQUALS	String
ResourceCloudPartition	Resource partition	EQUALS, PREFIX, CONTAINS, NOT_CONTAINS, NOT_EQUALS, PREFIX_NOT_EQUALS	String
ResourceRegion	Region	EQUALS, PREFIX, CONTAINS, NOT_CONTAINS, NOT_EQUALS, PREFIX_NOT_EQUALS	String

Resource field	Console filter value	Filter operators	Field type
ResourceGuid	Resource GUID	EQUALS, PREFIX, CONTAINS, NOT_CONTAINS, NOT_EQUALS, PREFIX_NOT_EQUALS	String
AccountId	Finding account	EQUALS, PREFIX, CONTAINS, NOT_CONTAINS, NOT_EQUALS, PREFIX_NOT_EQUALS	String
AccountName	Account name	EQUALS, PREFIX, CONTAINS, NOT_CONTAINS, NOT_EQUALS, PREFIX_NOT_EQUALS	String
Region	Finding region	EQUALS, PREFIX, CONTAINS, NOT_CONTAINS, NOT_EQUALS, PREFIX_NOT_EQUALS	String
ResourceOwnerAccountId	Account	EQUALS, PREFIX, CONTAINS, NOT_CONTAINS, NOT_EQUALS, PREFIX_NOT_EQUALS	String

Resource field	Console filter value	Filter operators	Field type
ResourceOwnerOrgId	Organization	EQUALS, PREFIX, CONTAINS, NOT_CONTAINS, NOT_EQUALS, PREFIX_NOT_EQUALS	String
ResourceCreationTime	Created at	Start, End, DateRange	Date
ResourceDetailCaptureTime	Resource detail capture time	Start, End, DateRange	Date
ResourceTags	Resource tags	EQUALS, NOT_EQUALS, CONTAINS, NOT_CONTAINS	Map

Security Hub does not support number filters. It does not support the `CONTAINS_WORD` operator for resource criteria. For the complete list of resource filter fields and their allowed values, see ResourcesFilters and GetResourcesV2 in the *Security Hub API Reference*.

Resource fields that can be updated

A resource rule updates the criticality of resources that match your criteria. You can set the criticality to one of the following values, listed from highest to lowest.

- `Very High`
- `High`
- `Medium`
- `Low`
- `Unknown`

Resource rules do not apply to self-hosted AI resources. These resource types are excluded from automation-rule criticality, and they continue to receive inferred criticality.

How automation rules evaluate findings

An automation rule evaluates new and updated findings that Security Hub generates or ingests after you create the rule.

Automation rules evaluate original, provider-supplied findings. Providers can supply new findings and update existing findings through their integration with Security Hub. Rules are not triggered when you update finding fields after rule creation through the `BatchUpdateFindingsV2` operation. If you create an automation rule and make a `BatchUpdateFindingsV2` update that both affect the same finding field, the last update sets the value for that field. Take the following example:

You use `BatchUpdateFindingsV2` to update the `Status` field of a finding from `New` to `In Process`. If you call `GetFindingsV2`, the `Status` field now has a value of `In Process`. You create an automation rule that changes the `Status` field of the finding from `New` to `Suppressed` (recall that rules ignore updates made with `BatchUpdateFindingsV2`). The finding provider updates the finding and changes the `Status` field to `New`. If you call `GetFindingsV2`, the `Status` field now has a value of `Suppressed` because the automation rule was applied, and the rule was the last action taken on the finding.

When you create or edit a rule on the Security Hub console, the console displays a preview of findings that match the rule criteria. Whereas automation rules evaluate original findings sent by the finding provider, the console preview reflects findings in their final state as they would be shown in a response to the `GetFindingsV2` API operation (that is, after rule actions or other updates are applied to the finding).

How automation rules are ordered

Each automation rule is assigned a rule order. This determines the order in which Security Hub applies your automation rules, and becomes important when multiple rules relate to the same finding or finding field.

When multiple rule actions relate to the same finding or finding field, the rule with the highest numerical value for rule order applies last and has the ultimate effect.

Rule order also determines the final criticality of a resource. When multiple resource rules match the same resource, the rule that applies last determines the criticality of the resource.

When you create a rule in the Security Hub console, Security Hub automatically assigns rule order based on the order of rule creation. The first rule you create will have a rule order of 1. When more than one rule exists each subsequently created rule will have the next highest available numerical value for rule order.

When you create a rule through CreateAutomationRuleV2 API or AWS CLI, Security Hub applies the rule with the lowest numerical value for `RuleOrder` first. It then applies subsequent rules in ascending order. If multiple findings have the same `RuleOrder`, Security Hub applies a rule with an earlier value for the `UpdatedAt` field first (that is, the rule that was most recently edited applies last).

You can modify rule order at any time.

Example of rule order:

Rule A (rule order is 1):

- Rule A criteria
  - `ProductName` = `Security Hub CSPM`
  - `Resources.Type` is `S3 Bucket`
  - `Compliance.Status` = `FAILED`
  - `RecordState` is `NEW`
  - `Workflow.Status` = `ACTIVE`
- Rule A actions
  - Update `Confidence` to 95
  - Update `Severity` to `CRITICAL`
  - Update `Comment` to `This needs attention`

Rule B (rule order is 2):

- Rule B criteria
  - `AwsAccountId` = `123456789012`
- Rule B actions
  - Update `Severity` to `INFORMATIONAL`

First, Rule A actions apply to Security Hub findings that match Rule A criteria. Then, Rule B actions apply to Security Hub findings with the specified account ID. In this example, since Rule B applies last, the end value of `Severity` in findings from the specified account ID is `INFORMATIONAL`. Based on the Rule A action, the end value of `Confidence` in matched findings is 95.

Third-party integrations

You can use automation rules to create tickets for integrations with Jira Cloud and ServiceNow ITSM. For more information, see Creating a rule for a third-party integration.

Scenarios where automation rules do not work

The following are scenarios where automation rules do not work.

- The standalone account becomes a member of an organization with a delegated admin
- The organization management account removes the delegated admin and sets a new delegated admin
- The aggregator configuration for the delegated admin or standalone account changes when an unlinked Region is made a linked Region

During these scenarios, a member of an organization can manage automation rules with list, get, and delete operations in the AWS CLI or APIs.

When an unlinked Region is made a linked Region, the delegated admin or standalone account can manage resources in a linked Region with list, get, and delete operations.

Creating automation rules in Security Hub

This topic describes how to create automation rules. You can use automation rules to update details for a finding, update the criticality of your resources, or create a ticket for a third-party integration. You must create automation rules individually and in the AWS Region where you want them applied. However, if you create an automation rule in an aggregation Region, it is applied in all Regions. Otherwise, if you create an automation rule in a non-linked Region, it is applied only in that Region.

Creating a rule that updates finding details

The following procedure describes how to create a rule that updates finding details.

1. Sign in to your AWS account. Open the Security Hub console at https://console.aws.amazon.com/securityhub/v2/home.
2. From the navigation pane, under **Management**, choose **Automations**.
3. Choose **Create rule**.
4. Under **Details**, enter a name for your automation rule.
   - (Optional) Enter a description for your automation rule.
5. Under **Actions**, choose **Update findings details**. You can search for criteria and add criteria in the search bar. To check if any findings match your criteria, choose **Preview matching findings**.
6. Under **Update finding details**, choose at least one finding detail to update when a finding matches your criteria. You can choose **Severity**, **Status**, or **Comment**.
7. Under **Rule settings**, select **Enabled** or **Disabled**. If you select **Enabled**, the automation rule is enabled and processes new findings. If you select **Disabled**, the automation rule is disabled and does not process any findings.
8. (Optional) Under **Tags**, choose **Add new tag** to enter a key-value pair to be applied to your automation rule.
9. Choose **Create rule**.

Creating a rule that updates resource criticality

The following procedure describes how to create a rule that updates the criticality of resources that match your criteria.

1. Sign in to your AWS account. Open the Security Hub console at https://console.aws.amazon.com/securityhub/v2/home.
2. From the navigation pane, under **Management**, choose **Automations**.
3. Choose **Create rule**.
4. Under **Details**, enter a name for your automation rule.
   - (Optional) Enter a description for your automation rule.
5. Under **Actions**, choose **Update resource details**. You can search for criteria and add criteria in the search bar. To check if any resources match your criteria, choose **Preview matching resources**.

6. Under **Update resource details**, for **Criticality**, choose the criticality to apply to resources that match your criteria. You can choose **Very High**, **High**, **Medium**, **Low**, or **Unknown**.

   > **Note**
   >
   > This rule does not apply to self-hosted AI resources. These resource types are excluded from automation-rule criticality.

7. Under **Rule settings**, select **Enabled** or **Disabled**. If you select **Enabled**, the automation rule is enabled and processes resources that match your criteria. If you select **Disabled**, the automation rule is disabled and does not process any resources.
8. (Optional) Under **Tags**, choose **Add new tag** to enter a key-value pair to be applied to your automation rule.
9. Choose **Create rule**.

Creating a rule for a third-party integration

The following procedure describes how to create a rule that creates a ticket for a third-party integration. For information about the integrations Security Hub CSPM supports, see Third-party integrations for Security Hub CSPM.

1. Sign in to your AWS account. Open the Security Hub console at https://console.aws.amazon.com/securityhub/v2/home.
2. From the navigation pane, under **Management**, choose **Automations**.
3. Choose **Create rule**.
4. Under **Details**, enter a name for your automation rule.
   - (Optional) Enter a description for your automation rule.
5. Under **Actions**, choose **Create ticket**. You can search for criteria and add criteria in the search bar. To check if any findings match your criteria, choose **Preview matching findings**.
6. Under **Create a ticket**, choose an IT ticketing integration from the dropdown, and then choose **Add integration**.
7. Under **Rule settings**, select **Enabled** or **Disabled**. If you select **Enabled**, the automation rule is enabled and processes new findings. If you select **Disabled**, the automation rule is disabled and does not process any findings.

8. (Optional) Under **Tags**, choose **Add new tag** to enter a key-value pair to be applied to your automation rule.
9. Choose **Create rule**.

Viewing details for automation rules in Security Hub

This topic describes how to view details for automation rules. You can view the following details for an automation rule:

- Name and description
- Actions and criteria

To view details for an automation rule

1. Sign in to your AWS account. Open the Security Hub console at https://console.aws.amazon.com/securityhub/v2/home.
2. From the navigation pane, under **Management**, choose **Automations**. This screen shows all of your created automation rules.
3. Select the automation rule you want to view. Choose **View details**. Alternatively, you can choose the name of the automation rule you want to view.

Updating the rule order in Security Hub

This topic describes how to update the rule order for automation rules in the console. If you want to edit the criteria for an automation rule, see Editing automation rules in Security Hub.

You cannot update the rule order for one automation rule without updating the rule order for every automation rule. For example, you have four automation rules: Rule A (1), Rule B (2), Rule C (3), and Rule D (4). You want Rule D to be applied first. To do this, you change its number from 4 to 1. As a result, Rule A gets 2, Rule B gets 3, and Rule C gets 4.

To update the rule order for your automation rules

1. Sign in to your AWS account. Open the Security Hub console at https://console.aws.amazon.com/securityhub/v2/home.

2. From the navigation pane, under **Management**, choose **Automations**.
3. Select the automation rule you want to edit. Under **Order**, choose the pencil icon next to the order number. Use the arrows to determine the new order number. Choose the ✓ icon to confirm. Choose the **X** icon to cancel. Alternatively, you can choose **Change order** to move the automation rule down, up, or to the top of the list.

Disabling automation rules in Security Hub

This topic describes how to disable automation rules. When you disable automation rules, Security Hub stops applying them. You can disable automation rules any time and in the AWS Region where you created them.

To disable a rule

1. Sign in to your AWS account. Open the Security Hub console at https://console.aws.amazon.com/securityhub/v2/home.
2. From the navigation pane, under **Management**, choose **Automations**.
3. Select the automation rule you want to disable. Under **Status**, choose the pencil icon next to **Enabled**. Choose the dropdown, and then choose **Disabled**. Choose the ✓ icon to confirm. Choose the **X** icon to cancel. You can also choose **Disable** from the **Actions** dropdown.

Enabling an automation rule in Security Hub

This topic describes how to enable automation rules. When you enable automation rules, Security Hub resumes applying them. You can enable automation rules any time and in the AWS Region where you created them.

To enable a rule

1. Sign in to your AWS account. Open the Security Hub console at https://console.aws.amazon.com/securityhub/v2/home.
2. From the navigation pane, under **Management**, choose **Automations**.
3. Select the automation rule you want to enable. Under **Status**, choose the pencil icon next to **Disabled**. Choose the dropdown, and then choose **Enabled**. Choose the ✓ icon to confirm. Choose the **X** icon to cancel. You can also choose **Enable** from the **Actions** dropdown.

Duplicating automation rules in Security Hub

This topic describes how to duplicate automation rules. Duplicating automation rules can help you save time if you want to avoid creating them from scratch. When you duplicate automation rules, you can update details, actions, rule settings, and tags. You can edit automation rules in the AWS Region where you created them.

To duplicate a rule

1. Sign in to your AWS account, and open the Security Hub console at https://console.aws.amazon.com/securityhub/v2/home.
2. From the navigation pane, choose **Management**, and choose **Automations**.
3. Select the automation rule that you want to duplicate. Then choose **Actions**, and then choose **Duplicate**.
4. Make and review your changes, and then choose **Create rule**.

Editing automation rules in Security Hub

This topic describes how to edit automation rules. You can edit automation rules in the AWS Region where you created them.

You can edit the following for automation rules:

- Name and description
- Actions
- Rule settings

You cannot edit tags for automation rules.

To edit a rule

1. Sign in to your AWS account. Open the Security Hub console at https://console.aws.amazon.com/securityhub/v2/home.
2. From the navigation pane, under **Management**, choose **Automations**.
3. Select the automation rule that you want to edit. Choose **Actions**, and then choose **Edit**.
4. Make and review your edits.

5. Choose **Save changes**.

Deleting automation rules in Security Hub

This topic describes how to delete automation rules. You can delete automation rules in the AWS Region where you created them.

To delete a rule

1. Sign in to your AWS account, and open the Security Hub console at https://console.aws.amazon.com/securityhub/v2/home.
2. From the navigation pane, choose **Management**, and then choose **Automations**.
3. Select the automation rule that you want to delete. Choose **Actions**, and then choose **Delete**.
4. Choose **Delete**.

Automation rules in EventBridge

You can use automation rules in Amazon EventBridge to respond to Security Hub findings. Security Hub sends findings to EventBridge as events in near real time. You can write basic rules that indicate what automated actions to take when an event matches a rule. Actions that can be automatically triggered include the following:

- Configuring an API destination in EventBridge.
- Invoking Amazon EC2 run commands
- Invoking Lambda functions
- Invoking Step Functions state machines
- Notifying an Amazon SNS topic or an Amazon SQS queue
- Relaying events to Kinesis Data Streams
- Sending a finding to a third-party ticketing, chat, SIEM, or incident response and management tool
- Sending an event to an EventBridge bus in another AWS account

Security Hub sends new findings and updated findings to EventBridge as events. Then you configure EventBridge rules to respond to each Security Hub event. For more information, see What is EventBridge? in the *EventBridge User Guide*.

> **Note**
>
> If you have EventBridge rules defined for findings in Security Hub CSPM, the rules could overlap with rules defined for Security Hub. To avoid sending duplicate findings, evaluate the rules you have defined for Security Hub CSPM to determine if they overlap with rules you have defined for Security Hub. Where applicable, disable any Security Hub CSPM rules that are replaced by Security Hub rules.

> **Note**
>
> As a best practice, make sure users with permission to access EventBridge use AWS Identity and Access Management policies that grant the minimum required permissions. For more information, see EventBridge and AWS Identity and Access Management in the *EventBridge User Guide*.

EventBridge event types

Security Hub uses the following Amazon EventBridge event types to integrate with EventBridge.

On the EventBridge dashboard for Security Hub, **All Events** includes all of these event types.

Findings Imported V2

Security Hub automatically sends all new findings and all updates to existing findings to EventBridge as **Findings Imported V2** events. Each **Findings Imported V2** event contains a single finding.

Every finding that is imported and every finding updated through a `BatchUpdateFindingsV2` request triggers a **Findings Imported V2** event.

For administrator accounts, the event feed in EventBridge includes events for findings from both their account and from their member accounts.

In an aggregation Region, the event feed includes events for findings from the aggregation Region and the linked Regions. Cross-Region findings are included in the event feed in near real time.

You can define rules in EventBridge that automatically route findings to a remediation workflow, third-party tool, or other supported EventBridge target. The rules can include filters that only apply the rule if the finding has specific attribute values.

You use this method to automatically send all findings, or all findings that have specific characteristics, to a response or remediation workflow.

> **Note**
>
> Security Hub and Security Hub CSPM both send findings to EventBridge under the source of `aws.securityhub`. Ensure that your EventBridge rules use the detail-type that is specific to Security Hub in order to avoid duplicate notifications related to Security Hub CSPM findings.

EventBridge event formats

The **Findings Imported V2** event type uses the following event format.

Example

This format is used when Security Hub sends an event to EventBridge.

```
{
   "version":"0",
   "id":"CWE-event-id",
   "detail-type":"Findings Imported V2",
   "source":"aws.securityhub",
   "account":"111122223333",
   "time":"2019-04-11T21:52:17Z",
   "region":"us-west-2",
   "resources":[
      "e51603d1054aad9d9f498d82d6e81acf4cf6bc88140e8ad2273123c73b81084"
   ],
   "detail":{
      "findings": [{
         <finding content>
       }]
   }
}
```

Each event sends a single finding. *<finding content>* is the content in JSON of the finding sent by the event.

For a complete list of finding attributes, see OCSF findings in Security Hub CSPM.

Configuring rules for EventBridge

You can create a rule in Amazon EventBridge that defines an action to take when a **Findings Imported V2** event is received. **Findings Imported V2** events are triggered by updates through `BatchUpdateFindingsV2`.

Each rule contains an event pattern, which identifies the events that trigger the rule. The event pattern always contains the event source (`aws.securityhub`) and the event type (**Findings Imported V2**). The event pattern can also specify filters to identify the findings that the rule applies to.

The event rule then identifies the rule targets. The targets are the actions to take when EventBridge receives a **Findings Imported V2** event and the finding matches the filters.

The instructions provided here use the EventBridge console. When you use the console, EventBridge automatically creates the required resource-based policy that enables EventBridge to write to Amazon CloudWatch Logs.

You can also use the `PutRule` operation of the EventBridge API. However, if you use the EventBridge API, then you must create the resource-based policy. For information about the required policy, see CloudWatch Logs permissions in the *Amazon EventBridge User Guide*.

Format of the event pattern

The format of the event pattern for **Findings Imported V2** events is as follows:

```
{
  "source": [
    "aws.securityhub"
  ],
  "detail-type": [
    "Findings Imported V2"
  ],
  "detail": {
    "findings": {
      <attribute filter values>
    }
```

```
  }
}
```

- `source` identifies Security Hub as the service that generates the event.
- `detail-type` identifies the type of event.
- `detail` is optional and provides the filter values for the event pattern. If the event pattern does not contain a `detail` field, then all findings trigger the rule.

You can filter the findings based on any finding attribute. For each attribute, you provide a comma-separated array of one or more values.

```
"<attribute name>": [ "<value1>", "<value2>"]
```

If you provide more than one value for an attribute, then those values are joined by `OR`. A finding matches the filter for an individual attribute if the finding has any of the listed values. For example, if you provide both `INFORMATIONAL` and `LOW` as values for `Severity.Label`, then the finding matches if it has a severity label of either `INFORMATIONAL` or `LOW`.

The attributes are joined by `AND`. A finding matches if it matches the filter criteria for all of the provided attributes.

When you provide an attribute value, it must reflect the location of that attribute within the AWS Open Cybersecurity Schema Framework (OCSF) structure.

In the following example, the event pattern provides filter values for `ProductArn` and `Severity.Label`, so a finding matches if it is generated by Amazon Inspector and it has a severity label of either `INFORMATIONAL` or `LOW`.

```
{
    "source": [
        "aws.securityhub"
     ],
    "detail-type": [
        "Findings Imported V2"
    ],
    "detail": {
        "findings": {
            "ProductArn": ["arn:aws:securityhub:us-east-1::product/aws/inspector"],
            "Severity": {
                "Label": ["INFORMATIONAL", "LOW"]
```

```
            }
        }
    }
}
```

Creating an event rule

You can use a predefined event pattern or a custom event pattern to create a rule in EventBridge. If you select a predefined pattern, EventBridge automatically fills in `source` and `detail-type`. EventBridge also provides fields to specify filter values for the following finding attributes:

- `cloud.account.uid`
- `compliance.status`
- `metadata.product.name`
- `resources.uid`
- `severity`
- `status`

To create an EventBridge rule (console)

1. Open the Amazon EventBridge console at https://console.aws.amazon.com/events/.
2. Using the following values, create an EventBridge rule that monitors finding events:
   - For **Rule type**, choose **Rule with an event pattern**.
   - Choose how to build the event pattern.

To build the event pattern with...	Do this...
A template	In the **Event pattern** section, choose the following options: • For **Event source**, choose **AWS services**. • For **AWS service**, choose **Security Hub**.

To build the event pattern with...	Do this...	
	• For **Event type**, choose **Findings Imported V2**. • (Optional) To make the rule more specific, add filter values. For example, to limit the rule to findings with active record states, for **Specific Record state(s)**, choose **Active**.	

To build the event pattern with...	Do this...
A custom event pattern (Use a custom pattern if you want to filter findings based on attributes that do not appear in the EventBridge console.)	• In the **Event pattern** section, choose **Custom patterns (JSON editor)**, and then paste the following event pattern into the text area: `{ "source": [ "aws.securityhub" ], "detail-type": [ "Findings Imported V2" ], "detail": { "findings": { "<attribute name>": [ "<value1>", "<value2>" ] } } }` • Update the event pattern to include the attribute and attribute values that you want to use as a filter. For example, to apply the rule to findings that have a severity of `Critical`, use the following pattern example:

To build the event pattern with...	Do this...

	<pre>{
	    "source":
	["aws.securityhub"
	],
	    "detail-type":
	["Findings Imported
	 V2"],
	    "detail":{
	        "findings":
	{
	           "Severity
	": ["Critical"]
	          }
	    }
	}</pre>

- For **Target types**, choose **AWS service**, and for **Select a target**, choose a target such as an Amazon SNS topic or AWS Lambda function. The target is triggered when an event is received that matches the event pattern defined in the rule.

For details about creating rules, see Creating Amazon EventBridge rules that react to events in the *Amazon EventBridge User Guide*.

Note

If you have EventBridge rules defined for findings in Security Hub CSPM, the rules could overlap with rules defined for Security Hub. To avoid sending duplicate findings, evaluate the rules you have defined for Security Hub CSPM to determine if they overlap with rules you have defined for Security Hub. Where applicable, disable any Security Hub CSPM rules that are replaced by Security Hub rules.

Exporting findings from Security Hub to Amazon S3

You can export findings from AWS Security Hub to an Amazon Simple Storage Service (Amazon S3) bucket that you own. An export captures the findings that match the filters on the page you start it from and writes them to your bucket as a CSV file or as JSON in the Open Cybersecurity Schema Framework (OCSF) format. Use exports to share findings with teams that do not use the Security Hub console, load findings into a data warehouse or business intelligence tool, or keep a point in time record for audits.

Exports are on demand. You start an export, Security Hub runs it in the background, and the files appear in your bucket when it finishes. You can track every export from the **Exports** page in the Security Hub console.

How findings export works

You start an export from one of the findings pages in the Security Hub console: **All findings**, **Exposure**, **Threats**, **Vulnerabilities**, **Sensitive data**, or **Posture management**. The export uses the page as its scope and carries over the filters you applied on that page. For example, if you filter the **Vulnerabilities** page to critical findings with the status `New`, the export contains only those findings.

Security Hub writes the export to the Amazon S3 bucket and prefix you choose and encrypts every object with the AWS Key Management Service (AWS KMS) key you choose.

> **Note**
>
> Only one export can run at a time in an account. To start another export, wait for the running export to finish or cancel it from the **Exports** page.

Prerequisites

Before you create an export, you need an Amazon S3 bucket, an AWS KMS key, policies on both that allow Security Hub to write to them, and IAM permissions for the identity that creates the export.

Creating an export

To create an export

1. Open the Security Hub console and choose the findings page you want to export from: **All findings**, **Exposure**, **Threats**, **Vulnerabilities**, **Sensitive data**, or **Posture management**.
2. Apply the filters you want the export to use.
3. Choose **Export**. The **Create export** page opens.
4. Under **Scope**, review the scope. It reads **All findings, using the filters carried over from the Vulnerabilities page** (or the name of the page you came from). To change the scope or filters, return to the findings page and adjust them there.

   Filters are applied to OCSF fields. If a filter on the source page does not apply to findings, the console shows a warning that names the filters it did not carry over.
5. Under **Export settings**, do the following:

   - **Export name** – Enter a name so you can find the export later on the exports list. The console suggests a name made from the source page and the current time, for example `vulnerabilities-202610081601`.
   - **Export format** – Choose **CSV** or **JSON (OCSF)**.
   - **CSV columns** (CSV only) – Each option shows the column name and the OCSF field path it comes from, for example **Finding account** (`cloud.account.uid`). Fields are grouped by OCSF object, such as Finding info, Cloud, Resources, Compliance, Vulnerabilities, and Evidences. The default set contains nine columns: Finding title, Severity, Resource ID, Created at, Status, Finding account, Finding region, Product vendor name, and Finding type.

     JSON (OCSF) exports always contain the complete finding, so there is no column selection.
6. Under **Export location**, select your Amazon S3 bucket and add your AWS KMS key for encryption.
7. Choose **Create export**.

If an export is already running in your account, the console shows the **Export in progress** dialog. You can wait for that export to finish, or choose **Cancel export and create new** to cancel it and start this one.

Third-party integrations for Security Hub

You can enhance your security posture with third-party integrations for AWS Security Hub. With this feature you can enable integrations that consume findings from Security Hub, allowing you to incorporate your operational, investigation, and response tools with Security Hub. Currently Security Hub supports integration with Jira Cloud and ServiceNow.

Topics

- Integrations for AWS Security Hub Jira Cloud
- Integrations for ServiceNow
- KMS key policies for Security Hub ticketing integrations
- Testing configured ticketing integrations

Integrations for AWS Security Hub Jira Cloud

This topic describes how to integrate Security Hub with Jira Cloud. Before completing any of the procedures in this topic, you must purchase a Jira Cloud subscription plan. For information about subscription plans, see Pricing on the Atlassian website.

This integration allows you to send Security Hub findings to Jira Cloud, manually or automatically, so you can manage them as part of your operational workflows. For example, you can assign ownership to issues that need investigation and remediation.

For accounts in an organization, only the delegated administrator can configure an integration. The delegated administrator can manually use the create ticket feature for any member account findings. Additionally, the delegated administrator can use automation rules to automatically create tickets for any findings associated with member accounts. When defining an automation rule, the delegated administrator can set criteria, which can include all member accounts or specific member accounts. For information about setting a delegated administrator, see Setting a delegated administrator account in Security Hub.

For accounts not in an organization, all aspects of this feature are available.

Prerequisites

Prior to connecting Security Hub with your Jira Cloud environment you must ensure that the following configuration steps are done in your Jira environment.

- Install the AWS Security Hub for Jira cloud app.
- Have at least one software development project that is company managed.
- Assign the AWS app to the software development projects you want to receive findings from Security Hub.

Steps for each of these prerequisites are listed below.

1. Install the AWS Security Hub for Jira Cloud app

Security Hub has an app to support its integration with Jira. This app installs custom fields and a custom issue type. Security Hub uses these to populate specific attributes about findings.

1. Sign in to your Atlassian site as the administrator.
2. Choose **Settings**, and choose **Apps**.
3. If directed to the marketplace page, choose **Find new apps**. If directed to the apps page, choose **Explore apps**, and then search for *AWS Security Hub for Jira Cloud*. Then choose **Get it now**.

2. Create a project or verify existing projects

This step is required if you haven't created a project. For information about how to create a project, see Create a new project in the Jira Cloud Support documentation.

Requirements for creating a project

Make sure to do the following when creating a new project.

- Choose **Software development** for the project template.
- Choose **Company-managed** for the project type.

Requirements for existing projects

Any existing projects in your Jira environment that are integrated with Security Hub must be a project type of **Company-managed**.

3. Add your projects to the AWS Security Hub for Jira Cloud app

In order for Security Hub to be able to successfully send findings to your Jira environment each project that you want to use with Security Hub must be associated with the AWS Security Hub for

Jira Cloud app. Associating a Jira project with the app ensures that the necessary custom fields for Security Hub are associated with the project and can be populated when Security Hub sends findings to the project.

1. Sign in to your Atlassian site as the administrator.
2. Choose **Settings**, and choose **Apps**.
3. From the list of apps, choose **AWS Security Hub for Jira Cloud**.
4. Choose the **Connector settings** tab.
5. Under **Projects enabled**, choose **Add Jira Project**.
    a. From the dropdown, choose **Add all**, or select a project. Repeat this part of the step if you want to add more than one project, but not all projects.
    b. Choose **Save**.

You can verify which projects have been successfully installed from the **Installation Manager** tab. You can also verify configurations for fields, screens, statuses, and workflows from the **Installation Manager** tab.

For additional information regarding Jira Cloud, see Jira Cloud resources on the Atlassian website.

Recommendations

Creating a dedicated system account for your Jira environment

The Security Hub integration with Jira Cloud uses an OAuth connection that is associated with a specific user within your Jira instance. Creating a dedicated system account to use for your Security Hub OAuth connection is recommended for your connection for the following reasons:

- A dedicated system user ensures that the connection is not associated with an employee who's permissions to the Jira environment could change over time, impacting the ability for Security Hub to integrate with your Jira environment.
- Each issue that Security Hub creates in Jira shows a Created By field containing the username that was used to create the OAuth connection. Using a system account for the OAuth connection results in this system account appearing as the ticket creator, helping to provide visibility that the finding was created through the Security Hub integration and not manually by another Jira user.

Configure an integration between Security Hub and Jira Cloud

The following procedure needs to be completed for each of your Jira Cloud projects that you want to send Security Hub findings to.

> **Note**
>
> When you create a Jira Cloud connector, you are redirected from the current AWS Region to `"https://3rdp.oauth.console.api.aws"`, so you can complete the connector registration. Afterwards, you are returned to the AWS Region where the connector is being created.

To configure an integration for Jira Cloud

1. Sign in to your AWS account with your credentials, and open the Security Hub console at https://console.aws.amazon.com/securityhub/v2/home?region=us-east-1.
2. From the navigation pane, choose **Management**, and then choose **Integrations**.
3. Choose **Add Jira Cloud**.
4. For **Details**, enter a unique and descriptive name for your integration, and determine whether to enter an optional description for your integration.
5. For **Encryptions** choose how you want to encrypt your integration credentials within Security Hub.

   - **Use AWS owned key** - With this option, a Security Hub owned service key is used to encrypt your integration credential data within Security Hub.
   - **Choose a different KMS key (advanced)** - With this option you choose an AWS KMS key that you have created which you want to be used for encrypting your integration credential data within Security Hub. For information about how to create an AWS KMS key, see Create a AWS KMS key in the *AWS Key Management Service Developer Guide*. If you choose to use your own key you must add policy statements to the KMS key that allow Security Hub access to the key. See AWS KMS key policies for Security Hub ticketing integrations for details on the necessary policies.

> **Note**
>
> You cannot change these settings once you complete this configuration. However, If you choose **Customized key**, you can edit your customized key policy at any time.

6. (Optional) For **Tags**, create and add a tag to your integration. You can add up to 50 tags.
7. For **Authorizations**, choose **Create connector and authorize**. A pop-up appears where you choose **Allow** to complete the authorization. After you complete the authorization, a check box appears letting you know the authorization was successful.
8. For **Configurations**, enter the Jira Cloud project ID.
9. Choose **Complete configuration**. After you complete the configuration, you can view your configured integrations in the **Configured integrations** tab.

After you configure your integration with Jira, you can test the connection to confirm that everything is configured properly in your Jira environment and in Security Hub. For more information, see Testing configured ticketing integrations.

Additional Jira integration details

Rate limit considerations

Jira enforces API rate limits to maintain service stability and ensure fair usage across their platform. When using the AWS Security Hub integration with Jira, these rate limits may impact the processing of Security Hub findings, particularly in environments generating high volumes of findings. This can result in delayed ticket creation, and in scenarios with extremely high finding volumes, some findings may not be processed into Jira tickets at all. To optimize your integration, consider implementing filters on Automation rules in Security Hub to prioritize ticketing on most important findings, monitoring your Jira API usage through their admin console, and planning your workflow based on your Jira license tier's specific rate limits. For business-critical implementations, contact your Jira administrator to review your rate limit allocations.

For detailed information about Jira API rate limits, refer to the Rate limiting documentation on the Atlassian Developers Guide website.

Authentication and security

Jira API authentication requires proper OAuth 2.0 configuration for secure access. Ensure your application follows Atlassian's security best practices for API integration.

- Manage Jira permissions: Manage project permissions on the Atlassian website

Creating a ticket for a Jira Cloud integration

After you create an integration with Jira Cloud, you can create a ticket for a finding.

> **Note**
>
> A finding will always be associated with a single ticket through its entire lifecycle. Security Hub sends all subsequent updates to a finding to the same ticket after initial creation. If a connector associated with an automation rule is changed, the updated connector is used only for new and incoming findings that match the rule criteria.

To create a ticket for a finding

1. Sign in to your AWS account with your credentials, and open the Security Hub console at https://console.aws.amazon.com/securityhub/v2/home?region=us-east-1.
2. From the navigation pane, under **Inventory**, choose **Findings**.
3. Choose a finding. In the finding, choose **Create ticket**.
4. For **Integration**, open the dropdown menu, and choose an integration. This integration is the integration you previously created when you configured the Jira Cloud project. Choose the integration where you want findings sent.
5. Choose **Create**.

Viewing a ticket for a Jira Cloud integration

After you create a ticket for a finding, you can open the ticket on your Jira Cloud instance.

To view a finding on your Jira Cloud instance

1. Sign in to your AWS account with your credentials, and open the Security Hub console at https://console.aws.amazon.com/securityhub/v2/home?region=us-east-1.
2. From the navigation pane, under **Inventory**, choose **Findings**.
3. Choose the finding where you created the ticket.
4. In the finding, choose the ticket ID to view the ticket on your Jira Cloud instance or **View JSON**.

Integrations for ServiceNow

This topic describes how to access the Security Hub console to configure an integration for ServiceNow ITSM. Before completing any of the procedures in this topic, you must have a subscription to ServiceNow ITSM before you can add this integration. For more information, see the pricing page on the ServiceNow website.

For accounts in an organization, only the delegated administrator can configure an integration. The delegated administrator can manually use the create ticket feature for any member account findings. Additionally, the delegated administrator can use automation rules to automatically create tickets for any findings associated with member accounts. When defining an automation rule, the delegated administrator can set criteria, which can include all member accounts or specific member accounts. For information about setting a delegated administrator, see Setting a delegated administrator account in Security Hub.

For accounts not in an organization, all aspects of this feature are available.

Prerequisites - configure ServiceNow environment

You must complete the following prerequisites before configuring an integration for ServiceNow ITSM. Otherwise, your integration between ServiceNow ITSM and Security Hub does not work.

1. Install Security Hubfindings integration for IT Service Management (ITSM)

The following procedure describes how to install Security Hub plugin.

1. Sign into your ServiceNow ITSM instance, and then open the application navigator.
2. Navigate to the ServiceNow Store.
3. Search for *Security Hub findings integration for IT Service Management (ITSM)*, and then choose **Get** to install the application.

> **Note**
>
> In the settings for the Security Hub application, choose which action to take when new Security Hub findings are sent to your ServiceNow ITSM environment. You can choose **Do nothing**, **Create incident**, **Create problem**, or **Create both (incident/problem)**.

2. Configure the Client Credentials grant type for inbound OAuth requests

You must configure this grant type for inbound OAuth requests. For more information, see Client Credentials grant type for Inbound OAuth is supported in the ServiceNow Support webpage.

3. Create an OAuth application

If you already created an OAuth application, you can skip this prerequisite. For information about creating an OAuth application, see Setting up OAuth on the ServiceNow website.

Prerequisites - configure AWS Secrets Manager

To use Security Hub's integration with ServiceNow, the credentials for your ServiceNow OAuth application must be stored in Secrets Manager. Storing your credentials in Secrets Manager allows you to have control and visibility into the use of the credentials while also allowing Security Hub to use the credentials to integrate with your ServiceNow instance. To store your credentials in Secrets Manager, you must use a customer managed AWS KMS key to protect the secrets. This AWS KMS key allows you to protect the secrets while stored at rest and also allows a policy to be attached to the key which gives Security Hub permissions to access the key that is protecting the secret.

Use the following steps to configure Secrets Manager for your ServiceNow credentials.

Step 1: Attach a policy to your AWS KMS key

To successfully configure your ServiceNow integration, you must first give Security Hub permissions to use the AWS KMS key that is associated with your ServiceNow credentials in Secrets Manager.

To modify the AWS KMS key policy for Security Hub to access your ServiceNow credentials

1. Open the AWS KMS console at https://console.aws.amazon.com/kms.
2. To change the AWS Region, use the Region selector in the upper-right corner of the page.
3. Select an existing AWS KMS key or perform the steps to Create a new key in the *AWS KMS Developer Guide*.

4. In the **Key policy** section, choose **Edit**.
5. If **Switch to policy view** is displayed, choose it to display the Key policy, and then choose **Edit**.
6. Copy the following policy block to your AWS KMS key policy, to grant Security Hub permission to use your key.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
        "Sid": "Enable IAM User Permissions",
        "Effect": "Allow",
        "Principal": {
            "AWS": "arn:aws:iam::your-account-id:root"
        },
        "Action": "kms:*",
        "Resource": "*"
        },
        {
        "Sid": "Allow Security Hub connector service to decrypt secrets",
        "Effect": "Allow",
        "Principal": {
            "Service": "connector.securityhub.amazonaws.com"
        },
        "Action": "kms:Decrypt",
        "Resource": "*",
        "Condition": {
            "StringEquals": {
            "kms:ViaService": "secretsmanager.your-region.amazonaws.com"
            },
            "StringLike": {
            "kms:EncryptionContext:SecretARN": "arn:aws:secretsmanager:your-
region:your-account-id:secret:ServiceNow*"
            }
        }
        }
    ]
    }
```

7. Edit the policy by replacing the following values in the policy example:
   - Replace *your-account-id* with your AWS account ID.
   - Replace *your-region* with your AWS region (for example, us-east-1).

8. If you added the policy statement before the final statement, add a comma before adding this statement. Make sure that the JSON syntax of your AWS KMS key policy is valid.
9. Choose **Save**.
10. (Optional) Copy the key ARN to a notepad for use in the later steps.

Step 2: Create the secret in Secrets Manager

Create a secret in Secrets Manager that will store your ServiceNow credentials. Security Hub will access this secret when interacting with your ServiceNow environment.

Follow the steps To create a secret in the *AWS Secrets Manager User Guide*. After you create your secret, copy the Secret ARN as you will need this when creating your Security Hub connector.

When creating the secret, ensure you configure the following:

Secret type

Other type of secret

Key/value pairs (Plaintext format)

```
{
    "ClientId": "your-servicenow-client-id",
    "ClientSecret": "your-servicenow-client-secret"
    }
```

> **Note**
>
> The field names must be exactly `ClientId` and `ClientSecret` (case-sensitive). Security Hub requires these exact names to retrieve the credentials.

Encryption key

Use the AWS KMS key you configured in Step 1

Resource policy

Use the following resource policy:

```
{
```

```
    "Version": "2012-10-17",
    "Statement": [
        {
        "Effect": "Allow",
        "Principal": {
            "Service": "connector.securityhub.amazonaws.com"
        },
        "Action": "secretsmanager:GetSecretValue",
        "Resource": "arn:aws:secretsmanager:your-region:your-account-
id:secret:ServiceNow*",
        "Condition": {
            "StringEquals": {
            "aws:SourceAccount": "your-account-id",
            "aws:SourceArn": "arn:aws:securityhub:your-region:your-account-id:*"
            }
        }
        }
    ]
    }
```

Now that your secret is configured, you can create a Security Hub connector using the CreateConnectorV2 API or AWS Console. You'll need to provide:

- **InstanceName**: Your ServiceNow instance URL (for example, `your-instance.service-now.com`)
- **SecretArn**: The ARN of the secret you created in this procedure

Configure an integration for ServiceNow ITSM

Security Hub can create incidents or problems automatically in ServiceNow ITSM.

To configure an integration for ServiceNow ITSM

1. Sign in to your AWS account with your credentials, and open the Security Hub console at https://console.aws.amazon.com/securityhub/v2/home?region=us-east-1.
2. From the navigation pane, choose **Management**, and then choose **Integrations**.
3. Under **ServiceNow ITSM**, choose **Add integration**.
4. For **Details**, enter a name for your integration, and determine whether to enter an optional description for your integration.

5. For **Encryptions** choose how you want to encrypt your integration credentials within Security Hub.

   - **Use AWS owned key** - With this option, a Security Hub owned service key is used to encrypt your integration credential data within Security Hub.
   - **Choose a different KMS key (advanced)** - With this option you choose an AWS KMS key that you have created which you want to be used for encrypting your integration credential data within Security Hub. For information about how to create an AWS KMS key, see Create a AWS KMS key in the *AWS Key Management Service Developer Guide*. If you choose to use your own key you must add policy statements to the KMS key that allow Security Hub access to the key. See AWS KMS key policies for Security Hub ticketing integrations for details on the necessary policies.

   > **Note**
   >
   > You cannot change these settings once you complete this configuration. However, If you choose **Customized key**, you can edit your customized key policy at any time.

6. For **Credentials**, enter your ServiceNow ITSM URL, and the ARN of your AWS Secrets Manager secret that was generated in the prerequisites section.
7. For **Tags**, determine whether to create and add an optional tag to your integration.
8. Choose **Add integration**. After you complete the configuration, you can view your configured integrations in the **Configured integrations** tab.

After you configure your integration with ServiceNow, you can test the connection to confirm that everything is configured properly in your ServiceNow environment and in Security Hub. For more information, see Testing configured ticketing integrations.

Creating a ticket for a ServiceNow ITSM integration

After you create an integration with ServiceNow ITSM, you can create a ticket for a finding.

> **Note**
>
> A finding will always be associated with a single ticket through its entire lifecycle. Security Hub sends all subsequent updates to a finding to the same ticket after initial creation. If a

connector associated with an automation rule is changed, the updated connector is used only for new and incoming findings that match the rule criteria.

To create a ticket for a finding

1. Sign in to your AWS account with your credentials, and open the Security Hub console at https://console.aws.amazon.com/securityhub/v2/home?region=us-east-1.
2. From the navigation pane, under **Inventory**, choose **Findings**.
3. Choose a finding. In the finding, choose **Create ticket**.
4. For **Integration**, open the dropdown menu, and choose an integration.
5. Choose **Create**.

Viewing a ticket for a ServiceNow ITSM integration

After you create a ticket for a finding, you can open the ticket on your ServiceNow ITSM instance.

To view a finding on your ServiceNow ITSM instance

1. Sign in to your AWS account with your credentials, and open the Security Hub console at https://console.aws.amazon.com/securityhub/v2/home?region=us-east-1.
2. From the navigation pane, under **Inventory**, choose **Findings**.
3. Choose the finding where you created the ticket.
4. In the finding, choose the ticket ID to view the ticket on your ServiceNow ITSM instance or **View JSON**.

KMS key policies for Security Hub ticketing integrations

When using customer-managed KMS keys with Security Hub ticketing integrations, additional policies need to be added to the KMS key to allow Security Hub to interact with the key. Additionally, policies need to be added which allow the principal who is adding the key to the Security Hub connector permissions to access the key.

Security Hub permissions policy

The following policy outlines the permissions that Security Hub needs to be able to access and use the KMS key that is associated with your Jira and ServiceNow connectors. This policy needs to be added to each KMS key that is associated with a Security Hub connector.

The policy contains the following permissions:

- Permits Security Hub to protect, temporary access or refresh tokens used to communicate with your ticketing integrations, using the key. The permissions are restricted to operations related to specific Security Hub connectors through the condition block that checks the source ARN and encryption context.
- Permits Security Hub to read metadata about the KMS key by allowing the `DescribeKey` operation. This permission is necessary for Security Hub to verify the key's status and configuration. The access is limited to specific Security Hub connectors through the source ARN condition.

```
{
    "Sid": "Allow Security Hub access to the customer managed key",
    "Effect": "Allow",
    "Principal": {
        "Service": "connector.securityhub.amazonaws.com"
    },
    "Action": [
        "kms:GenerateDataKey",
        "kms:Decrypt",
        "kms:ReEncrypt*"
    ],
    "Resource": "*",
    "Condition": {
        "ArnLike": {
            "aws:SourceArn": "arn:aws:securityhub:Region:AccountId:connectorv2/*"
        },
        "StringLike": {
            "kms:EncryptionContext:aws:securityhub:connectorV2Arn":
 "arn:aws:securityhub:Region:AccountId:connectorv2/*",
            "kms:EncryptionContext:aws:securityhub:providerName": "CloudProviderName"
        }
    }
},
```

```
{
    "Sid": "Allow Security Hub read access to the customer managed key",
    "Effect": "Allow",
    "Principal": {
        "Service": "connector.securityhub.amazonaws.com"
    },
    "Action": [
        "kms:DescribeKey"
    ],
    "Resource": "*",
    "Condition": {
        "ArnLike": {
            "aws:SourceArn": "arn:aws:securityhub:Region:AccountId:connectorv2/*"
        }
    }
}
```

Edit the policy by replacing the following values in the policy example:

- Replace *CloudProviderName* with JIRA_CLOUD or SERVICENOW
- Replace *AccountId* with the account ID where you are creating the Security Hub connector.
- Replace *Region* with your AWS region (for example, us-east-1).

IAM principal access for Security Hub operations

Any principal that assigns customer-managed KMS keys to a Security Hub connector needs to have permissions to perform key operations (describe, generate, decrypt, re-encrypt, and list aliases) for the key being added to the connector. This applies to the CreateConnectorV2 and CreateTicketV2 APIs. The following policy statement should be included as part of the policy for any principal that interacts with these APIs.

```
{
    "Sid": "Allow permissions to access key through Security Hub",
    "Effect": "Allow",
    "Principal": {
        "AWS": "arn:aws:iam::AccountId:role/RoleName"
    },
    "Action": [
        "kms:GenerateDataKey",
```

```
            "kms:Decrypt",
            "kms:ReEncrypt*"
        ],
        "Resource": "*",
        "Condition": {
            "StringEquals": {
                "kms:ViaService": [
                    "securityhub.Region.amazonaws.com"
                ]
            },
            "StringLike": {
                "kms:EncryptionContext:aws:securityhub:providerName": "CloudProviderName"
            }
        }
    },
    {
        "Sid": "Allow read permissions to access key through Security Hub",
        "Effect": "Allow",
        "Principal": {
            "AWS": "arn:aws:iam::AccountId:role/RoleName"
        },
        "Action": [
            "kms:DescribeKey"
        ],
        "Resource": "*",
        "Condition": {
            "StringEquals": {
                "kms:ViaService": [
                    "securityhub.Region.amazonaws.com"
                ]
            }
        }
    }
```

Edit the policy by replacing the following values in the policy example:

- Replace *RoleName* with the name of the IAM role that is making calls to Security Hub.
- Replace *CloudProviderName* with `JIRA_CLOUD` or `SERVICENOW`.
- Replace *AccountId* with the account ID where you are creating the Security Hub connector.
- Replace *Region* with your AWS region (for example, `us-east-1`).

Testing configured ticketing integrations

For configured Jira and ServiceNow integrations you can test the connection to ensure that all the configuration in Security Hub and in your Jira or ServiceNow environment is complete.

The test ticket feature creates a ticket with a title of `TESTING Test CreateTicketV2 Finding`. The test ticket is populated with sample data such as Account ID and region of the account where the test is performed, sample resource details, and sample AWS Finding JSON.

Testing integrations using the console

Use the following steps to test your integration:

1. In the Security Hub navigation panel choose **Integrations**.
2. In the **Configured integrations** tab chose the integration that you want to test.
3. In the overview page for your integration choose **Create test ticket**.
4. Security Hub displays a success message and a link to the test ticket if the test succeeds. If the test does not succeed, Security Hub displays an error. Based on the error message, address the configuration issues in Security Hub or in your Jira or ServiceNow environment.

> **Note**
>
> The test ticket feature intended to help verify end to end functionality for the setup of a new connection or when you make changes to an existing connection. This feature creates a new ticket in your Jira or ServiceNow environment every time it is used and is not intended for regular verification of your connection.

Testing with the AWS CLI

To test your integration using the AWS CLI, use the `create-ticket-v2` command with the `--mode DRYRUN` parameter:

```
aws securityhub create-ticket-v2 \
  --mode DRYRUN \
  --region <your-region> \
```

```
  --connector-id <your-connector-id> \
  --finding-metadata-uid "TEST_FINDING"
```

Example

The following example shows how to test an integration:

```
aws securityhub create-ticket-v2 \
  --mode DRYRUN \
  --region us-east-1 \
  --connector-id "a1b2c3d4-5678-90ab-cdef-EXAMPLE11111" \
  --finding-metadata-uid "TEST_FINDING"
```

Successful Response

A successful response returns the following:

```
{
    "TicketId": "a1b2c3d4e5f6g7h8i9j0k1l2m3n4o5p6",
    "TicketSrcUrl": "https://your-instance.service-now.com/nav_to.do?
uri=x_aws_se_0_finding.do?sys_id=a1b2c3d4e5f6g7h8i9j0k1l2m3n4o5p6"
}
```

The `TicketSrcUrl` in the response provides a direct link to view the test ticket in your Jira or ServiceNow environment.

If the test fails, an error message is displayed indicating the configuration issue that needs to be addressed.

Troubleshooting Jira cloud integration errors

When testing your integration to Jira Cloud from Security Hub, the following error messages might be returned. These error messages can provide insight on where the configuration issue with the connector could be and how to resolve.

Jira Cloud integration error messages

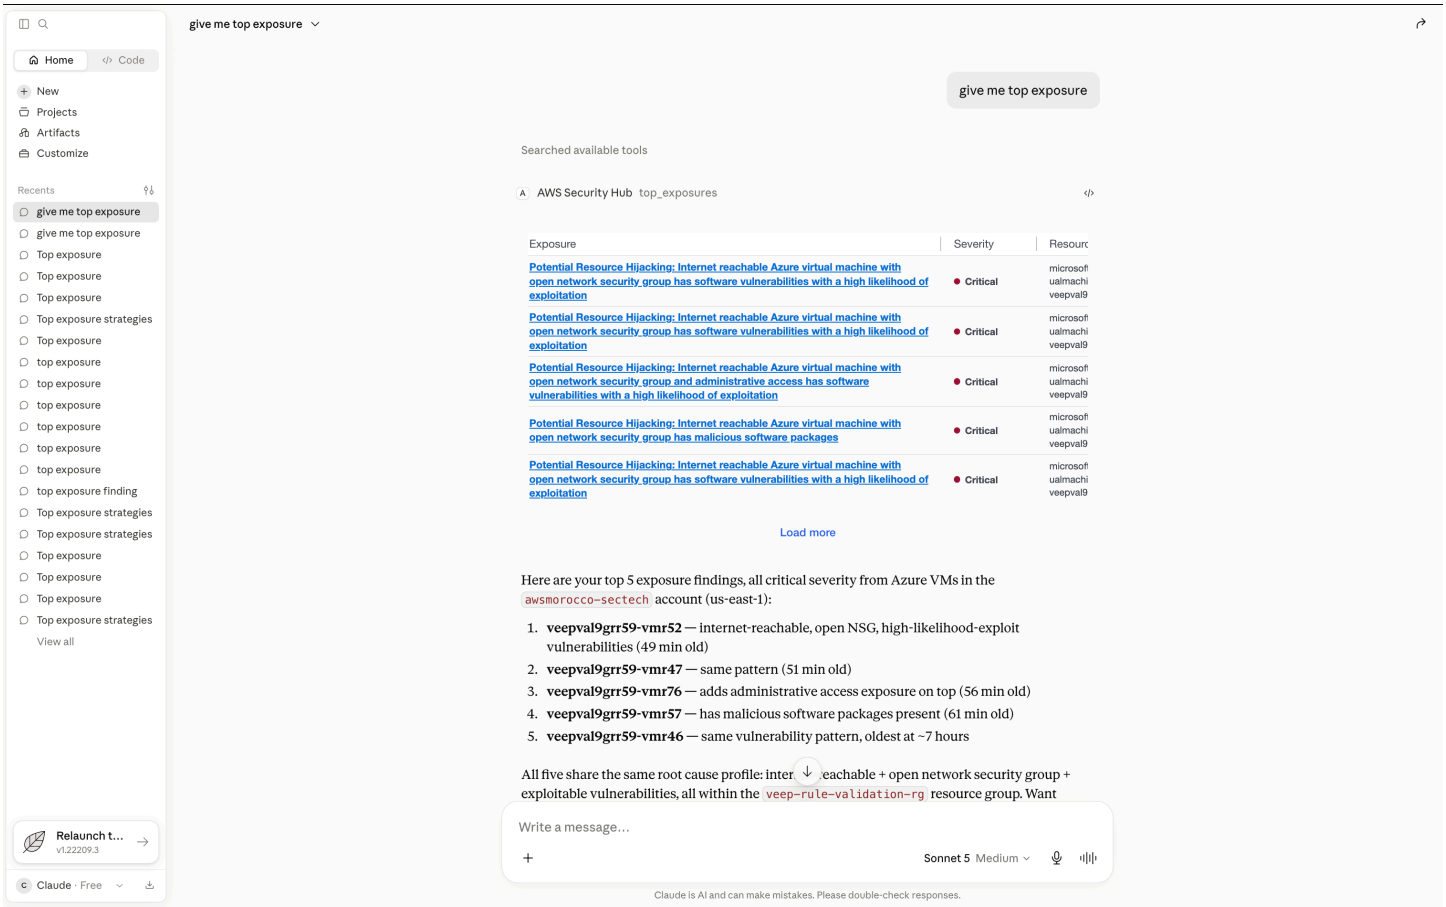
Error	Error Message	Likely cause and resolution
ConflictException	Cannot find jira project	**Likely cause:** Project on the connector is incorrect, or credentials/permissions issue preventing us from accessing the project. **Likely resolution:** Add the correct project to the connector or re-authenticate to Jira with the correct credentials.
ConflictException	Security Hub issue type not found	**Likely cause:** App installation issue or issue type is not associated with the project. **Likely resolution:** Perform the pre-requisite step to install the Jira app into your Jira environment and associate the app with the project.

MCP App (Preview)

Security Hub provides an agentic experience with a Model Context Protocol (MCP) App. With this app, your AI agent can investigate exposure findings. It can also diagnose an existing Azure connector or assess Azure connector prerequisites before creation.

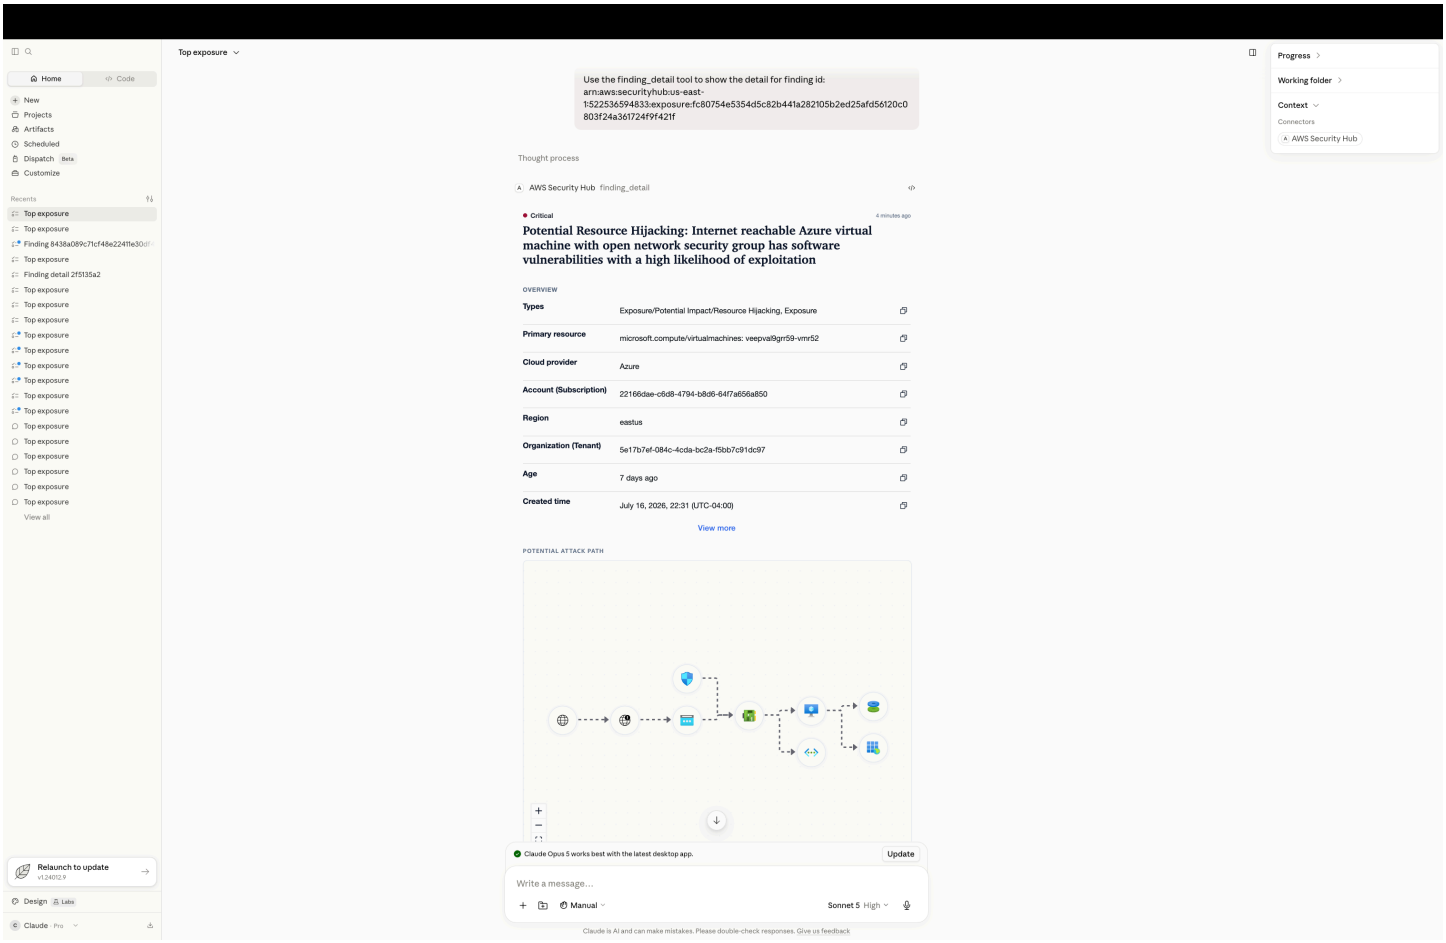
Each findings tool call returns a text summary for the agent to reason over. When available, it also returns an interactive visualization for you to verify in the same conversation. Connector Diagnostics returns structured text that separates confirmed findings from checks that could not be verified.

The MCP App is a local MCP server that runs on your machine and calls Security Hub APIs directly using your existing AWS credentials. Connector Diagnostics can also run bounded, read-only Azure CLI queries using your existing Azure CLI session. Every tool is read-only and does not modify your



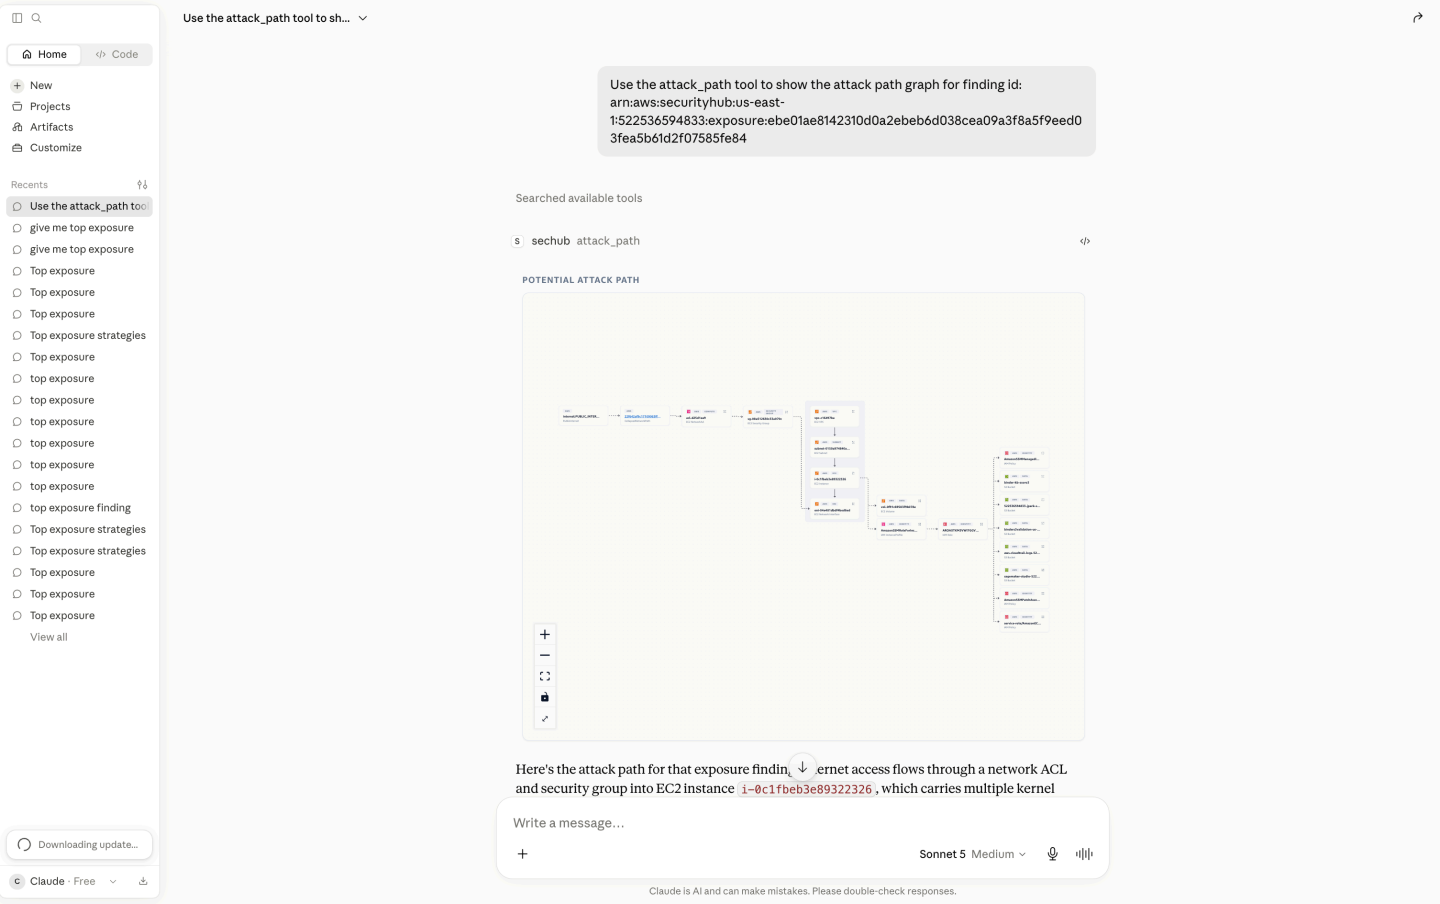
security posture or connector resources. The MCP App is available in all AWS commercial Regions where Security Hub is available.

> **Important**
>
> The Security Hub MCP App is in public preview.

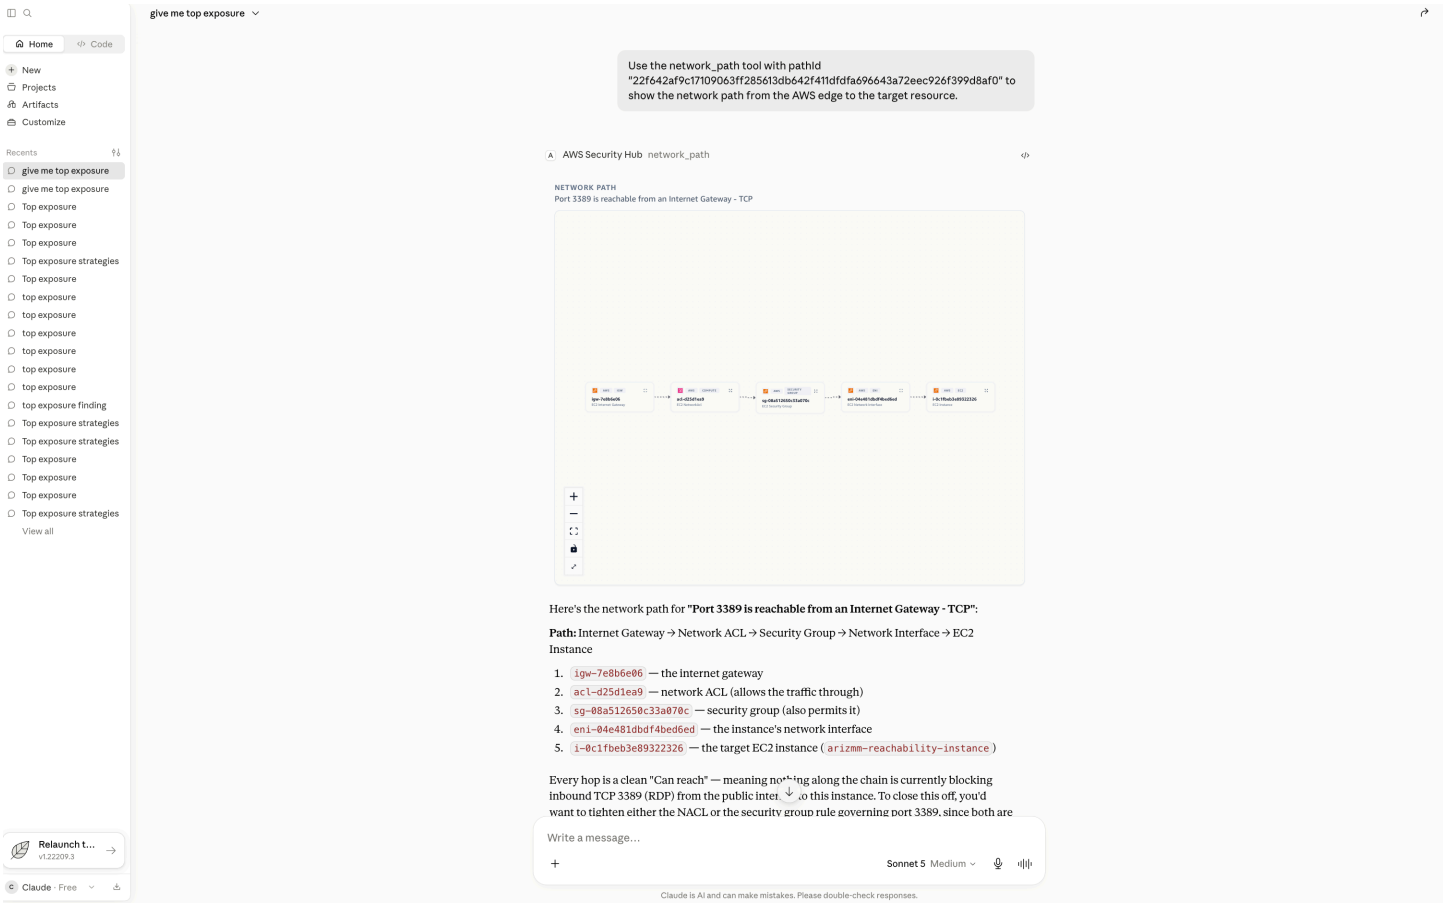


MCP App examples

The following examples show how the MCP App renders interactive visualizations inside Claude Desktop while you investigate your exposures.



Top exposures – Lists your most critical exposure findings, in an interactive table. The following image shows the top exposures table.



Finding detail – Review a single exposure finding's overview alongside its correlated-finding trait summary, attack path, and remediation guidance. The following image shows the finding detail view.

Attack path – Visualize how an exposure is reachable as an interactive graph. Nodes represent resources, identities, and services. Edges represent the relationships between them. The following image shows the attack path graph.

Network path – Explore the ordered network hops from the AWS edge to the target resource (for example, Internet Gateway to NACL to Security Group to ENI to Instance). The following image shows the network path.

Connector diagnosis – Ask why an existing Azure connector is degraded or failed. The agent identifies confirmed issues, distinguishes checks that could not be verified, and recommends the smallest repair without changing your environment.

Connector readiness – Check Azure prerequisites before you create a connector. The agent reports which prerequisites passed, failed, or could not be verified.

Key concepts

Exposure finding – A finding that correlates multiple signals — such as vulnerabilities, misconfigurations, network reachability, and sensitive data — into a single view of a resource that is exposed to risk.

Connector Diagnostics – Three read-only tools for Azure connectors. The tools diagnose an existing connector, assess a proposed setup, and retrieve exact excerpts from the supported Azure setup script. The agent selects the tools and translates their structured results into an explanation.

Local MCP server – A program that runs on your computer and acts as a secure, two-way bridge between Claude Desktop and Security Hub. The server contains the tools your AI agent uses,

including the tools that render the UI within Claude Desktop. It uses your machine's AWS credential chain and holds no credentials of its own.

MCP App – An interactive application that renders inside Claude Desktop. Each MCP App view performs a single job, such as showing the top exposures table or an attack path graph.

Dual response – A single findings tool call returns two outputs: a compact text summary that your agent reasons over, and an interactive visualization rendered in the same conversation for you to review.

Prerequisites

- An AWS account with Security Hub enabled. Exposure findings are required only for the findings and exposure tools.
- Claude Desktop installed. For the installer, see the Claude Desktop download on the Claude website.
- AWS credentials configured in your standard AWS SDK credential chain.
- For Azure-side Connector Diagnostics, install the Azure CLI. Authenticate to the connector's tenant by running `az login --tenant` *`tenant-id`*, where *`tenant-id`* is the ID of the Azure tenant that contains the connector. The MCP App uses the resulting local Azure CLI session. Do not add Azure credentials to the MCP configuration.

> **Note**
>
> You can run Connector Diagnostics without an authenticated Azure CLI session. The result includes the available AWS-side assessment and marks Azure-dependent checks as not verified. It never treats unavailable Azure evidence as healthy.

Setting up the MCP server

The MCP App installs in Claude Desktop from a bundle file. Before you install, confirm that `aws sts get-caller-identity` succeeds and that `aws configure get region` returns a Region in your terminal, so that the server can read your AWS credentials and Region.

1. Download the Security Hub MCP App bundle.

2. Open the downloaded `.mcpb` file. Claude Desktop starts a configuration flow. Follow the instructions to install the server.
3. To verify the connection, enter a question in Claude Desktop, such as “What are my top security exposures?” or “My Azure connector in us-west-2 is degraded. Can you determine what is wrong?” If you receive an error, review the guidance in the error message and confirm your credentials and Region.

Using Connector Diagnostics

Describe the connector problem or proposed setup in natural language. The agent selects the appropriate read-only tool, interprets its structured result, and tells you which checks were confirmed and which checks were not verified.

Diagnose an existing connector

1. Identify the connector by its connector ID or exact name. Also provide the AWS account and Region that contain the connector if the agent cannot determine them from your request.
2. Ask a question such as “My Azure connector in us-west-2 is degraded. Can you determine what is wrong and tell me what to fix first?”
3. Review the confirmed findings separately from the checks that were not verified. When Azure authentication is unavailable, the agent limits its conclusions to AWS-side evidence.

Assess a proposed connector

1. Provide the AWS account, AWS Region, and Azure tenant ID. Also provide 1–10 Azure subscription IDs that the proposed connector will cover. Tell the agent which service prerequisites to assess: Cloud Security Posture Management (CSPM), Inspector VM scanning, or threat detection. These selections scope the readiness checks. They are not connector-creation settings.
2. Ask a question such as “Before I create my Azure connector, check whether the prerequisites are ready for these subscriptions.”
3. Review the passed, failed, and unverified checks. A healthy readiness result means that the checked prerequisites passed. It does not mean that a connector exists, is running, or has recovered.

Retrieve setup instructions

If a result refers to an onboarding step, ask the agent to show that step. For example, ask "Show me step 6 from the supported Azure connector setup script." For the complete script, see Configuring Microsoft Azure to integrate with Security Hub. The tool returns an exact excerpt but does not execute it. Run the complete supported script because its steps share configuration and helper functions.

> **Note**
>
> Connector Diagnostics never repairs or changes resources. Remediation is guidance for a separate action that you control. Diagnosis reports recovery only when fresh runtime evidence proves it.

Available tools

`top_exposures` – Lists your most urgent exposure findings as an interactive table. Call this tool first because the per-finding tools require a finding ID from this list.

`finding_detail` – Returns the overview of one finding, including its correlated-finding trait summary.

`finding_overview` – Returns a text summary of one finding by finding ID.

`correlated_finding_detail` – Lists the findings correlated to one exposure for a single trait, such as Vulnerability, Misconfiguration, or Reachability.

`attack_path` – Builds the attack path graph for one finding.

`network_path` – Expands a finding's network path into ordered hops from the AWS edge to the target resource.

`recommendation` – Returns remediation guidance for one finding, including documentation links.

`resource_detail` – Returns the configuration of one AWS resource by short ID (for example, `i-1234`) or ARN.

`diagnose_connector` – Diagnoses an existing Azure connector using Security Hub state and bounded Azure CLI evidence when available. It returns confirmed findings, affected scope, remediation guidance, and data freshness. It also lists any checks that could not be verified.

`assess_connector_readiness` – Assesses AWS-side and Azure-side prerequisites for a proposed Azure connector before creation. It does not create a connector.

`get_connector_setup_instructions` – Returns exact excerpts from the packaged, supported Azure onboarding script. It does not execute the script.

Monitoring usage and costs in Security Hub

The Usage page helps you understand and manage the costs of running Security Hub across your organization. From this page, you can view your current costs, see projected monthly costs, explore usage by capability or by account, and find strategies to optimize your spending.

Who can access the Usage page

The Usage page is available from any account that has Security Hub enabled. To access it, open the Security Hub console and choose **Usage** under **Settings** in the navigation pane.

> **Important**
>
> If your account is a member account in an AWS Organization and a Security Hub delegated administrator has not been designated, usage data is not available. To view usage data, your organization's management account must designate a delegated administrator. For more information, see the section called “Designating a delegated administrator”.

The experience differs depending on your account type:

- **Delegated administrator or management account** – You see the full Usage page with an Organization Cost Summary, usage by capability, usage by account, and cost optimization strategies.
- **Member account or standalone account** – You see an Account Cost Summary with usage by capability for your account only. The **By account** tab is not available because you are viewing a single account.

Organization and account cost summary

> **Note**
>
> Organization cost summary section is visible only from the delegated administrator account or the management account. Member accounts and standalone accounts see an Account cost summary instead.

When you open the Usage page from a delegated administrator or management account, the Organization Cost Summary section displays a high-level overview of your organization's Security Hub costs for the current billing cycle. This section includes the following:

- **Data last refreshed** – The date when Security Hub last refreshed the usage data for your organization. Security Hub refreshes this data periodically. If the data is more than 24 hours old when you visit the Usage page, Security Hub automatically triggers a refresh. The refresh completes within a few hours, depending on the size of your organization. While the data is being refreshed, an alert appears with a message that the data will be available shortly.
- **Current costs** – The total amount your organization has incurred for using Security Hub from the start of the current billing cycle through the date the data was last refreshed.
- **Projected monthly costs (30 days)** – An estimated monthly cost based on the last 7 days of usage, extrapolated to a full 30-day billing cycle. This projection includes both paid and free trial usage to give you a realistic estimate of what your monthly costs would look like. Projected costs do not account for any discounts (EDPs) you have negotiated with AWS. If your projected costs appear to be lower than your current costs, that means that your usage has been decreasing and based on last 7 day of usage, the 30 day bill is going to be lower than your bill in the current billing cycle.

Capability view

The Capability view shows your costs and usage across the entire organization, organized by security capability. Capabilities are organized into three expandable groups. You can expand or collapse each group to see the individual usage types within it. Each usage type maps directly to a corresponding usage type in AWS Cost Explorer.

Security Hub essentials plan – Monitors your EC2 instances, ECR container images, Lambda functions, IAM users, and IAM roles. Covers risk and exposure analytics, vulnerability management

(powered by Amazon Inspector), security posture management (powered by Security Hub CSPM), and security response. All of these capabilities are included in the essentials plan at a single per-resource price — you do not need to separately enable or pay for Amazon Inspector or AWS Security Hub CSPM, and you are not double-charged for the underlying service usage.

Threat analytics – Includes CloudTrail management events and data events, network activity, and other logs. These capabilities cover threat detection powered by Amazon GuardDuty.

Additional capabilities – Includes Lambda functions code scan. This is an optional enhancement powered by Amazon Inspector for analyzing Lambda function application code for security vulnerabilities.

For more information about pricing for each capability, see Security Hub pricing.

The table in this view includes the following columns for each usage type:

- **Current usage** – The total usage volume for this usage type from the start of the billing cycle through the date the data was last refreshed, across all accounts and all regions.
- **Free usage** – The total usage volume for this usage type from accounts that are currently in the free trial. Free usage values appear in green.
- **Current costs** – The total cost for this usage type from the start of the billing cycle through the date the data was last refreshed, across all accounts and all regions.
- **Free trial value** – The cost you would have incurred for this usage type if the accounts currently in the free trial were not in the trial. This helps you understand the value of the free trial.
- **Projected monthly costs (30 days)** – The estimated monthly cost for this usage type, extrapolated from the last 7 days of usage across all accounts and all regions. This includes both paid and free trial usage to provide an estimated monthly cost.

Account view

> **Note**
>
> The **account** view is available only from the delegated administrator account or the management account.

Choose the **account** view to view your costs organized by individual member accounts across all regions. This view helps you identify which accounts are driving the most cost.

The table lists each account with the following columns:

- **Account** – The AWS account ID, displayed as a clickable link. Choosing an account opens a detailed breakdown panel.
- **Current costs** – The total cost for this account from the start of the billing cycle through the date the data was last refreshed, across all regions.
- **Free trial value** – The cost this account would have incurred if it were not in the free trial.
- **Projected monthly costs (30 days)** – An estimated monthly cost for this account, extrapolated from the last 7 days of usage across all regions to a full 30-day billing cycle. The projection includes both paid and free trial usage to provide a representative estimate of your monthly costs. Projected costs do not account for any discounts you have negotiated with AWS (EDPs).

  If Security Hub was enabled on this account within the last 7 days, the projection is based on the number of days since enablement. After 7 days, the projection uses the full last 7 days of usage. The Usage page does not currently detect when Security Hub has been disabled on an account. If Security Hub has recently been disabled on one or more accounts, those accounts continue to appear in the projection until their usage ages out. Allow 7 days after making these changes for the projection to reflect the updated state of your organization.

Account detail view

When you choose an account from the list, a detail panel opens on the right side of the page. This panel shows the same capability-level breakdown as the Capability view, but filtered to that specific account. You can see the current usage, free usage, current costs, free trial value, and projected monthly costs for each usage type within that account, across all regions.

Cost optimization strategies

Choose **Cost optimization strategies** on the Usage page to navigate to a dedicated page with actionable ways to manage your costs while maintaining your security coverage.

Each strategy is presented as an independent option that you can evaluate and apply based on your organization's needs. Options without security tradeoffs are listed first. After applying any strategy, changes typically take 24 to 48 hours to reflect in your billing.

Disabling Security Hub

Disabling Security Hub for a single account

If your account is not part of an organization, you can disable Security Hub in the Security Hub console at any time or use DisableSecurityHubV2 API. When you disable Security Hub, it stops ingesting findings from detection engines, you also lose access to existing findings, integrations and configurations.

When you disable Security Hub for your account in all Regions, Security Hub also deletes the service-linked IAM Access Analyzer that was created when you enabled the service. If automatic deletion fails, you can delete the analyzer by calling the IAM Access Analyzer `DeleteServiceLinkedAnalyzer` API operation. This operation succeeds only after Security Hub is fully disabled for your account. If you disable Security Hub in a single Region but remain enabled in other Regions, the unused access analyzer continues to run and findings continue to be replicated to your remaining enabled Regions.

To disable Security Hub

1. Sign in to your AWS account with your credentials, and open the Security Hub console at https://console.aws.amazon.com/securityhub/v2/home.
2. From the navigation pane, choose **General**.
3. In Security Hub, choose **Disable**. In the pop-up window, enter **`Disable`**, and choose **Disable**.

Disabling Security Hub across an organization

If you are the delegated administrator for an AWS Organization, you have two options for disabling Security Hub across member accounts.

Option 1: Disabling Security Hub with detection engines

You can use the **Security Hub (essential and add-on capabilities)** deployment and policy from the policy catalog in your delegated administrator account to disable Security Hub along with Amazon Inspector for specific organizational units, accounts, or Regions.

To disable Security Hub and Amazon Inspector across member accounts using a policy

1. Sign in using your AWS account with your delegated administrator credentials. Open the Security Hub console at https://console.aws.amazon.com/securityhub/v2/home.
2. From the navigation pane, choose **Management**, and then choose **Configurations**.
3. Choose **Security Hub (essential and add-on capabilities)** from the Configuration catalog.
4. On the **Configure Security Hub** page in the **Details** section, enter a name and description for the policy (for example, "Security Hub Disablement Policy").
5. In the **Account selection** section, select one of the following options. Choose **All organizational units and accounts** if you want to apply the disablement to all organizational units and accounts. Choose **Specific organizational units and accounts** if you want to apply the disablement to specific organizational units and accounts. If you choose this option, use the search bar or organizational structure tree to specify the target organizational units and accounts.
6. In the **Regions** section, choose **Disable all Regions** to disable Security Hub in all Regions. Optionally choose whether to automatically disable new Regions. Choose **Specify Regions** to choose which specific Regions you want to disable.
7. (Optional) For **Advanced settings**, refer to the guidance from AWS Organizations.
8. (Optional) For **Resource tags**, add tags as key-value pairs to help you easily identify the configuration.
9. Choose **Next**.
10. Review your changes, and then choose **Apply**. Your target accounts are configured based on the policy. The configuration status of your policy displays at the top of the Policies page.

Disabling Amazon GuardDuty and AWS Security Hub CSPM

For GuardDuty and Security Hub CSPM capabilities, you must manually disable the capabilities from the respective delegated administrator accounts. GuardDuty and Security Hub CSPM use deployments (one-time actions) rather than policies, so disablement must be performed manually from their respective consoles.

Option 2: Disabling Security Hub only

If you have an existing Security Hub policy and want to disable Security Hub only, without affecting Amazon Inspector, GuardDuty, or Security Hub CSPM, follow these steps.

To disable Security Hub only across member accounts

1. Sign in using your AWS account with your delegated administrator credentials. Open the Security Hub console at https://console.aws.amazon.com/securityhub/v2/home.
2. From the navigation pane, choose **Management**, and then choose **Configurations**.
3. Choose any of your **Security Hub policies** from the **Configured policies**.
4. Choose **Edit policy** and in the **Account selection** section, select one of the following options. Choose **All organizational units and accounts** if you want to apply the disablement to all organizational units and accounts. Choose **Specific organizational units and accounts** if you want to apply the disablement to specific organizational units and accounts. If you choose this option, use the search bar or organizational structure tree to specify the target organizational units and accounts.
5. In the **Regions** section, choose **Disable all Regions** to disable Security Hub in all Regions. Optionally choose whether to automatically disable new Regions. Choose **Specify Regions** to choose which specific Regions you want to disable.
6. (Optional) For **Advanced settings**, refer to the guidance from AWS Organizations.
7. (Optional) For **Resource tags**, add tags as key-value pairs to help you easily identify the configuration.
8. Choose **Next**.
9. Review your changes, and then choose **Apply**. Your target accounts are configured based on the policy. The configuration status of your policy displays at the top of the Configurations page.

Impact on other security services

Disabling Security Hub through an Security Hub policy has **no impact** on Security Hub CSPM, GuardDuty, and Amazon Inspector configurations.

If you need to disable Amazon Inspector only across member accounts, you can use the **Vulnerability management** policy from the Security Hub configuration catalog. Navigate to the Security Hub Configuration page, choose **Vulnerability management from Amazon Inspector**, and create a disable policy following steps similar to the Security Hub disable procedure above.

Security in AWS Security Hub

Cloud security at AWS is the highest priority. As an AWS customer, you benefit from a data center and network architecture that is built to meet the requirements of the most security-sensitive organizations.

Security is a shared responsibility between AWS and you. The shared responsibility model describes this as security *of* the cloud and security *in* the cloud:

- **Security of the cloud** – AWS is responsible for protecting the infrastructure that runs AWS services in the AWS Cloud. AWS also provides you with services that you can use securely. Third-party auditors regularly test and verify the effectiveness of our security as part of the AWS compliance programs. To learn about the compliance programs that apply to Security Hub, see AWS Services in Scope by Compliance Program.
- **Security in the cloud** – Your responsibility is determined by the AWS service that you use. You are also responsible for other factors including the sensitivity of your data, your company's requirements, and applicable laws and regulations.

This documentation helps you understand how to apply the shared responsibility model when using Security Hub. The following topics show you how to configure Security Hub to meet your security and compliance objectives. You also learn how to use other AWS services that help you to monitor and secure your Security Hub resources.

Topics

- Data protection in AWS Security Hub
- AWS Identity and Access Management for Security Hub
- Compliance validation for AWS Security Hub
- Resilience in AWS Security Hub
- Infrastructure security in AWS Security Hub
- AWS Security Hub and interface VPC endpoints (AWS PrivateLink)

Data protection in AWS Security Hub

The AWS shared responsibility model applies to data protection in AWS Security Hub. As described in this model, AWS is responsible for protecting the global infrastructure that runs all of the

AWS Cloud. You are responsible for maintaining control over your content that is hosted on this infrastructure. You are also responsible for the security configuration and management tasks for the AWS services that you use. For more information about data privacy, see Data Privacy FAQ. For information about data protection in Europe, see the General Data Protection Regulation (GDPR) Center.

For data protection purposes, we recommend that you protect AWS account credentials and set up individual users with AWS IAM Identity Center or AWS Identity and Access Management (IAM). That way, each user is given only the permissions necessary to fulfill their job duties. We also recommend that you secure your data in the following ways:

- Use multi-factor authentication (MFA) with each account.
- Use SSL/TLS to communicate with AWS resources. We require TLS 1.2 and recommend TLS 1.3.
- Set up API and user activity logging with AWS CloudTrail. For information about using CloudTrail trails to capture AWS activities, see Working with CloudTrail trails in the *AWS CloudTrail User Guide*.
- Use AWS encryption solutions, along with all default security controls within AWS services.
- Use advanced managed security services such as Amazon Macie, which assists in discovering and securing sensitive data that is stored in Amazon S3.
- If you require FIPS 140-3 validated cryptographic modules when accessing AWS through a command line interface or an API, use a FIPS endpoint. For more information about the available FIPS endpoints, see Federal Information Processing Standard (FIPS) 140-3.

We strongly recommend that you never put confidential or sensitive information, such as your customers' email addresses, into tags or free-form text fields such as a **Name** field. This includes when you work with Security Hub or other AWS services using the console, API, AWS CLI, or AWS SDKs. Any data that you enter into tags or free-form text fields used for names may be used for billing or diagnostic logs. If you provide a URL to an external server, we strongly recommend that you do not include credentials information in the URL to validate your request to that server.

Security Hub is a multi-tenant service offering. To help protect your data, Security Hub encrypts data at rest and data in transit between component services.

Opting out of using your data for service improvement

> **Note**
>
> This documentation page is only applicable to the enhanced AWS Security Hub launched on December 2, 2025. If you are a customer of the original AWS Security Hub (now AWS Security Hub CSPM), the data usage described below will apply only after you have enabled the enhanced AWS Security Hub.

You can choose to opt out of having your data (defined as "Security Hub Content" in the Security Hub service terms) used to develop and improve AWS Security Hub and other AWS security services by using the AWS Organizations opt-out policy. For more information about how to opt out, see AI services opt-out policies in the *AWS Organizations User Guide*.

> **Note**
>
> For you to use the opt-out policy, your AWS accounts must be centrally managed by AWS Organizations. If you haven't already created an organization for your AWS accounts, see Creating and managing an organization in the *AWS Organizations User Guide*.

Opting out has the following effects:

- Security Hub will delete the Content that it collected and stored for service improvement purposes prior to your opt out (if any).
- After you opt out, Security Hub will no longer collect or store this Content for service improvement purposes.

The following section explains how Security Hub uses your Content for service improvement.

AWS Security Hub data usage

AWS Security Hub collects and uses the following categories of Security Hub Content to develop and improve exposure findings and resource criticality inference:

- Third-party security findings that you aggregate in Security Hub from partner products or external integrations

- Resource configuration data for resources in other cloud environments, such as Microsoft Azure, that you integrate with Security Hub
- Software inventory data for your resources, such as the software bill of materials (SBOM) that Amazon Inspector collects and that is available in Security Hub

For information about how Security Hub uses data to provide the capabilities that you enable, see How Security Hub uses data to provide the capabilities you enable.

Your trust, privacy, and the security of your Content are our highest priority. You can opt out of this Security Hub Content collection at any time using the AWS Organizations opt-out policy described above. For more information about AWS data privacy practices, see Data Privacy FAQ.

References

For similar opt-out procedures in other AWS security services, see:

- Opting out of using your data for service improvement in the *Amazon GuardDuty User Guide*.
- Opting out of using your data for service improvement in the *Amazon Security Lake User Guide*.

How Security Hub uses data to provide the capabilities you enable

When you enable AWS Security Hub, you'll see a notice explaining that Security Hub may access and use data it already has access to in order to power the capabilities you choose to enable. This notice exists because Security Hub is designed to grow and improve over time. New detection, correlation, and enrichment capabilities are added on an ongoing basis, and many of these draw on data (such as findings, configuration data, and other Content or metadata) that Security Hub already has visibility into as part of your existing setup. Rather than asking you to opt-in every time we introduce a way to use data you've already granted Security Hub access to, this notice gives you clear, upfront visibility into how that access can be used (now and as the service evolves).

In practice, this means that enabling a Security Hub capability is your instruction to Security Hub to use the relevant Content and metadata already within its reach to deliver that capability's functionality. If a capability you've enabled doesn't yet make full use of a particular data type, that may change as we roll out enhancements. For example, an existing capability might begin incorporating additional context (such as business criticality signals) to improve accuracy or provide you with deeper insights, at no additional cost to you. You won't need to take any new action for these enhancements to take effect, since they operate within the scope of data access you've already established by enabling Security Hub and its capabilities.

This approach is designed to benefit your experience by letting Security Hub continuously enhance the value of the capabilities you've already turned on, without introducing friction through repeated consent or configuration requests for incremental enhancements. That said, you remain in control: you can review, manage, or disable your Security Hub integrations and enabled capabilities at any time through the Security Hub console, which determines what data Security Hub can access and use going forward.

AWS Identity and Access Management for Security Hub

AWS Identity and Access Management (IAM) is an AWS service that helps an administrator securely control access to AWS resources. IAM administrators control who can be *authenticated* (signed in) and *authorized* (have permissions) to use Security Hub resources. IAM is an AWS service that you can use with no additional charge.

Topics

- Audience
- Authenticating with identities
- Managing access using policies
- How Security Hub works with IAM
- Identity-based policy examples for AWS Security Hub
- Service-linked roles for AWS Security Hub
- AWS managed policies for Security Hub
- Troubleshooting AWS Security Hub identity and access

Audience

How you use AWS Identity and Access Management (IAM) differs based on your role:

- **Service user** - request permissions from your administrator if you cannot access features (see Troubleshooting AWS Security Hub identity and access)
- **Service administrator** - determine user access and submit permission requests (see How Security Hub works with IAM)
- **IAM administrator** - write policies to manage access (see Identity-based policy examples for AWS Security Hub)

Authenticating with identities

Authentication is how you sign in to AWS using your identity credentials. You must be authenticated as the AWS account root user, an IAM user, or by assuming an IAM role.

You can sign in as a federated identity using credentials from an identity source like AWS IAM Identity Center (IAM Identity Center), single sign-on authentication, or Google/Facebook credentials. For more information about signing in, see How to sign in to your AWS account in the *AWS Sign-In User Guide*.

For programmatic access, AWS provides an SDK and CLI to cryptographically sign requests. For more information, see AWS Signature Version 4 for API requests in the *IAM User Guide*.

AWS account root user

When you create an AWS account, you begin with one sign-in identity called the AWS account *root user* that has complete access to all AWS services and resources. We strongly recommend that you don't use the root user for everyday tasks. For tasks that require root user credentials, see Tasks that require root user credentials in the *IAM User Guide*.

Federated identity

As a best practice, require human users to use federation with an identity provider to access AWS services using temporary credentials.

A *federated identity* is a user from your enterprise directory, web identity provider, or Directory Service that accesses AWS services using credentials from an identity source. Federated identities assume roles that provide temporary credentials.

For centralized access management, use AWS IAM Identity Center. For more information, see What is IAM Identity Center? in the *AWS IAM Identity Center User Guide*.

IAM users and groups

An *IAM user* is an identity with specific permissions for a single person or application. As a best practice, use temporary credentials instead of IAM users with long-term credentials. For more information, see Require human users to use federation with an identity provider to access AWS using temporary credentials in the *IAM User Guide*.

An *IAM group* specifies a collection of IAM users and makes permissions easier to manage for large sets of users. For more information, see Use cases for IAM users in the *IAM User Guide*.

IAM roles

An *IAM role* is an identity with specific permissions that provides temporary credentials. You can assume a role by switching from a user to an IAM role (console) or by calling an AWS CLI or AWS API operation. For more information, see Methods to assume a role in the *IAM User Guide*.

IAM roles are useful for federated user access, temporary IAM user permissions, cross-account access, cross-service access, and applications running on Amazon EC2. For more information, see Cross account resource access in IAM in the *IAM User Guide*.

Managing access using policies

You control access in AWS by creating policies and attaching them to AWS identities or resources. A policy defines permissions when associated with an identity or resource. AWS evaluates these policies when a principal makes a request. Most policies are stored in AWS as JSON documents. For more information about JSON policy documents, see Overview of JSON policies in the *IAM User Guide*.

Using policies, administrators specify who has access to what by defining which **principal** can perform **actions** on what **resources**, and under what **conditions**.

By default, users and roles have no permissions. An IAM administrator creates IAM policies and adds them to roles, which users can then assume. IAM policies define permissions regardless of the method used to perform the operation.

Identity-based policies

Identity-based policies are JSON permissions policy documents that you attach to an identity (user, group, or role). These policies control what actions identities can perform, on which resources, and under what conditions. To learn how to create an identity-based policy, see Define custom IAM permissions with customer managed policies in the *IAM User Guide*.

Identity-based policies can be *inline policies* (embedded directly into a single identity) or *managed policies* (standalone policies attached to multiple identities). To learn how to choose between managed and inline policies, see Choose between managed policies and inline policies in the *IAM User Guide*.

Resource-based policies

Resource-based policies are JSON policy documents that you attach to a resource. Examples include IAM *role trust policies* and Amazon S3 *bucket policies*. In services that support resource-

based policies, service administrators can use them to control access to a specific resource. You must specify a principal in a resource-based policy.

Resource-based policies are inline policies that are located in that service. You can't use AWS managed policies from IAM in a resource-based policy.

Other policy types

AWS supports additional policy types that can set the maximum permissions granted by more common policy types:

- **Permissions boundaries** – Set the maximum permissions that an identity-based policy can grant to an IAM entity. For more information, see Permissions boundaries for IAM entities in the *IAM User Guide*.
- **Service control policies (SCPs)** – Specify the maximum permissions for an organization or organizational unit in AWS Organizations. For more information, see Service control policies in the *AWS Organizations User Guide*.
- **Resource control policies (RCPs)** – Set the maximum available permissions for resources in your accounts. For more information, see Resource control policies (RCPs) in the *AWS Organizations User Guide*.
- **Session policies** – Advanced policies passed as a parameter when creating a temporary session for a role or federated user. For more information, see Session policies in the *IAM User Guide*.

Multiple policy types

When multiple types of policies apply to a request, the resulting permissions are more complicated to understand. To learn how AWS determines whether to allow a request when multiple policy types are involved, see Policy evaluation logic in the *IAM User Guide*.

How Security Hub works with IAM

Before you use AWS Identity and Access Management (IAM) to manage access to AWS Security Hub, learn which IAM features are available to use with Security Hub.

IAM features you can use with AWS Security Hub

IAM feature	Security Hub support
Identity-based policies	Yes

IAM feature	Security Hub support
Resource-based policies	No
Policy actions	Yes
Policy resources	No
Policy condition keys	Yes
Access control lists (ACLs)	No
Attribute-based access control (ABAC) – tags in policies	Yes
Temporary credentials	Yes
Forward access sessions (FAS)	Yes
Service roles	No
Service-linked roles	Yes

For a high-level view of how Security Hub and other AWS services work with most IAM features, see AWS services that work with IAM in the *IAM User Guide*.

Identity-based policies for Security Hub

Supports identity-based policies: Yes

Identity-based policies are JSON permissions policy documents that you can attach to an identity, such as an IAM user, group of users, or role. These policies control what actions users and roles can perform, on which resources, and under what conditions. To learn how to create an identity-based policy, see Define custom IAM permissions with customer managed policies in the *IAM User Guide*.

With IAM identity-based policies, you can specify allowed or denied actions and resources as well as the conditions under which actions are allowed or denied. To learn about all of the elements that you can use in a JSON policy, see IAM JSON policy elements reference in the *IAM User Guide*.

Security Hub supports identity-based policies. For more information, see Identity-based policy examples for AWS Security Hub.

Resource-based policies for Security Hub

Supports resource-based policies: No

Resource-based policies are JSON policy documents that you attach to a resource. Examples of resource-based policies are IAM *role trust policies* and Amazon S3 *bucket policies*. In services that support resource-based policies, service administrators can use them to control access to a specific resource. For the resource where the policy is attached, the policy defines what actions a specified principal can perform on that resource and under what conditions. You must specify a principal in a resource-based policy. Principals can include accounts, users, roles, federated users, or AWS services.

To enable cross-account access, you can specify an entire account or IAM entities in another account as the principal in a resource-based policy. For more information, see Cross account resource access in IAM in the *IAM User Guide*.

Security Hub does not support resource-based policies. You cannot attach an IAM policy directly to a Security Hub resource.

Policy actions for Security Hub

Supports policy actions: Yes

Administrators can use AWS JSON policies to specify who has access to what. That is, which **principal** can perform **actions** on what **resources**, and under what **conditions**.

The `Action` element of a JSON policy describes the actions that you can use to allow or deny access in a policy. Include actions in a policy to grant permissions to perform the associated operation.

Policy actions in Security Hub use the following prefix before the action:

```
securityhub:
```

For example, to grant a user permission to enable Security Hub, which is an action that corresponds to the `EnableSecurityHubV2` operation of the Security Hub API, include the `securityhub:EnableSecurityHubV2` action in their policy. Policy statements must include either an `Action` or `NotAction` element. Security Hub defines its own set of actions that describe tasks that you can perform with this service.

```
"Action": "securityhub:EnableSecurityHubV2"
```

To specify multiple actions in a single statement, separate them with commas. For example:

```
"Action": [
      "securityhub:EnableSecurityHubV2",
      "securityhub:CreateAutomationRuleV2"
```

You can also specify multiple actions using wildcards (*). For example, to specify all actions that begin with the word `Get`, include the following action:

```
"Action": "securityhub:Get*"
```

However, as a best practice, you should create policies that follow the principle of least privilege. In other words, you should create policies that include only the permissions that are required to perform a specific task.

For a list of Security Hub actions, see Actions Defined by AWS Security Hub in the *Service Authorization Reference*. For examples of policies that specify Security Hub actions, see Identity-based policy examples for AWS Security Hub.

Policy resources for Security Hub

Supports policy resources: No

Administrators can use AWS JSON policies to specify who has access to what. That is, which **principal** can perform **actions** on what **resources**, and under what **conditions**.

The `Resource` JSON policy element specifies the object or objects to which the action applies. As a best practice, specify a resource using its Amazon Resource Name (ARN). For actions that don't support resource-level permissions, use a wildcard (*) to indicate that the statement applies to all resources.

```
"Resource": "*"
```

Security Hub defines the following resource types:

- Hub
- Product
- Finding aggregator, also referred to as a *cross-Region aggregator*
- Automation rule

You can specify these types of resources in policies by using ARNs.

For a list of Security Hub resource types and the ARN syntax for each one, see Resources Defined by AWS Security Hub in the *Service Authorization Reference*. To learn which actions you can specify for each type of resource, see Actions Defined by AWS Security Hub in the *Service Authorization Reference*. For examples of policies that specify resources, see Identity-based policy examples for AWS Security Hub.

Policy condition keys for Security Hub

Supports service-specific policy condition keys: Yes

Administrators can use AWS JSON policies to specify who has access to what. That is, which **principal** can perform **actions** on what **resources**, and under what **conditions**.

The `Condition` element specifies when statements execute based on defined criteria. You can create conditional expressions that use condition operators, such as equals or less than, to match the condition in the policy with values in the request. To see all AWS global condition keys, see AWS global condition context keys in the *IAM User Guide*.

For a list of Security Hub condition keys, see Condition Keys for AWS Security Hub in the *Service Authorization Reference*. To learn which actions and resources you can use a condition key with, see Actions Defined by AWS Security Hub. For examples of policies that use condition keys, see Identity-based policy examples for AWS Security Hub.

Access control lists (ACLs) in Security Hub

Supports ACLs: No

Access control lists (ACLs) control which principals (account members, users, or roles) have permissions to access a resource. ACLs are similar to resource-based policies, although they do not use the JSON policy document format.

Security Hub does not support ACLs, which means you cannot attach an ACL to a Security Hub resource.

Attribute-based access control (ABAC) with Security Hub

Supports ABAC (tags in policies): Yes

Attribute-based access control (ABAC) is an authorization strategy that defines permissions based on attributes called tags. You can attach tags to IAM entities and AWS resources, then design ABAC policies to allow operations when the principal's tag matches the tag on the resource.

To control access based on tags, you provide tag information in the condition element of a policy using the `aws:ResourceTag/key-name`, `aws:RequestTag/key-name`, or `aws:TagKeys` condition keys.

If a service supports all three condition keys for every resource type, then the value is **Yes** for the service. If a service supports all three condition keys for only some resource types, then the value is **Partial**.

For more information about ABAC, see Define permissions with ABAC authorization in the *IAM User Guide*. To view a tutorial with steps for setting up ABAC, see Use attribute-based access control (ABAC) in the *IAM User Guide*.

You can attach tags to Security Hub resources. You can also control access to resources by providing tag information in the `Condition` element of a policy.

For information about tagging Security Hub resources, see Tagging Security Hub resources. For an example of an identity-based policy that controls access to a resource based on tags, see Identity-based policy examples for AWS Security Hub.

Using temporary credentials with Security Hub

Supports temporary credentials: Yes

Temporary credentials provide short-term access to AWS resources and are automatically created when you use federation or switch roles. AWS recommends that you dynamically generate temporary credentials instead of using long-term access keys. For more information, see Temporary security credentials in IAM and AWS services that work with IAM in the *IAM User Guide*.

You can use temporary credentials to sign in with federation, assume an IAM role, or to assume a cross-account role. You obtain temporary security credentials by calling AWS STS API operations such as AssumeRole or GetFederationToken.

Security Hub supports the use of temporary credentials.

Forward access sessions for Security Hub

Supports forward access sessions (FAS): Yes

Forward access sessions (FAS) use the permissions of the principal calling an AWS service, combined with the requesting AWS service to make requests to downstream services. For policy details when making FAS requests, see Forward access sessions.

For example, Security Hub makes FAS requests to downstream AWS services when you integrate Security Hub with AWS Organizations and when you designate the delegated Security Hub administrator account for an organization in Organizations.

For other tasks, Security Hub uses a service-linked role to perform actions on your behalf. For details about this role, see Service-linked roles for AWS Security Hub.

Service roles for Security Hub

Security Hub does not assume or use service roles. To perform actions on your behalf, Security Hub uses a service-linked role. For details about this role, see Service-linked roles for AWS Security Hub.

> **Warning**
>
> Changing the permissions for a service role may create operational issues with your use of Security Hub. Edit service roles only when Security Hub provides guidance to do so.

Service-linked roles for Security Hub

Supports service-linked roles: Yes

A service-linked role is a type of service role that is linked to an AWS service. The service can assume the role to perform an action on your behalf. Service-linked roles appear in your AWS account and are owned by the service. An IAM administrator can view, but not edit the permissions for service-linked roles.

Security Hub uses a service-linked role to perform actions on your behalf. For details about this role, see Service-linked roles for AWS Security Hub.

Identity-based policy examples for AWS Security Hub

By default, users and roles do not have permission to create or modify AWS Security Hub resources. They also cannot perform tasks using the AWS Management Console, AWS CLI, or AWS API. An administrator must create IAM policies that grant users and roles permission to perform specific API operations on the specified resources they need. The administrator must then attach those policies to the users or groups that require those permissions.

To learn how to create an IAM identity-based policy using these example JSON policy documents, see Creating Policies on the JSON Tab in the *IAM User Guide*.

Topics

- Policy best practices
- Using the Security Hub console
- Example: Allow users to view their own permissions
- Example: Allow users to view findings
- Example: Allow users to create and manage automation rules

Policy best practices

Identity-based policies determine whether someone can create, access, or delete Security Hub resources in your account. These actions can incur costs for your AWS account. When you create or edit identity-based policies, follow these guidelines and recommendations:

- **Get started with AWS managed policies and move toward least-privilege permissions** – To get started granting permissions to your users and workloads, use the *AWS managed policies* that grant permissions for many common use cases. They are available in your AWS account. We recommend that you reduce permissions further by defining AWS customer managed policies that are specific to your use cases. For more information, see AWS managed policies or AWS managed policies for job functions in the *IAM User Guide*.
- **Apply least-privilege permissions** – When you set permissions with IAM policies, grant only the permissions required to perform a task. You do this by defining the actions that can be taken on specific resources under specific conditions, also known as *least-privilege permissions*. For more information about using IAM to apply permissions, see Policies and permissions in IAM in the *IAM User Guide*.
- **Use conditions in IAM policies to further restrict access** – You can add a condition to your policies to limit access to actions and resources. For example, you can write a policy condition to specify that all requests must be sent using SSL. You can also use conditions to grant access to service actions if they are used through a specific AWS service, such as CloudFormation. For more information, see IAM JSON policy elements: Condition in the *IAM User Guide*.
- **Use IAM Access Analyzer to validate your IAM policies to ensure secure and functional permissions** – IAM Access Analyzer validates new and existing policies so that the policies adhere to the IAM policy language (JSON) and IAM best practices. IAM Access Analyzer provides more than 100 policy checks and actionable recommendations to help you author secure and functional policies. For more information, see Validate policies with IAM Access Analyzer in the *IAM User Guide*.

- **Require multi-factor authentication (MFA)** – If you have a scenario that requires IAM users or a root user in your AWS account, turn on MFA for additional security. To require MFA when API operations are called, add MFA conditions to your policies. For more information, see Secure API access with MFA in the *IAM User Guide*.

For more information about best practices in IAM, see Security best practices in IAM in the *IAM User Guide*.

Using the Security Hub console

To access the AWS Security Hub console, you must have a minimum set of permissions. These permissions must allow you to list and view details about the Security Hub resources in your AWS account. If you create an identity-based policy that is more restrictive than the minimum required permissions, the console will not function as intended for entities (users or roles) with that policy.

You do not need to allow minimum console permissions for users that are making calls only to the AWS CLI or the AWS API. Instead, allow access to only the actions that match the API operation that they're trying to perform.

To ensure that those users and roles can use the Security Hub console, also attach the following AWS managed policy to the entity. For more information, see Adding permissions to a user in the *IAM User Guide*:

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": "securityhub:*",
            "Resource": "*"
        },
        {
            "Effect": "Allow",
            "Action": "iam:CreateServiceLinkedRole",
            "Resource": "*",
            "Condition": {
                "StringLike": {
                    "iam:AWSServiceName": "securityhub.amazonaws.com"
```

```
                }
            }
        }
    ]
}
```

Example: Allow users to view their own permissions

This example shows how you might create a policy that allows IAM users to view the inline and managed policies that are attached to their user identity. This policy includes permissions to complete this action on the console or programmatically using the AWS CLI or AWS API.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "ViewOwnUserInfo",
            "Effect": "Allow",
            "Action": [
                "iam:GetUserPolicy",
                "iam:ListGroupsForUser",
                "iam:ListAttachedUserPolicies",
                "iam:ListUserPolicies",
                "iam:GetUser"
            ],
            "Resource": ["arn:aws:iam::*:user/${aws:username}"]
        },
        {
            "Sid": "NavigateInConsole",
            "Effect": "Allow",
            "Action": [
                "iam:GetGroupPolicy",
                "iam:GetPolicyVersion",
                "iam:GetPolicy",
                "iam:ListAttachedGroupPolicies",
                "iam:ListGroupPolicies",
                "iam:ListPolicyVersions",
                "iam:ListPolicies",
                "iam:ListUsers"
            ],
            "Resource": "*"
        }
```

```
    ]
}
```

Example: Allow users to view findings

This example shows how you might create an IAM policy that allows a user to view Security Hub findings.

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Sid": "ReviewFindings",
            "Effect": "Allow",
            "Action": [
                "securityhub:GetFindingsV2"
            ],
            "Resource": "*"
        }
    ]
}
```

Example: Allow users to create and manage automation rules

This example shows how you might create an IAM policy that allows a user to create, view, update, and delete Security Hub automation rules. For this IAM policy to work, the user must be a Security Hub administrator. To limit permissions— for example, to allow a user to only view automation rules—you can remove the create, update, and delete permissions.

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Sid": "CreateAndUpdateAutomationRules",
            "Effect": "Allow",
            "Action": [
                "securityhub:CreateAutomationRuleV2"
            ],
            "Resource": "*"
        },
        {
```

```
            "Sid": "ViewAutomationRules",
            "Effect": "Allow",
            "Action": [
                "securityhub:ListAutomationRulesV2",
                "securityhub:GetAutomationRuleV2"
            ],
            "Resource": "*"
        },
        {
            "Sid": "DeleteAutomationRules",
            "Effect": "Allow",
            "Action": [
                "securityhub:DeleteAutomationRuleV2"
            ],
            "Resource": "*"
        }
    ]
}
```

Service-linked roles for AWS Security Hub

AWS Security Hub uses an AWS Identity and Access Management (IAM) service-linked role named `AWSServiceRoleForSecurityHubV2`. This service-linked role is an IAM role that is linked directly to Security Hub. It's predefined by Security Hub, and it includes all the permissions that Security Hub requires to call other AWS services and monitor AWS resources on your behalf. Security Hub uses this service-linked role in all the AWS Regions where Security Hub is available.

A service-linked role makes setting up Security Hub easier because you do not have to manually add the necessary permissions. Security Hub defines the permissions of its service-linked role, and unless defined otherwise, only Security Hub can assume the role. The defined permissions include the trust policy and the permissions policy, and you cannot attach that permissions policy to any other IAM entity.

To review the details of the service-linked role, you can use the Security Hub console. In the navigation pane, choose **General** under **Settings**. Then, in the **Service permissions** section, choose **View service permissions**.

You can delete the Security Hub service-linked role only after you disable Security Hub in all the Regions where it is enabled. This protects your Security Hub resources because you cannot inadvertently remove permissions to access them.

For information about other services that support service-linked roles, see AWS services that work with IAM in the *IAM User Guide* and locate the services that have **Yes** in the **Service-linked roles** column. Choose a **Yes** with a link to review the service-linked role documentation for that service.

Topics

- Service-linked role permissions for Security Hub
- Creating a service-linked role for Security Hub
- Editing a service-linked role for Security Hub
- Deleting a service-linked role for Security Hub

Service-linked role permissions for Security Hub

Security Hub uses the service-linked role named `AWSServiceRoleForSecurityHubV2`. It's a service-linked role required for AWS Security Hub to access your resources. This service-linked role allows Security Hub to perform tasks such as receive findings from other AWS services and configure the requisite AWS Config infrastructure to run security checks for controls. The `AWSServiceRoleForSecurityHubV2` service-linked role trusts the `securityhub.amazonaws.com` service to assume the role.

The `AWSServiceRoleForSecurityHubV2` service-linked role uses the managed policy `AWSSecurityHubV2ServiceRolePolicy`.

You must grant permissions to allow an IAM identity (such as a role, group, or user) to create, edit, or delete a service-linked role. For the `AWSServiceRoleForSecurityHubV2` service-linked role to be successfully created, the IAM identity that you use to access Security Hub must have the required permissions. To grant the required permissions, attach the following policy to the IAM identity.

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": "securityhub:*",
            "Resource": "*"
        },
```

```
        {
            "Effect": "Allow",
            "Action": "iam:CreateServiceLinkedRole",
            "Resource": "*",
            "Condition": {
                "StringLike": {
                    "iam:AWSServiceName": "securityhub.amazonaws.com"
                }
            }
        }
    ]
}
```

Creating a service-linked role for Security Hub

The `AWSServiceRoleForSecurityHubV2` service-linked role is created automatically when you enable Security Hub for the first time or you enable Security Hub in a Region where you didn't previously enable it. You can also create the `AWSServiceRoleForSecurityHubV2` service-linked role manually by using the IAM console, the IAM CLI, or the IAM API. For more information about creating the role manually, see Creating a service-linked role in the *IAM User Guide*.

> **Important**
>
> The service-linked role that is created for a Security Hub administrator account does not apply to associated Security Hub member accounts.

Editing a service-linked role for Security Hub

Security Hub does not allow you to edit the `AWSServiceRoleForSecurityHubV2` service-linked role. After you create a service-linked role, you cannot change the name of the role because various entities might reference the role. However, you can edit the description of the role by using IAM. For more information, see Editing a service-linked role in the *IAM User Guide*.

Deleting a service-linked role for Security Hub

If you no longer need to use a feature or service that requires a service-linked role, delete the role. That way, you do not have an unused entity that is not actively monitored or maintained.

When you disable Security Hub, Security Hub does not automatically delete the `AWSServiceRoleForSecurityHubV2` service-linked role for you. If you enable Security Hub

again, the service can then start using the existing service-linked role again. If you no longer need to use Security Hub, you can manually delete the service-linked role.

> **Important**
>
> Before you delete the `AWSServiceRoleForSecurityHubV2` service-linked role, you must first disable Security Hub in all the Regions where it is enabled. For more information, see Disabling Security Hub. If Security Hub is not disabled when you try to delete the service-linked role, the deletion fails.

To delete the `AWSServiceRoleForSecurityHubV2` service-linked role, you can use the IAM console, the IAM CLI, or the IAM API. For more information, see Deleting a service-linked role in the *IAM User Guide*.

AWS managed policies for Security Hub

An AWS managed policy is a standalone policy that is created and administered by AWS. AWS managed policies are designed to provide permissions for many common use cases so that you can start assigning permissions to users, groups, and roles.

Keep in mind that AWS managed policies might not grant least-privilege permissions for your specific use cases because they're available for all AWS customers to use. We recommend that you reduce permissions further by defining customer managed policies that are specific to your use cases.

You cannot change the permissions defined in AWS managed policies. If AWS updates the permissions defined in an AWS managed policy, the update affects all principal identities (users, groups, and roles) that the policy is attached to. AWS is most likely to update an AWS managed policy when a new AWS service is launched or new API operations become available for existing services.

For more information, see AWS managed policies in the *IAM User Guide*.

AWS managed policy: AWSSecurityHubFullAccess

You can attach the `AWSSecurityHubFullAccess` policy to your IAM identities.

This policy grants administrative permissions that allow a principal full access to all Security Hub actions. This policy must be attached to a principal before they enable Security Hub manually for

their account. For example, principals with these permissions can both view and update the status of findings. They can also configure custom insights, enable integrations, and enable and disable standards and controls. Principals for an administrator account can also manage member accounts.

Permissions details

This policy includes the following permissions:

- `securityhub` – Allows principals full access to all Security Hub actions.
- `guardduty` – Allows principals to get information about account status in Amazon GuardDuty.
- `iam` – Allows principals to create a service-linked role for Security Hub.
- `inspector` – Allows principals to get information about account status in Amazon Inspector.
- `pricing` – Allows principals to get a price list of AWS services and products.

To review the permissions for this policy, see AWSSecurityHubFullAccess in the *AWS Managed Policy Reference Guide*.

AWS managed policy: AWSSecurityHubReadOnlyAccess

You can attach the `AWSSecurityHubReadOnlyAccess` policy to your IAM identities.

This policy grants read-only permissions that allow users to view information in Security Hub. Principals with this policy attached cannot make any updates in Security Hub. For example, principals with these permissions can view the list of findings associated with their account, but cannot change the status of a finding. They can view the results of insights, but cannot create or configure custom insights. They cannot configure controls or product integrations.

Permissions details

This policy includes the following permissions:

- `securityhub` – Allows users to perform actions that return a list of items or details about an item. This includes API operations that start with `Get`, `List`, or `Describe`.

To review the permissions for this policy, see AWSSecurityHubReadOnlyAccess in the *AWS Managed Policy Reference Guide*.

AWS managed policy: AWSSecurityHubOrganizationsAccess

You can attach the `AWSSecurityHubOrganizationsAccess` policy to your IAM identities.

This policy grants administrative permissions to enable and manage Security Hub for an organization in AWS Organizations. The permissions for this policy allow the organization management account to designate the delegated administrator account for Security Hub. They also allow the delegated administrator account to enable organization accounts as member accounts.

This policy only provides permissions for AWS Organizations. The organization management account and delegated administrator account also require permissions for associated actions. These permissions can be granted using the `AWSSecurityHubFullAccess` managed policy.

Permissions details

This policy includes the following permissions:

- `organizations:ListAccounts` – Allows principals to retrieve the list of accounts that are part of an organization.
- `organizations:DescribeOrganization` – Allows principals to retrieve information about the organization.
- `organizations:ListRoots` – Allows principals to list the root of an organization.
- `organizations:ListDelegatedAdministrators` – Allows principals to list the delegated administrator of an organization.
- `organizations:ListAWSServiceAccessForOrganization` – Allows principals to list the AWS services that an organization uses.
- `organizations:ListOrganizationalUnitsForParent` – Allows principals to list the child organizational units (OU) of a parent OU.
- `organizations:ListAccountsForParent` – Allows principals to list the child accounts of a parent OU.
- `organizations:ListParents` – Lists the root or organizational units (OUs) that serve as the immediate parent of the specified child OU or account.
- `organizations:DescribeAccount` – Allows principals to retrieve information about an account in the organization.
- `organizations:DescribeOrganizationalUnit` – Allows principals to retrieve information about an OU in the organization.
- `organizations:ListPolicies` – Retrieves the list of all policies in an organization of a specified type.

- `organizations:ListPoliciesForTarget` – Lists the policies that are directly attached to the specified target root, organizational unit (OU), or account.
- `organizations:ListTargetsForPolicy` – Lists all the roots, organizational units (OUs), and accounts that the specified policy is attached to.
- `organizations:EnableAWSServiceAccess` – Allows principals to enable the integration with Organizations.
- `organizations:RegisterDelegatedAdministrator` – Allows principals to designate the delegated administrator account.
- `organizations:DeregisterDelegatedAdministrator` – Allows principals to remove the delegated administrator account.
- `organizations:DescribePolicy` – Retrieves information about a policy.
- `organizations:DescribeEffectivePolicy` – Returns the contents of the effective policy for specified policy type and account.
- `organizations:CreatePolicy` – Creates a policy of a specified type that you can attach to a root, an organizational unit (OU), or an individual AWS account.
- `organizations:UpdatePolicy` – Updates an existing policy with a new name, description, or content.
- `organizations:DeletePolicy` – Deletes the specified policy from your organization.
- `organizations:AttachPolicy` – Attaches a policy to a root, an organizational unit (OU), or an individual account.
- `organizations:DetachPolicy` – Detaches a policy from a target root, organizational unit (OU), or account.
- `organizations:EnablePolicyType` – Enables a policy type in a root.
- `organizations:DisablePolicyType` – Disables an organizational policy type in a root.
- `organizations:TagResource` – Adds one or more tags to a specified resource.
- `organizations:UntagResource` – Removes any tags with the specified keys from a specified resource.
- `organizations:ListTagsForResource` – Lists tags that are attached to a specified resource.

To review the permissions for this policy, see AWSSecurityHubOrganizationsAccess in the *AWS Managed Policy Reference Guide*.

AWS managed policy: AWSSecurityHubV2ServiceRolePolicy

This policy allows Security Hub to manage AWS Config rules and Security Hub resources for your organization and on your behalf. This policy is attached to a service-linked role that allows the service to perform actions on your behalf. You cannot attach this policy to your IAM identities. For more information, see the section called “Service-linked roles”.

Permissions details

This policy includes the following permissions:

- `access-analyzer` – Create and delete service-linked IAM Access Analyzers when customers enable or disable Security Hub, list analyzers to verify that analyzer state is consistent with enablement state, and generate and retrieve policy recommendations for unused access findings.
- `cloudwatch` – Retrieve metrics data to support metering capabilities for Security Hub resources and Connector health metrics.
- `config` – Manage service-linked configuration recorders and third-party service-linked configuration recorders for Security Hub resources, including support for global Config recorders. List configuration recorders and get connector information to support third-party cloud integrations.
- `ecr` – Retrieve information about Amazon Elastic Container Registry images and repositories to support metering capabilities.
- `iam` – Create the following service-linked roles: AWS Config, IAM Access Analyzer in the customer account, and Amazon Inspector for third-party scanning. Retrieve account information to support metering capabilities. Retrieve existing IAM policies so that customers can view a comparison of their current policy and the recommended least-privilege replacement.
- `inspector2` – Create, update, delete, and list Amazon Inspector connectors and connector scan configurations to support third-party cloud integrations.
- `lambda` – Retrieve AWS Lambda function information to support metering capabilities.
- `organizations` – Retrieve account and organizational unit (OU) information for an organization.
- `securityhub` – Manage the Security Hub configuration. Create, update, and delete Security Hub connectors to support third-party cloud integrations.
- `sts` – Obtain web identity tokens for outbound identity federation to support third-party cloud integrations.
- `tag` – Retrieve information about resource tags.

To review the permissions for this policy, see AWSSecurityHubV2ServiceRolePolicy in the *AWS Managed Policy Reference Guide*.

Security Hub updates to AWS managed policies

The following table provides details about updates to AWS managed policies for AWS Security Hub since this service began tracking these changes. For automatic alerts about updates to the policies, subscribe to the RSS feed on the Security Hub document history page.

Change	Description	Date
AWSSecurityHubV2ServiceRolePolicy – Updated policy	Security Hub updated the policy to support third-party integrations. The update adds the following permissions: manage third-party configuration recorders, create and manage Security Hub and Amazon Inspector connectors, retrieve Connector health metrics from CloudWatch, create the Amazon Inspector service-linked role for third-party scanning, and obtain web identity tokens for federation.	June 30, 2026
AWSSecurityHubV2ServiceRolePolicy – Updated policy	Security Hub updated the policy to add IAM Access Analyzer permissions. The update allows Security Hub to create and manage service-managed analyzers, list analyzers to verify that the analyzer configuration is consistent with	May 10, 2026

Change	Description	Date
	the enablement state, generate and retrieve policy recommendations for unused access findings, and retrieve IAM policies for recommend ation display.	
AWSSecurityHubOrganizationsAccess – Updated policy	Security Hub updated the policy to add permissions to describe resource policies to support Security Hub features. Security Hub is in preview release and subject to change.	November 12, 2025
AWSSecurityHubFullAccess – Updated policy	Security Hub updated the policy to add capabilities around managing GuardDuty , Amazon Inspector, and account management to support Security Hub features. Security Hub is in preview release and subject to change.	November 17, 2025

Change	Description	Date
AWSSecurityHubV2ServiceRolePolicy – Updated policy	Security Hub updated the policy to add metering capabilities for Amazon Elastic Container Registry, AWS Lambda, Amazon CloudWatch, and AWS Identity and Access Management to support Security Hub features. The update also added support for global AWS Config recorders. Security Hub is in preview release and subject to change.	November 5, 2025
AWSSecurityHubOrganizationsAccess – Update to an existing policy	Security Hub added new permissions to the policy. The permissions allow the organization management to enable and manage Security Hub and Security Hub CSPM for an organization.	June 17, 2025
AWSSecurityHubFullAccess – Update to an existing policy	Security Hub CSPM added new permissions that allow principals to create a service-linked role for Security Hub.	June 17, 2025

Change	Description	Date
AWSSecurityHubV2ServiceRolePolicy – New policy	Security Hub added a new policy to allow Security Hub to manage AWS Config rules and Security Hub resources for a customer's organization and on the customer's behalf. Security Hub is in preview release and subject to change.	June 17, 2025
AWSSecurityHubFullAccess – Update to an existing policy	Security Hub CSPM updated the policy to get pricing details for AWS services and products.	April 24, 2024
AWSSecurityHubReadOnlyAccess – Update to an existing policy	Security Hub CSPM updated this managed policy by adding a `Sid` field.	February 22, 2024
AWSSecurityHubFullAccess – Update to an existing policy	Security Hub CSPM updated the policy so it can determine if Amazon GuardDuty and Amazon Inspector are enabled in an account. This helps customers bring together security-related information from multiple AWS services.	November 16, 2023

Change	Description	Date
AWSSecurityHubOrganizationsAccess – Update to an existing policy	Security Hub CSPM updated the policy to grant additional permissions to allow read-only access to AWS Organizations delegated administrator functionality. This includes details like the root, organizational units (OUs), accounts, organizational structure, and service access.	November 16, 2023
AWSSecurityHubOrganizationsAccess – New policy	Security Hub CSPM added a new policy that grants permissions that are needed for the Security Hub CSPM integration with Organizations.	March 15, 2021
Security Hub CSPM started tracking changes	Security Hub CSPM started tracking changes for its AWS managed policies.	March 15, 2021

Troubleshooting AWS Security Hub identity and access

Use the following information to help you diagnose and fix common issues that you might encounter when working with AWS Security Hub and IAM.

Topics

- I am not authorized to perform an action in Security Hub
- I am not authorized to perform iam:PassRole
- I want programmatic access to Security Hub
- I'm an administrator and want to allow others to access Security Hub
- I want to allow people outside my AWS account to access my Security Hub resources

I am not authorized to perform an action in Security Hub

If the AWS Management Console tells you that you are not authorized to perform an action, then you must contact your administrator for assistance. Your administrator is the person that provided you with your sign-in credentials.

The following example error occurs when the user `mateojackson` tries to use the console to view details about a *`widget`* but does not have `securityhub:`*`GetWidget`* permissions.

```
User: arn:aws:iam::123456789012:user/mateojackson is not authorized to perform:
 securityhub:GetWidget on resource: my-example-widget
```

In this case, Mateo asks his administrator to update his policies to allow him to access the *`my-example-widget`* resource using the `securityhub:`*`GetWidget`* action.

I am not authorized to perform iam:PassRole

If you receive an error that you're not authorized to perform the `iam:PassRole` action, your policies must be updated to allow you to pass a role to Security Hub.

Some AWS services allow you to pass an existing role to that service instead of creating a new service role or service-linked role. To do this, you must have permissions to pass the role to the service.

The following example error occurs when an IAM user named `marymajor` tries to use the console to perform an action in Security Hub. However, the action requires the service to have permissions that are granted by a service role. Mary does not have permissions to pass the role to the service.

```
User: arn:aws:iam::123456789012:user/marymajor is not authorized to perform:
 iam:PassRole
```

In this case, Mary's policies must be updated to allow her to perform the `iam:PassRole` action.

If you need help, contact your AWS administrator. Your administrator is the person who provided you with your sign-in credentials.

I want programmatic access to Security Hub

Users need programmatic access if they want to interact with AWS outside of the AWS Management Console. The way to grant programmatic access depends on the type of user that's accessing AWS.

To grant users programmatic access, choose one of the following options.

Which user needs programmatic access?	To	By
IAM	(Recommended) Use console credentials as temporary credentials to sign programmatic requests to the AWS CLI, AWS SDKs, or AWS APIs.	Following the instructions for the interface that you want to use. • For the AWS CLI, see Login for AWS local development in the *AWS Command Line Interface User Guide*. • For AWS SDKs, see Login for AWS local development in the *AWS SDKs and Tools Reference Guide*.
Workforce identity (Users managed in IAM Identity Center)	Use temporary credentials to sign programmatic requests to the AWS CLI, AWS SDKs, or AWS APIs.	Following the instructions for the interface that you want to use. • For the AWS CLI, see Configuring the AWS CLI to use AWS IAM Identity Center in the *AWS Command Line Interface User Guide*. • For AWS SDKs, tools, and AWS APIs, see IAM Identity Center authentication in the *AWS SDKs and Tools Reference Guide*.
IAM	Use temporary credentials to sign programmatic requests	Following the instructions in Using temporary credentia

Which user needs programmatic access?	To	By
	to the AWS CLI, AWS SDKs, or AWS APIs.	ls with AWS resources in the *IAM User Guide*.
IAM	(Not recommended) Use long-term credentials to sign programmatic requests to the AWS CLI, AWS SDKs, or AWS APIs.	Following the instructions for the interface that you want to use. • For the AWS CLI, see Authenticating using IAM user credentials in the *AWS Command Line Interface User Guide*. • For AWS SDKs and tools, see Authenticate using long-term credentials in the *AWS SDKs and Tools Reference Guide*. • For AWS APIs, see Managing access keys for IAM users in the *IAM User Guide*.

I'm an administrator and want to allow others to access Security Hub

To provide access, add permissions to your users, groups, or roles:

- Users and groups in AWS IAM Identity Center:

  Create a permission set. Follow the instructions in Create a permission set in the *AWS IAM Identity Center User Guide*.

- Users managed in IAM through an identity provider:

  Create a role for identity federation. Follow the instructions in Create a role for a third-party identity provider (federation) in the *IAM User Guide*.

- IAM users:
  - Create a role that your user can assume. Follow the instructions in Create a role for an IAM user in the *IAM User Guide*.
  - (Not recommended) Attach a policy directly to a user or add a user to a user group. Follow the instructions in Adding permissions to a user (console) in the *IAM User Guide*.

I want to allow people outside my AWS account to access my Security Hub resources

You can create a role that users in other accounts or people outside of your organization can use to access your resources. You can specify who is trusted to assume the role. For services that support resource-based policies or access control lists (ACLs), you can use those policies to grant people access to your resources.

To learn more, consult the following:

- To learn whether Security Hub supports these features, see How Security Hub works with IAM.
- To learn how to provide access to your resources across AWS accounts that you own, see Providing access to an IAM user in another AWS account that you own in the *IAM User Guide*.
- To learn how to provide access to your resources to third-party AWS accounts, see Providing access to AWS accounts owned by third parties in the *IAM User Guide*.
- To learn how to provide access through identity federation, see Providing access to externally authenticated users (identity federation) in the *IAM User Guide*.
- To learn the difference between using roles and resource-based policies for cross-account access, see Cross account resource access in IAM in the *IAM User Guide*.

Compliance validation for AWS Security Hub

Our new AWS sign-up experience is not designed for regulated workloads. If you're using our new AWS sign-up experience, but you want to use AWS for regulated workloads, you can sign up for AWS (advanced) or activate advanced features for your AWS environment.

To learn whether an AWS service is within the scope of specific compliance programs, see AWS services in Scope by Compliance Program and choose the compliance program that you are interested in. For general information, see AWS Compliance Programs.

You can download third-party audit reports using AWS Artifact. For more information, see Downloading Reports in AWS Artifact.

Your compliance responsibility when using AWS services is determined by the sensitivity of your data, your company's compliance objectives, and applicable laws and regulations. For more information about your compliance responsibility when using AWS services, see AWS Security Documentation.

Resilience in AWS Security Hub

The AWS global infrastructure is built around AWS Regions and Availability Zones. Regions provide multiple physically separated and isolated Availability Zones, which are connected through low-latency, high-throughput, and highly redundant networking. With Availability Zones, you can design and operate applications and databases that automatically fail over between zones without interruption. Availability Zones are more highly available, fault tolerant, and scalable than traditional single or multiple data center infrastructures.

For more information about AWS Regions and Availability Zones, see AWS Global Infrastructure.

Infrastructure security in AWS Security Hub

As a managed service, AWS Security Hub is protected by AWS global network security. For information about AWS security services and how AWS protects infrastructure, see AWS Cloud Security. To design your AWS environment using the best practices for infrastructure security, see Infrastructure Protection in *Security Pillar AWS Well-Architected Framework*.

You use AWS published API calls to access Security Hub through the network. Clients must support the following:

- Transport Layer Security (TLS). We require TLS 1.2 and recommend TLS 1.3.
- Cipher suites with perfect forward secrecy (PFS) such as DHE (Ephemeral Diffie-Hellman) or ECDHE (Elliptic Curve Ephemeral Diffie-Hellman). Most modern systems such as Java 7 and later support these modes.

AWS Security Hub and interface VPC endpoints (AWS PrivateLink)

You can establish a private connection between your VPC and AWS Security Hub by creating an *interface VPC endpoint*. Interface endpoints are powered by AWS PrivateLink, a technology that enables you to privately access Security Hub APIs without an internet gateway, NAT device, VPN connection, or AWS Direct Connect connection. Instances in your VPC do not need public IP addresses to communicate with Security Hub APIs. Traffic between your VPC and Security Hub does not leave the Amazon network.

Each interface endpoint is represented by one or more Elastic Network Interfaces in your subnets. For more information, see Access an AWS service using an interface VPC endpoint in the *Amazon Virtual Private Cloud Guide*.

Considerations for Security Hub VPC endpoints

Before you set up an interface VPC endpoint for Security Hub, ensure that you review the prerequisites and other information in the Amazon Virtual Private Cloud Guide.

Security Hub supports making calls to all of its API actions from your VPC.

Creating an interface VPC endpoint for Security Hub

You can create a VPC endpoint for the Security Hub service using either the Amazon VPC console or the AWS Command Line Interface (AWS CLI). For more information, see Create a VPC endpoint in the *Amazon Virtual Private Cloud Guide*.

Create a VPC endpoint for Security Hub using the following service name:

`com.amazonaws.`*`region`*`.securityhub`

Where *`region`* is the Region code for the applicable AWS Region.

If you enable private DNS for the endpoint, you can make API requests to Security Hub using its default DNS name for the Region, for example, `securityhub.us-east-1.amazonaws.com` for the US East (N. Virginia) Region.

Creating a VPC endpoint policy for Security Hub

You can attach an endpoint policy to your VPC endpoint that controls access to Security Hub. The policy specifies the following information:

- The principal that can perform actions.
- The actions that can be performed.
- The resources on which actions can be performed.

For more information, see Control access to VPC endpoints using endpoint policies in the *Amazon Virtual Private Cloud Guide*.

Example: VPC endpoint policy for Security Hub actions

The following is an example of an endpoint policy for Security Hub. When attached to an endpoint, this policy grants access to the listed Security Hub actions for all principals on all resources.

```
{
   "Statement":[
      {
         "Principal":"*",
         "Effect":"Allow",
         "Action":[
            "securityhub:getFindings",
            "securityhub:getEnabledStandards",
            "securityhub:getInsights"
         ],
         "Resource":"*"
      }
   ]
}
```

Shared subnets

You cannot create, describe, modify, or delete VPC endpoints in subnets that are shared with you. However, you can use the VPC endpoints in subnets that are shared with you. For information about VPC sharing, see Share your VPC subnets with other accounts in the *Amazon Virtual Private Cloud Guide*.

Logging Security Hub API calls with CloudTrail

is integrated with AWS CloudTrail, a service that provides a record of actions taken by a user, role, or an AWS service in Security Hub. CloudTrail captures API calls for Security Hub as events. The captured calls include calls from the Security Hub console and code calls to the Security Hub API operations. If you create a trail, you can enable continuous delivery of CloudTrail events to an Amazon S3 bucket, including events for Security Hub. If you do not configure a trail, you can still view the most recent events on the CloudTrail console in **Event history**. Using the information that CloudTrail collects, you can determine the request that was made to Security Hub, the IP address that the request was made from, who made the request, when it was made, and additional details.

To learn more about CloudTrail, including how to configure and enable it, see the AWS CloudTrail User Guide.

Security Hub information in CloudTrail

CloudTrail is enabled on your AWS account when you create the account. When supported event activity occurs in Security Hub, that activity is recorded in a CloudTrail event along with other AWS service events in **Event history**. You can view, search, and download recent events in your account. For more information, see Viewing events with CloudTrail event history.

For an ongoing record of events in your account, including events for Security Hub, create a trail. A *trail* enables CloudTrail to deliver log files to an Amazon S3 bucket. By default, when you create a trail on the console, the trail applies to all AWS Regions. The trail logs events from all Regions in the AWS partition and delivers the log files to the Amazon S3 bucket that you specify. Additionally, you can configure other AWS services to further analyze and act upon the event data collected in CloudTrail logs. For more information, see the following:

- Overview for creating a trail
- CloudTrail supported services and integrations
- Configuring Amazon SNS notifications for CloudTrail
- Receiving CloudTrail log files from multiple regions and Receiving CloudTrail log files from multiple accounts

Security Hub supports logging all of the Security Hub API actions as events in CloudTrail logs. To view a list of Security Hub operations, see the Security Hub API Reference.

When activity for the following actions is logged to CloudTrail, the value for `responseElements` is set to `null`. This ensures that sensitive information is not included in CloudTrail logs.

- `GetFindingsV2`

Every event or log entry contains information about who generated the request. The identity information helps you determine the following:

- Whether the request was made with root or AWS Identity and Access Management (IAM) user credentials
- Whether the request was made with temporary security credentials for a role or federated user
- Whether the request was made by another AWS service

For more information, see the CloudTrail userIdentity element.

Example: Security Hub log file entries

A trail is a configuration that enables delivery of events as log files to an Amazon S3 bucket that you specify. CloudTrail log files contain one or more log entries. An event represents a single request from any source and includes information about the requested action, the date and time of the action, request parameters, and so on. CloudTrail log files are not an ordered stack trace of the public API calls, so they do not appear in any specific order.

The following example shows a CloudTrail log entry that demonstrates the `CreateAutomationRuleV2` action. In this example, an automation rule called `TestAutomationRule` is created. The `Severity` and `Account ID` attributes are specified as the **Criteria**. When the rule is matched the `Severity` is updated to **High**. For more information about automation rules, see Automation rules in Security Hub.

Introduction to AWS Security Hub CSPM

AWS Security Hub Cloud Security Posture Management (AWS Security Hub CSPM) provides you with a comprehensive view of your security state in AWS and helps you assess your AWS environment against security industry standards and best practices.

AWS Security Hub CSPM collects security data across AWS accounts, AWS services, and supported third-party products and helps you analyze your security trends and identify the highest priority security issues.

To help you manage the security state of your organization, Security Hub CSPM supports multiple security standards. These include the AWS Foundational Security Best Practices (FSBP) standard developed by AWS, and external compliance frameworks such as the Center for Internet Security (CIS), the Payment Card Industry Data Security Standard (PCI DSS), and the National Institute of Standards and Technology (NIST). Each standard includes several security controls, each of which represents a security best practice. Security Hub CSPM runs checks against security controls and generates control findings to help you assess your compliance against security best practices.

In addition to generating control findings, Security Hub CSPM also receives findings from other AWS services—such as Amazon GuardDuty, Amazon Inspector, and Amazon Macie— and supported third-party products. This gives you a single pane of glass into a variety of security-related issues. You can also send Security Hub CSPM findings to other AWS services and supported third-party products.

Security Hub CSPM offers automation features that help you triage and remediate security issues. For example, you can use automation rules to automatically update critical findings when a security check fails. You can also leverage the integration with Amazon EventBridge to trigger automatic responses to specific findings.

Benefits of Security Hub CSPM

Here are some of the key ways that Security Hub CSPM helps you monitor your compliance and security posture across your AWS environment.

Reduced effort to collect and prioritize findings

Security Hub CSPM reduces the effort to collect and prioritize security findings across accounts from integrated AWS services and AWS partner products. Security Hub CSPM processes finding data using the AWS Security Finding Format (ASFF), a standard finding format. This eliminates the need to manage findings from myriad sources in multiple formats. Security Hub CSPM also correlates findings across providers to help you prioritize the most important ones.

Automatic security checks against best practices and standards

Security Hub CSPM automatically runs continuous, account-level configuration and security checks based on AWS best practices and industry standards. Security Hub CSPM uses the results

of these checks to calculate security scores, and identifies specific accounts and resources that require attention.

Consolidated view of findings across accounts and providers

Security Hub CSPM consolidates your security findings across accounts and provider products and displays results on the Security Hub CSPM console. You can also retrieve findings through the Security Hub CSPM API, AWS CLI, or SDKs. With a holistic view of your current security status, you can spot trends, identify potential issues, and take necessary remediation steps.

Ability to automate finding updates and remediation

You can create automation rules that modify or suppress findings based on your defined criteria. Security Hub CSPM also supports an integration with Amazon EventBridge. To automate the remediation of specific findings, you can define custom actions to take when a finding is generated. For example, you can configure custom actions to send findings to a ticketing system or to an automated remediation system.

Accessing Security Hub CSPM

Security Hub CSPM is available in most AWS Regions. For a list of Regions where Security Hub CSPM is currently available, see AWS Security Hub CSPM endpoints and quotas in the *AWS General Reference*. For information about managing AWS Regions for your AWS account, see Specifying which AWS Regions your account can use in the *AWS Account Management Reference Guide*.

In each Region, you can access and use Security Hub CSPM in any of the following ways:

Security Hub CSPM console

The AWS Management Console is a browser-based interface that you can use to create and manage AWS resources. As part of that console, the Security Hub CSPM console provides access to your Security Hub CSPM account, data, and resources. You can perform Security Hub CSPM tasks by using the Security Hub CSPM console—view findings, create automation rules, create an aggregation Region, and more.

Security Hub CSPM API

The Security Hub CSPM API gives you programmatic access to your Security Hub CSPM account, data, and resources. With the API, you can send HTTPS requests directly to Security Hub CSPM. For information about the API, see the *AWS Security Hub API Reference*.

AWS CLI

With the AWS CLI, you can run commands at your system's command line to perform Security Hub CSPM tasks. In some cases, using the command line can be faster and more convenient than using the console. The command line is also useful if you want to build scripts that perform tasks. For information about installing and using the AWS CLI, see the AWS Command Line Interface User Guide.

AWS SDKs

AWS provides SDKs that consist of libraries and sample code for various programming languages and platforms—for example, Java, Go, Python, C++, and .NET. The SDKs provide convenient, programmatic access to Security Hub CSPM and other AWS services in your preferred language. They also handle tasks such as cryptographically signing requests, managing errors, and retrying requests automatically. For information about installing and using the AWS SDKs, see Tools to Build on AWS.

Important

Security Hub CSPM only detects and consolidates findings that are generated after you enable Security Hub CSPM. It doesn't retroactively detect and consolidate security findings that were generated before you enabled Security Hub CSPM.
Security Hub CSPM only receives and processes findings in the Region where you enabled Security Hub CSPM in your account.
For full compliance with CIS AWS Foundations Benchmark security checks, you must enable Security Hub CSPM in all supported AWS Regions.

Related services

To further secure your AWS environment, consider using other AWS services in combination with Security Hub CSPM. Some AWS services send their findings to Security Hub CSPM, and Security Hub CSPM normalizes the findings into a standard format. Some AWS services can also receive findings from Security Hub CSPM.

For a list of other AWS services that send or receive Security Hub CSPM findings, see AWS service integrations with Security Hub CSPM.

Security Hub CSPM uses service-linked rules from AWS Config to run security checks for most controls. Controls refer to specific AWS services and AWS resources. For a list of Security Hub CSPM controls, see Control reference for Security Hub CSPM. You must enable AWS Config and record resources in AWS Config for Security Hub CSPM to generate most control findings. For more information, see Considerations before enabling and configuring AWS Config.

Security Hub CSPM free trial and pricing

When you enable Security Hub CSPM in an AWS account for the first time, that account is automatically enrolled in a 30-day Security Hub CSPM free trial.

When you use Security Hub CSPM during the free trial, you are charged for usage of other services that Security Hub CSPM interacts with, such as AWS Config items. You are not charged for AWS Config rules that are activated only by Security Hub CSPM security standards.

You are not charged for using Security Hub CSPM until your free trial ends.

Viewing usage details

Security Hub CSPM provides usage information, including the number of security checks and findings processed by your account. The usage details also include the time remaining in the free trial. This information can help you understand your Security Hub CSPM usage after the free trial ends. The usage information is also available after the free trial ends.

To display usage information (console)

1. Open the AWS Security Hub CSPM console at https://console.aws.amazon.com/securityhub/.
2. In the navigation pane, choose **Usage** under **Settings**.

The usage information is only for the current account and current Region. In an aggregation Region, the usage information doesn't include linked Regions. For more information about linked Regions, see the section called “Types of data that are aggregated”.

To view cost details for your account, use the AWS Billing console.

Pricing details

For more information about how Security Hub CSPM charges for ingested findings and security checks, see Security Hub CSPM pricing.

Concepts and terminology in Security Hub CSPM

In AWS Security Hub CSPM, we build on common AWS concepts and terminology and use these additional terms.

Account

A standard Amazon Web Services (AWS) account that contains your AWS resources. You can sign in to AWS with your account and enable Security Hub CSPM.

An account can invite other accounts to enable Security Hub CSPM and become associated with that account in Security Hub CSPM. Accepting a membership invitation is optional. If the invitations are accepted, the account becomes an administrator account, and the added accounts are member accounts. Administrator accounts can view findings in their member accounts.

If you are enrolled in AWS Organizations, then your organization designates a Security Hub CSPM administrator account for the organization. The Security Hub CSPM administrator account can enable other organization accounts as member accounts.

An account cannot be both an administrator account and a member account at the same time. An account can only have one administrator account.

For more information, see Managing administrator and member accounts in Security Hub CSPM.

Administrator account

An account in Security Hub CSPM that is granted access to view findings for associated member accounts.

An account becomes an administrator account in one of the following ways:

- The account invites other accounts to become associated with it in Security Hub CSPM. When those accounts accept the invitation, they become member accounts, and the inviting account becomes their administrator account.
- The account is designated by an organization management account as the Security Hub CSPM administrator account. The Security Hub CSPM administrator account can enable any organization account as a member account, and can also invite other accounts to be member accounts.

An account can only have one administrator account. An account cannot be both an administrator account and a member account at the same time.

Aggregation Region

Setting an aggregation Region allows you to view security findings from multiple AWS Regions in a single pane of glass.

The aggregation Region is the Region from which you view and manage findings. Findings are aggregated to the aggregation Region from linked Regions. Updates to findings are replicated across Regions.

In the aggregation Region, the **Security standards**, **Insights**, and **Findings** pages include data from all linked Regions.

For more information, see the section called “Aggregating data across Regions”.

Archived finding

A finding whose record state (`RecordState`) is `ARCHIVED`. Archiving a finding indicates that the finding provider believes that the finding is no longer relevant. Record state is different from workflow status, which tracks the status of the investigation into a finding.

Finding providers can use the BatchImportFindings operation of the Security Hub CSPM API to archive findings that they created. Security Hub CSPM automatically archives control findings that meet certain criteria. For more information, see Generating, updating, and archiving control findings.

On the Security Hub CSPM console, default filter settings exclude archived findings from finding lists and tables. You can update the settings to include archived findings. If you retrieve findings by using the GetFindings operation of the Security Hub CSPM API, the operation retrieves both archived and active findings. To exclude archived findings, you can filter the results. For example:

```
"RecordState": [
    {
        "Comparison": "EQUALS",
        "Value": "ARCHIVED"
    }
],
```

AWS Security Finding Format (ASFF)

A standardized format for the contents of findings that Security Hub CSPM aggregates or generates. The AWS Security Finding Format enables you to use Security Hub CSPM to view and analyze findings that are generated by AWS security services, third-party solutions, or Security Hub CSPM itself from running security checks. For more information, see AWS Security Finding Format (ASFF).

Control

A safeguard or countermeasure prescribed for an information system or an organization designed to protect the confidentiality, integrity, and availability of its information and to meet a set of defined security requirements. A security standard is associated with a collection of controls.

The term *security control* refers to controls that have a single control ID and title across standards. The term *standard control* refers to controls that have standard-specific control IDs and titles. Currently, Security Hub CSPM supports standard controls only in the China Regions and AWS GovCloud (US) Regions. Security controls are supported in all other Regions.

Custom action

A Security Hub CSPM mechanism for sending selected findings to EventBridge. A custom action is created in Security Hub CSPM. It is then linked to an EventBridge rule. The rule defines a specific action to take when a finding is received that is associated with the custom action ID. Custom actions can be used, for example, to send a specific finding, or a small set of findings, to a response or remediation workflow. For more information, see the section called “Creating a custom action”.

Delegated administrator account (Organizations)

In AWS Organizations, the delegated administrator account for a service is able to manage the use of a service for the organization.

In Security Hub CSPM, the Security Hub CSPM administrator account is also the delegated administrator account for Security Hub CSPM. When the organization management account first designates a Security Hub CSPM administrator account, Security Hub CSPM calls Organizations to make that account the delegated administrator account.

The organization management account must then choose the delegated administrator account as the Security Hub CSPM administrator account in all Regions.

Finding

The observable record of a security check or security-related detection. Security Hub CSPM generates and updates findings after completing security checks for controls. These are called *control findings*. Findings can also come from integrations with other AWS services and third-party products.

For more information, see the section called "Findings".

Cross-Region aggregation

The aggregation of findings, insights, control compliance statuses, and security scores from linked Regions to an aggregation Region. You can then view all of your data from the aggregation Region and update findings and insights from the aggregation Region.

For more information, see the section called "Aggregating data across Regions".

Finding ingestion

The import of findings into Security Hub CSPM from other AWS services and from third-party partner providers.

Finding ingestion events include both new findings and updates to existing findings.

Insight

A collection of related findings defined by an aggregation statement and optional filters. An insight identifies a security area that requires attention and intervention. Security Hub CSPM offers several managed (default) insights that you can't modify. You can also create custom Security Hub CSPM insights to track security issues that are unique to your AWS environment and usage. For more information, see the section called "Insights".

Linked Region

When you enable cross-Region aggregation, a linked Region is a region that aggregates findings, insights, control compliance statuses, and security scores to the aggregation Region.

In a linked Region, the **Findings** and **Insights** pages contain findings only from that Region.

For more information, see the section called "Aggregating data across Regions".

Member account

An account that has granted permission to an administrator account to view and take action on their findings.

An account becomes a member account in one of the following ways:

- The account accepts an invitation from another account.
- For an organization account, the Security Hub CSPM administrator account enables the account as a member account.

Related requirements

A set of industry or regulatory requirements that are mapped to a control.

Rule

A set of automated criteria that is used to assess whether a control is being adhered to. When a rule is evaluated, it can pass or fail. If the evaluation cannot determine whether rule passes or fails, then the rule is in a warning state. If the rule cannot be evaluated, then it is in a not available state.

Security check

A specific point-in-time evaluation of a rule against a single resource resulting in a `PASSED`, `FAILED`, `WARNING`, or `NOT_AVAILABLE` state. Running a security check produces a finding.

Security Hub CSPM administrator account

An organization account that manages Security Hub CSPM membership for an organization.

The organization management account designates the Security Hub CSPM administrator account in each Region. The organization management account must choose the same Security Hub CSPM administrator account in all Regions.

The Security Hub CSPM administrator account is also the delegated administrator account for Security Hub CSPM in Organizations.

The Security Hub CSPM administrator account can enable any organization account as a member account. The Security Hub CSPM administrator account can also invite other accounts to be member accounts.

Security standard

A published statement on a topic specifying the characteristics, usually measurable and in the form of controls, that must be satisfied or achieved for compliance. Security standards can be based on regulatory frameworks, best practices, or internal company policies. A control may be associated with one or more supported standards in Security Hub CSPM. To learn more about

security standards in Security Hub CSPM, see Understanding security standards in Security Hub CSPM.

Severity

The severity assigned to a Security Hub CSPM control identifies the importance of the control. The severity of a control can be **Critical**, **High**, **Medium**, **Low**, or **Informational**. The severity assigned to control findings is equal to the severity of the control itself. To learn about how Security Hub CSPM assigns severity to a control, see Severity levels for control findings.

Workflow status

The status of an investigation into a finding. This is tracked using the `Workflow.Status` attribute.

The workflow status is initially `NEW`. If you notified the resource owner to take action on the finding, you can set the workflow status to `NOTIFIED`. If the finding is not an issue, and does not require any action, set the workflow status to `SUPPRESSED`. After you review and remediate a finding, set the workflow status to `RESOLVED`.

By default, most finding lists only include findings with a workflow status of `NEW` or `NOTIFIED`. Finding lists for controls also include `RESOLVED` findings.

For the GetFindings operation, you can include a filter for the workflow status.

```
"WorkflowStatus": [
    {
        "Comparison": "EQUALS",
        "Value": "RESOLVED"
    }
],
```

The Security Hub CSPM console provides an option to set the workflow status for findings. Customers (or SIEM, ticketing, incident management, or SOAR tools working on behalf of a customer to update findings from finding providers) can also use BatchUpdateFindings to update the workflow status.

Enabling Security Hub CSPM

There are two ways to enable AWS Security Hub CSPM, by integrating with AWS Organizations or manually.

We strongly recommend integrating with Organizations for multi-account and multi-Region environments. If you have a standalone account, it's necessary to set up Security Hub CSPM manually.

Verifying necessary permissions

After you sign up for Amazon Web Services (AWS), you must enable Security Hub CSPM to use its capabilities and features. To enable Security Hub CSPM, you first have to set up permissions that allow you to access the Security Hub CSPM console and API operations. You or your AWS administrator can do this by using AWS Identity and Access Management (IAM) to attach the AWS managed policy called `AWSSecurityHubFullAccess` to your IAM identity.

To enable and manage Security Hub CSPM through the Organizations integration, you also should attach the AWS managed policy called `AWSSecurityHubOrganizationsAccess`.

For more information, see AWS managed policies for Security Hub.

Enabling Security Hub CSPM with Organizations integration

To start using Security Hub CSPM with AWS Organizations, the AWS Organizations management account for the organization designates an account as the delegated Security Hub CSPM administrator account for the organization. Security Hub CSPM is automatically enabled in the delegated administrator account in the current Region.

Choose your preferred method, and follow the steps to designate the delegated administrator.

Security Hub CSPM console

To designate the delegated Security Hub CSPM administrator when onboarding

1. Open the AWS Security Hub CSPM console at https://console.aws.amazon.com/securityhub/.
2. Choose **Go to Security Hub CSPM**. You're prompted to sign in to the Organizations management account.
3. On the **Designate delegated administrator** page, in the **Delegated administrator account** section, specify the delegated administrator account. We recommend choosing the same delegated administrator that you have set for other AWS security and compliance services.
4. Choose **Set delegated administrator**.

Security Hub CSPM API

Invoke the `EnableOrganizationAdminAccount` API from the Organizations management account. Provide the AWS account ID of the Security Hub CSPM delegated administrator account.

AWS CLI

Run the `enable-organization-admin-account` command from the Organizations management account. Provide the AWS account ID of the Security Hub CSPM delegated administrator account.

Example command:

```
aws securityhub enable-organization-admin-account --admin-account-id 777788889999
```

For more information about the integration with Organizations, see Integrating Security Hub CSPM with AWS Organizations.

Configuring Security Hub CSPM with declarative policies

After you designate a delegated administrator, we recommend using Security Hub CSPM declarative policies to enable and configure Security Hub CSPM across the accounts, organizational units (OUs), and AWS Regions in your organization. For prerequisites and instructions, see Managing accounts with declarative policies in Security Hub CSPM. For a comparison of the ways to configure Security Hub CSPM in an organization, see Managing accounts with AWS Organizations.

Enabling Security Hub CSPM manually

You must enable Security Hub CSPM manually if you have a standalone account, or if you don't integrate with AWS Organizations. Standalone accounts can't integrate with AWS Organizations and must use manual enablement.

When you enable Security Hub CSPM manually, you designate a Security Hub CSPM administrator account and invite other accounts to become member accounts. The administrator-member relationship is established when a prospective member account accepts the invitation.

Choose your preferred method, and follow the steps to enable Security Hub CSPM. When you enable Security Hub CSPM from the console, you also have the option to enable the supported security standards.

Security Hub CSPM console

1. Open the AWS Security Hub CSPM console at https://console.aws.amazon.com/securityhub/.
2. When you open the Security Hub CSPM console for the first time, choose **Go to Security Hub CSPM**.
3. On the welcome page, the **Security standards** section lists the security standards that Security Hub CSPM supports.

   Select the check box for a standard to enable it, and clear the check box to disable it.

   You can enable or disable a standard or its individual controls at any time. For information about managing security standards, see Understanding security standards in Security Hub CSPM.
4. Choose **Enable Security Hub**.

Security Hub CSPM API

Invoke the `EnableSecurityHub` API. When you enable Security Hub CSPM from the API, it automatically enables the following default security standards:

- AWS Foundational Security Best Practices
- Center for Internet Security (CIS) AWS Foundations Benchmark v1.2.0

If you do not want to enable these standards, then set `EnableDefaultStandards` to `false`.

You can also use the `Tags` parameter to assign tag values to the hub resource.

AWS CLI

Run the `enable-security-hub` command. To enable the default standards, include `--enable-default-standards`. To not enable the default standards, include `--no-enable-default-standards`. The default security standards are as follows:

- AWS Foundational Security Best Practices
- Center for Internet Security (CIS) AWS Foundations Benchmark v1.2.0

```
aws securityhub enable-security-hub [--tags <tag values>] [--enable-default-
standards | --no-enable-default-standards]
```

Example

```
aws securityhub enable-security-hub --enable-default-standards --tags
 '{"Department": "Security"}'
```

Next steps: Posture management and integrations

After enabling Security Hub CSPM, we recommend enabling security standards and controls to monitor your security posture. After you enable controls, Security Hub CSPM begins running security checks and generating control findings that help you detect misconfigurations in your AWS environment. To receive control findings, you must enable and configure AWS Config for Security Hub CSPM. For more information, see Enabling and configuring AWS Config for Security Hub CSPM.

After enabling Security Hub CSPM, you can also leverage integrations between Security Hub CSPM and other AWS services and third-party solutions to see their findings in Security Hub CSPM. Security Hub CSPM aggregates findings from different sources and ingests them in a consistent format. For more information, see Understanding integrations in Security Hub CSPM.

Enabling and configuring AWS Config for Security Hub CSPM

AWS Security Hub CSPM uses AWS Config rules to run security checks and generate findings for most controls. AWS Config provides a detailed view of the configuration of AWS resources in your AWS account. It uses rules to establish a baseline configuration for your resources and a configuration recorder to detect whether a particular resource violates the conditions of a rule.

Some rules, referred to as AWS Config managed rules, are predefined and developed by AWS Config. Other rules are custom AWS Config rules that Security Hub CSPM develops. AWS Config rules that Security Hub CSPM uses for controls are referred to as *service-linked rules*. Service-linked rules allow AWS services such as Security Hub CSPM to create AWS Config rules in your account.

If you have both AWS Security Hub CSPM and Security Hub enabled, Security Hub CSPM automatically creates a service-linked configuration recorder to assess your security controls. You don't need to manually enable or configure AWS Config. For more information, see Using the service-linked configuration recorder.

If you have Security Hub CSPM enabled without Security Hub, you must manually enable AWS Config and turn on resource recording. For more information, see Manually configuring AWS Config.

The AWS Config prerequisites described on this page apply only to AWS security standards, such as AWS Foundational Security Best Practices and CIS AWS Foundations Benchmark. Multicloud standards, such as CIS Azure Foundations Benchmark v4.0.0, do *not* require you to enable AWS Config recording or configure a configuration recorder. The Security Hub CSPM multicloud connector automatically sets up a service-linked recorder to evaluate external cloud resources. The only prerequisite for multicloud standards is a Security Hub CSPM connector for the external cloud provider.

Topics

- Using the service-linked configuration recorder
- Manually configuring AWS Config
- Understanding the Config.1 control
- Generating service-linked rules

Using the service-linked configuration recorder

When you have both AWS Security Hub CSPM and Security Hub enabled, Security Hub CSPM automatically creates and manages a service-linked configuration recorder across your accounts and Regions. You don't need to manually enable or configure AWS Config.

The name of this configuration recorder is `AWSConfigurationRecorderForSecurityHubCSPM`. Security Hub CSPM creates a corresponding service-linked configuration recorder for each account and Region where both Security Hub CSPM and Security Hub are enabled. As you enable Security Hub CSPM for new AWS accounts and AWS Regions, Security Hub CSPM automatically creates the service-linked configuration recorder.

Security Hub CSPM manages the resource configuration of the service-linked configuration recorder, ensuring that recording is enabled for all resources that are tied to controls supported by Security Hub. For a list of required resources, see Required AWS Config resources for control findings.

When Security Hub CSPM creates this service-linked configuration recorder, Security Hub does not use the customer-managed configuration recorder in AWS Config.

For more information about configuration recorders, see Working with the configuration recorder in the *AWS Config Developer Guide*.

Manually configuring AWS Config

The following steps apply when you have Security Hub CSPM enabled without Security Hub. In this case, you must enable AWS Config for your account and turn on resource recording for the types of resources that your enabled controls evaluate. After you do this, Security Hub CSPM creates the appropriate AWS Config rules and begins running security checks to generate findings.

Considerations before enabling and configuring AWS Config

To receive control findings in Security Hub CSPM, AWS Config must be enabled for your account in each AWS Region where Security Hub CSPM is enabled. If you use Security Hub CSPM for a multi-account environment, AWS Config must be enabled in each Region for the administrator account and all member accounts.

We strongly recommend that you turn on resource recording in AWS Config *before* you enable any Security Hub CSPM standards and controls. This helps you ensure that your control findings are accurate.

To turn on resource recording in AWS Config, you must have sufficient permissions to record resources in the AWS Identity and Access Management (IAM) role that's attached to the configuration recorder. In addition, ensure that no IAM policies or AWS Organizations policies prevent AWS Config from having permission to record your resources. Security Hub CSPM controls evaluate resource configurations directly and don't take AWS Organizations policies into account. For more information about AWS Config recording, see Working with the configuration recorder in the *AWS Config Developer Guide*.

If you enable a standard in Security Hub CSPM but haven't enabled AWS Config, Security Hub CSPM tries to create service-linked AWS Config rules according to the following schedule:

- On the day that you enable the standard.
- The day after you enable the standard.
- 3 days after you enable the standard.
- 7 days after you enable the standard, and continuously every 7 days thereafter.

Recording resources in AWS Config

When you enable AWS Config, you must specify which AWS resources you want the AWS Config configuration recorder to record. Through the service-linked rules, the configuration recorder allows Security Hub CSPM to detect changes to your resource configurations.

For Security Hub CSPM to generate accurate control findings, you must turn on recording in AWS Config for the types of resources that correspond to your enabled controls. It's primarily enabled controls with a *change triggered* schedule type that require resource recording. Some controls with a *periodic* schedule type also require resource recording. For a list of these controls and their corresponding resources, see Required AWS Config resources for control findings.

Warning

If you don't configure AWS Config recording correctly for Security Hub CSPM controls, it can result in inaccurate control findings, particularly in the following instances:

- You never recorded the resource for a given control, or you disabled recording of a resource before creating that type of resource. In these cases, you receive a `WARNING` finding for the control at issue, even though you might have created resources in scope of the control after you disabled recording. This `WARNING` finding is a default finding that doesn't actually evaluate the configuration state of the resource.
- You disable recording for a resource that's evaluated by a particular control. In this case, Security Hub CSPM retains the control findings that were generated before you disabled recording, even though the control isn't evaluating new or updated resources. Security Hub CSPM also changes the compliance status of the findings to `WARNING`. These retained findings might not accurately reflect a resource's current configuration state.

By default, AWS Config records all supported *Regional resources* that it discovers in the AWS Region in which it is running. To receive all Security Hub CSPM control findings, you must also configure AWS Config to record *global resources*. To conserve costs, we recommend recording global resources in a single Region only. If you use cross-Region aggregation, this Region should be your home Region.

In AWS Config, you can choose between *continuous recording* and *daily recording* of changes in resource state. If you choose daily recording, AWS Config delivers resource configuration data at the end of each 24–hour period if there are changes in resource state. If there are no changes,

no data is delivered. This can delay the generation of Security Hub CSPM findings for change-triggered controls until a 24–hour period is complete.

For more information about AWS Config recording, see Recording AWS resources in the *AWS Config Developer Guide*.

Ways to enable and configure AWS Config

You can enable AWS Config and turn on resource recording in any of the following ways:

- **AWS Config console** – You can enable AWS Config for an account by using the AWS Config console. For instructions, see Setting up AWS Config with the console in the *AWS Config Developer Guide*.
- **AWS CLI or SDKs** – You can enable AWS Config for an account by using the AWS Command Line Interface (AWS CLI). For instructions, see Setting up AWS Config with the AWS CLI in the *AWS Config Developer Guide*. AWS software development kits (SDKs) are also available for many programming languages.
- **CloudFormation template** – To enable AWS Config for many accounts, we recommend using the AWS CloudFormation template named **Enable AWS Config**. To access this template, see AWS CloudFormation StackSet sample templates in the *AWS CloudFormation User Guide*.

  By default, this template excludes recording for IAM global resources. Ensure that you turn on recording for IAM global resources in only one AWS Region to conserve recording costs. If you have cross-Region aggregation enabled, this should be your Security Hub CSPM home Region. Otherwise, it can be any Region that Security Hub CSPM is available in that supports recording of IAM global resources. We recommend running one StackSet to record all resources, including IAM global resources, in the home Region or other selected Region. Then, run a second StackSet to record all resources except IAM global resources in other Regions.
- **GitHub script** – Security Hub CSPM offers a GitHub script that enables Security Hub CSPM and AWS Config for multiple accounts across Regions. This script is useful if you haven't integrated with AWS Organizations, or you have some member accounts that aren't part of an organization.

For more information, see the following blog post on the *AWS Security blog*: Optimize AWS Config for AWS Security Hub CSPM to effectively manage your cloud security posture.

Cost considerations

Security Hub CSPM can impact your AWS Config configuration recorder costs by updating the `AWS::Config::ResourceCompliance` configuration item. Updates can occur each time

a Security Hub CSPM control associated with an AWS Config rule changes compliance state, is enabled or disabled, or has parameter updates. If you use the AWS Config configuration recorder only for Security Hub CSPM, and don't use this configuration item for other purposes, we recommend turning off recording for it in AWS Config. This can reduce your AWS Config costs. You don't need to record `AWS::Config::ResourceCompliance` for security checks to work in Security Hub CSPM.

For information about the costs associated with resource recording, see AWS Security Hub CSPM pricing and AWS Config pricing.

Understanding the Config.1 control

> **Note**
>
> When AWS Security Hub CSPM and Security Hub are both enabled, the Config.1 control always has a status of `PASSED`. Security Hub CSPM has direct access to configuration items through a service-linked configuration recorder. For more information, see Using the service-linked configuration recorder.

In Security Hub CSPM, the Config.1 control generates `FAILED` findings in your account if AWS Config is disabled. It also generates `FAILED` findings in your account if AWS Config is enabled but resource recording isn't turned on.

If AWS Config is enabled and resource recording is turned on, but resource recording isn't turned on for a type of resource that an enabled control checks, Security Hub CSPM generates a `FAILED` finding for the Config.1 control. In addition to this `FAILED` finding, Security Hub CSPM generates `WARNING` findings for the enabled control and the types of resources that the control checks. For example, if you enable the KMS.5 control and resource recording isn't turned on for AWS KMS keys, Security Hub CSPM generates a `FAILED` finding for the Config.1 control. Security Hub CSPM also generates `WARNING` findings for the KMS.5 control and your KMS keys.

To receive a `PASSED` finding for the Config.1 control, turn on resource recording for all the resource types that correspond to enabled controls. Also disable controls that aren't required for your organization. This helps ensure that you don't have configuration gaps in your security control checks. It also helps ensure that you receive accurate findings about misconfigured resources.

If you're the delegated Security Hub CSPM administrator for an organization, AWS Config recording must be configured correctly for your account and your member accounts. If you use cross-Region

aggregation, AWS Config recording must be configured correctly in the home Region and all linked Regions. Global resources do not need to be recorded in linked Regions.

Generating service-linked rules

For every control that uses a service-linked AWS Config rule, Security Hub CSPM creates instances of the required rule in your AWS environment.

These service-linked rules are specific to Security Hub CSPM. Security Hub CSPM creates these service-linked rules even if other instances of the same rules already exist. The service-linked rule adds `securityhub` before the original rule name and a unique identifier after the rule name. For example, for the AWS Config managed rule `vpc-flow-logs-enabled`, the service-linked rule name might be `securityhub-vpc-flow-logs-enabled-12345`.

There are quotas for the number of AWS Config managed rules that can be used to evaluate controls. AWS Config rules that Security Hub CSPM creates don't count towards those quotas. You can enable a security standard even if you've already reached the AWS Config quota for managed rules in your account. To learn more about quotas for AWS Config rules, see Service limits for AWS Config in the *AWS Config Developer Guide*.

> **Note**
>
> If you are using Security Hub CSPM and Security Hub you can see the service-linked rules in AWS Config but you will not be able to see the compliant or noncompliant resources associated with the rule. Compliant and noncompliant resources will only be visible in Security Hub CSPM and Security Hub.

Understanding local configuration in Security Hub CSPM

Local configuration is the default way that an AWS organization is configured in Security Hub CSPM. If you don't use declarative policies or central configuration, your organization uses local configuration by default.

Under local configuration, the delegated Security Hub CSPM administrator account has limited control over configuration settings. The only settings that the delegated administrator can enforce are automatically enabling Security Hub CSPM and default security standards in new organization accounts. These settings apply only in the Region in which you designated the

delegated administrator account. The default security standards are AWS Foundational Security Best Practices (FSBP) and Center for Internet Security (CIS) AWS Foundations Benchmark v1.2.0. Local configuration settings don't apply to existing organization accounts or to Regions other than the one in which the delegated administrator account was designated.

Aside from enabling Security Hub CSPM and default standards in new organization accounts in a single Region, you must configure other Security Hub CSPM settings, including standards and controls, separately in each Region and account. Because this can be a duplicative process, we recommend using declarative policies for a multi-account environment if one or more of the following applies to you:

- You want different configuration settings for various parts of your organization (for example, different enabled standards or controls for different teams).
- You operate in multiple Regions and want to reduce the time and complexity of configuring the service across these Regions.
- You want new accounts to use specific configuration settings when they join the organization.
- You want organization accounts to inherit specific configuration settings from a parent account or root.

For information about declarative policies, see Managing accounts with declarative policies in Security Hub CSPM. For a comparison of the ways to configure Security Hub CSPM in an organization, see Managing accounts with AWS Organizations.

Managing administrator and member accounts in Security Hub CSPM

If your AWS environment has multiple accounts, you can treat the accounts that use AWS Security Hub CSPM as member accounts and associate them with a single administrator account. The administrator can monitor your overall security posture and take allowed actions on member accounts. The administrator can also perform various account management and administration tasks at scale, such as monitoring estimated usage costs and assessing account quotas.

You can associate member accounts with an administrator in two ways, by integrating Security Hub CSPM with AWS Organizations or by manually sending and accepting membership invitations in Security Hub CSPM.

Managing accounts with AWS Organizations

AWS Organizations is a global account management service that allows AWS administrators to consolidate and manage multiple AWS accounts. It provides account management and consolidated billing features that are designed to support budgetary, security, and compliance needs. It's offered at no additional charge, and it integrates with multiple AWS services, including AWS Security Hub, AWS Security Hub CSPM, Amazon Macie, and Amazon GuardDuty. For more information, see the *AWS Organizations User Guide*.

When you integrate Security Hub CSPM and AWS Organizations, the Organizations management account designates a Security Hub CSPM delegated administrator. Security Hub CSPM is automatically enabled in the delegated administrator account in the AWS Region in which it was designated.

After you designate a delegated administrator, you can configure Security Hub CSPM for the accounts in your organization in the following ways. We recommend declarative policies.

Approach	How it works	When to use it
Declarative policies (recommended)	An AWS Organizations declarative policy of type `SECURITYHUB_CSPM_POLICY` centrally enables and configures Security Hub CSPM, standards, controls, and control parameters for the organization root, organizational units (OUs), or accounts in each AWS Region. Accounts that join the organization or move into a covered OU inherit the policy. Security Hub CSPM associates governed accounts with the delegated administrator automatically.	Use declarative policies for all multi-account configuration in an organization.

Approach	How it works	When to use it
Local configuration	Local configuration is the default configuration type after you integrate with Organizations. The delegated administrator can automatically enable Security Hub CSPM and default security standards in new organization accounts in the current Region. Existing accounts don't use these settings, and each account configures Security Hub CSPM, standards, and controls separately in each Region.	Use local configuration for accounts and Regions that no declarative policy governs.
Central configuration (legacy)	The delegated administrator creates Security Hub CSPM configuration policies and associates them with accounts and OUs. Declarative policies are replacing central configuration.	If your organization uses central configuration, migrate to declarative policies. For more information, see Declarative policies and central configuration in Security Hub CSPM.

Important

You can't use declarative policies and central configuration in the same organization at the same time. When you attach the first Security Hub CSPM policy to any target, Security Hub CSPM disables central configuration for the entire organization. For more information, see Declarative policies and central configuration in Security Hub CSPM.

Managing accounts manually by invitation

You must manually manage member accounts by invitation in Security Hub CSPM if you have a standalone account or if you don't integrate with Organizations. A standalone account can't integrate with Organizations, so it's necessary to manage it manually. If you add more accounts in the future, we recommend integrating with AWS Organizations and using declarative policies.

When you use manual account management, you designate an account to be the Security Hub CSPM administrator. The administrator account can view data in member accounts and take certain actions on member account findings. The Security Hub CSPM administrator invites other accounts to be member accounts, and the administrator-member relationship is established when a prospective member account accepts the invitation.

Manual account management doesn't support the use of configuration policies. Without configuration policies, the administrator can't centrally customize Security Hub CSPM by configuring variable settings for different accounts. Instead, each organization account must enable and configure Security Hub CSPM for itself separately in each Region. This can make it more difficult and time consuming to ensure adequate security coverage across all of the accounts and Regions in which you use Security Hub CSPM. It can also cause configuration drift as member accounts can specify their own settings without input from the administrator.

To manage accounts by invitation, see Managing accounts by invitation in Security Hub CSPM.

Recommendations for managing multiple accounts in Security Hub CSPM

The following section summarizes some restrictions and recommendations to keep in mind when managing member accounts in AWS Security Hub CSPM.

Using declarative policies

For multi-account environments, we recommend integrating Security Hub CSPM with AWS Organizations and using declarative policies to enable and configure Security Hub CSPM. A declarative policy configures Security Hub CSPM, standards, and controls across accounts, organizational units (OUs), and AWS Regions. The policy also applies automatically to accounts that join the organization. For other options, see Managing accounts with AWS Organizations.

Maximum number of member accounts

If you use the integration with AWS Organizations, Security Hub CSPM supports up to 10,000 member accounts per delegated administrator account in each AWS Region. If you enable and manage Security Hub CSPM manually, Security Hub CSPM supports up to 1,000 member account invitations per administrator account in each Region.

Creating administrator-member relationships

> **Note**
>
> If you use the Security Hub CSPM integration with AWS Organizations, and haven't manually invited any member accounts, this section doesn't apply to you.

An account can't be an administrator account and a member account at the same time.

A member account can only be associated with one administrator account. If an organization account is enabled by the Security Hub CSPM administrator account, the account cannot accept an invitation from another account. If an account has already accepted an invitation, the account cannot be enabled by the Security Hub CSPM administrator account for the organization. It also cannot receive invitations from other accounts.

For the manual invitation process, accepting a membership invitation is optional.

Membership through AWS Organizations

If you integrate Security Hub CSPM with AWS Organizations, the Organizations management account can designate a delegated administrator (DA) account for Security Hub CSPM. The organization management account can't be set as the DA in Organizations. While this is permitted in Security Hub CSPM, we recommend that the Organizations management account should *not* be the DA.

We recommend that you choose the same DA account in all Regions. If you use declarative policies, Security Hub CSPM designates the DA account as the Security Hub CSPM administrator in each Region where a policy enables Security Hub CSPM.

We also recommend that you choose the same DA account across AWS security and compliance services to help you manage security-related issues in a single pane of glass.

Membership by invitation

For member accounts created by invitation, the administrator-member account association is created only in the Region that the invitation is sent from. The administrator account must enable Security Hub CSPM in each Region that you want to use it in. The administrator account then invites each account to become a member account in that Region.

> **Note**
>
> We recommend using AWS Organizations and declarative policies instead of Security Hub CSPM invitations to manage your member accounts.

Coordinating administrator accounts across services

Security Hub CSPM aggregates findings from various AWS services, such as Amazon GuardDuty, Amazon Inspector, and Amazon Macie. Security Hub CSPM also allows users to pivot from a GuardDuty finding to start an investigation in Amazon Detective.

However, the administrator-member relationships that you set up in these other services do not automatically apply to Security Hub CSPM. Security Hub CSPM recommends that you use the same account as the administrator account for all of these services. This administrator account should be an account that is responsible for security tools. The same account should also be the aggregator account for AWS Config.

For example, a user from the GuardDuty administrator account A can see findings for GuardDuty member accounts B and C on the GuardDuty console. If account A then enables Security Hub CSPM, users from account A do *not* automatically see GuardDuty findings for accounts B and C in Security Hub CSPM. A Security Hub CSPM administrator-member relationship is also required for these accounts.

To do this, make account A the Security Hub CSPM administrator account and enable accounts B and C to become Security Hub CSPM member accounts.

Managing Security Hub CSPM for multiple accounts with AWS Organizations

You can integrate AWS Security Hub CSPM with AWS Organizations, and then manage Security Hub CSPM for accounts in your organization.

To integrate Security Hub CSPM with AWS Organizations, you create an organization in AWS Organizations. The Organizations management account designates one account as the Security Hub CSPM delegated administrator for the organization. The delegated administrator can then enable Security Hub CSPM for other accounts in the organization, add those accounts as Security Hub CSPM member accounts, and take allowed actions on the member accounts. The Security Hub CSPM delegated administrator can enable and manage Security Hub CSPM for up to 10,000 member accounts.

How much the delegated administrator can configure depends on the configuration type that your organization uses: AWS Organizations declarative policies (recommended), local configuration, or central configuration (legacy). For a comparison, see Managing accounts with AWS Organizations.

When a declarative policy governs an account, Security Hub CSPM associates the account with the delegated administrator automatically, without invitations. A declarative policy that disables Security Hub CSPM removes the account's administrator and member associations, including invitation-based associations, which Security Hub CSPM doesn't restore. For more information, see How declarative policies work in Security Hub CSPM.

The Security Hub CSPM delegated administrator account can perform the following actions on member accounts:

- Centrally configure Security Hub CSPM for member accounts and organizational units (OUs) by using declarative policies. If your organization still uses central configuration, the delegated administrator uses Security Hub CSPM configuration policies instead.
- Automatically treat *new* accounts as Security Hub CSPM member accounts when they join the organization. If you use declarative policies, accounts that join the organization or move into a covered OU inherit the effective policy.
- Treat *existing* organization accounts as Security Hub CSPM member accounts. This happens automatically for accounts that a declarative policy governs.
- Disassociate member accounts that belong to the organization. If a declarative policy governs a member account, the delegated administrator can't disassociate it. If you use central configuration, you can disassociate a member account only after designating it as self-managed. Alternatively, you can associate a configuration policy that disables Security Hub CSPM with specific centrally managed member accounts.

For a full list of actions that the delegated administrator can perform on member accounts, see Allowed actions by administrator and member accounts in Security Hub CSPM.

The topics in this section explain how to integrate Security Hub CSPM with AWS Organizations and how to manage Security Hub CSPM for accounts in an organization. Where relevant, each section identifies management benefits and differences for users of declarative policies and central configuration.

Topics

- Integrating Security Hub CSPM with AWS Organizations
- Managing accounts with declarative policies in Security Hub CSPM
- Automatically enabling Security Hub CSPM in new organization accounts
- Manually enabling Security Hub CSPM in new organization accounts
- Disassociating Security Hub CSPM member accounts from your organization

Integrating Security Hub CSPM with AWS Organizations

To integrate AWS Security Hub CSPM and AWS Organizations, you create an organization in Organizations and use the organization management account to designate a delegated Security Hub CSPM administrator account. This enables Security Hub CSPM as a trusted service in Organizations. It also enables Security Hub CSPM in the current AWS Region for the delegated administrator account, and it allows the delegated administrator to enable Security Hub CSPM for member accounts, view data in member accounts, and perform other allowed actions on member accounts.

If you use central configuration, then the delegated administrator can also create Security Hub CSPM configuration policies that specify how the Security Hub CSPM service, standards, and controls should be configured in organization accounts.

Creating an organization

An organization is an entity that you create to consolidate your AWS accounts so that you can administer them as a single unit.

You can create an organization by using either the AWS Organizations console or by using a command from the AWS CLI or one of the SDK APIs. For detailed instructions, see Create an organization in the *AWS Organizations User Guide*.

You can use AWS Organizations to centrally view and manage all of the accounts within your organization. An organization has one management account along with zero or more member accounts. You can organize the accounts in a hierarchical, tree-like structure with a root at the

top and organizational units (OUs) nested under the root. Each account can be directly under the root, or placed in one of the OUs in the hierarchy. An OU is a container for specific accounts. For example, you can create a finance OU that includes all accounts related to financial operations.

Recommendations for choosing the delegated Security Hub CSPM administrator

If you have an administrator account in place from the manual invitation process and are transitioning to account management with AWS Organizations, we recommend designating that account as the delegated Security Hub CSPM administrator.

Although the Security Hub CSPM APIs and console allow the organization management account to be the delegated Security Hub CSPM administrator, we recommend choosing two different accounts. This is because users who have access to the organization management account to manage billing are likely to be different from users who need access to Security Hub CSPM for security management.

We recommend using the same delegated administrator across Regions. If you opt in to central configuration, Security Hub CSPM automatically designates the same delegated administrator in your home Region and any linked Regions.

Verify permissions to configure the delegated administrator

To designate and remove a delegated Security Hub CSPM administrator account, the organization management account must have permissions for the `EnableOrganizationAdminAccount` and `DisableOrganizationAdminAccount` actions in Security Hub CSPM. The Organizations management account must also have administrative permissions for Organizations.

To grant all of the required permissions, attach the following Security Hub CSPM managed policies to the IAM principal for the organization management account:

- AWSSecurityHubFullAccess
- AWSSecurityHubOrganizationsAccess

Designating the delegated administrator

To designate the delegated Security Hub CSPM administrator account, you can use the Security Hub CSPM console, Security Hub CSPM API, or AWS CLI. Security Hub CSPM sets the delegated administrator in the current AWS Region only, and you must repeat the action in other Regions. If you start using central configuration, then Security Hub CSPM automatically sets the same delegated administrator in the home Region and linked Regions.

The organization management account doesn't have to enable Security Hub CSPM in order to designate the delegated Security Hub CSPM administrator account.

We recommend that the organization management account is not the delegated Security Hub CSPM administrator account. However, if you do choose the organization management account as the Security Hub CSPM delegated administrator, the management account must have Security Hub CSPM enabled. If the management account does not have Security Hub CSPM enabled, you must enable Security Hub CSPM for it manually. Security Hub CSPM can't be enabled automatically for the organization management account.

You must designate the delegated Security Hub CSPM administrator using one of the following methods. Designating the delegated Security Hub CSPM administrator with Organizations APIs doesn't reflect in Security Hub CSPM.

Choose your preferred method, and follow the steps to designate the delegated Security Hub CSPM administrator account.

Security Hub CSPM console

To designate the delegated administrator while onboarding

1. Open the AWS Security Hub CSPM console at https://console.aws.amazon.com/securityhub/.
2. Choose **Go to Security Hub CSPM**. You're prompted to sign in to the organization management account.
3. On the **Designate delegated administrator** page, in the **Delegated administrator account** section, specify the delegated administrator account. We recommend choosing the same delegated administrator that you have set for other AWS security and compliance services.
4. Choose **Set delegated administrator**. You're prompted to sign in to the delegated administrator account (if you're not already) to continue onboarding with central configuration. If you don't want to start central configuration, choose **Cancel**. Your delegated administrator is set, but you aren't yet using central configuration.

To designate the delegated administrator from the Settings page

1. Open the AWS Security Hub CSPM console at https://console.aws.amazon.com/securityhub/.
2. In the Security Hub CSPM navigation pane, choose **Settings**. Then choose **General**.

3. If a Security Hub CSPM administrator account is currently assigned, then before you can designate a new account, you must remove the current account.

   Under **Delegated Administrator**, to remove the current account, choose **Remove**.
4. Enter the account ID of the account you want to designate as the **Security Hub CSPM** administrator account.

   You must designate the same Security Hub CSPM administrator account in all Regions. If you designate an account that is different from the account designated in other Regions, the console returns an error.
5. Choose **Delegate**.

Security Hub CSPM API, AWS CLI

From the organization management account, use the EnableOrganizationAdminAccount operation of the Security Hub CSPM API. If you're using the AWS CLI, run the enable-organization-admin-account command. Provide the AWS account ID of the delegated Security Hub CSPM administrator.

The following example designates the delegated Security Hub CSPM administrator. This example is formatted for Linux, macOS, or Unix, and it uses the backslash (\) line-continuation character to improve readability.

```
$ aws securityhub enable-organization-admin-account --admin-account-id 123456789012
```

Removing or changing the delegated administrator

Only the organization management account can remove the delegated Security Hub CSPM administrator account.

To change the delegated Security Hub CSPM administrator, you must first remove the current delegated administrator account and then designate a new one.

> **Warning**
>
> When you use central configuration, you can't use the Security Hub CSPM console or Security Hub CSPM APIs to change or remove the delegated administrator account. If the organization management account uses the AWS Organizations console or AWS

Organizations APIs to change or remove the delegated Security Hub CSPM administrator, Security Hub CSPM automatically stops central configuration, and deletes your configuration policies and policy associations. Member accounts retain the configurations they had before the delegated administrator was changed or removed.

If you use the Security Hub CSPM console to remove the delegated administrator in one Region, it is automatically removed in all Regions.

The Security Hub CSPM API only removes the delegated Security Hub CSPM administrator account from the Region where the API call or command is issued. You must repeat the action in other Regions.

If you use the Organizations API to remove the delegated Security Hub CSPM administrator account, it is automatically removed in all Regions.

Removing the delegated administrator (Organizations API, AWS CLI)

You can use Organizations to remove the delegated Security Hub CSPM administrator in all Regions.

If you use central configuration to manage accounts, removing the delegated administrator account results in the deletion of your configuration policies and policy associations. Member accounts retain the configurations that they had before the delegated administrator was changed or removed. However, these accounts can't be managed by the removed delegated administrator account anymore. They become self-managed accounts that must be configured separately in each Region.

Choose your preferred method, and follow the instructions to remove the delegated Security Hub CSPM administrator account with AWS Organizations.

Organizations API, AWS CLI

To remove the delegated Security Hub CSPM administrator

From the organization management account, use the DeregisterDelegatedAdministrator operation of the Organizations API. If you're using the AWS CLI, run the deregister-delegated-administrator command. Provide the account ID of the delegated administrator, and the service principal for Security Hub CSPM, which is `securityhub.amazonaws.com`.

The following example removes the delegated Security Hub CSPM administrator. This example is formatted for Linux, macOS, or Unix, and it uses the backslash (\) line-continuation character to improve readability.

```
$ aws organizations deregister-delegated-administrator --account-id 123456789012 --
service-principal securityhub.amazonaws.com
```

Removing the delegated administrator (Security Hub CSPM console)

You can use the Security Hub CSPM console to remove the delegated Security Hub CSPM administrator in all Regions.

When the delegated Security Hub CSPM administrator account is removed, the member accounts are disassociated from the removed delegated Security Hub CSPM administrator account.

Security Hub CSPM is still enabled in the member accounts. They become standalone accounts until a new Security Hub CSPM administrator enables them as member accounts.

If the organization management account isn't an enabled account in Security Hub CSPM, then use the option on the **Welcome to Security Hub CSPM** page.

To remove the delegated Security Hub CSPM administrator account from the Welcome to Security Hub CSPM page

1. Open the AWS Security Hub CSPM console at https://console.aws.amazon.com/securityhub/.
2. Choose **Go to Security Hub**.
3. Under **Delegated Administrator**, choose **Remove**.

If the organization management account is an enabled account in **Security Hub**, then use the option on the **General** tab of the **Settings** page.

To remove the delegated Security Hub CSPM administrator account from the Settings page

1. Open the AWS Security Hub CSPM console at https://console.aws.amazon.com/securityhub/.
2. In the Security Hub CSPM navigation pane, choose **Settings**. Then choose **General**.
3. Under **Delegated Administrator**, choose **Remove**.

Removing the delegated administrator (Security Hub CSPM API, AWS CLI)

You can use the Security Hub CSPM API or Security Hub CSPM operations for the AWS CLI to remove the delegated Security Hub CSPM administrator. When you remove the delegated administrator with one of these methods, it is only removed in the Region where the API call or command was issued. Security Hub CSPM doesn't update other Regions, and it doesn't remove the delegated administrator account in AWS Organizations.

Choose your preferred method, and follow these steps to remove the delegated Security Hub CSPM administrator account with Security Hub CSPM.

Security Hub CSPM API, AWS CLI

To remove the delegated Security Hub CSPM administrator

From the organization management account, use the DisableOrganizationAdminAccount operation of the Security Hub CSPM API. If you're using the AWS CLI, run the disable-organization-admin-account command. Provide the account ID of the delegated Security Hub CSPM administrator.

The following example removes the delegated Security Hub CSPM administrator. This example is formatted for Linux, macOS, or Unix, and it uses the backslash (\) line-continuation character to improve readability.

```
$ aws securityhub disable-organization-admin-account --admin-account-id 123456789012
```

Disabling Security Hub CSPM integration with AWS Organizations

After an AWS Organizations organization is integrated with AWS Security Hub CSPM, the Organizations management account can subsequently disable the integration. As a user of the Organizations management account, you can do this by disabling trusted access for Security Hub CSPM in AWS Organizations.

When you disable trusted access for Security Hub CSPM, the following occurs:

- Security Hub CSPM loses its status as a trusted service in AWS Organizations.
- The Security Hub CSPM delegated administrator account loses access to Security Hub CSPM settings, data, and resources for all Security Hub CSPM member accounts in all AWS Regions.

- If you were using central configuration, Security Hub CSPM automatically stops using it for your organization. Your configuration policies and policy associations are deleted. Accounts retain the configurations that they had before you disabled trusted access.
- All Security Hub CSPM member accounts become standalone accounts and retain their current settings. If Security Hub CSPM was enabled for a member account in one or more Regions, Security Hub CSPM continues to be enabled for the account in those Regions. Enabled standards and controls are also unchanged. You can change these settings separately in each account and Region. However, the account is no longer associated with a delegated administrator in any Region.

For additional information about the results of disabling trusted service access, see Using AWS Organizations with other AWS services in the *AWS Organizations User Guide*.

To disable trusted access, you can use the AWS Organizations console, Organizations API, or the AWS CLI. Only a user of the Organizations management account can disable trusted service access for Security Hub CSPM. For details about the permissions that you need, see Permissions required to disable trusted access in the *AWS Organizations User Guide*.

Before you disable trusted access, we recommend working with the delegated administrator for your organization to disable Security Hub CSPM in member accounts and to clean up Security Hub CSPM resources in those accounts.

Choose your preferred method, and follow the steps to disable trusted access for Security Hub CSPM.

Organizations console

To disable trusted access for Security Hub CSPM

1. Sign in to the AWS Management Console using the credentials of the AWS Organizations management account.
2. Open the Organizations console at https://console.aws.amazon.com/organizations/.
3. In the navigation pane, choose **Services**.
4. Under **Integrated services**, choose **AWS Security Hub CSPM**.
5. Choose **Disable trusted access**.
6. Confirm that you want to disable trusted access.

Organizations API

To disable trusted access for Security Hub CSPM

Invoke the DisableAWSServiceAccess operation of the AWS Organizations API. For the `ServicePrincipal` parameter, specify the Security Hub CSPM service principal (`securityhub.amazonaws.com`).

AWS CLI

To disable trusted access for Security Hub CSPM

Run the disable-aws-service-access command of the AWS Organizations API. For the `service-principal` parameter, specify the Security Hub CSPM service principal (`securityhub.amazonaws.com`).

Example:

```
aws organizations disable-aws-service-access --service-principal
 securityhub.amazonaws.com
```

Managing accounts with declarative policies in Security Hub CSPM

With an AWS Security Hub CSPM declarative policy, you can centrally enable and configure Security Hub CSPM across the accounts in your organization. You use an AWS Organizations declarative policy to specify where Security Hub CSPM is enabled or disabled in each AWS Region. You can target the organization root, organizational units (OUs), or individual accounts. You also specify the standards, controls, and control parameters that apply. Accounts that join the organization, or move into an OU that has an attached declarative policy, inherit the declarative policy. Security Hub CSPM then configures them according to their effective declarative policy.

Security Hub CSPM declarative policies replace central configuration as the recommended way to manage Security Hub CSPM across an organization. The two mechanisms are mutually exclusive. When you attach your first declarative policy, Security Hub CSPM disables central configuration for the entire organization. For more information about declarative policy structure, inheritance, validation, and example declarative policies, see Security Hub CSPM policies in the *AWS Organizations User Guide*.

Prerequisites

Before you use Security Hub CSPM declarative policies, complete the following prerequisites:

1. Enable trusted access for Security Hub CSPM in AWS Organizations.
2. (Optional) Designate a delegated Security Hub CSPM administrator account. Security Hub CSPM requires a delegated administrator to automatically associate governed accounts as members.
3. Attach the delegation policy that grants the delegated administrator permission to manage Security Hub CSPM declarative policies.
4. Make sure that the `AWSServiceRoleForSecurityHub` service-linked role exists in the organization's management account.
5. Enable the `SECURITYHUB_CSPM_POLICY` policy type on the organization root. For instructions, see Enabling a policy type in the *AWS Organizations User Guide*. If you create your first declarative policy in the Security Hub console, the console enables the policy type for you.

> **Warning**
>
> If you use central configuration, attaching a Security Hub CSPM declarative policy to any target, even a single account, disables central configuration for the entire organization. Accounts that central configuration governed but that the new declarative policy doesn't cover become self-managed. To move your existing configuration without coverage gaps, use the import tool described in Declarative policies and central configuration in Security Hub CSPM.

For instructions on completing these prerequisites, see Getting started with Security Hub CSPM policies in the *AWS Organizations User Guide*.

How declarative policies work in Security Hub CSPM

An AWS Security Hub CSPM declarative policy determines where Security Hub CSPM is enabled, by account and AWS Region. It also determines which standards and controls are enabled and which control parameter values apply. The following sections describe how a declarative policy applies across Regions, how it's inherited, and how it changes Security Hub CSPM account management after you attach it. They also provide common use cases.

Regional configuration

A Security Hub CSPM declarative policy sets configuration per Region in two parts:

- **Enablement.** The declarative policy lists the Regions where Security Hub CSPM is enabled and the Regions where it is disabled. If a Region is in both lists, Security Hub CSPM is disabled there.

You can use `ALL_SUPPORTED` to include all current and future Regions. A Region in neither list is ungoverned, and the declarative policy doesn't change Security Hub CSPM in that Region.

- **Standards and controls.** In each Region where the declarative policy enables Security Hub CSPM, a default configuration sets the enabled standards, control statuses, and custom control parameters. You can add a Regional override to give a specific Region a different configuration.

A Regional override fully replaces the default configuration for that Region. It doesn't merge with the default, so you must specify every standard, control setting, and parameter that you want in that Region. As a result, the standards and controls that a declarative policy enables can differ from one Region to the next.

A declarative policy applies standards and controls only in Regions where they're available. If a declarative policy enables a standard or control in a Region where it isn't available, Security Hub CSPM skips it in that Region without an error. Before you configure a declarative policy, review Regional limits for Security Hub CSPM.

Declarative policies don't have a home Region. Controls that evaluate global resources generate findings in every Region where they're enabled. To evaluate global resources once, enable those controls in a single Region by using a Regional override. For an example, see Security Hub CSPM policy syntax and examples in the *AWS Organizations User Guide*.

For more information about the declarative policy structure and how Regions are resolved, see Security Hub CSPM policies in the *AWS Organizations User Guide*.

Declarative policy inheritance and precedence

Security Hub CSPM declarative policies follow the AWS Organizations inheritance model. A declarative policy attached at the organization root applies to every account in the organization. Accounts also inherit any declarative policy attached to a parent OU. When more than one applies to an account, Organizations merges them into a single effective declarative policy. The one attached closest to the account takes precedence over those attached higher in the hierarchy, unless a parent declarative policy restricts the inheritance operators that child declarative policies can use.

Within the effective declarative policy, a disabled setting takes precedence over an enabled setting at the same level. A Region in both Region lists is disabled, and a control in both `enabled_controls` and `disabled_controls` is disabled.

For more information about inheritance rules, see Understanding declarative policy inheritance in the *AWS Organizations User Guide*.

How a declarative policy affects Security Hub CSPM account management

When a Security Hub CSPM declarative policy governs an account in a Region, the following changes apply:

- The declarative policy governs Security Hub CSPM completely in that Region. Security Hub CSPM enablement, standards, control statuses, custom control parameters, and the setting that automatically enables new controls all come from the declarative policy.
- The account can't change these settings through the Security Hub CSPM console or API. For example, Security Hub CSPM denies calls to EnableSecurityHub, DisableSecurityHub, BatchEnableStandards, BatchDisableStandards, UpdateStandardsControl, BatchUpdateStandardsControlAssociations, UpdateSecurityControl, and UpdateSecurityHubConfiguration from governed accounts and Regions. To change a governed setting, update the declarative policy.
- The delegated administrator can't disassociate a governed account from its administrator.
- Accounts and Regions that no declarative policy governs remain self-managed. You can change their settings through the console and API.
- Central configuration is disabled for the entire organization. For more information, see Declarative policies and central configuration in Security Hub CSPM.

> **Note**
>
> Attaching a Security Hub CSPM declarative policy can enable Security Hub CSPM, standards, and controls across many accounts and Regions in your organization. Enabling Security Hub CSPM and its controls incurs charges, including charges for AWS Config rule evaluations. For more information, see AWS Security Hub pricing.

Automatic administrator and member account management

Security Hub CSPM uses administrator and member account associations to give a delegated administrator visibility into member accounts' findings. These associations are Regional. When a declarative policy governs an account, Security Hub CSPM aligns these associations with your

organization, in the same way that central configuration does. You don't need to send or accept invitations.

When a declarative policy enables Security Hub CSPM in a Region, Security Hub CSPM manages associations as follows:

- **Delegated administrator designation.** If your organization has a Security Hub CSPM delegated administrator, Security Hub CSPM designates that account as the Security Hub CSPM administrator in the Region. This happens only if no other administrator is designated in that Region and no declarative policy disables Security Hub CSPM for the delegated administrator in that Region.
- **Member associations.** Security Hub CSPM associates each governed account as a member of the Region's administrator account. Security Hub CSPM doesn't associate the administrator account with itself.
- **Invitation-based associations.** If a governed account is a member of an administrator through an invitation, Security Hub CSPM removes that association and associates the account with the delegated administrator instead. If a governed account is itself an invitation-based administrator, Security Hub CSPM first disassociates its member accounts.

When a declarative policy disables Security Hub CSPM in a Region, Security Hub CSPM must first remove administrator and member associations, because you typically can't disable Security Hub CSPM in an account that has them. When you attach a declarative policy that disables Security Hub CSPM to an organization target, Security Hub CSPM removes the associations as follows:

- For a member account, Security Hub CSPM disassociates the account from its administrator.
- For an administrator account, including an invitation-based administrator, Security Hub CSPM disassociates all of its member accounts.
- For the delegated administrator, Security Hub CSPM also removes its administrator designation in that Region. The delegated administrator designation in Organizations doesn't change.

Important

Security Hub CSPM doesn't restore invitation-based associations that it removes. If you need them again, you must re-create them manually. Before you attach a declarative policy that disables Security Hub CSPM, review which accounts are administrators or members.

For more information, see Reviewing a declarative policy's impact before you apply it in Security Hub CSPM.

Security Hub CSPM manages these associations on a best-effort basis and repairs missing associations over time. If your organization has no Security Hub CSPM delegated administrator, Security Hub CSPM still applies the declarative policy but doesn't create associations. Security Hub CSPM records administrator designation changes as AWS CloudTrail events in your account.

A declarative policy doesn't manage cross-Region aggregation. To view findings from multiple Regions in one Region, configure cross-Region aggregation from the delegated administrator account.

Example use cases

The following examples show common ways to use a Security Hub CSPM declarative policy. For the declarative policy JSON that implements each pattern, see Security Hub CSPM policy syntax and examples in the *AWS Organizations User Guide*.

- **Enable a security baseline across the entire organization.** Attach a declarative policy at the organization root that enables Security Hub CSPM in all Regions and enables the standards you require. Security Hub CSPM automatically configures every account, including accounts that join later, and associates it with the delegated administrator.
- **Vary configuration by organizational unit.** Use a broad declarative policy at the root for your baseline. Then attach more specific declarative policies to individual OUs to add standards or adjust controls for accounts that have different compliance or workload requirements.
- **Vary configuration by Region.** Use Regional overrides to enable additional standards in Regions with specific compliance requirements, or to evaluate global resources in only one Region.
- **Maintain coverage as your organization grows.** Accounts that join the organization or move into a covered OU inherit the effective declarative policy, so new accounts match your baseline without manual setup.

Declarative policies and central configuration in Security Hub CSPM

With both AWS Security Hub CSPM declarative policies and Security Hub CSPM central configuration, a delegated administrator can configure Security Hub CSPM across an organization. The two mechanisms are mutually exclusive, so they can't apply conflicting configurations to the

same accounts. Declarative policies are the recommended mechanism. This topic describes how the two interact and how to move from central configuration to declarative policies.

How mutual exclusivity works

When a Security Hub CSPM declarative policy first governs an account in your organization, Security Hub CSPM disables central configuration for the entire organization. This happens even if the declarative policy governs only a single account. If you attach a declarative policy to an organizational unit (OU) that doesn't contain any accounts, central configuration remains enabled. When central configuration is disabled:

- The organization configuration status, returned by DescribeOrganizationConfiguration, is `DISABLED`, with a message that indicates that declarative policies are in use.
- Your configuration policies and policy associations aren't deleted. Each association shows an `AssociationStatus` of `DISABLED` and is no longer applied.
- Declarative policies configure the accounts that they govern.
- Accounts that central configuration governed but that no declarative policy covers keep their current settings and become self-managed.
- Security Hub CSPM records the change to central configuration as an AWS CloudTrail event.

> **Warning**
>
> Because the change applies to the entire organization, attaching a narrow declarative policy, such as a test declarative policy on one account, replaces all of your central configuration governance. To move your full configuration without coverage gaps, use the import tool.

Central configuration API behavior while disabled

While central configuration is disabled, the following API behavior applies:

API operations	Behavior
`CreateConfigurationPolicy` , `UpdateConfigurationPolicy` ,	Denied with an error that states that central configuration is disabled.

API operations	Behavior
`StartConfigurationPolicyAssociation`	
`GetConfigurationPolicy` , `ListConfigurationPolicies` , `GetConfigurationPolicyAssociation` , `BatchGetConfigurationPolicyAssociations` , `ListConfigurationPolicyAssociations`	Allowed. Associations return `DISABLED`.
`DeleteConfigurationPolicy` , `StartConfigurationPolicyDisassociation`	Allowed, so that you can clean up central configuration resources.
`UpdateFindingAggregator`	Allowed, so that you can adjust cross-Region aggregation.
`UpdateOrganizationConfiguration` with `ConfigurationType` set to `CENTRAL`	Denied with a `ConflictException` while any Security Hub CSPM declarative policy is attached in the organization.
Security Hub CSPM APIs for self-managed accounts	Not restricted by the central configuration status.

Migrating your central configuration policies to AWS Organizations declarative policies by using the import tool

The Security Hub console provides an import tool that converts your central configuration setup to equivalent Security Hub CSPM declarative policies. Only the delegated administrator can use the tool. The tool is available only in the console and only while central configuration is enabled.

The import tool does the following:

- Shows your current configuration policies and associations, and previews the equivalent Security Hub CSPM declarative policies.
- Asks you to acknowledge that the resulting declarative policies become the source of truth for governed accounts and can overwrite existing member settings.

- Creates a Security Hub CSPM declarative policy for each configuration policy, with the same description and tags. Each declarative policy name uses the format *ID_original-policy-name*, where *ID* is the central configuration policy ID and *original-policy-name* is the name of the central configuration policy. The maximum length of a declarative policy name is 128 characters, so the tool might truncate the name of your central configuration policy to fit this limit. If a declarative policy with that name exists, the tool overwrites it.
- Attaches each declarative policy to the same targets as the original association. If a target is ungoverned, the tool attaches an ungoverned (empty) policy to that target. The tool also detaches Security Hub CSPM declarative policies from targets that your central configuration doesn't cover.
- Preserves protections that central configuration provides. Central configuration doesn't disable Security Hub CSPM in the delegated administrator account, and it doesn't apply to invitation-based administrator accounts. Declarative policies don't make these exceptions, so the tool attaches a declarative policy that governs no Regions to these accounts. As a result, these accounts become self-managed.
- Translates home Region behavior for controls that apply to global resources. If a central configuration policy enables controls for global resources, the tool enables those controls only in your Security Hub CSPM home Region. The tool expresses this behavior with Regional overrides, and in the declarative policy's default configuration, it disables all controls for global resources that belong to your enabled standards.

To migrate your central configuration policies to Security Hub CSPM declarative policies, use the import tool in the Security Hub console.

To migrate central configuration policies by using the console

1. Sign in using your AWS account with your delegated administrator credentials. Open the Security Hub console at https://console.aws.amazon.com/securityhub/v2/home.
2. From the navigation pane, choose **Management**, and then choose **Configurations**.
3. In the **Import your Central Configuration policies** banner, choose **Import**. If the banner isn't shown, you don't have central configuration policies to import, and you can start using Security Hub CSPM declarative policies.
4. On the **Before you begin** page, review **What happens during import**. Under **Prerequisites**, confirm that all prerequisites are met. If a prerequisite isn't met, resolve the issue before you continue. Then, choose **Next**.

5. On the **Review existing policies** page, review the **Target Regions** and the central configuration policies that the tool will import. Then, choose **Next**.
6. On the **Review import plan** page, review the ungoverned policy assignments, the new declarative policy that applies to your home Region for each central configuration policy, and the post-import state. Then, select **I have reviewed the import plan**, and choose **Import**.

   After you choose **Import**, a progress banner at the top of the page shows the status of the import. Keep the console page open until the import completes. When the import completes, the banner shows the results, including any errors.

Until the import is complete, you can't create or edit Security Hub CSPM policies in the Security Hub console. You can view policies that the import tool has already created or attached.

For large organizations, the import can take several minutes because the tool attaches many declarative policies. Keep the console page open until the import completes. If you leave the page or your session expires, your declarative policy coverage can be smaller than your central configuration coverage was. In that case, the console prompts you to run the import again from the beginning.

After a successful import, the delegated administrator is self-managed if no central configuration policy is applied to it or if it inherits a policy where central configuration is disabled. All other accounts have the same configuration that central configuration applies.

If central configuration is disabled and your import isn't complete, Security Hub CSPM sends an AWS Health notification to the delegated administrator. To resolve the issue, run the import tool again or return to central configuration.

If you attach Security Hub CSPM declarative policies through the Organizations console, the AWS CLI, or an API before you run the import tool, the Security Hub console continues to show an import alert until you complete the import. We recommend that you use the import tool to implement declarative policies.

Consider the following after you migrate:

- Declarative policies and cross-Region aggregation are configured independently. If a declarative policy enables Security Hub CSPM in a Region that isn't a linked Region in your cross-Region aggregation for Security Hub, the delegated administrator doesn't see findings from that Region. To see those findings, update your cross-Region aggregation configuration to include the Region.

After central configuration is disabled, adding a linked Region to cross-Region aggregation doesn't enable Security Hub CSPM in that Region. For example, suppose that your declarative policies govern Regions A, B, and C after you migrate. If you later add Region D to cross-Region aggregation, you must also update your declarative policies to include Region D.

- When a declarative policy governs a member account that isn't the delegated administrator for Security Hub CSPM, Security Hub CSPM removes any invitation-based administrator-member associations for that account and associates the member account with the delegated administrator. To restore the associations, revert the member account to self-managed, disassociate it from the delegated administrator, and then invite its members again.
- If a declarative policy disables Security Hub CSPM in an account that's an invitation-based member, Security Hub CSPM removes the account's association with its administrator. To restore the association, enable Security Hub CSPM in the account and invite it again.

Return to using central configuration over declarative policies

To return to central configuration, do the following:

1. Detach every Security Hub CSPM declarative policy from every target in your organization. You can do this from the AWS Organizations console or APIs. For more information, see Detaching organization policies with AWS Organizations in the *AWS Organizations User Guide*.
2. From the delegated administrator account, in your home Region, call UpdateOrganizationConfiguration with `ConfigurationType` set to `CENTRAL`, or turn on central configuration in the console.

When central configuration is enabled again, Security Hub CSPM reapplies your previous configuration policy associations. Each association moves from `DISABLED` to `PENDING`, and then to `SUCCESS` or `FAILED`. Allow time for your configuration to converge.

While central configuration is disabled, Security Hub CSPM doesn't create inherited associations for accounts that joined the organization or moved between OUs. Security Hub CSPM creates those associations after you return to central configuration. If you returned after using the import tool, you must run the import again to move back to declarative policies.

To turn off central configuration without moving to declarative policies, see Disabling central configuration in Security Hub CSPM.

Creating a Security Hub CSPM declarative policy in the console

You create and manage Security Hub CSPM declarative policies from the delegated administrator account in the Security Hub console. Creating your first declarative policy also enables the `SECURITYHUB_CSPM_POLICY` policy type for your organization. If your organization uses central configuration, the console directs you to the import tool instead. For more information, see Declarative policies and central configuration in Security Hub CSPM.

You can also create Security Hub CSPM declarative policies by using the Organizations console, the AWS CLI, or the AWS SDKs. For more information, see Getting started with Security Hub CSPM policies in the *AWS Organizations User Guide*.

To create a Security Hub CSPM declarative policy

1. Sign in to the AWS Management Console by using the delegated administrator account. Then open the Security Hub console at https://console.aws.amazon.com/securityhub/v2.
2. In the navigation pane, choose **Management**, and then choose **Configurations**.
3. In the **Configuration catalog**, choose **Posture management from AWS Security Hub CSPM**.
4. In the **Details** section, enter a name and an optional description for the declarative policy.
5. In the **Account selection** section, choose one of the following options:
   - **All organizational units and accounts** attaches the declarative policy to the organization root.
   - **Specific organizational units and accounts** attaches the declarative policy to the entities you select.
   - **No organizational units or accounts** creates the declarative policy without attaching it.
6. In the **Regions** section, choose the Regions where you want to enable Security Hub CSPM and the Regions where you want to disable it. To include new Regions automatically, select the option to include them. Regions that you don't select remain ungoverned.
7. In the **Standards** section, select the standards to enable. Standards that you don't select are disabled in governed Regions.
8. In the **Controls** section, choose whether controls in the selected standards are enabled or disabled by default, and then select any controls that are exceptions to that default.
9. (Optional) In the **Control parameters** section, customize parameter values for specific controls. Parameters that you don't customize use their default values.

10. (Optional) Choose **Add Regional override**, select one or more Regions, and set the standards, controls, and parameters for those Regions. A Regional override fully replaces the default configuration for the Region.
11. (Optional) Under **Advanced settings**, choose the inheritance operators that child declarative policies can use. For more information, see Inheritance operators in the *AWS Organizations User Guide*.
12. (Optional) For **Resource tags**, add tags as key-value pairs.
13. Choose **Next**.
14. Review the declarative policy details, accounts, Regions, and configuration. To see the generated JSON, expand **Policy document**. Then choose **Create policy**.

You can review or edit the generated JSON at any step by expanding **Policy document**. For the declarative policy structure, inheritance rules, and example declarative policies, see Security Hub CSPM policy syntax and examples in the *AWS Organizations User Guide*.

Reviewing a declarative policy's impact before you apply it in Security Hub CSPM

Before you save a declarative policy change, review the current AWS Security Hub CSPM configuration in the accounts and AWS Regions that the change affects. Because a Security Hub CSPM declarative policy governs configuration completely in each Region, it can disable standards and controls that the declarative policy doesn't list. Check the current state for each account and Region.

> **Warning**
>
> A declarative policy completely governs Security Hub CSPM, standards, controls, and control parameters in each Region where it enables Security Hub CSPM. Standards that the declarative policy doesn't list are disabled, and parameters that it doesn't specify are reset to their default values. A declarative policy that disables Security Hub CSPM also removes administrator and member associations, including invitation-based associations that Security Hub CSPM doesn't restore. Governed accounts can't change these settings back through the console or API. Before you create or update a declarative policy, identify the accounts and Regions that the change affects and confirm that the impact is intended.

As the delegated administrator, you can review the current configuration of member accounts in the Security Hub CSPM console or programmatically. In the console, switch Regions to review each

Region. To review the configuration programmatically, complete the following steps. Perform the Security Hub CSPM API steps in each Region that you want to review.

To identify the accounts and Regions that a declarative policy affects

1. **Enumerate the accounts in your organization.** Use the AWS Organizations ListAccounts API operation to list every account, including accounts that aren't yet Security Hub CSPM members.
2. **Enumerate your Security Hub CSPM member accounts.** Use the Security Hub CSPM ListMembers API operation to list the member accounts of the delegated administrator and their `MemberStatus`.
3. **Identify administrator accounts.** For accounts in scope, use GetAdministratorAccount to find accounts that are members of an administrator other than the delegated administrator. Then use `ListMembers` to find accounts that have their own members. Security Hub CSPM replaces or removes these associations when it applies a declarative policy.
4. **Review current central configuration governance.** If you use central configuration, use ListConfigurationPolicyAssociations to see which configuration policy applies to each account. Attaching a Security Hub CSPM declarative policy disables all of these associations.
5. **Review the current standards and controls.** In the accounts you plan to cover, use GetEnabledStandards, ListStandardsControlAssociations, and BatchGetSecurityControls to see which standards and controls are enabled and which control parameters are customized.
6. **Compare the configurations.** Compare the current configuration with the effective configuration that your declarative policy defines. This identifies the accounts and Regions that the change affects.

After you create and attach a declarative policy, confirm the effective policy for a specific account. The effective declarative policy combines the policies that the account inherits with those attached directly to the account. To view it, use the Organizations DescribeEffectivePolicy API operation, or its AWS CLI or AWS SDK equivalent, with the `SECURITYHUB_CSPM_POLICY` policy type. Any account with permission to call this operation can use it, including the delegated administrator. For more information, see Viewing effective declarative policies in the *AWS Organizations User Guide*.

Considerations and limitations for declarative policies in Security Hub CSPM

Keep the following in mind when you plan and manage AWS Security Hub CSPM declarative policies:

- **A declarative policy applies only to accounts in AWS Organizations.** A declarative policy can manage Security Hub CSPM only in accounts that belong to your organization. It can't manage accounts that are associated only by invitation. Manage Security Hub CSPM in those accounts from their administrator account or in each account.
- **A declarative policy governs configuration completely.** In each AWS Region where a declarative policy enables Security Hub CSPM, the declarative policy governs enablement, standards, control status, custom control parameters, and the automatic enablement of new controls. Standards that the declarative policy doesn't list are disabled, and parameters that it doesn't specify use their default values. A declarative policy can't govern only some of these settings.
- **Governed settings are read-only in the console and API.** Governed accounts can't change these settings through the Security Hub CSPM console or API. To change them, update the declarative policy. Accounts and Regions that no declarative policy governs remain editable.
- **An ungoverned Region is left unchanged, not disabled.** A Region that appears in neither `enable_in_regions` nor `disable_in_regions` is ungoverned. The declarative policy doesn't enable or disable Security Hub CSPM there, and existing settings don't change.
- **Declarative policies and central configuration are mutually exclusive.** Attaching the first Security Hub CSPM declarative policy to any target disables central configuration for the entire organization. You can't turn central configuration back on until you detach every Security Hub CSPM declarative policy. For more information, see Declarative policies and central configuration in Security Hub CSPM.
- **A declarative policy manages administrator and member associations.** When a declarative policy enables Security Hub CSPM, Security Hub CSPM designates the delegated administrator as the administrator in the Region and associates governed accounts as members, on a best-effort basis. Security Hub CSPM replaces invitation-based associations for governed accounts. Automatic associations require a Security Hub CSPM delegated administrator. An administrator account can have up to 10,000 member accounts in each Region.
- **Disabling Security Hub CSPM removes associations, including for administrators.** A declarative policy that disables Security Hub CSPM removes the account's administrator and member associations. For the delegated administrator, it also removes the Regional administrator designation. Security Hub CSPM doesn't restore invitation-based associations that it removes.
- **The delegated administrator needs the AWS Organizations delegation policy to manage declarative policies.** A delegated administrator can manage Security Hub CSPM members. It can't create, update, or attach Security Hub CSPM declarative policies unless the delegation policy grants it permission to manage the `SECURITYHUB_CSPM_POLICY` policy type.

- **A declarative policy can enable Security Hub CSPM in the management account only if the service-linked role already exists there.** If the `AWSServiceRoleForSecurityHub` role doesn't exist in the management account, Security Hub CSPM isn't enabled there, even if the declarative policy enables it. Create the role first. For more information, see Service-linked roles for AWS Security Hub CSPM.
- **A declarative policy doesn't configure AWS Config.** Security Hub CSPM uses AWS Config rules to evaluate most controls. Enable AWS Config and record the required resources in governed accounts and Regions separately. For more information, see Enabling and configuring AWS Config for Security Hub CSPM.
- **A declarative policy doesn't manage other Security Hub CSPM settings.** A declarative policy doesn't manage cross-Region aggregation, automation rules, custom insights, or product integrations. Configure these separately.
- **Some standards aren't supported.** A declarative policy can't configure multicloud standards or service-managed standards, such as Service-Managed Standard: AWS Control Tower.
- **Declarative policies don't have a home Region.** To evaluate controls for global resources in only one Region, use a Regional override.
- **Controls without an enabled standard use a service-managed standard.** If an effective declarative policy enables a control without enabling a standard that contains it, Security Hub CSPM enables the control through Service-Managed Standard: AWS Organizations. While the account is governed, you can't disable this standard.
- **Deprecated controls are ignored.** If a declarative policy references a deprecated control, Security Hub CSPM skips that control.
- **Declarative policy changes apply asynchronously.** A declarative policy change propagates across your organization, and Security Hub CSPM reconciles it over time. Security Hub CSPM also periodically corrects drift, such as a newly released control that hasn't yet been configured. Allow time for a change to apply before you conclude that it didn't take effect.
- **Detaching a declarative policy doesn't disable Security Hub CSPM.** When you detach a declarative policy from an entity, declarative policies inherited from parent entities can still apply. If no effective declarative policy remains, Security Hub CSPM, its standards, and its controls stay in their current state, and the account becomes self-managed. Future organization changes no longer configure Security Hub CSPM automatically unless an inherited declarative policy still covers them.
- **Disabling the policy type turns off all Security Hub CSPM declarative policies.** Disabling Security Hub CSPM in a declarative policy, detaching one, and disabling the `SECURITYHUB_CSPM_POLICY` policy type are three different actions. When you disable the

policy type on the organization root, Security Hub CSPM declarative policies no longer govern any account. In previously governed accounts, Security Hub CSPM stays in its current state.

- **Availability.** Security Hub CSPM declarative policies are available in the AWS commercial, AWS GovCloud (US), and China Regions.

Automatically enabling Security Hub CSPM in new organization accounts

When new accounts join your organization, they are added to the list on the **Accounts** page of the AWS Security Hub CSPM console. For organization accounts, **Type** is **By organization**. By default, new accounts don't become Security Hub CSPM members when they join the organization. Their status is **Not a member**. The delegated administrator account can automatically add new accounts as members and enable Security Hub CSPM in these accounts when they join the organization.

> **Note**
>
> Although many AWS Regions are active by default for your AWS account, you must activate certain Regions manually. These Regions are called opt-in Regions in this document. To automatically enable Security Hub CSPM in a new account in an opt-in Region, the account must have that Region activated first. Only the account owner can activate the opt-in Region. For more information about opt-in Regions, see Specify which AWS Regions your account can use.

If a declarative policy governs an account, Security Hub CSPM is enabled in the account and the account is associated as a member, according to the account's effective policy. This also applies to accounts that join the organization later. For more information, see How declarative policies work in Security Hub CSPM. For accounts that no declarative policy governs, the process is different based on whether you use central configuration or local configuration.

Automatically enabling new organization accounts (central configuration)

If you use central configuration, you can automatically enable Security Hub CSPM in new and existing organization accounts by creating a configuration policy in which Security Hub CSPM is enabled. You can then associate the policy with the organization root or specific organizational units (OUs).

If you associate a configuration policy in which Security Hub CSPM is enabled with a specific OU, Security Hub CSPM is automatically enabled in all accounts (existing and new) that belong to that

OU. New accounts that don't belong to the OU are self-managed and don't automatically have Security Hub CSPM enabled. If you associate a configuration policy in which Security Hub CSPM is enabled with the root, Security Hub CSPM is automatically enabled in all accounts (existing and new) that join the organization. The exceptions are if an account uses a different policy through application or inheritance, or is self-managed.

In your configuration policy, you can also define which security standards and controls should be enabled in the OU. To generate control findings for enabled standards, the accounts in the OU must have AWS Config enabled and configured to record required resources. For more information about AWS Config recording, see Enabling and configuring AWS Config.

For instructions on creating a configuration policy, see Creating and associating configuration policies.

Automatically enabling new organization accounts (local configuration)

When you use local configuration and turn on automatic enablement of default standards, Security Hub CSPM adds *new* organization accounts as members and enables Security Hub CSPM in them in the current Region. Other Regions aren't affected. In addition, turning on automatic enablement doesn't enable Security Hub CSPM in *existing* organization accounts unless they were already added as member accounts.

After turning on automatic enablement, default security standards are enabled for new member accounts in the current Region when they join the organization. The default standards are AWS Foundational Security Best Practices (FSBP) and Center for Internet Security (CIS) AWS Foundations Benchmark v1.2.0. You can't change the default standards. If you want to enable other standards throughout your organization, or enable standards for select accounts and OUs, we recommend using declarative policies.

To generate control findings for the default standards (and other enabled standards), accounts in your organization must have AWS Config enabled and configured to record required resources. For more information about AWS Config recording, see Enabling and configuring AWS Config.

Choose your preferred method, and follow the steps to automatically enable Security Hub CSPM in new organization accounts. These instructions apply only if you use local configuration.

Security Hub CSPM console

To automatically enable new organization accounts as Security Hub CSPM members

1. Open the AWS Security Hub CSPM console at https://console.aws.amazon.com/securityhub/.

   Sign is using the credentials of the delegated administrator account.
2. In the Security Hub CSPM navigation pane, under **Settings**, choose **Configuration**.
3. In the **Accounts** section, turn on **Auto-enable accounts**.

Security Hub CSPM API

To automatically enable new organization accounts as Security Hub CSPM members

Invoke the `UpdateOrganizationConfiguration` API from the delegated administrator account. Set the `AutoEnable` field to `true` to automatically enable Security Hub CSPM in new organization accounts.

AWS CLI

To automatically enable new organization accounts as Security Hub CSPM members

Run the `update-organization-configuration` command from the delegated administrator account. Include the `auto-enable` parameter to automatically enable Security Hub CSPM in new organization accounts.

```
aws securityhub update-organization-configuration --auto-enable
```

Manually enabling Security Hub CSPM in new organization accounts

If you don't automatically enable Security Hub CSPM in new organization accounts when they join the organization, then you can add those accounts as members and enable Security Hub CSPM in them manually after they join the organization. You must also manually enable Security Hub CSPM in AWS accounts that you previously disassociated from an organization.

> **Note**
>
> This section doesn't apply to you if you use central configuration. If you use central configuration, you can create configuration policies that enable Security Hub CSPM in

specified member accounts and organizational units (OUs). You can also enable specific standards and controls in those accounts and OUs.

You can't enable Security Hub CSPM in an account if it is already a member account within a different organization.

You also can't enable Security Hub CSPM in an account that is currently suspended. If you try to enable the service in a suspended account, the account status changes to **Account Suspended**.

- If the account doesn't have Security Hub CSPM enabled, Security Hub CSPM is enabled in that account. The AWS Foundational Security Best Practices (FSBP) standard and CIS AWS Foundations Benchmark v1.2.0 also are enabled in the account unless your turn off default security standards.

  The exception to this is the Organizations management account. Security Hub CSPM cannot be enabled automatically in the Organizations management account. You must manually enable Security Hub CSPM in the Organizations management account before you can add it as a member account.
- If the account already has Security Hub CSPM enabled, Security Hub CSPM doesn't make any other changes to the account. It only enables the membership.

In order for Security Hub CSPM to generate control findings, member accounts must have AWS Config enabled and configured to record required resources. For more information, see Enabling and configuring AWS Config.

Choose your preferred method, and follow the steps to enable an organization account as a Security Hub CSPM member account.

Security Hub CSPM console

To manually enable organization accounts as Security Hub CSPM members

1. Open the AWS Security Hub CSPM console at https://console.aws.amazon.com/securityhub/.

   Sign in using the credentials of the delegated administrator account.
2. In the Security Hub CSPM navigation pane, under **Settings**, choose **Configuration**.
3. In the **Accounts** list, select each organization account that you want to enable.

4. Choose **Actions**, and then choose **Add member**.

Security Hub CSPM API

To manually enable organization accounts as Security Hub CSPM members

Invoke the `CreateMembers` API from the delegated administrator account. For each account to enable, provide the account ID.

Unlike the manual invitation process, when you invoke `CreateMembers` to enable an organization account, you don't need to send an invitation.

AWS CLI

To manually enable organization accounts as Security Hub CSPM members

Run the `create-members` command from the delegated administrator account. For each account to enable, provide the account ID.

Unlike the manual invitation process, when you run `create-members` to enable an organization account, you don't need to send an invitation.

```
aws securityhub create-members --account-details '[{"AccountId": "<accountId>"}]'
```

Example

```
aws securityhub create-members --account-details '[{"AccountId": "123456789111"},
 {"AccountId": "123456789222"}]'
```

Disassociating Security Hub CSPM member accounts from your organization

To stop receiving and viewing findings from an AWS Security Hub CSPM member account, you can disassociate the member account from your organization.

> **Note**
>
> If you use central configuration, disassociation works differently. You can create a configuration policy that disables Security Hub CSPM in one or more centrally managed member accounts. After that, these accounts are still part of the organization, but won't generate Security Hub CSPM findings. If you use central configuration but also have

manually-invited member accounts, you can disassociate one or more manually-invited accounts.

Member accounts that are managed using AWS Organizations can't disassociate their accounts from the administrator account. Only the administrator account can disassociate a member account.

Disassociating a member account does not close the account. Instead, it removes the member account from the organization. The disassociated member account becomes a standalone AWS account that is no longer managed by the Security Hub CSPM integration with AWS Organizations.

Choose your preferred method, and follow the steps to disassociate a member account from the organization.

Security Hub CSPM console

To disassociate a member account from the organization

1. Open the AWS Security Hub CSPM console at https://console.aws.amazon.com/securityhub/.

   Sign in using the credentials of the delegated administrator account.
2. In the navigation pane, under **Settings**, choose **Configuration**.
3. In the **Accounts** section, select the accounts that you want to disassociate. If you use central configuration, you can select a manually-invited account to disassociate from the `Invitation accounts` tab. This tab is visible only if you use central configuration.
4. Choose **Actions**, and then choose **Disassociate account**.

Security Hub CSPM API

To disassociate a member account from the organization

Invoke the `DisassociateMembers` API from the delegated administrator account. You must provide the AWS account IDs for the member accounts to disassociate. To view a list of member accounts, invoke the `ListMembers` API.

AWS CLI

To disassociate a member account from the organization

Run the `>disassociate-members` command from the delegated administrator account. You must provide the AWS account IDs for the member accounts to disassociate. To view a list of member accounts, run the `>list-members` command.

```
aws securityhub disassociate-members --account-ids "<accountIds>"
```

Example

```
aws securityhub disassociate-members --account-ids "123456789111" "123456789222"
```

You can also use the AWS Organizations console, AWS CLI, or AWS SDKs to disassociate a member account from your organization. For more information, see Removing a member account from your organization in the *AWS Organizations User Guide*.

Managing accounts by invitation in Security Hub CSPM

You can centrally manage multiple AWS Security Hub CSPM accounts in two ways, by integrating Security Hub CSPM with AWS Organizations or by manually sending and accepting membership invitations. You must use the manual process if you have a standalone account or you don't integrate with AWS Organizations. In manual account management, the Security Hub CSPM administrator invites accounts to become members. The administrator-member relationship is established when a prospective member accepts the invitation. A Security Hub CSPM administrator account can manage Security Hub CSPM for up 1,000 invitation-based member accounts.

Note

If you create an invitation-based organization in Security Hub CSPM, you can subsequently transition to using AWS Organizations instead. If you have more than one member account, we recommend using AWS Organizations instead of Security Hub CSPM invitations to manage your member accounts. For information, see Managing Security Hub CSPM for multiple accounts with AWS Organizations.

Cross-Region aggregation of findings and other data is available for accounts that you invite through the manual invitation process. However, the administrator must invite the member account from the aggregation Region and all linked Regions in order for cross-Region aggregation to work. In addition, the member account must have Security Hub CSPM enabled in the

aggregation Region and all linked Regions to give the administrator the ability to view findings from the member account.

Configuration policies aren't supported for manually-invited member accounts. Instead, you must configure Security Hub CSPM settings separately in each member account and AWS Region when you use the manual invitation process.

You must also use the manual invitation-based process for accounts that don't belong to your organization. For example, you might not include a test account in your organization. Or, you might want to consolidate accounts from multiple organizations under a single Security Hub CSPM administrator account. The Security Hub CSPM administrator account must send invitations to accounts that belong to other organizations.

On the **Configuration** page of the Security Hub CSPM console, accounts that were added by invitation are listed in the **Invitation accounts** tab. If you use central configuration, but also invite accounts outside of your organization, you can view findings from invitation-based accounts in this tab. However, the Security Hub CSPM administrator can't configure invitation-based accounts across Regions through the use of configuration policies.

The topics in this section explain how to manage member accounts through invitations.

Topics

- Adding and inviting member accounts in Security Hub CSPM
- Responding to an invitation to be a Security Hub CSPM member account
- Disassociating member accounts in Security Hub CSPM
- Deleting member accounts in Security Hub CSPM
- Disassociating from a Security Hub CSPM administrator account
- Transitioning to Organizations to manage accounts in Security Hub CSPM
- Multi-account enablement script

Adding and inviting member accounts in Security Hub CSPM

> **Note**
>
> We recommend using AWS Organizations instead of Security Hub CSPM invitations to manage your member accounts. For information, see Managing Security Hub CSPM for multiple accounts with AWS Organizations.

Your account becomes the AWS Security Hub CSPM administrator for accounts that accept your invitation to become a Security Hub CSPM member account.

When you accept an invitation from another account, your account becomes a member account, and that account becomes your administrator.

If your account is an administrator account, you can't accept an invitation to become a member account.

Adding a member account consists of the following steps:

1. The administrator account adds the member account to their list of member accounts.
2. The administrator account sends an invitation to the member account.
3. The member account accepts the invitation.

Adding member accounts

From the Security Hub CSPM console, you can add accounts to your list of member accounts. In the Security Hub CSPM console, you can select accounts individually, or upload a `.csv` file that contains the account information.

For each account, you must provide the account ID and an email address. The email address should be the email address to contact about security issues in the account. It is not used to verify the account.

Choose your preferred method, and follow the steps to add member accounts.

Security Hub CSPM console

To add accounts to your list of member accounts

1. Open the AWS Security Hub CSPM console at https://console.aws.amazon.com/securityhub/.

   Sign in using the credentials of the administrator account.
2. In the left pane, choose **Settings**.
3. On the **Settings** page, choose **Accounts** and then choose **Add accounts**. You can then either add accounts individually or upload a `.csv` file containing the list of accounts.
4. To select the accounts, do one of the following:

- To add the accounts individually, under **Enter accounts**, enter the account ID and email address of the account to add, and then choose **Add**.

  Repeat this process for each account.

- To use a comma-separated values (.csv) file to add multiple accounts, first create the file. The file must contain the account ID and email address for each account to add.

  In your `.csv` list, accounts must appear one per line. The first line of the `.csv` file must contain the header. In the header, the first column is **`Account ID`** and the second column is **`Email`**.

  Each subsequent line must contain a valid account ID and email address for the account to add.

  Here is an example of a `.csv` file when viewed in a text editor.

  ```
  Account ID,Email
  111111111111,user@example.com
  ```

  In a spreadsheet program, the fields appear in separate columns. The underlying format is still comma-separated. You must format the account IDs as non-decimal numbers. For example, the account ID 444455556666 cannot be formatted as 444455556666.0. Also make sure that the number formatting does not remove any leading zeros from the account ID.

  To select the file, on the console, choose **Upload list (.csv)**. Then choose **Browse**.

  After you select the file, choose **Add accounts**.

5. After you finish adding accounts, under **Accounts to be added**, choose **Next**.

Security Hub CSPM API

To add accounts to your list of member accounts

Invoke the `CreateMembers` API from the administrator account. For each member account to add, you must provide the AWS account ID.

AWS CLI

To add accounts to your list of member accounts

Run the `create-members` command from the administrator account. For each member account to add, you must provide the AWS account ID.

```
aws securityhub create-members --account-details '[{"AccountId": "<accountID1>"}]'
```

Example

```
aws securityhub create-members --account-details '[{"AccountId": "123456789111"},
 {"AccountId": "123456789222"}]'
```

Inviting member accounts

After you add the member accounts, you send an invitation to the member account. You can also resend an invitation to an account that you disassociated from the administrator.

Security Hub CSPM console

To invite prospective member accounts

1. Open the AWS Security Hub CSPM console at https://console.aws.amazon.com/securityhub/.

   Sign in using the credentials of the administrator account.
2. In the navigation pane, choose **Settings**, and then choose **Accounts**.
3. For the account to invite, choose **Invite** in the **Status** column.
4. When prompted to confirm, choose **Invite**.

> **Note**
>
> To resend invitations to disassociated accounts, select each disassociated account on the **Accounts** page. For **Actions**, choose **Resend invitation**.

Security Hub CSPM API

To invite prospective member accounts

Invoke the `InviteMembers` API from the administrator account. For each account to invite, you must provide the AWS account ID.

AWS CLI

To invite prospective member accounts

Run the `invite-members` command from the administrator account. For each account to invite, you must provide the AWS account ID.

```
aws securityhub invite-members --account-ids <accountIDs>
```

Example

```
aws securityhub invite-members --account-ids "123456789111" "123456789222"
```

Responding to an invitation to be a Security Hub CSPM member account

> **Note**
>
> We recommend using AWS Organizations instead of Security Hub CSPM invitations to manage your member accounts. For information, see Managing Security Hub CSPM for multiple accounts with AWS Organizations.

You can accept or decline an invitation to be an AWS Security Hub CSPM member account.

If you accept an invitation, your account becomes a Security Hub CSPM member account. The account that sent the invitation becomes your Security Hub CSPM administrator account. The administrator account user can view findings for your member account in Security Hub CSPM.

If you decline the invitation, then your account is marked as **Resigned** on the administrator account's list of member accounts.

You can only accept one invitation to be a member account.

Before you can accept or decline an invitation, you must enable Security Hub CSPM.

Remember that all Security Hub CSPM accounts must have AWS Config enabled and configured to record all resources. For details on the requirement for AWS Config, see Enabling and configuring AWS Config.

Accepting an invitation

You can send an invitation to be a Security Hub CSPM member account from the administrator account. You can then accept the invitation after signing in to the member account.

Choose your preferred method, and follow the steps to accept an invitation to be a member account.

Security Hub CSPM console

To accept a membership invitation

1. Open the AWS Security Hub CSPM console at https://console.aws.amazon.com/securityhub/.
2. In the navigation pane, choose **Settings**, and then choose **Accounts**.
3. In the **Administrator account** section, turn on **Accept**, and then choose **Accept invitation**.

Security Hub CSPM API

To accept a membership invitation

Invoke the `AcceptAdministratorInvitation` API. You must provide the invitation identifier and the AWS account ID of the administrator account. To retrieve details about the invitation, use the `ListInvitations` operation.

AWS CLI

To accept a membership invitation

Run the `accept-administrator-invitation` command. You must provide the invitation identifier and the AWS account ID of the administrator account. To retrieve details about the invitation, run the `list-invitations` command.

```
aws securityhub accept-administrator-invitation --administrator-
id <administratorAccountID> --invitation-id <invitationID>
```

Example

```
aws securityhub accept-administrator-invitation --administrator-id 123456789012 --
invitation-id 7ab938c5d52d7904ad09f9e7c20cc4eb
```

Note

The Security Hub CSPM console continues to use `AcceptInvitation`. It will eventually change to use `AcceptAdministratorInvitation`. Any IAM policies that specifically control access to this function must continue to use `AcceptInvitation`. You should also add `AcceptAdministratorInvitation` to your policies to ensure that the correct permissions are in place after the console begins to use `AcceptAdministratorInvitation`.

Declining an invitation

You can decline an invitation to be a Security Hub CSPM member account. When you decline an invitation in the Security Hub CSPM console, your account is marked as **Resigned** on the administrator account's list of member accounts. The **Resigned** status appears only when you sign in to the Security Hub CSPM console using the administrator account. However, the invitation remains unchanged in the console for the member account until you sign in to the administrator account and delete the invitation.

To decline an invitation, you must sign in to the member account that received the invitation.

Choose your preferred method, and follow the steps to decline an invitation to be a member account.

Security Hub CSPM console

To decline a membership invitation

1. Open the AWS Security Hub CSPM console at https://console.aws.amazon.com/securityhub/.
2. In the navigation pane, choose **Settings**, and then choose **Accounts**.
3. In the **Administrator account** section, choose **Decline invitation**.

Security Hub CSPM API

To decline a membership invitation

Invoke the `DeclineInvitations` API. You must provide the AWS account ID of the administrator account that issued the invitation. To view information about your invitations, use the `ListInvitations` operation.

AWS CLI

To decline a membership invitation

Run the `decline-invitations` command. You must provide the AWS account ID of the administrator account that issued the invitation. To view information about your invitations, run the `list-invitations` command.

```
aws securityhub decline-invitations --account-ids "<administratorAccountId>"
```

Example

```
aws securityhub decline-invitations --account-ids "123456789012"
```

Disassociating member accounts in Security Hub CSPM

> **Note**
>
> We recommend using AWS Organizations instead of Security Hub CSPM invitations to manage your member accounts. For information, see Managing Security Hub CSPM for multiple accounts with AWS Organizations.

An AWS Security Hub CSPM administrator account can disassociate a member account to stop receiving and viewing findings from that account. You must disassociate a member account before you can delete it.

When you disassociate a member account, it remains in your list of member accounts with a status of **Removed (Disassociated)**. Your account is removed from the administrator account information for the member account.

To resume receiving findings for the account, you can resend the invitation. To remove the member account entirely, you can delete the member account.

Choose your preferred method, and follow the steps to disassociate a manually-invited member account from the administrator account.

Security Hub CSPM console

To disassociate a manually-invited member account

1. Open the AWS Security Hub CSPM console at https://console.aws.amazon.com/securityhub/.

   Sign in using the credentials of the administrator account.
2. In the navigation pane, under **Settings**, choose **Configuration**.
3. In the **Accounts** section, select the accounts that you want to disassociate.
4. Choose **Actions**, and then choose **Disassociate account**.

Security Hub CSPM API

To disassociate a manually-invited member account

Invoke the `DisassociateMembers` API from the administrator account. You must provide the AWS account IDs of the member accounts that you want to disassociate. To view a list of member accounts, use the `ListMembers` operation.

AWS CLI

To disassociate a manually-invited member account

Run the `disassociate-members` command from the administrator account. You must provide the AWS account IDs of the member accounts that you want to disassociate. To view a list of member accounts, run the `list-members` command.

```
aws securityhub disassociate-members --account-ids <accountIds>
```

Example

```
aws securityhub disassociate-members --account-ids "123456789111" "123456789222"
```

Deleting member accounts in Security Hub CSPM

> **Note**
>
> We recommend using AWS Organizations instead of Security Hub CSPM invitations to manage your member accounts. For information, see Managing Security Hub CSPM for multiple accounts with AWS Organizations.

As an AWS Security Hub CSPM administrator account, you can delete member accounts that were added by invitation. Before you can delete an enabled account, you must disassociate it.

When you delete a member account, it is completely removed from the list. To restore the account's membership, you must add and invite it again as if it were a completely new member account.

You can't delete accounts that belong to an organization and that are managed using the integration with AWS Organizations.

Choose your preferred method, and follow the steps to delete manually-invited member accounts.

Security Hub CSPM console

To delete a manually-invited member account

1. Open the AWS Security Hub CSPM console at https://console.aws.amazon.com/securityhub/.

   Sign in using the administrator account.
2. In the navigation pane, choose **Settings**, and then choose **Configuration**.
3. Choose the **Invitation accounts** tab. Then, select the accounts to delete.
4. Choose **Actions**, and then choose **Delete**. This option is available only if you have disassociated the account. You must disassociate a member account before it can be deleted.

Security Hub CSPM API

To delete a manually-invited member account

Invoke the `DeleteMembers` API from the administrator account. You must provide the AWS account IDs of the member accounts that you want to delete. To retrieve the list of member accounts, invoke the `ListMembers` API.

AWS CLI

To delete a manually-invited member account

Run the `delete-members` command from the administrator account. You must provide the AWS account IDs of the member accounts that you want to delete. To retrieve the list of member accounts, run the `list-members` command.

```
aws securityhub delete-members --account-ids <memberAccountIDs>
```

Example

```
aws securityhub delete-members --account-ids "123456789111" "123456789222"
```

Disassociating from a Security Hub CSPM administrator account

> **Note**
>
> We recommend using AWS Organizations instead of Security Hub CSPM invitations to manage your member accounts. For information, see Managing Security Hub CSPM for multiple accounts with AWS Organizations.

If your account was added as an AWS Security Hub CSPM member account by invitation, you can disassociate the member account from the administrator account. After you disassociate a member account, Security Hub CSPM doesn't send findings from the account to the administrator account.

Member accounts that are managed using the integration with AWS Organizations can't disassociate their accounts from the administrator account. Only the Security Hub CSPM delegated administrator can disassociate member accounts that are managed with Organizations.

When you disassociate from your administrator account, your account remains in the administrator account's member list with a status of **Resigned**. However, the administrator account does not receive any findings for your account.

After you disassociate yourself from the administrator account, the invitation to be a member still remains. You can accept the invitation again in the future.

Security Hub CSPM console

To disassociate from your administrator account

1. Open the AWS Security Hub CSPM console at https://console.aws.amazon.com/securityhub/.
2. In the navigation pane, choose **Settings**, and then choose **Accounts**.
3. In the **Administrator account** section, turn off **Accept**, and then choose **Update**.

Security Hub CSPM API

To disassociate from your administrator account

Invoke the `DisassociateFromAdministratorAccount` API.

AWS CLI

To disassociate from your administrator account

Run the `disassociate-from-administrator-account` command.

```
aws securityhub disassociate-from-administrator-account
```

Note

The Security Hub CSPM console continues to use `DisassociateFromMasterAccount`. It will eventually change to use `DisassociateFromAdministratorAccount`. Any IAM policies that specifically control access to this function must continue to use `DisassociateFromMasterAccount`. You should also add `DisassociateFromAdministratorAccount` to your policies to ensure that the correct permissions are in place after the console begins to use `DisassociateFromAdministratorAccount`.

Transitioning to Organizations to manage accounts in Security Hub CSPM

When you manage accounts manually in AWS Security Hub CSPM, you must invite prospective member accounts and configure each member account separately in each AWS Region.

By integrating Security Hub CSPM and AWS Organizations, you can eliminate the need to send invitations and gain more control over how Security Hub CSPM is configured and customized in your organization. For this reason, we recommend using AWS Organizations instead of Security Hub CSPM invitations to manage your member accounts. For information, see Managing Security Hub CSPM for multiple accounts with AWS Organizations.

It's possible to use a combined approach in which you use the AWS Organizations integration, but also manually invite accounts outside of your organization. However, we recommend exclusively using the Organizations integration. Central configuration, a feature which helps you manage Security Hub CSPM across multiple accounts and Regions, is only available when you integrate with Organizations.

This section covers how you can transition from manual invitation-based account management to managing accounts with AWS Organizations.

Integrating Security Hub CSPM with AWS Organizations

First, you must integrate Security Hub CSPM and AWS Organizations.

You can integrate these services by completing the following steps:

- Create an organization in AWS Organizations. For instructions, see Create an organization in the *AWS Organizations User Guide*.
- From the Organizations management account, designate a Security Hub CSPM delegated administrator account.

> **Note**
>
> The organization management account *cannot* be set as the DA account.

For detailed instructions, see Integrating Security Hub CSPM with AWS Organizations.

By completing the preceding steps, you grant trusted access for Security Hub CSPM in AWS Organizations. This also enables Security Hub CSPM in the current AWS Region for the delegated administrator account.

The delegated administrator can manage the organization in Security Hub CSPM, primarily by adding the organization's accounts as Security Hub CSPM member accounts. The administrator can also access certain Security Hub CSPM settings, data, and resources for those accounts.

When you transition to account management using Organizations, invitation-based accounts don't automatically become Security Hub CSPM members. Only the accounts that you add to your new organization can become Security Hub CSPM members.

After activating the integration, you can manage accounts with Organizations. For information, see Managing Security Hub CSPM for multiple accounts with AWS Organizations. Account management varies based on your organization's configuration type.

Multi-account enablement script

> **Note**
>
> Instead of this script, we recommend integrating with AWS Organizations and using declarative policies to enable and configure Security Hub CSPM across multiple accounts and Regions.

You can use the Security Hub CSPM multi-account enablement script in GitHub to enable Security Hub CSPM across accounts and Regions. The script also automates the process of sending invitations to member accounts and enabling AWS Config.

The script automatically enables AWS Config resource recording for all resources, including global resources, in all Regions. It does not limit recording of global resources to a single Region. To conserve costs, we recommend recording global resources in a single Region only. If you use cross-Region aggregation, this Region should be your home Region. For more information, see Recording resources in AWS Config.

There is a corresponding script to disable Security Hub CSPM across accounts and Regions.

Allowed actions by administrator and member accounts in Security Hub CSPM

Administrator and member accounts have access to AWS Security Hub CSPM actions noted in the following tables. In the tables, the values have the following meanings:

- **Any –** The account can perform the action for any member account under the same administrator.
- **Current –** The account can perform the action only for itself (the account that you're currently signed in to).
- **Dash –** Indicates that the account cannot perform the action.
- **Through declarative policy –** The account can't perform the action directly through Security Hub CSPM. Instead, the setting comes from the account's effective Security Hub CSPM declarative policy, which the management account or an authorized delegated administrator manages in AWS Organizations.

As noted in the tables, allowed actions differ based on whether you integrate with AWS Organizations and how you manage accounts: with Security Hub CSPM declarative policies, central configuration, or local configuration. For information about these options, see Managing accounts with AWS Organizations.

Security Hub CSPM doesn't copy member account findings into the administrator account. In Security Hub CSPM, all findings are ingested into a specific Region for a specific account. In each Region, the administrator account can view and manage findings for their member accounts in that Region.

If you set an aggregation Region, the administrator account can view and manage member account findings from linked Regions that are replicated to the aggregation Region. For more information about cross-Region aggregation, see Cross-Region aggregation.

The following tables specify the default permissions for administrator and member accounts. You can use custom IAM policies to further restrict access to Security Hub CSPM features and functions. For guidance and examples, see the blog post Aligning IAM policies to user personas for AWS Security Hub CSPM.

Allowed actions if you integrate with Organizations and use declarative policies

Administrator and member accounts can access Security Hub CSPM actions as follows if you integrate with Organizations and use Security Hub CSPM declarative policies. A declarative policy governs an account separately in each Region. In this table, a *governed member account* is a member account in a Region that its effective Security Hub CSPM declarative policy governs. A *self-managed member account* is a member account in a Region that no declarative policy governs.

Action	Security Hub CSPM delegated administrator account (with delegated permissions for Security Hub CSPM declarative policies)	Governed member account	Self-managed member account
Create and manage Security Hub CSPM declarative policies	Any (requires an AWS Organizations delegation policy for the `SECURITYHUB_CSPM_POLICY` policy type)	–	–
Create and manage Security Hub CSPM central configuration policies	– (can view and delete existing configuration policies)	–	–
View organization accounts	Any	–	–
Disassociate member account	Self-managed member accounts only	–	–
Delete member account	Any non-organization account	–	–

Action	Security Hub CSPM delegated administrator account (with delegated permissions for Security Hub CSPM declarative policies)	Governed member account	Self-managed member account
Enable and disable Security Hub CSPM	Through declarative policy for governed accounts, including the current account if a declarative policy governs it	Through declarative policy	Current (to disable, the account must first disassociate from the administrator account)
View findings and finding history	Any	Current	Current
Update findings	Any	Current	Current
View insight results	Any	Current	Current
View control details	Any	Current	Current
Turn consolidated control findings on or off	Any	–	–
Enable and disable standards	Through declarative policy for governed accounts, or current if no declarative policy governs the current account	Through declarative policy	Current

Action	Security Hub CSPM delegated administrator account (with delegated permissions for Security Hub CSPM declarative policies)	Governed member account	Self-managed member account
Enable and disable controls	Through declarative policy for governed accounts, or current if no declarative policy governs the current account	Through declarative policy	Current
Automatically enable new controls	Through declarative policy for governed accounts, or current if no declarative policy governs the current account	Through declarative policy	Current
Customize control parameters	Through declarative policy for governed accounts, or current if no declarative policy governs the current account	Through declarative policy	Current
Enable and disable integrations	Current	Current	Current
Configure cross-Region aggregation	Any	–	–
Configure custom actions	Current	Current	Current

Action	Security Hub CSPM delegated administrator account (with delegated permissions for Security Hub CSPM declarative policies)	Governed member account	Self-managed member account
Configure automation rules	Any	–	–
Configure custom insights	Current	Current	Current

> **Note**
>
> The organization's management account can also create and manage Security Hub CSPM declarative policies. Declarative policies don't use a home Region or linked Regions, so the action to select a home Region and linked Regions doesn't apply. When a declarative policy enables Security Hub CSPM, Security Hub CSPM associates governed accounts with the delegated administrator automatically. When a declarative policy disables Security Hub CSPM, Security Hub CSPM removes the administrator and member associations for the affected accounts, including invitation-based associations. For more information, see How declarative policies work in Security Hub CSPM.

Allowed actions if you integrate with Organizations and use central configuration

Administrator and member accounts can access Security Hub CSPM actions as follows if you integrate with Organizations and use central configuration.

Action	Security Hub CSPM delegated administrator account	Centrally managed member account	Self-managed member account
Create and manage Security Hub CSPM configuration policies	For self and centrally managed accounts	–	–
View organization accounts	Any	–	–
Disassociate member account	Any	–	–
Delete member account	Any non-organization account	–	–
Disable Security Hub CSPM	For current account and centrally managed accounts	–	Current (must be disassociated from the administrator account)
View findings and finding history	Any	Current	Current
Update findings	Any	Current	Current
View insight results	Any	Current	Current
View control details	Any	Current	Current
Turn consolidated control findings on or off	Any	–	–
Enable and disable standards	For current account and centrally managed accounts	–	Current

Action	Security Hub CSPM delegated administrator account	Centrally managed member account	Self-managed member account
Enable and disable controls	For current account and centrally managed accounts	–	Current
Enable and disable integrations	Current	Current	Current
Configure cross-Region aggregation	Any	–	–
Select home Region and linked Regions	Any (must stop and restart central configuration to change home Region)	–	–
Configure custom actions	Current	Current	Current
Configure automation rules	Any	–	–
Configure custom insights	Current	Current	Current

Allowed actions if you integrate with Organizations and use local configuration

Administrator and member accounts can access Security Hub CSPM actions as follows if you integrate with Organizations and use local configuration.

Action	Security Hub CSPM delegated administrator account	Member account
Create and manage Security Hub CSPM configuration policies	–	–
View organization accounts	Any	–
Disassociate member account	Any	–
Delete member account	–	–
Disable Security Hub CSPM	–	Current (if account is disassociated from delegated administrator)
View findings and finding history	Any	Current
Update findings	Any	Current
View insight results	Any	Current
View control details	Any	Current
Turn consolidated control findings on or off	Any	–
Enable and disable standards	Current	Current
Automatically enable Security Hub CSPM and default standards in new organization accounts	For current account and new organization accounts	–
Enable and disable controls	Current	Current

Action	Security Hub CSPM delegated administrator account	Member account
Enable and disable integrations	Current	Current
Configure cross-Region aggregation	Any	–
Configure custom actions	Current	Current
Configure automation rules	Any	–
Configure custom insights	Current	Current

Allowed actions for invitation-based accounts

Administrator and member accounts can access Security Hub CSPM actions as follows if you use the invitation-based method to manually manage accounts instead of integrating with AWS Organizations.

Action	Security Hub CSPM administrator account	Member account
Create and manage Security Hub CSPM configuration policies	–	–
View organization accounts	Any	–
Disassociate member account	Any	Current
Delete member account	Any	–
Disable Security Hub CSPM	Current (if there are no enabled member accounts)	Current (if account is disassociated from administrator account)

Action	Security Hub CSPM administrator account	Member account
View findings and finding history	Any	Current
Update findings	Any	Current
View insight results	Any	Current
View control details	Any	Current
Turn consolidated control findings on or off	Any	–
Enable and disable standards	Current	Current
Automatically enable Security Hub CSPM and default standards in new organization accounts	–	–
Enable and disable controls	Current	Current
Enable and disable integrati ons	Current	Current
Configure cross-Region aggregation	Any	–
Configure custom actions	Current	Current
Configure automation rules	Any	–
Configure custom insights	Current	Current

Effect of account actions on Security Hub CSPM data

These account actions have the following effects on AWS Security Hub CSPM data.

Security Hub CSPM disabled

If you use central configuration, the delegated administrator (DA) can create Security Hub CSPM configuration policies that disable AWS Security Hub CSPM in specific accounts and organizational units (OUs). In this case, Security Hub CSPM is disabled in the specified accounts and OUs in your home Region and any linked Regions. If you don't use central configuration, you must disable Security Hub CSPM separately in each account and Region where you enabled it. You can't use central configuration if Security Hub CSPM is disabled in the DA account.

No findings are generated or updated for the administrator account if Security Hub CSPM is disabled in the administrator account. Existing archived findings are deleted after 30 days. Existing active findings are deleted after 90 days.

Integrations with other AWS services are removed.

Enabled security standards and controls are disabled.

Other Security Hub CSPM data and settings, including custom actions, insights, and subscriptions to third-party products are retained for 90 days.

Member account disassociated from administrator account

When a member account is disassociated from the administrator account, the administrator account loses permission to view findings in the member account. However, Security Hub CSPM is still enabled in both accounts.

If you use central configuration, the DA can't configure Security Hub CSPM for a member account that's disassociated from the DA account.

Custom settings or integrations that are defined for the administrator account are not applied to findings from the former member account. For example, after the accounts are disassociated, you might have a custom action in the administrator account used as the event pattern in an Amazon EventBridge rule. However, this custom action cannot be used in the member account.

In the **Accounts** list for the Security Hub CSPM administrator account, a removed account has a status of **Disassociated**.

Member account is removed from an organization

When a member account is removed from an organization, the Security Hub CSPM administrator account loses permission to view findings in the member account. However, Security Hub CSPM is still enabled in both accounts with the same settings they had before removal.

If you use central configuration, you can't configure Security Hub CSPM for a member account after it's removed from the organization to which the delegated administrator belongs. However, the account retains the settings it had prior to removal unless you manually change them.

In the **Accounts** list for the Security Hub CSPM administrator account, a removed account has a status of **Deleted**.

Account is suspended

When an AWS account is suspended, the account loses permission to view their findings in Security Hub CSPM. No findings are generated or updated for that account. The administrator account for a suspended account can view existing findings for the account.

For an organization account, the member account status can also change to **Account Suspended**. This happens if the account is suspended at the same time that the administrator account attempts to enable the account. The administrator account for an **Account Suspended** account cannot view findings for that account. Otherwise, the suspended status doesn't affect the member account status.

If you use central configuration, policy association fails if the delegated administrator tries to associate a configuration policy with a suspended account.

After 90 days, the account is either terminated or reactivated. When the account is reactivated, its Security Hub CSPM permissions are restored. If the member account status is **Account Suspended**, the administrator account must enable the account manually.

Account is closed

When an AWS account is closed, Security Hub CSPM responds to the closure as follows.

If the account is a Security Hub CSPM administrator account, it is removed as an administrator account and all the member accounts are removed. If the account is a member account, it is disassociated and removed as a member from the Security Hub CSPM administrator account.

Security Hub CSPM retains existing archived findings in the account for 30 days. For a control finding, the calculation of 30 days is based on the value for the `UpdatedAt` field of the finding. For another type of finding, the calculation is based on the value for the `UpdatedAt` or `ProcessedAt` field of the finding, whichever date is latest. At the end of this 30-day period, Security Hub CSPM permanently deletes the finding from the account.

Security Hub CSPM retains existing active findings in the account for 90 days. For a control finding, the calculation of 90 days is based on the value for the `UpdatedAt` field of the finding. For another type of finding, the calculation is based on the value for the `UpdatedAt` or `ProcessedAt` field of the finding, whichever date is latest. At the end of this 90-day period, Security Hub CSPM permanently deletes the finding from the account.

For longer-term retention of existing findings, you can export the findings to an S3 bucket. You can do this by using a custom action with an Amazon EventBridge rule. For more information, see Using EventBridge for automated response and remediation.

Important

For customers in AWS GovCloud (US) Regions, back up and then delete your policy data and other account resources before you close your account. You won't have access to the resources and data after you close your account.

For more information, see Close an AWS account in the *AWS Account Management Reference Guide*.

Understanding central configuration in Security Hub CSPM

Note

Central configuration is a legacy feature. Security Hub CSPM declarative policies are replacing it as the way to manage Security Hub CSPM across an organization. If your organization currently uses central configuration, you can continue to use the information in this section. For more information about declarative policies, see Managing accounts with declarative policies in Security Hub CSPM.

Central configuration is an AWS Security Hub CSPM feature that helps you set up and manage Security Hub CSPM across multiple AWS accounts and AWS Regions. To use central configuration, you must first integrate Security Hub CSPM and AWS Organizations. You can integrate the services by creating an organization and designating a delegated Security Hub CSPM administrator account for the organization.

From the delegated Security Hub CSPM administrator account, you can enable Security Hub CSPM for your organization's accounts and organizational units (OUs) across Regions. You can also

enable, configure, and disable individual security standards and security controls for accounts and OUs across Regions. You can configure these settings in just a few steps from one primary Region, referred to as the *home Region*.

When you use central configuration, the delegated administrator can choose which accounts and OUs to configure. If the delegated administrator designates a member account or OU as *self-managed*, the member can configure its own settings separately in each Region. If the delegated administrator designates a member account or OU as *centrally managed*, only the delegated administrator can configure the member account or OU across Regions. You can designate all accounts and OUs in your organization as centrally managed, all self-managed, or a combination of both.

To configure centrally managed accounts, the delegated administrator uses Security Hub CSPM configuration policies. Configuration policies let the delegated administrator specify whether Security Hub CSPM is enabled or disabled, and which standards and controls are enabled or disabled. They can also be used to customize parameters for certain controls.

Configuration policies take effect in the home Region and all linked Regions. The delegated administrator specifies the organization's home Region and linked Regions before starting to use central configuration. Specifying linked Regions is optional. The delegated administrator can create a single configuration policy for the whole organization, or create multiple configuration policies to configure variable settings for different accounts and OUs.

Important

Security Hub CSPM declarative policies are the recommended way to manage Security Hub CSPM across an organization. Declarative policies and central configuration are mutually exclusive.
When you attach a Security Hub CSPM policy to any target in your organization, even a single account, Security Hub CSPM disables central configuration for the entire organization. If central configuration governed an account and no declarative policy covers that account, the account keeps its current settings and becomes self-managed. To move your existing configuration without coverage gaps, use the import tool in the Security Hub console before you attach any Security Hub CSPM policies. For more information, see Declarative policies and central configuration in Security Hub CSPM.

> **Tip**
>
> If you don't use central configuration, you must largely configure Security Hub CSPM separately in each account and Region. This is called *local configuration*. Under local configuration, the delegated administrator can automatically enable Security Hub CSPM and a limited set of security standards in new organization accounts in the current Region. Local configuration doesn't apply to existing organization accounts or to Regions other than the current Region. Local configuration also doesn't support the use of configuration policies.

This section provides an overview of central configuration.

Benefits of using central configuration

Benefits of central configuration include the following:

Simplify configuration of the Security Hub CSPM service and capabilities

When you use central configuration, Security Hub CSPM guides you through the process of configuring security best practices for your organization. It also deploys the resulting configuration policies to specified accounts and OUs automatically. If you have existing Security Hub CSPM settings, such as automatically enabling new security controls, you can use those as a starting point for your configuration policies. In addition, the **Configuration** page on the Security Hub CSPM console displays a real-time summary of your configuration policies and which accounts and OUs use each policy.

Configure across accounts and Regions

You can use central configuration to configure Security Hub CSPM across multiple accounts and Regions. This helps ensure that each part of your organization maintains a consistent configuration and adequate security coverage.

Accommodate different configurations in different accounts and OUs

With central configuration, you can choose to configure your organization's accounts and OUs in different ways. For example, your test accounts and production accounts might require different configurations. You can also create a configuration policy that covers new accounts when they join the organization.

Prevent configuration drift

Configuration drift occurs when a user makes a change to a service or feature that conflicts with the delegated administrator's selections. Central configuration prevents this drift. When you designate an account or OU as centrally managed, it's configurable only by the delegated administrator for the organization. If you prefer a specific account or OU to configure its own settings, you can designate it as self-managed.

When to use central configuration?

Central configuration is most beneficial for AWS environments that include multiple Security Hub CSPM accounts. It's designed to help you centrally manage Security Hub CSPM for multiple accounts.

You can use central configuration to configure the Security Hub CSPM service, security standards, and security controls. You can also use it to customize parameters of certain controls. For more information about security standards, see Understanding security standards in Security Hub CSPM. For more information about security controls, see Understanding security controls in Security Hub CSPM.

If you're setting up multi-account management for the first time, we recommend that you use Security Hub CSPM declarative policies instead of central configuration. Declarative policies use AWS Organizations to enable and configure Security Hub CSPM, standards, controls, and control parameters across accounts and Regions. You can't use central configuration and declarative policies in the same organization at the same time. For more information, see Managing accounts with declarative policies in Security Hub CSPM.

Central configuration terms and concepts

Understanding the following key terms and concepts can help you use Security Hub CSPM central configuration.

Central configuration

A Security Hub CSPM feature that helps the delegated Security Hub CSPM administrator account for an organization configure the Security Hub CSPM service, security standards, and security controls across multiple accounts and Regions. To configure these settings, the delegated administrator creates and manages Security Hub CSPM configuration policies for

centrally managed accounts in their organization. Self-managed accounts can configure their own settings separately in each Region. To use central configuration, you must integrate Security Hub CSPM and AWS Organizations.

While any Security Hub CSPM policy is attached to a target in the organization, Security Hub CSPM disables central configuration for the entire organization. While central configuration is disabled, the `DescribeOrganizationConfiguration` operation returns a status of `DISABLED`, with a message that indicates that declarative policies are in use. To enable central configuration again, detach every Security Hub CSPM policy in the organization.

Home Region

The AWS Region from which the delegated administrator centrally configures Security Hub CSPM, by creating and managing configuration policies. Configuration policies take effect in the home Region and all linked Regions.

The home Region also serves as the Security Hub CSPM aggregation Region, receiving findings, insights, and other data from linked Regions.

Regions that AWS introduced on or after March 20, 2019 are known as opt-in Regions. An opt-in Region can't be the home Region, but it can be a linked Region. For a list of opt-in Regions, see Considerations before enabling and disabling Regions in the *AWS Account Management Reference Guide*.

Linked Region

An AWS Region that is configurable from the home Region. Configuration policies are created by the delegated administrator in the home Region. The policies take effect in the home Region and all linked Regions. Specifying linked Regions is optional.

A linked Region also sends findings, insights, and other data to the home Region.

Regions that AWS introduced on or after March 20, 2019 are known as opt-in Regions. You must enable such a Region for an account before a configuration policy can be applied to it. The Organizations management account can enable opt-in Regions for a member account. For more information, see Specify which AWS Regions your account can use in the *AWS Account Management Reference Guide*.

Target

An AWS account, organizational unit (OU), or the organization root.

Security Hub CSPM configuration policy

A collection of Security Hub CSPM settings that the delegated administrator can configure for centrally managed targets. This includes:

- Whether to enable or disable Security Hub CSPM.
- Whether to enable one or more security standards.
- Which security controls to enable across the enabled standards. The delegated administrator can do this by providing a list of specific controls that should be enabled, and Security Hub CSPM disables all other controls (including new controls when they are released). Alternatively, the delegated administrator can provide a list of specific controls that should be disabled, and Security Hub CSPM enables all other controls (including new controls when they are released).
- Optionally, customize parameters for select enabled controls across the enabled standards.

A configuration policy takes effect in the home Region and all linked Regions after it's associated with at least one account, organizational unit (OU), or the root.

On the Security Hub CSPM console, the delegated administrator can choose the Security Hub CSPM recommended configuration policy or create custom configuration policies. With the Security Hub CSPM API and AWS CLI, the delegated administrator can only create custom configuration policies. The delegated administrator can create a maximum of 20 custom configuration policies.

In the recommended configuration policy, Security Hub CSPM, the AWS Foundational Security Best Practices (FSBP) standard, and all existing and new FSBP controls are enabled. Controls that accept parameters use the default values. The recommended configuration policy applies to the entire organization.

To apply different settings to the organization, or apply different configuration policies to different accounts and OUs, create a custom configuration policy.

> **Note**
>
> Configuration policies support AWS security standards and controls only. Multicloud standards, such as CIS Azure Foundations Benchmark v4.0.0, and their associated multicloud controls cannot be included in a configuration policy. To enable or configure multicloud standards, use local configuration mechanisms directly in the desired AWS account.

Local configuration

The default configuration type for an organization, after integrating Security Hub CSPM and AWS Organizations. With local configuration, the delegated administrator can choose to automatically enable Security Hub CSPM and default security standards in *new* organization accounts in the current Region. If the delegated administrator automatically enables default standards, all controls that are part of these standards are also automatically enabled with default parameters for new organization accounts. These settings don't apply to existing accounts, so configuration drift is possible after an account joins the organization. Disabling specific controls that are part of the default standards, and configuring additional standards and controls, must be done separately in each account and Region.

Local configuration doesn't support the use of configuration policies. To use configuration policies, you must switch to central configuration.

Manual account management

If you don't integrate Security Hub CSPM with AWS Organizations or you have a standalone account, you must specify settings for each account separately in each Region. Manual account management doesn't support the use of configuration policies.

Central configuration APIs

Security Hub CSPM operations that only the Security Hub CSPM delegated Security Hub CSPM administrator can use in the home Region to manage configuration policies for centrally managed accounts. The operations include:

- `CreateConfigurationPolicy`
- `DeleteConfigurationPolicy`
- `GetConfigurationPolicy`
- `ListConfigurationPolicies`
- `UpdateConfigurationPolicy`
- `StartConfigurationPolicyAssociation`
- `StartConfigurationPolicyDisassociation`
- `GetConfigurationPolicyAssociation`
- `BatchGetConfigurationPolicyAssociations`
- `ListConfigurationPolicyAssociations`

While central configuration is disabled because Security Hub CSPM policies are in use, Security Hub CSPM denies requests to `CreateConfigurationPolicy`, `UpdateConfigurationPolicy`, and `StartConfigurationPolicyAssociation`. The delegated administrator can still use the preceding `Get`, `List`, and `BatchGet` operations, `DeleteConfigurationPolicy`, and `StartConfigurationPolicyDisassociation` to review and clean up central configuration resources.

Account-specific APIs

Security Hub CSPM operations that can be used to enable or disable Security Hub CSPM, standards, and controls on an account-by-account basis. These operations are used in each individual Region.

Self-managed accounts can use account-specific operations to configure their own settings. Centrally managed accounts can't use the following account-specific operations in the home Region and linked Regions. In those Regions, only the delegated administrator can configure centrally managed accounts through central configuration operations and configuration policies.

- `BatchDisableStandards`
- `BatchEnableStandards`
- `BatchUpdateStandardsControlAssociations`
- `DisableSecurityHub`
- `EnableSecurityHub`
- `UpdateStandardsControl`

To check account status, the owner of a centrally managed account *can* use any `Get` or `Describe` operations of the Security Hub CSPM API.

If you use local configuration or manual account management, instead of central configuration, these account-specific operations can be used.

Self-managed accounts can also use `*Invitations` and `*Members` operations. However, we recommend that self-managed accounts don't use these operations. Policy associations can fail if a member account has its own members that are part of a different organization than the delegated administrator's.

Accounts that a Security Hub CSPM policy governs also can't use these operations in the Regions that the policy governs. For more information, see How declarative policies work in Security Hub CSPM.

Organizational unit (OU)

In AWS Organizations and Security Hub CSPM, a container for a group of AWS accounts. An organizational unit (OU) also can contain other OUs, enabling you to create a hierarchy that resembles an upside-down tree, with a parent OU at the top and branches of OUs that reach down, ending in accounts that are the leaves of the tree. An OU can have exactly one parent, and each organization account can be a member of exactly one OU.

You can manage OUs in AWS Organizations or AWS Control Tower. For more information, see Managing organizational units in the *AWS Organizations User Guide* or Govern organizations and accounts with AWS Control Tower in the *AWS Control Tower User Guide*.

The delegated administrator can associate configuration policies with specific accounts or OUs, or with the root to cover all accounts and OUs in an organization.

Centrally managed

A target that only the delegated administrator can configure across Regions by using configuration policies.

The delegated administrator account specifies whether a target is centrally managed. The delegated administrator can also change a target's status from centrally managed to self-managed, or the other way around.

Self-managed

A target that manages its own Security Hub CSPM settings. A self-managed target uses account-specific operations to configure Security Hub CSPM for itself separately in each Region. This is in contrast to centrally managed targets, which are configurable only by the delegated administrator across Regions through configuration policies.

The delegated administrator account specifies whether a target is self-managed. The delegated administrator can apply self-managed behavior to a target. Alternatively, an account or OU can inherit self-managed behavior from a parent.

The delegated administrator account can itself be a self-managed account.The delegated administrator account can change a target's status from self-managed to centrally managed, or the other way around.

Configuration policy association

A link between a configuration policy and an account, organizational unit (OU), or root. When a policy association exists, the account, OU, or root uses the settings defined by the configuration policy. An association exists in either of these cases:

- When the delegated administrator directly applies a configuration policy to an account, OU, or root
- When an account or OU inherits a configuration policy from a parent OU or the root

An association exists until a different configuration is applied or inherited.

While central configuration is disabled, Security Hub CSPM keeps existing associations but doesn't apply them. The `AssociationStatus` of each association is `DISABLED`. When you enable central configuration again, Security Hub CSPM reapplies these associations. Each association moves from `DISABLED` to `PENDING`, and then to `SUCCESS` or `FAILED`.

Applied configuration policy

A type of configuration policy association in which the delegated administrator directly applies a configuration policy to target accounts, OUs, or the root. Targets are configured in the way that the configuration policy defines, and only the delegated administrator can change their configuration. If applied to root, the configuration policy affects all accounts and OUs in the organization that don't use a different configuration through application or inheritance from the closest parent.

The delegated administrator can also apply a self-managed configuration to specific accounts, OUs, or the root.

Inherited configuration policy

A type of configuration policy association in which an account or OU adopts the configuration of the closest parent OU or the root. If a configuration policy isn't directly applied to an account or OU, it inherits the configuration of the closest parent. All elements of a policy are inherited. In other words, an account or OU can't choose to selectively inherit only parts of a policy. If the closest parent is self-managed, the child account or OU inherits the self-managed behavior of the parent.

Inheritance can't override an applied configuration. That is, if a configuration policy or self-managed configuration is directly applied to an account or OU, it uses that configuration and doesn't inherit the configuration of the parent.

Root

In AWS Organizations and Security Hub CSPM, the top-level parent node in an organization. If the delegated administrator applies a configuration policy to root, the policy is associated with all accounts and OUs in the organization unless they use a different policy, through application or inheritance, or are designated as self-managed. If the administrator designates the root as self-managed, all accounts and OUs in the organization are self-managed unless they use a configuration policy through application or inheritance. If the root is self-managed and no configuration policies currently exist, all new accounts in the organization retain their current settings.

New accounts that join an organization fall under the root until they are assigned to a specific OU. If a new account isn't assigned to an OU, it inherits the root configuration unless the delegated administrator designates it as a self-managed account.

Security Hub CSPM declarative policy

An AWS Organizations declarative policy of the `SECURITYHUB_CSPM_POLICY` type that enables and configures Security Hub CSPM, security standards, security controls, and control parameters for the accounts and Regions in its scope. This documentation also calls it a *Security Hub CSPM policy*. The management account, or a delegated administrator that has permission to manage the policy type, attaches these policies to the root, OUs, or accounts. Security Hub CSPM declarative policies are the recommended alternative to central configuration, and the two can't be used in the same organization at the same time. For more information, see Managing accounts with declarative policies in Security Hub CSPM.

Enabling central configuration in Security Hub CSPM

Important

Security Hub CSPM declarative policies are replacing central configuration as the recommended way to manage Security Hub CSPM across an organization. You can't use declarative policies and central configuration in the same organization at the same time. To move your existing configuration without coverage gaps, use the import tool in the Security Hub console. For more information, see Declarative policies and central configuration in Security Hub CSPM.

The delegated AWS Security Hub CSPM administrator account can use central configuration to configure Security Hub CSPM, standards, and controls for multiple accounts and organizational units (OUs) across AWS Regions.

If you're setting up multi-account management for the first time, use Security Hub CSPM declarative policies instead of enabling central configuration. For more information, see Managing accounts with declarative policies in Security Hub CSPM.

For background information about the benefits of central configuration and how it works, see Understanding central configuration in Security Hub CSPM.

This section explains prerequisites for central configuration and how to begin using it.

Prerequisites for central configuration

Before you can start using central configuration, you must integrate Security Hub CSPM with AWS Organizations and designate a home Region. If you use the Security Hub CSPM console, these prerequisites are included in the opt-in workflow for central configuration.

Integrate with Organizations

You must integrate Security Hub CSPM and Organizations to use central configuration.

To integrate these services, you begin by creating an organization in Organizations. From the Organizations management account, you then designate a Security Hub CSPM delegated administrator account. For instructions, see Integrating Security Hub CSPM with AWS Organizations.

Ensure that you designate your delegated administrator in your **intended home Region**. When you start using central configuration, the same delegated administrator is automatically set in all linked Regions as well. The Organizations management account *cannot* be set as the delegated administrator account.

> **Important**
>
> When you use central configuration, you can't use the Security Hub CSPM console or Security Hub CSPM APIs to change or remove the delegated administrator account. If the Organizations management account uses AWS Organizations APIs to change or remove the Security Hub CSPM delegated administrator, Security Hub CSPM automatically stops central configuration. Your configuration policies are also disassociated and

deleted. Member accounts retain the configuration that they had before the delegated administrator was changed or removed.

Designate a home Region

You must designate a home Region to use central configuration. The home Region is the Region from which the delegated administrator configures the organization.

> **Note**
>
> The home Region cannot be a Region that AWS has designated as an opt-in Region. An opt-in Region is disabled by default. For a list of opt-in Regions, see Considerations before enabling and disabling Regions in the *AWS Account Management Reference Guide*.

Optionally, you can specify one or more linked Regions that are configurable from the home Region.

The delegated administrator can create and manage configuration policies only from the home Region. Configuration policies take effect in the home Region and all linked Regions. You can't create a configuration policy that applies only to a subset of these Regions, and not others. The exception to this is controls that involve global resources. If you use central configuration, Security Hub CSPM automatically disables controls that involve global resources in all Regions except the home Region. For more information, see Controls that use global resources.

The home Region is also your Security Hub CSPM aggregation Region that receives findings, insights, and other data from linked Regions.

If you have already set an aggregation Region for cross-Region aggregation, then that's your default home Region for central configuration. You can change the home Region before you start to use central configuration by deleting your current finding aggregator and creating a new one in your desired home Region. A finding aggregator is a Security Hub CSPM resource that specifies the home Region and linked Regions.

To designate a home Region, see the steps for setting an aggregation Region. If you already have a home Region, you can invoke the GetFindingAggregator API to see details about it, including which Regions currently are linked to it.

Instructions for enabling central configuration

Choose your preferred method, and follow the steps to enable central configuration for your organization.

Security Hub CSPM console

To enable central configuration (console)

1. Open the AWS Security Hub CSPM console at https://console.aws.amazon.com/securityhub/.
2. On the navigation pane, choose **Settings** and **Configuration**. Then, choose **Start central configuration**.

   If you're onboarding to Security Hub CSPM, choose **Go to Security Hub CSPM**.
3. On the **Designate delegated administrator** page, select your delegated administrator account or enter its account ID. If applicable, we recommend choosing the same delegated administrator that you have set for other AWS security and compliance services. Choose **Set delegated administrator**.
4. On the **Centralize organization** page, in the **Regions** section, select your home Region. You must be signed in to the home Region to proceed. If you've already set an aggregation Region for cross-Region aggregation, it's displayed as the home Region. To change the home Region, choose **Edit Region settings**. You can then select your preferred home Region and return to this workflow.
5. Select at least one Region to link to the home Region. Optionally, choose whether you want to automatically link future supported Regions to the home Region. The Regions you select here will be configurable from the home Region by the delegated administrator. Configuration policies take effect in your home Region and all linked Regions.
6. Choose **Confirm and continue**.
7. You can now use central configuration. Continue following the console prompts to create your first configuration policy. If you're not ready to create a configuration policy yet, choose **I'm not ready to configure yet**. You can create a policy later by choosing **Settings** and **Configuration** in the navigation pane. For instructions on creating a configuration policy, see Creating and associating configuration policies.

Security Hub CSPM API

To enable central configuration (API)

1. Using the credentials of the delegated administrator account, invoke the UpdateOrganizationConfiguration API from the home Region.
2. Set the `AutoEnable` field to `false`.
3. Set the `ConfigurationType` field in the `OrganizationConfiguration` object to `CENTRAL`. This action has the following impact:
   - Designates the calling account as the Security Hub CSPM delegated administrator in all linked Regions.
   - Enables Security Hub CSPM in the delegated administrator account in all linked Regions.
   - Designates the calling account as the Security Hub CSPM delegated administrator for new and existing accounts that use Security Hub CSPM and belong to the organization. This occurs in the home Region and all linked Regions. The calling account is set as the delegated administrator for new organization accounts only if they are associated with a configuration policy that has Security Hub CSPM enabled. The calling account is set as the delegated administrator for existing organization accounts only if they already have Security Hub CSPM enabled.
   - Sets AutoEnable to `false` in all linked Regions, and sets AutoEnableStandards to `NONE` in the home Region and all linked Regions. These parameters aren't relevant in the home and linked Regions when you use central configuration, but you can automatically enable Security Hub CSPM and default security standards in organization accounts through the use of configuration policies.
4. You can now use central configuration. The delegated administrator can create configuration policies to configure Security Hub CSPM in your organization. For instructions on creating a configuration policy, see Creating and associating configuration policies.

Example API request:

```
{
    "AutoEnable": false,
    "OrganizationConfiguration": {
        "ConfigurationType": "CENTRAL"
    }
}
```

AWS CLI

To enable central configuration (AWS CLI)

1. Using the credentials of the delegated administrator account, run the update-organization-configuration command from the home Region.
2. Include the `no-auto-enable` parameter.
3. Set the `ConfigurationType` field in the `organization-configuration` object to `CENTRAL`. This action has the following impact:
   - Designates the calling account as the Security Hub CSPM delegated administrator in all linked Regions.
   - Enables Security Hub CSPM in the delegated administrator account in all linked Regions.
   - Designates the calling account as the Security Hub CSPM delegated administrator for new and existing accounts that use Security Hub CSPM and belong to the organization. This occurs in the home Region and all linked Regions. The calling account is set as the delegated administrator for new organization accounts only if they are associated with a configuration policy that has Security Hub enabled. The calling account is set as the delegated administrator for existing organization accounts only if they already have Security Hub CSPM enabled.
   - Sets the auto-enablement option to no-auto-enable in all linked Regions, and sets auto-enable-standards to `NONE` in the home Region and all linked Regions. These parameters aren't relevant in the home and linked Regions when you use central configuration, but you can automatically enable Security Hub CSPM and default security standards in organization accounts through the use of configuration policies.
4. You can now use central configuration. The delegated administrator can create configuration policies to configure Security Hub CSPM in your organization. For instructions on creating a configuration policy, see Creating and associating configuration policies.

Example command:

```
aws securityhub --region us-east-1 update-organization-configuration \
--no-auto-enable \
--organization-configuration '{"ConfigurationType": "CENTRAL"}'
```

Centrally managed versus self-managed targets

> **Important**
>
> Security Hub CSPM declarative policies are replacing central configuration as the recommended way to manage Security Hub CSPM across an organization. You can't use declarative policies and central configuration in the same organization at the same time. To move your existing configuration without coverage gaps, use the import tool in the Security Hub console. For more information, see Declarative policies and central configuration in Security Hub CSPM.

When you enable central configuration, the delegated AWS Security Hub CSPM administrator can designate each organization account, organizational unit (OU), and the root as *centrally managed* or *self-managed*. The management type of a target determines how you can specify its Security Hub CSPM settings.

For background information about the benefits of central configuration and how it works, see Understanding central configuration in Security Hub CSPM.

This section explains the differences between a centrally managed and self-managed designation and how to choose the management type of an account, OU, or the root.

Self-managed

The owner of a self-managed account, OU, or root must configure its settings separately in each AWS Region. The delegated administrator can't create configuration policies for self-managed targets.

Centrally managed

Only the delegated Security Hub CSPM administrator can configure settings for centrally managed accounts, OUs, or the root across the home Region and linked Regions. Configuration policies can be associated with centrally managed accounts and OUs.

The delegated administrator can switch the status of a target between self-managed and centrally managed. By default, all accounts and OU are self-managed when you start central configuration

through the Security Hub CSPM API. In the console, management type depends on your first configuration policy. Accounts and OUs that you associate with your first policy are centrally managed. Other accounts and OUs are self-managed by default.

If you associate a configuration policy with a previously self-managed account, the policy settings override the self-managed designation. The account becomes centrally managed and adopts the settings reflected in the configuration policy.

If you change a centrally managed account to a self-managed account, the settings that were previously applied to the account through a configuration policy remain in place. For example, a centrally managed account could initially be associated with a policy that enabled Security Hub CSPM, enabled AWS Foundational Security Best Practices, and disabled CloudTrail.1. If you then designate the account as self-managed, all of the settings remain unchanged. However, the account owner can independently change the settings for the account going forward.

Child accounts and OUs can inherit self-managed behavior from a self-managed parent, in the same way that child accounts and OUs can inherit configuration policies from a centrally managed parent. For more information, see Policy association through application and inheritance.

A self-managed account or OU can't inherit a configuration policy from a parent node or from the root. For example, if you want all accounts and OUs in your organization to inherit a configuration policy from the root, you must change the management type of self-managed nodes to centrally managed.

Options to configure settings in self-managed accounts

Self-managed accounts must configure their own settings separately in each Region.

Owners of self-managed accounts can invoke the following operations of the Security Hub CSPM API in each Region to configure their settings:

- `EnableSecurityHub` and `DisableSecurityHub` to enable or disable the Security Hub CSPM service (if a self-managed account has a delegated Security Hub CSPM administrator, the administrator must disassociate the account before the account owner can disable Security Hub CSPM).
- `BatchEnableStandards` and `BatchDisableStandards` to enable or disable standards
- `BatchUpdateStandardsControlAssociations` or `UpdateStandardsControl` to enable or disable controls

Self-managed accounts can also use `*Invitations` and `*Members` operations. However, we recommend that self-managed accounts don't use these operations. Policy associations can fail if a member account has its own members that are part of a different organization than the delegated administrator's.

For descriptions of Security Hub CSPM API actions, see the *AWS Security Hub CSPM API Reference*.

Self-managed accounts can also use the Security Hub CSPM console or AWS CLI to configure their settings in each Region.

Self-managed accounts can't invoke any APIs related to Security Hub CSPM configuration policies and policy associations. Only the delegated administrator can invoke central configuration APIs and use configuration policies to configure centrally managed accounts.

Choosing the management type of a target

Choose your preferred method, and follow the steps to designate an account or OU as centrally managed or self-managed in AWS Security Hub CSPM.

Security Hub CSPM console

To choose the management type of an account or OU

1. Open the AWS Security Hub CSPM console at https://console.aws.amazon.com/securityhub/.

   Sign in using the credentials of the delegated Security Hub CSPM administrator account in the home Region.
2. Choose **Configuration**.
3. On the **Organization** tab, select the target account or OU. Choose **Edit**.
4. On the **Define configuration** page, for **Management type**, choose **Centrally managed** if you want the delegated administrator to configure the target account or OU. Then, choose **Apply a specific policy** if you want to associate an existing configuration policy with the target. Choose **Inherit from my organization** if you want the target to inherit the configuration of its closest parent. Choose **Self-managed** if you want the account or OU to configure its own settings.
5. Choose **Next**. Review your changes, and choose **Save**.

Security Hub CSPM API

To choose the management type of an account or OU

1. Invoke the StartConfigurationPolicyAssociation API from the Security Hub CSPM delegated administrator account in the home Region.
2. For the `ConfigurationPolicyIdentifier` field, provide `SELF_MANAGED_SECURITY_HUB` if you want the account or OU to control its own settings. Provide the Amazon Resource Name (ARN) or ID of the relevant configuration policy if you want the delegated administrator to control settings for the account or OU.
3. For the `Target` field, provide the AWS account ID, OU ID, or root ID of the target whose management type you want to change. This associates the self-managed behavior or specified configuration policy with the target. Child accounts of the target may inherit the self-managed behavior or configuration policy.

Example API request to designate a self-managed account:

```
{
    "ConfigurationPolicyIdentifier": "SELF_MANAGED_SECURITY_HUB",
    "Target": {"AccountId": "123456789012"}
}
```

AWS CLI

To choose the management type of an account or OU

1. Run the start-configuration-policy-association command from the Security Hub CSPM delegated administrator account in the home Region.
2. For `configuration-policy-identifier` field, provide `SELF_MANAGED_SECURITY_HUB` if you want the account or OU to control its own settings. Provide the Amazon Resource Name (ARN) or ID of the relevant configuration policy if you want the delegated administrator to control settings for the account or OU..
3. For the `target` field, provide the AWS account ID, OU ID, or root ID of the target whose management type you want to change. This associates the self-managed behavior or specified configuration policy with the target. Child accounts of the target may inherit the self-managed behavior or configuration policy.

Example command to designate a self-managed account:

```
aws securityhub --region us-east-1 start-configuration-policy-association \
--configuration-policy-identifier "SELF_MANAGED_SECURITY_HUB" \
--target '{"AccountId": "123456789012"}'
```

How configuration policies work in Security Hub CSPM

Important

Security Hub CSPM declarative policies are replacing central configuration as the recommended way to manage Security Hub CSPM across an organization. You can't use declarative policies and central configuration in the same organization at the same time. To move your existing configuration without coverage gaps, use the import tool in the Security Hub console. For more information, see Declarative policies and central configuration in Security Hub CSPM.

The delegated AWS Security Hub CSPM administrator can create configuration policies to configure Security Hub CSPM, security standards, and security controls for an organization. After creating a configuration policy, the delegated administrator can associate it with specific accounts, organizational units (OUs), or the root. The policy then takes effect in the specified accounts, OUs, or the root.

For background information about the benefits of central configuration and how it works, see Understanding central configuration in Security Hub CSPM.

This section provides a detailed overview of configuration policies.

Policy considerations

Before you create a configuration policy in Security Hub CSPM, consider the following details.

- **Configuration policies must be associated to take effect** – After you create a configuration policy, you can associate it with one or more accounts, organizational units (OUs), or the root. A configuration policy can be associated with accounts or OUs through direct application, or through inheritance from a parent OU.

- **An account or OU can be associated with only one configuration policy** – To prevent conflicting settings, an account or OU can only be associated with one configuration policy at any given time. Alternatively, an account or OU can be self-managed.
- **Configuration policies are complete** – Configuration policies provide a complete specification of settings. For example, a child account can't accept settings for some controls from one policy and settings for other controls from another policy. When you associate a policy with a child account, ensure that the policy specifies all of the settings that you want the child account to use.
- **Configuration policies can't be reverted** – There's no option to revert a configuration policy after you associate it with accounts or OUs. For example, if you associate a configuration policy that disables CloudWatch controls with a specific account, and then dissociate that policy, the CloudWatch controls continue to be disabled in that account. To enable CloudWatch controls again, you can associate the account with a new policy that enables the controls. Alternatively, you can change the account to self-managed and enable each CloudWatch control in the account.
- **Configuration policies take effect in your home Region and all linked Regions** – A configuration policy affects all associated accounts in the home Region and all linked Regions. You can't create a configuration policy that takes effect in only some of these Regions and not others. The exception to this is controls that use global resources. Security Hub CSPM automatically disables controls that involve global resources in all Regions except the home Region.

  Regions that AWS introduced on or after March 20, 2019 are known as opt-in Regions. You must enable such a Region for an account before a configuration policy takes effect there. The Organizations management account can enable opt-in Regions for a member account. For instructions on enabling opt-in Regions, see Specify which AWS Regions your account can use in the *AWS Account Management Reference Guide*.

  If your policy configures a control that isn't available in the home Region or one or more linked Regions, Security Hub CSPM skips the control configuration in unavailable Regions but applies the configuration in Regions where the control is available. You lack coverage for a control that isn't available in the home Region or any of the linked Regions.
- **Configuration policies are resources** – As a resource, a configuration policy has an Amazon Resource Name (ARN) and a universally unique identifier (UUID). The ARN uses the following format: `arn:`*`partition:`*`securityhub:`*`region`*`:`*`delegated administrator account ID`*`:configuration-policy/`*`configuration policy UUID`*. A self-managed

configuration has no ARN or UUID. The identifier for a self-managed configuration is `SELF_MANAGED_SECURITY_HUB`.

- **Multicloud standards are not supported in configuration policies** – Configuration policies can only include AWS security standards and controls. Multicloud standards, such as CIS Azure Foundations Benchmark v4.0.0, and their associated controls (for example, `Azure.Storage.1`) cannot be included in a configuration policy. If you include a multicloud standard ARN or control ID in a configuration policy, the request returns an `InvalidInputException`. To enable or configure multicloud standards, use local configuration mechanisms directly in the desired AWS account.

Types of configuration policies

Each configuration policy specifies the following settings:

- Enable or disable Security Hub CSPM.
- Enable one or more security standards.
- Indicate which security controls are enabled across enabled standards. You can do this by providing a list of specific controls that should be enabled, and Security Hub CSPM disables all other controls, including new controls when they are released. Alternatively, you can provide a list of specific controls that should be disabled, and Security Hub CSPM enables all other controls, including new controls when they are released.
- Optionally, customize parameters for select enabled controls across enabled standards.

Central configuration policies don't include AWS Config recorder settings. You must separately enable AWS Config and turn on recording for required resources in order for Security Hub CSPM to generate control findings. For more information, see Considerations before enabling and configuring AWS Config.

If you enable a standard but haven't enabled AWS Config, Security Hub CSPM tries to create service-linked AWS Config rules on a schedule. With central configuration, Security Hub CSPM also tries to create these rules each time you associate a configuration policy with accounts, OUs, or the root. This applies only if the policy enables one or more standards.

If you use central configuration, Security Hub CSPM automatically disables controls that involve global resources in all Regions except the home Region. Other controls that you choose to enable though a configuration policy are enabled in all Regions where they are available. To limit findings

for these controls to just one Region, you can update your AWS Config recorder settings and turn off global resource recording in all Regions except the home Region.

If an enabled control that involves global resources isn't supported in the home Region, Security Hub CSPM tries to enable the control in one linked Region where the control is supported. With central configuration, you lack coverage for a control that isn't available in the home Region or any of the linked Regions.

For a list of controls that involve global resources, see Controls that use global resources.

Recommended configuration policy

When creating a configuration policy for the *first time in the Security Hub CSPM console*, you have the option to choose the Security Hub CSPM recommended policy.

The recommended policy enables Security Hub CSPM, the AWS Foundational Security Best Practices (FSBP) standard, and all existing and new FSBP controls. Controls that accept parameters use the default values. The recommended policy applies to root (all accounts and OUs, both new and existing). After creating the recommended policy for your organization, you can modify it from the delegated administrator account. For example, you can enable additional standards or controls or disable specific FSBP controls. For instructions on modifying a configuration policy, see Updating configuration policies.

Custom configuration policy

Instead of the recommended policy, the delegated administrator can create up to 20 custom configuration policies. You can associate a single custom policy with your entire organization or different custom policies with different accounts and OUs. For a custom configuration policy, you specify your desired settings. For example, you can create a custom policy that enables FSBP, the Center for Internet Security (CIS) AWS Foundations Benchmark v1.4.0, and all controls in those standards except Amazon Redshift controls. The level of granularity that you use in custom configuration policies depends on the intended scope of security coverage throughout your organization.

> **Note**
>
> You can't associate a configuration policy that disables Security Hub CSPM with the delegated administrator account. Such a policy can be associated with other accounts but skips association with the delegated administrator. The delegated administrator account retains its current configuration.

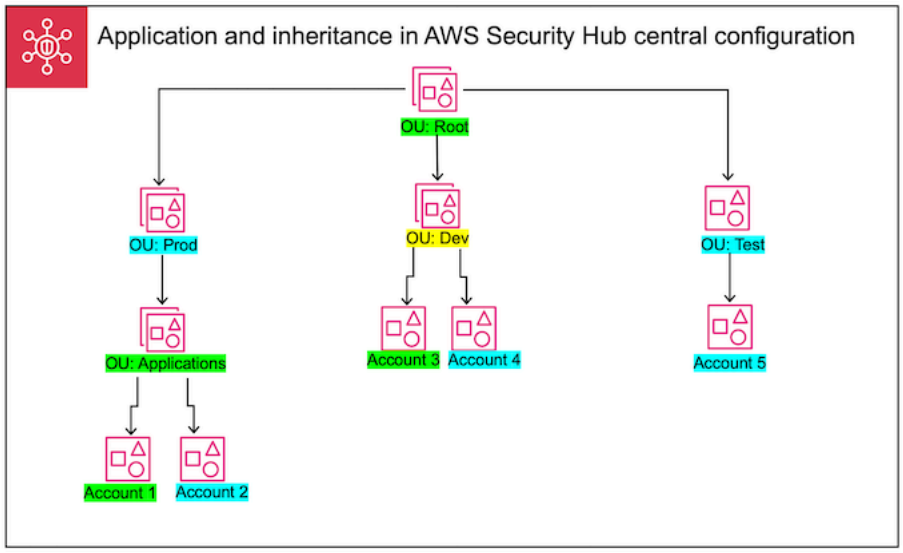
After creating a custom configuration policy, you can switch to the recommended configuration policy by updating your configuration policy to reflect the recommended configuration. However, you don't see the choice to create the recommended configuration policy in the Security Hub CSPM console after your first policy is created.

Policy association through application and inheritance

When you first opt in to central configuration, your organization has no associations and behaves in the same way that it did prior to opt-in. The delegated administrator can then establish associations between a configuration policy or self-managed behavior and accounts, OUs, or the root. Associations can be established through *application* or *inheritance*.

From the delegated administrator account, you can directly apply a configuration policy to an account, OU, or the root. Alternatively, the delegated administrator can directly apply a self-managed designation to an account, OU, or the root.

In the absence of direct application, an account or OU inherits the settings of the closest parent that has a configuration policy or self-managed behavior. If the closest parent is associated with a configuration policy, the child inherits that policy and is configurable only by the delegated administrator from the home Region. If the closest parent is self-managed, the child inherits the self-managed behavior and has the ability to specify its own settings in each AWS Region.



Application takes precedence over inheritance. In other words, inheritance doesn't override a configuration policy or self-managed designation that the delegated administrator has directly applied to an account or OU.

If you directly apply a configuration policy to a self-managed account, the policy overrides the self-managed designation. The account becomes centrally managed and adopts the settings reflected in the configuration policy.

We recommend directly applying a configuration policy to the root. If you apply a policy to the root, then new accounts that join your organization will automatically inherit the root policy unless you associate them with a different policy or designate them as self-managed.

Only one configuration policy can be associated with an account or OU at a given time, either through application or inheritance. This is designed to prevent conflicting settings.

The following diagram illustrates how policy application and inheritance work in central configuration.

In this example, a node highlighted in green has a configuration policy that's been applied to it. A node highlighted in blue has no configuration policy that's been applied to it. A node highlighted in yellow has been designated as self-managed. Each account and OU uses the following configuration:

- **OU:Root (Green)** – This OU uses the configuration policy that's been applied to it.
- **OU:Prod (Blue)** – This OU inherits the configuration policy from OU:Root.
- **OU:Applications (Green)** – This OU uses the configuration policy that's been applied to it.
- **Account 1 (Green)** – This account uses the configuration policy that's been applied to it.
- **Account 2 (Blue)** – This account inherits the configuration policy from OU:Applications.
- **OU:Dev (Yellow)** – This OU is self-managed.
- **Account 3 (Green)** – This account uses the configuration policy that's been applied to it.
- **Account 4 (Blue)** – This account inherits self-managed behavior from OU:Dev.
- **OU:Test (Blue)** – This account inherits the configuration policy from OU:Root.
- **Account 5 (Blue)** – This account inherits the configuration policy from OU:Root since its immediate parent, OU:Test, isn't associated with a configuration policy.

Testing a configuration policy

To make sure you understand how configuration policies work, we recommend creating one policy and associating it with a test account or OU.

To test a configuration policy

1. Create a custom configuration policy, and verify that the specified settings for Security Hub CSPM enablement, standards, and controls are correct. For instructions, see Creating and associating configuration policies.
2. Apply the configuration policy to a test account or OU that doesn't have any child accounts or OUs.
3. Verify that the test account or OU uses the configuration policy in the expected way in your home Region and all linked Regions. You can also verify that all other accounts and OUs in your organization remain self-managed and can change their own settings in each Region.

After you've tested a configuration policy in a single account or OU, you can associate it with other accounts and OUs.

Creating and associating configuration policies

> **Important**
>
> Before you create a new configuration policy, consider migrating to Security Hub CSPM declarative policies instead. Declarative policies are replacing central configuration, and you can't use the two in the same organization at the same time. To move your existing configuration policies to declarative policies without coverage gaps, use the import tool in the Security Hub console. For more information, see Declarative policies and central configuration in Security Hub CSPM.

Create a configuration policy only if your organization will continue to use central configuration until you migrate. If you're setting up multi-account management for the first time, use declarative policies instead. For more information, see Managing accounts with declarative policies in Security Hub CSPM.

The delegated AWS Security Hub CSPM administrator account can create configuration policies that specify how Security Hub CSPM, standards, and controls are configured in specified accounts and organizational units (OUs). A configuration policy takes effect only after the delegated administrator associates it with at least one account or organizational unit (OUs), or the root. The delegated administrator can also associate a self-managed configuration with accounts, OUs, or the root.

If this is your first time creating a configuration policy, we recommend first reviewing How configuration policies work in Security Hub CSPM.

> **Note**
>
> Configuration policies support AWS standards and controls only. You cannot include multicloud standards (such as CIS Azure Foundations Benchmark v4.0.0) or Azure controls in a configuration policy. Including a multicloud standard ARN or control ID returns `InvalidInputException`. To enable or configure multicloud standards, use local configuration mechanisms directly in the desired AWS account.

Steps to create and associate a configuration policy

Choose your preferred access method, and follow the steps to create and associate a configuration policy or self-managed configuration. When using the Security Hub CSPM console, you can associate a configuration with multiple accounts or OUs at the same time. When using the Security Hub CSPM API or AWS CLI, you can associate a configuration with only one account or OU in each request.

> **Note**
>
> If you use central configuration, Security Hub CSPM automatically disables controls that involve global resources in all Regions except the home Region. Other controls that you choose to enable though a configuration policy are enabled in all Regions where they are available. To limit findings for these controls to just one Region, you can update your AWS Config recorder settings and turn off global resource recording in all Regions except the home Region.
>
> If an enabled control that involves global resources isn't supported in the home Region, Security Hub CSPM tries to enable the control in one linked Region where the control is supported. With central configuration, you lack coverage for a control that isn't available in the home Region or any of the linked Regions.
>
> For a list of controls that involve global resources, see Controls that use global resources.

Security Hub CSPM console

To create and associate configuration policies

1. Open the AWS Security Hub CSPM console at https://console.aws.amazon.com/securityhub/.

   Sign in using the credentials of the delegated Security Hub CSPM administrator account in the home Region.

2. In the navigation pane, choose **Configuration** and the **Policies** tab. Then, choose **Create policy**.

3. On the **Configure organization** page, if this is your first time creating an configuration policy, you see three options under **Configuration type**. If you've already created at least one configuration policy, you only see the **Custom policy** option.

   - Choose **Use the AWS recommended Security Hub CSPM configuration across my entire organization** to use our recommended policy. The recommended policy enables Security Hub CSPM in all organization accounts, enables the AWS Foundational Security Best Practices (FSBP) standard, and enables all new and existing FSBP controls. The controls use default parameter values.
   - Choose **I'm not ready to configure yet** to create a configuration policy later.
   - Choose **Custom policy** to create a custom configuration policy. Specify whether to enable or disable Security Hub CSPM, which standards to enable, and which controls to enable across those standards. Optionally, specify custom parameter values for one or more enabled controls that support custom parameters.

4. In the **Accounts** section, choose which target accounts, OUs, or the root that you want your configuration policy to apply to.

   - Choose **All accounts** if you want to apply the configuration policy to the root. This includes all accounts and OUs in the organization that don't have another policy applied to them or inherited.
   - Choose **Specific accounts** if you want to apply the configuration policy to specific accounts or OUs. Enter the account IDs, or select the accounts and OUs from the organization structure. You can apply the policy to a maximum of 15 targets (accounts, OUs, or root) when you create it. To specify a larger number, edit your policy after creation, and apply it to additional targets.

- Choose **The delegated administrator only** to apply the configuration policy to the current delegated administrator account.

5. Choose **Next**.
6. On the **Review and apply** page, review your configuration policy details. Then, choose **Create policy and apply**. In your home Region and linked Regions, this action overrides the existing configuration settings of accounts that are associated with this configuration policy. Accounts may be associated with the configuration policy through application, or inheritance from a parent node. Child accounts and OUs of the applied targets will automatically inherit this configuration policy unless they are specifically excluded, self-managed, or use a different configuration policy.

Security Hub CSPM API

To create and associate configuration policies

1. Invoke the CreateConfigurationPolicy API from the Security Hub CSPM delegated administrator account in the home Region.
2. For `Name`, provide a unique name for the configuration policy. Optionally, for `Description`, provide a description for the configuration policy.
3. For the `ServiceEnabled` field, specify if you want Security Hub CSPM to be enabled or disabled in this configuration policy.
4. For the `EnabledStandardIdentifiers` field, specify which Security Hub CSPM standards you want to enable in this configuration policy.
5. For the `SecurityControlsConfiguration` object, specify which controls you want to enable or disable in this configuration policy. Choosing `EnabledSecurityControlIdentifiers` means that the specified controls are enabled. Other controls that are part of your enabled standards (including newly released controls) are disabled. Choosing `DisabledSecurityControlIdentifiers` means that the specified controls are disabled. Other controls that are part of your enabled standards (including newly released controls) are enabled.
6. Optionally, for the `SecurityControlCustomParameters` field, specify enabled controls for which you want to customize parameters. Provide `CUSTOM` for the `ValueType` field and the custom parameter value for the `Value` field. The value must be the correct data type and within valid ranges specified by Security Hub CSPM. Only select controls support

custom parameter values. For more information, see Understanding control parameters in Security Hub CSPM.

7. To apply your configuration policy to accounts or OUs, invoke the StartConfigurationPolicyAssociation API from the Security Hub CSPM delegated administrator account in the home Region.
8. For the `ConfigurationPolicyIdentifier` field, provide the Amazon Resource Name (ARN) or universally unique identifier (UUID) of the policy. The ARN and UUID are returned by the `CreateConfigurationPolicy` API. For a self-managed configuration, the `ConfigurationPolicyIdentifier` field is equal to `SELF_MANAGED_SECURITY_HUB`.
9. For the `Target` field, provide the OU, account, or the root ID to which you want this configuration policy to apply. You can only provide one target in each API request. Child accounts and OUs of the selected target will automatically inherit this configuration policy unless they are self-managed or use a different configuration policy.

Example API request to create a configuration policy:

```
{
    "Name": "SampleConfigurationPolicy",
    "Description": "Configuration policy for production accounts",
    "ConfigurationPolicy": {
        "SecurityHub": {
             "ServiceEnabled": true,
             "EnabledStandardIdentifiers": [
                    "arn:aws:securityhub:us-east-1::standards/aws-foundational-
security-best-practices/v/1.0.0",
                    "arn:aws:securityhub:::ruleset/cis-aws-foundations-benchmark/
v/1.2.0"
                ],
            "SecurityControlsConfiguration": {
                "DisabledSecurityControlIdentifiers": [
                    "CloudTrail.2"
                ],
                "SecurityControlCustomParameters": [
                    {
                        "SecurityControlId": "ACM.1",
                        "Parameters": {
                            "daysToExpiration": {
                                "ValueType": "CUSTOM",
                                "Value": {
                                    "Integer": 15
```

```
                                }
                            }
                        }
                    }
                ]
            }
        }
    }
}
```

Example API request to associate a configuration policy:

```
{
    "ConfigurationPolicyIdentifier": "arn:aws:securityhub:us-
east-1:123456789012:configuration-policy/a1b2c3d4-5678-90ab-cdef-EXAMPLE11111",
    "Target": {"OrganizationalUnitId": "ou-examplerootid111-exampleouid111"}
}
```

AWS CLI

To create and associate configuration policies

1. Run the create-configuration-policy command from the Security Hub CSPM delegated administrator account in the home Region.
2. For `name`, provide a unique name for the configuration policy. Optionally, for `description`, provide a description for the configuration policy.
3. For the `ServiceEnabled` field, specify if you want Security Hub CSPM to be enabled or disabled in this configuration policy.
4. For the `EnabledStandardIdentifiers` field, specify which Security Hub CSPM standards you want to enable in this configuration policy.
5. For the `SecurityControlsConfiguration` field, specify which controls you want to enable or disable in this configuration policy. Choosing `EnabledSecurityControlIdentifiers` means that the specified controls are enabled. Other controls that are part of your enabled standards (including newly released controls) are disabled. Choosing `DisabledSecurityControlIdentifiers` means that the specified controls are disabled. Other controls that apply to your enabled standards (including newly released controls) are enabled.

6. Optionally, for the `SecurityControlCustomParameters` field, specify enabled controls for which you want to customize parameters. Provide `CUSTOM` for the `ValueType` field and the custom parameter value for the `Value` field. The value must be the correct data type and within valid ranges specified by Security Hub CSPM. Only select controls support custom parameter values. For more information, see Understanding control parameters in Security Hub CSPM.
7. To apply your configuration policy to accounts or OUs, run the start-configuration-policy-association command from the Security Hub CSPM delegated administrator account in the home Region.
8. For the `configuration-policy-identifier` field, provide the Amazon Resource Name (ARN) or ID of the configuration policy. This ARN and ID are returned by the `create-configuration-policy` command.
9. For the `target` field, provide the OU, account, or the root ID to which you want this configuration policy to apply. You can only provide one target each time you run the command. Children of the selected target will automatically inherit this configuration policy unless they are self-managed or use a different configuration policy.

Example command to create a configuration policy:

```
aws securityhub --region us-east-1 create-configuration-policy \
--name "SampleConfigurationPolicy" \
--description "Configuration policy for production accounts" \
--configuration-policy '{"SecurityHub": {"ServiceEnabled": true,
 "EnabledStandardIdentifiers": ["arn:aws:securityhub:us-east-1::standards/aws-
foundational-security-best-practices/v/1.0.0","arn:aws:securityhub:::ruleset/
cis-aws-foundations-benchmark/v/1.2.0"],"SecurityControlsConfiguration":
{"DisabledSecurityControlIdentifiers": ["CloudTrail.2"],
 "SecurityControlCustomParameters": [{"SecurityControlId": "ACM.1", "Parameters":
 {"daysToExpiration": {"ValueType": "CUSTOM", "Value": {"Integer": 15}}}}]}}}'
```

Example command to associate a configuration policy:

```
aws securityhub --region us-east-1 start-configuration-policy-association \
--configuration-policy-identifier "arn:aws:securityhub:us-
east-1:123456789012:configuration-policy/a1b2c3d4-5678-90ab-cdef-EXAMPLE11111" \
--target '{"OrganizationalUnitId": "ou-examplerootid111-exampleouid111"}'
```

The `StartConfigurationPolicyAssociation` API returns a field called `AssociationStatus`. This field tells you whether a policy association is pending or in a state of success or failure. It can take up to 24 hours for the status to change from `PENDING` to `SUCCESS` or `FAILURE`. For more information about association status, see Reviewing the association status of a configuration policy.

Reviewing the status and details of configuration policies

> **Important**
>
> Security Hub CSPM declarative policies are replacing central configuration as the recommended way to manage Security Hub CSPM across an organization. You can't use declarative policies and central configuration in the same organization at the same time. To move your existing configuration without coverage gaps, use the import tool in the Security Hub console. For more information, see Declarative policies and central configuration in Security Hub CSPM.

The delegated AWS Security Hub CSPM administrator can view configuration policies for an organization and their details. This includes which accounts and organizational units (OUs) a policy is associated with.

For background information about the benefits of central configuration and how it works, see Understanding central configuration in Security Hub CSPM.

Choose your preferred method, and follow the steps to view your configuration policies.

Security Hub CSPM console

To view configuration policies (console)

1. Open the AWS Security Hub CSPM console at https://console.aws.amazon.com/securityhub/.

   Sign in using the credentials of the delegated Security Hub CSPM administrator account in the home Region.
2. In the navigation pane, choose **Settings** and **Configuration**.
3. Choose the **Policies** tab for an overview of your configuration policies.

4. Select a configuration policy, and choose **View details** to see additional details about it, including which accounts and OUs it's associated with.

Security Hub CSPM API

To view a summary list of all your configuration policies, use the ListConfigurationPolicies operation of the Security Hub CSPM API. If you use the AWS CLI, run the list-configuration-policies command. The delegated Security Hub CSPM administrator account should invoke the operation in the home Region.

```
$ aws securityhub list-configuration-policies \
--max-items 5 \
--starting-token U2FsdGVkX19nUI2zoh+Pou9YyutlYJHWpn9xnG4hqSOhvw3o2JqjI23QDxdf
```

To view details about a specific configuration policy, use the GetConfigurationPolicy operation. If you use the AWS CLI, run the get-configuration-policy. The delegated administrator account should invoke the operation in the home Region. Provide the Amazon Resource Name (ARN) or ID of the configuration policy whose details you want to see.

```
$ aws securityhub get-configuration-policy \
--identifier "arn:aws:securityhub:us-east-1:123456789012:configuration-policy/
a1b2c3d4-5678-90ab-cdef-EXAMPLE11111"
```

To view a summary list of all your configuration policies and their account associations, use the use the ListConfigurationPolicyAssociations operation. If you use the AWS CLI, run the list-configuration-policy-associations command. The delegated administrator account should invoke the operation in the home Region. Optionally, you can provide pagination parameters or filter the results by a specific policy ID, association type, or association status.

```
$ aws securityhub list-configuration-policy-associations \
--filters '{"AssociationType": "APPLIED"}'
```

To view associations for a specific account, use the GetConfigurationPolicyAssociation operation. If you use the AWS CLI, run the get-configuration-policy-association command. The delegated administrator account should invoke the operation in the home Region. For `target`, provide the account number, OU ID, or root ID.

```
$ aws securityhub get-configuration-policy-association \
```

```
--target '{"AccountId": "123456789012"}'
```

Reviewing the association status of a configuration policy

The following central configuration API operations return a field called `AssociationStatus`:

- `BatchGetConfigurationPolicyAssociations`
- `GetConfigurationPolicyAssociation`
- `ListConfigurationPolicyAssociations`
- `StartConfigurationPolicyAssociation`

This field is returned both when the underlying configuration is a configuration policy and when it's self-managed behavior.

The value of `AssociationStatus` tells you whether a policy association is pending or in a state of success or failure for a specific account. It can take up to 24 hours for the status to change from `PENDING` to `SUCCESS` or `FAILED`. A status of `SUCCESS` means that all settings specified in the configuration policy are associated with the account. A status of `FAILED` means that one or more settings specified in the configuration policy failed to associate with the account. Despite a `FAILED` status, the account could be partially configured in accordance with the policy. For example, you might try to associate an account with a configuration policy that enables Security Hub CSPM, enables AWS Foundational Security Best Practices, and disables CloudTrail.1. The initial two settings could succeed, but the CloudTrail.1 setting could fail. In this example, the association status is `FAILED` even though some settings were correctly configured.

The association status of a parent OU or the root depends on the status of its children. If the association status of all the children is `SUCCESS`, the association status of the parent is `SUCCESS`. If the association status of one or more children is `FAILED`, the association status of the parent is `FAILED`.

The value of `AssociationStatus` depends on the association status of the policy in all relevant Regions. If the association succeeds in the home Region and all linked Regions, the value of `AssociationStatus` is `SUCCESS`. If the association fails in one or more of these Regions, the value of `AssociationStatus` is `FAILED`.

The following behavior also impacts the value of `AssociationStatus`:

- If the target is a parent OU or the root, it has an `AssociationStatus` of `SUCCESS` or `FAILED` only when all of the children have a `SUCCESS` or `FAILED` status. If the association status of a child account or OU changes (for example, when a linked Region is added or removed) after you first associate the parent with a configuration, the change doesn't update the association status of the parent unless you invoke the `StartConfigurationPolicyAssociation` API again.
- If the target is an account, it has an `AssociationStatus` of `SUCCESS` or `FAILED` only if the association has a result of `SUCCESS` or `FAILED` in the home Region and all linked Regions. If the association status of a target account changes (for example, when a linked Region is added or removed) after you first associate it with a configuration, its association status is updated. However, the change doesn't update the association status of the parent unless you invoke the `StartConfigurationPolicyAssociation` API again.

If you add a new linked Region, Security Hub CSPM replicates your existing associations that are in a `PENDING`, `SUCCESS`, or `FAILED` state in the new Region.

Even when the association status is `SUCCESS`, the enablement status of a standard that is part of the policy can transition into an incomplete state. In that case, Security Hub CSPM can't generate findings for the standard's controls. For more information, see Checking the status of a standard.

Troubleshooting association failure

In AWS Security Hub CSPM, a configuration policy association might fail for the following common reasons.

- **Organizations management account isn't a member** – If you want to associate a configuration policy with the Organizations management account, that account must already have AWS Security Hub CSPM enabled. This makes the management account a member account in the organization.
- **AWS Config isn't enabled or properly configured** – To enable standards in a configuration policy, AWS Config must be enabled and configured to record relevant resources.
- **Must associate from delegated administrator account** – You can only associate a policy with target accounts and OUs when you're signed in to the delegated Security Hub CSPM administrator account.
- **Must associate from home Region** – You can only associate a policy with target accounts and OUs when you're signed in to your home Region.

- **Opt-in Region not enabled** – Policy association fails for a member account or OU in a linked Region if it's an opt-in Region that the delegated administrator hasn't enabled. You can retry after enabling the Region from the delegated administrator account.
- **Member account suspended** – Policy association fails if you try to associate a policy with a suspended member account.

Updating configuration policies

> **Important**
>
> Security Hub CSPM declarative policies are replacing central configuration as the recommended way to manage Security Hub CSPM across an organization. You can't use declarative policies and central configuration in the same organization at the same time. To move your existing configuration without coverage gaps, use the import tool in the Security Hub console. For more information, see Declarative policies and central configuration in Security Hub CSPM.

After creating a configuration policy, the delegated AWS Security Hub CSPM administrator account can update the policy details and policy associations. When policy details are updated, accounts that are associated with the configuration policy automatically start using the updated policy.

For background information about the benefits of central configuration and how it works, see Understanding central configuration in Security Hub CSPM.

> **Note**
>
> Configuration policies support AWS standards and controls only. You cannot include multicloud standards (such as CIS Azure Foundations Benchmark v4.0.0) or Azure controls in a configuration policy. Including a multicloud standard ARN or control ID returns `InvalidInputException`. To enable or configure multicloud standards, use local configuration mechanisms directly in the desired AWS account.

The delegated administrator can update the following policy settings:

- Enable or disable Security Hub CSPM.

- Enable one or more security standards.
- Indicate which security controls are enabled across enabled standards. You can do this by providing a list of specific controls that should be enabled, and Security Hub CSPM disables all other controls, including new controls when they are released. Alternatively, you can provide a list of specific controls that should be disabled, and Security Hub CSPM enables all other controls, including new controls when they are released.
- Optionally, customize parameters for select enabled controls across enabled standards.

Choose your preferred method, and follow the steps to update a configuration policy.

> **Note**
>
> If you use central configuration, Security Hub CSPM automatically disables controls that involve global resources in all Regions except the home Region. Other controls that you choose to enable though a configuration policy are enabled in all Regions where they are available. To limit findings for these controls to just one Region, you can update your AWS Config recorder settings and turn off global resource recording in all Regions except the home Region.
> If an enabled control that involves global resources isn't supported in the home Region, Security Hub CSPM tries to enable the control in one linked Region where the control is supported. With central configuration, you lack coverage for a control that isn't available in the home Region or any of the linked Regions.
> For a list of controls that involve global resources, see Controls that use global resources.

Console

To update configuration policies

1. Open the AWS Security Hub CSPM console at https://console.aws.amazon.com/securityhub/.

   Sign in using the credentials of the delegated Security Hub CSPM administrator account in the home Region.
2. In the navigation pane, choose **Settings** and **Configuration**.
3. Choose the **Policies** tab.

4. Select the configuration policy that you want to edit, and choose **Edit**. If desired, edit the policy settings. Leave this section as is if you want to keep the policy settings unchanged.
5. Choose **Next**.If desired, edit the policy associations. Leave this section as is if you want to keep the policy associations unchanged. You can associate or disassociate the policy with a maximum of 15 targets (accounts, OUs, or root) when you update it.
6. Choose **Next**.
7. Review your changes, and choose **Save and apply**. In your home Region and linked Regions, this action overrides the existing configuration settings of accounts that are associated with this configuration policy. Accounts may be associated with a configuration policy through application, or inheritance from a parent node.

API

To update configuration policies

1. To update the settings in a configuration policy, invoke the UpdateConfigurationPolicy API from the Security Hub CSPM delegated administrator account in the home Region.
2. Provide the Amazon Resource Name (ARN) or ID of the configuration policy that you want to update.
3. Provide updated values for the fields under `ConfigurationPolicy`. Optionally, you can also provide a reason for the update.
4. To add new associations for this configuration policy, invoke the StartConfigurationPolicyAssociation API from the Security Hub CSPM delegated administrator account in the home Region. To remove one or more current associations, invoke the StartConfigurationPolicyDisassociation API from the Security Hub CSPM delegated administrator account in the home Region.
5. For the `ConfigurationPolicyIdentifier` field, provide the ARN or ID of the configuration policy whose associations you want to update.
6. For the `Target` field, provide the accounts, OUs, or root ID that you want to associate or disassociate. This action overrides previous policy associations for the specified OUs or accounts.

> **Note**
>
> When you invoke the `UpdateConfigurationPolicy` API, Security Hub CSPM performs a full list replacement for the `EnabledStandardIdentifiers`, `EnabledSecurityControlIdentifiers`, `DisabledSecurityControlIdentifiers`, and `SecurityControlCustomParameters` fields. Each time you invoke this API, provide the full list of standards that you want to enable and the full list of controls that you want to enable or disable and customize parameters for.

Example API request to update a configuration policy:

```
{
    "Identifier": "arn:aws:securityhub:us-east-1:123456789012:configuration-policy/
a1b2c3d4-5678-90ab-cdef-EXAMPLE11111",
    "Description": "Updated configuration policy",
    "UpdatedReason": "Disabling CloudWatch.1",
    "ConfigurationPolicy": {
        "SecurityHub": {
             "ServiceEnabled": true,
             "EnabledStandardIdentifiers": [
                    "arn:aws:securityhub:us-east-1::standards/aws-foundational-
security-best-practices/v/1.0.0",
                    "arn:aws:securityhub:::ruleset/cis-aws-foundations-benchmark/
v/1.2.0"
                ],
            "SecurityControlsConfiguration": {
                "DisabledSecurityControlIdentifiers": [
                    "CloudTrail.2",
                    "CloudWatch.1"
                ],
                "SecurityControlCustomParameters": [
                    {
                        "SecurityControlId": "ACM.1",
                        "Parameters": {
                            "daysToExpiration": {
                                "ValueType": "CUSTOM",
                                "Value": {
                                    "Integer": 15
                                }
```

```
                            }
                        }
                    }
                ]
            }
        }
    }
}
```

AWS CLI

To update configuration policies

1. To update the settings in a configuration policy, run the update-configuration-policy command from the Security Hub CSPM delegated administrator account in the home Region.
2. Provide the Amazon Resource Name (ARN) or ID of the configuration policy that you want to update.
3. Provide updated values for the fields under `configuration-policy`. Optionally, you can also provide a reason for the update.
4. To add new associations for this configuration policy, run the start-configuration-policy-association command from the Security Hub CSPM delegated administrator account in the home Region. To remove one or more current associations, run the start-configuration-policy-disassociation command from the Security Hub CSPM delegated administrator account in the home Region.
5. For the `configuration-policy-identifier` field, provide the ARN or ID of the configuration policy whose associations you want to update.
6. For the `target` field, provide the accounts, OUs, or root ID that you want to associate or disassociate. This action overrides previous policy associations for the specified OUs or accounts.

Note

When you run the `update-configuration-policy` command, Security Hub CSPM performs a full list replacement for the `EnabledStandardIdentifiers`, `EnabledSecurityControlIdentifiers`,

`DisabledSecurityControlIdentifiers`, and `SecurityControlCustomParameters` fields. Each time you run this command, provide the full list of standards that you want to enable and the full list of controls that you want to enable or disable and customize parameters for.

Example command to update a configuration policy:

```
aws securityhub update-configuration-policy \
--region us-east-1 \
--identifier "arn:aws:securityhub:us-east-1:123456789012:configuration-policy/
a1b2c3d4-5678-90ab-cdef-EXAMPLE11111" \
--description "Updated configuration policy" \
--updated-reason "Disabling CloudWatch.1" \
--configuration-policy '{"SecurityHub": {"ServiceEnabled": true,
 "EnabledStandardIdentifiers": ["arn:aws:securityhub:us-east-1::standards/aws-
foundational-security-best-practices/v/1.0.0","arn:aws:securityhub:::ruleset/
cis-aws-foundations-benchmark/v/1.2.0"],"SecurityControlsConfiguration":
{"DisabledSecurityControlIdentifiers": ["CloudTrail.2","CloudWatch.1"],
 "SecurityControlCustomParameters": [{"SecurityControlId": "ACM.1", "Parameters":
 {"daysToExpiration": {"ValueType": "CUSTOM", "Value": {"Integer": 15}}}}]}}'
```

The `StartConfigurationPolicyAssociation` API returns a field called `AssociationStatus`. This field tells you whether a policy association is pending or in a state of success or failure. It can take up to 24 hours for the status to change from `PENDING` to `SUCCESS` or `FAILURE`. For more information about association status, see Reviewing the association status of a configuration policy.

Deleting configuration policies

Important

Security Hub CSPM declarative policies are replacing central configuration as the recommended way to manage Security Hub CSPM across an organization. You can't use declarative policies and central configuration in the same organization at the same time. To move your existing configuration without coverage gaps, use the import tool in the Security

Hub console. For more information, see Declarative policies and central configuration in Security Hub CSPM.

After creating a configuration policy, the delegated AWS Security Hub CSPM administrator can delete it. Alternatively, the delegated administrator can retain the policy, but disassociate it from specific accounts or organizational units (OUs), or from the root. For instructions on disassociating a policy, see Disassociating a configuration from its targets.

For background information about the benefits of central configuration and how it works, see Understanding central configuration in Security Hub CSPM.

This section explains how to delete configuration policies.

When you delete a configuration policy, it no longer exists for your organization. Target accounts, OUs, and the organization root can no longer use the configuration policy. Targets that were associated with a deleted configuration policy inherit the configuration policy of the closest parent, or become self-managed if the closest parent is self-managed. If you want a target to use a different configuration, you can associate the target with a new configuration policy. For more information, see Creating and associating configuration policies.

We recommend creating and associating at least one configuration policy with your organization to provide adequate security coverage.

Before you can delete a configuration policy, you must disassociate the policy from any accounts, OUs, or the root to which it currently applies.

Choose your preferred method, and follow the steps to delete a configuration policy.

Console

To delete a configuration policy

1. Open the AWS Security Hub CSPM console at https://console.aws.amazon.com/securityhub/.

   Sign in using the credentials of the delegated Security Hub CSPM administrator account in the home Region.

2. In the navigation pane, choose **Settings** and **Configuration**.

3. Choose the **Policies** tab. Select the configuration policy that you want to delete, and choose **Delete**. If the configuration policy is still associated with any accounts or OUs, you're prompted to first disassociate the policy from those targets before you can delete it.
4. Review the confirmation message. Enter **`confirm`**, and choose **Delete**.

API

To delete a configuration policy

Invoke the DeleteConfigurationPolicy API from the Security Hub CSPM delegated administrator account in the home Region.

Provide the Amazon Resource Name (ARN) or ID of the configuration policy that you want to delete. If you receive a `ConflictException` error, the configuration policy still applies to accounts or OUs in your organization. To resolve the error, disassociate the configuration policy from these accounts or OUs before trying to delete it.

Example API request to delete a configuration policy:

```
{
    "Identifier": "arn:aws:securityhub:us-east-1:123456789012:configuration-policy/
a1b2c3d4-5678-90ab-cdef-EXAMPLE11111"
}
```

AWS CLI

To delete a configuration policy

Run the delete-configuration-policy command from the Security Hub CSPM delegated administrator account in the home Region.

Provide the Amazon Resource Name (ARN) or ID of the configuration policy that you want to delete. If you receive a `ConflictException` error, the configuration policy still applies to accounts or OUs in your organization. To resolve the error, disassociate the configuration policy from these accounts or OUs before trying to delete it.

```
aws securityhub --region us-east-1 delete-configuration-policy \
--identifier "arn:aws:securityhub:us-east-1:123456789012:configuration-policy/
a1b2c3d4-5678-90ab-cdef-EXAMPLE11111"
```

Disassociating a configuration from its targets

> **Important**
>
> Security Hub CSPM declarative policies are replacing central configuration as the recommended way to manage Security Hub CSPM across an organization. You can't use declarative policies and central configuration in the same organization at the same time. To move your existing configuration without coverage gaps, use the import tool in the Security Hub console. For more information, see Declarative policies and central configuration in Security Hub CSPM.

From the delegated AWS Security Hub CSPM administrator account, you can disassociate a configuration policy or self-managed configuration from an account, OU, or root. Disassociation retains the policy for future use, but removes existing associations from specific accounts, OUs, or the root.You can disassociate only a directly applied configuration, not an inherited configuration. To change an inherited configuration, you can apply a configuration policy or self-managed behavior to the affected account or OU. You can also apply a new configuration policy, which includes your desired modifications, to the closest parent.

Disassociation *doesn't* delete a configuration policy. The policy is retained in your account, so you can associate it with other targets in your organization. For instructions on deleting a configuration policy, see Deleting configuration policies. When disassociation is complete, an affected target inherits the configuration policy or self-managed behavior of the closest parent. If there's no inheritable configuration, a target retains the settings it had prior to disassociation but becomes self-managed.

Choose your preferred method, and follow the steps to disassociate an account, OU, or root from its current configuration.

Console

To disassociate an account or OU from its current configuration

1. Open the AWS Security Hub CSPM console at https://console.aws.amazon.com/securityhub/.

Sign in using the credentials of the delegated Security Hub CSPM administrator account in the home Region.

2. In the navigation pane, choose **Settings** and **Configuration**.
3. On the **Organizations** tab, select the account, OU, or the root that you want to disassociate from its current configuration. Choose **Edit**.
4. On the **Define configuration** page, for **Management**, choose **Policy applied** if you want the delegated administrator to be able to apply policies directly to the target. Choose **Inherited** if you want the target to inherit the configuration of its closest parent. In either of these cases, the delegated administrator controls settings for the target. Choose **Self-managed** if you want the account or OU to control its own settings.
5. After reviewing your changes, choose **Next** and **Apply**. This action overrides existing configurations of any accounts or OUs that are in scope, if those configurations conflict with your current selections.

API

To disassociate an account or OU from its current configuration

1. Invoke the StartConfigurationPolicyDisassociation API from the Security Hub CSPM delegated administrator account in the home Region.
2. For `ConfigurationPolicyIdentifier`, provide the Amazon Resource Name (ARN) or ID of the configuration policy that you want to disassociate. Provide `SELF_MANAGED_SECURITY_HUB` for this field to disassociate self-managed behavior.
3. For `Target`, provide the accounts, OUs, or the root that you want to dissociate from this configuration policy.

Example API request to disassociate a configuration policy:

```
{
    "ConfigurationPolicyIdentifier": "arn:aws:securityhub:us-
east-1:123456789012:configuration-policy/a1b2c3d4-5678-90ab-cdef-EXAMPLE11111",
    "Target": {"RootId": "r-f6g7h8i9j0example"}
}
```

AWS CLI

To disassociate an account or OU from its current configuration

1. Run the start-configuration-policy-disassociation command from the Security Hub CSPM delegated administrator account in the home Region.
2. For `configuration-policy-identifier`, provide the Amazon Resource Name (ARN) or ID of the configuration policy that you want to disassociate. Provide `SELF_MANAGED_SECURITY_HUB` for this field to disassociate self-managed behavior.
3. For `target`, provide the accounts, OUs, or the root that you want to dissociate from this configuration policy.

Example command to disassociate a configuration policy:

```
aws securityhub --region us-east-1 start-configuration-policy-disassociation \
--configuration-policy-identifier "arn:aws:securityhub:us-
east-1:123456789012:configuration-policy/a1b2c3d4-5678-90ab-cdef-EXAMPLE11111" \
--target '{"RootId": "r-f6g7h8i9j0example"}'
```

Configuring a standard or control in context

Important

Security Hub CSPM declarative policies are replacing central configuration as the recommended way to manage Security Hub CSPM across an organization. You can't use declarative policies and central configuration in the same organization at the same time. To move your existing configuration without coverage gaps, use the import tool in the Security Hub console. For more information, see Declarative policies and central configuration in Security Hub CSPM.

When you use central configuration in AWS Security Hub CSPM, the delegated Security Hub CSPM administrator can create configuration policies that specify how Security Hub CSPM, security standards, and security controls are configured for an organization. The delegated administrator can associate policies with specific accounts and organizational units (OU). The policies take effect

in your home Region and all linked Regions. The delegated administrator can update configuration policies as necessary.

On the Security Hub CSPM console, the delegated administrator can update configuration policies in two ways—from the **Configuration** page, or in context with existing workflows. The latter can be beneficial because, as you view security findings, you can discover which standards and controls are most relevant to your environment and configure them at the same time.

In-context configuration is available only on the Security Hub CSPM console. Programmatically, the delegated administrator must invoke the UpdateConfigurationPolicy operation of the Security Hub CSPM API to change how specific standards or controls are configured in the organization.

Follow these steps to configure a Security Hub CSPM standard or control in context.

To configure a standard or control in context (console)

1. Open the AWS Security Hub CSPM console at https://console.aws.amazon.com/securityhub/.

   Sign in using the credentials of the delegated Security Hub CSPM administrator account in the home Region.
2. In the navigation pane, choose one of the follow options:

   - To configure a standard, choose **Security standards**, and choose a specific standard.
   - To configure a control, choose **Controls**, and choose a specific control.
3. The console lists your existing Security Hub CSPM configuration policies and the status of the selected standard or control in each one. Choose the options to enable or disable the standard or control in each existing configuration policy. For controls, you can also choose to customize control parameters. You can't create a new policy during in-context configuration. To create a new policy, you must go to the **Configuration** page, choose the **Policies** tab, and then choose **Create policy**.
4. After making your changes, choose **Next**.
5. Review your changes, and choose **Apply**. The updates affect all accounts and OUs that are associated with a changed configuration policy. The updates also take effect in the home Region and all linked Regions.

Disabling central configuration in Security Hub CSPM

> **Important**
>
> Security Hub CSPM declarative policies are replacing central configuration as the recommended way to manage Security Hub CSPM across an organization. You can't use declarative policies and central configuration in the same organization at the same time. To move your existing configuration without coverage gaps, use the import tool in the Security Hub console. For more information, see Declarative policies and central configuration in Security Hub CSPM.

When you disable central configuration in AWS Security Hub CSPM, the delegated administrator loses the ability to configure Security Hub CSPM, security standards, and security controls across multiple AWS accounts, organizational units (OUs), and AWS Regions. Instead, you must configure most settings separately for each account in each Region.

If you plan to move to Security Hub CSPM declarative policies, import your configuration before you disable central configuration. The import tool is available only while central configuration is enabled. For more information, see Migrating your central configuration policies to AWS Organizations declarative policies by using the import tool.

> **Important**
>
> Before you can disable central configuration, you must first disassociate your accounts and OUs from their current configuration, whether that's a configuration policy or self-managed behavior.
>
> Before you can disable central configuration, you must also delete existing configuration policies.

When you disable central configuration, the following changes occur:

- The delegated administrator can no longer create configuration policies for the organization.
- Accounts that had an applied or inherited configuration policy retain their current settings, but become self-managed.
- Your organization switches to *local configuration*. Under local configuration, the majority of Security Hub CSPM settings must be configured separately in each organization account

and Region. The delegated administrator can choose to automatically enable Security Hub CSPM, default security standards, and all controls that are part of the default standards in new organization accounts. The default standards are AWS Foundational Security Best Practices (FSBP) and Center for Internet Security (CIS) AWS Foundations Benchmark v1.2.0. These settings take effect in the current Region only and impact new organization accounts only. The delegated administrator can't change which standards are default. Local configuration doesn't support the use of configuration policies or configuration at the OU level.

The identity of the delegated administrator account remains the same when you stop using central configuration. Your home Region and linked Regions also remain the same (your home Region is now called the aggregation Region, and can be used for finding aggregation).

Choose your preferred method, and follow the steps to stop using central configuration and switch to local configuration.

Security Hub CSPM console

To disable central configuration (console)

1. Open the AWS Security Hub CSPM console at https://console.aws.amazon.com/securityhub/.

   Sign in using the credentials of the delegated Security Hub CSPM administrator account in the home Region.
2. On the navigation pane, choose **Settings** and **Configuration**.
3. In the **Overview** section, choose **Edit**.
4. In the **Edit organization configuration** box, choose **Local configuration**. If you haven't already, you're prompted to disassociate and delete your current configuration policies before you can stop central configuration. Accounts or OUs that are designated as self-managed must be disassociated from their self-managed configuration. You can do this in the console by changing the management type of each self-managed account or OU to **Centrally managed** and **Inherit from my organization**.
5. Optionally, select the local configuration default settings for new organization accounts.
6. Choose **Confirm**.

Security Hub CSPM API

To disable central configuration (API)

1. Invoke the UpdateOrganizationConfiguration API.
2. Set the `ConfigurationType` field in the `OrganizationConfiguration` object to `LOCAL`. The API returns an error if you have existing configuration policies or policy associations. To disassociate a configuration policy, invoke the `StartConfigurationPolicyDisassociation` API. To delete a configuration policy, invoke the `DeleteConfigurationPolicy` API.
3. If you want to automatically enable Security Hub CSPM in new organization accounts, set the `AutoEnable` field to `true`. By default, the value of this field is `false`, and Security Hub CSPM isn't automatically enabled in new organization accounts. Optionally, if you want to automatically enable default security standards in new organization accounts, set the `AutoEnableStandards` field to `DEFAULT`. This the default value. If you don't want to automatically enable default security standards in new organization accounts, set the `AutoEnableStandards` field to `NONE`.

Example API request:

```
{
    "AutoEnable": true,
    "OrganizationConfiguration": {
        "ConfigurationType" : "LOCAL"
    }
}
```

AWS CLI

To disable central configuration (AWS CLI)

1. Run the update-organization-configuration command.
2. Set the `ConfigurationType` field in the `organization-configuration` object to `LOCAL`. The command returns an error if you have existing configuration policies or policy associations. To disassociate a configuration policy, run the `start-configuration-policy-disassociation` command. To delete a configuration policy, run the `delete-configuration-policy` command.

3. If you want to automatically enable Security Hub CSPM in new organization accounts, include the `auto-enable` parameter. By default, the value of this parameter is `no-auto-enable`, and Security Hub CSPM isn't automatically enabled in new organization accounts. Optionally, if you want to automatically enable default security standards in new organization accounts, set the `auto-enable-standards` field to `DEFAULT`. This the default value. If you don't want to automatically enable default security standards in new organization accounts, set the `auto-enable-standards` field to `NONE`.

```
aws securityhub --region us-east-1 update-organization-configuration \
--auto-enable \
--organization-configuration '{"ConfigurationType": "LOCAL"}'
```

Understanding cross-Region aggregation in Security Hub CSPM

> **Note**
>
> The *aggregation Region* is now called the *home Region*. Some Security Hub CSPM API operations still use the older term aggregation Region.

By using cross-Region aggregation in AWS Security Hub CSPM, you can aggregate findings, finding updates, insights, control compliance statuses, and security scores from multiple AWS Regions to a single home Region. You can then manage all of this data from the home Region.

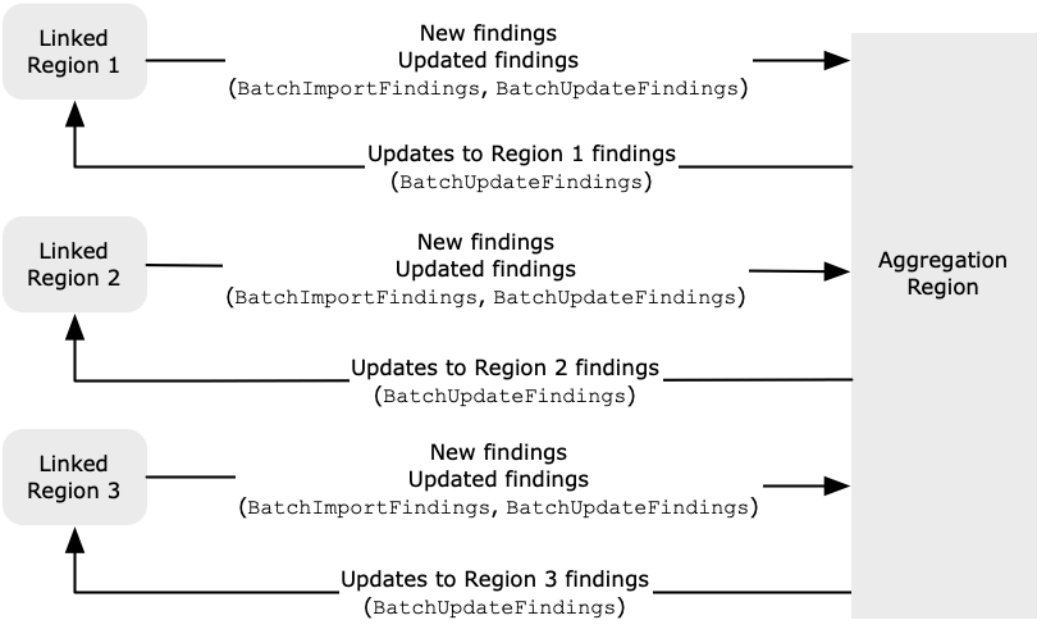
Suppose you set US East (N. Virginia) as the home Region, and US West (Oregon) and US West (N. California) as the linked Regions. When you view the **Findings** page in US East (N. Virginia), you see the findings from all three Regions. Updates to those findings are also reflected in all three Regions.

> **Note**
>
> In AWS GovCloud (US), cross-Region aggregation is supported only for findings, finding updates, and insights across AWS GovCloud (US). Specifically, you can only aggregate findings, finding updates, and insights between AWS GovCloud (US-East) and AWS GovCloud (US-West). In the China Regions, cross-Region aggregation is supported only for findings, finding updates, and insights across the China Regions. Specifically, you can

only aggregate findings, finding updates, and insights between China (Beijing) and China (Ningxia).

If a control is enabled in a linked Region but disabled in the home Region, you can see the compliance status of the control from the home Region, but you can't enable or disable that control from the home Region. The exception is if you use central configuration. If you use central configuration, the delegated Security Hub CSPM administrator can configure controls in the home Region and linked Regions from the home Region.

If you have set an home Region, security scores account for control statuses in all linked Regions. To view cross-Region security scores and compliance statuses, add the following permissions to your IAM role that uses Security Hub CSPM:



- `ListSecurityControlDefinitions`
- `BatchGetStandardsControlAssociations`
- `BatchUpdateStandardsControlAssociations`

Types of data that are aggregated

When cross-Region aggregation is enabled with one or more linked Regions, Security Hub CSPM replicates the following data from the linked Regions to the home Region. This occurs in every account that has cross-Region aggregation enabled.

- Findings
- Insights
- Control compliance statuses
- Security scores

In addition to new data in the previous list, Security Hub CSPM also replicates updates to this data between the linked Regions and the home Region. Updates that occur in a linked Region are replicated to the home Region. Updates that occur in the home Region are replicated back to the linked Region. If there are conflicting updates in the home Region and the linked Region, then the most recent update is used.

Cross-Region aggregation does not add to the cost of Security Hub CSPM. You are not charged when Security Hub CSPM replicates new data or updates.

In the home Region, the **Summary** page provides a view of your active findings across linked Regions. For information, see Viewing a cross-Region summary of findings by severity. Other **Summary** page panels that analyze findings also display information from across the linked Regions.

Your security scores in the home Region are calculated by comparing the number of passed controls to the number of enabled controls in all linked Regions. In addition, if a control is enabled in at least one linked Region, it is visible on the **Security standards** details pages of the home Region. The compliance status of controls on the standards details pages reflects findings across linked Regions. If a security check associated with a control fails in one or more linked Regions, the compliance status of that control shows as **Failed** on the standards details pages of the home Region. The number of security checks includes findings from all linked Regions.

Security Hub CSPM only aggregates data from Regions where an account has Security Hub CSPM enabled. Security Hub CSPM is not automatically enabled for an account based on the cross-Region aggregation configuration.

It's possible to have cross-Region aggregation enabled without any linked Regions selected. In this case, no data replication occurs.

Aggregation for administrator and member accounts

Standalone accounts, member accounts, and administrator accounts can configure cross-Region aggregation. If configured by an administrator, the presence of the administrator account is essential for cross-Region aggregation to work in administered accounts. If the administrator account is removed or disassociated from a member account, cross-Region aggregation for the member account stops. This is true even if the account had cross-Region aggregation enabled before the administrator-member relationship begins.

When an administrator account enables cross-Region aggregation, Security Hub CSPM replicates the data that the administrator account generates in all linked Regions to the home Region. In addition, Security Hub CSPM identifies the member accounts that are associated with that administrator, and each member account inherits the cross-Region aggregation settings of the administrator. Security Hub CSPM replicates the data that a member account generates in all linked Regions to the home Region.

The administrator can access and manage security findings from all member accounts within the administered regions. However, as a Security Hub CSPM administrator, you must be signed in to the home Region to view aggregated data from all member accounts and linked Regions.

As a Security Hub CSPM member account, you must be signed in to the home Region to view aggregated data from your account from all linked Regions. Member accounts don't have permissions to view data from other member accounts.

An administrator account may manually invite member accounts or serve as the delegated administrator of an organization that is integrated with AWS Organizations. For a manually-invited member account, the administrator must invite the account from the home Region and all linked Regions in order for cross-Region aggregation to work. In addition, the member account must have Security Hub CSPM enabled in the home Region and all linked Regions to give the administrator the ability to view findings from the member account. If you don't use the home Region for other purposes, you can disable Security Hub CSPM standards and integrations in that Region to prevent charges.

If you plan to use cross-Region aggregation, and have multiple administrator accounts, we recommend following these best practices:

- Each administrator account has different member accounts.
- Each administrator account has the same member accounts across Regions.

- Each administrator account uses a different home Region.

> **Note**
>
> To understand how cross-Region aggregation impacts central configuration, see Impact of central configuration on cross-Region aggregation.

Impact of central configuration on cross-Region aggregation

Central configuration is an opt-in feature in AWS Security Hub CSPM that you can use if you integrate with AWS Organizations. If you use central configuration, the delegated administrator account can configure the Security Hub CSPM service, standards, and controls for accounts and organizational units (OU) in the organization. To configure accounts and OUs, the delegated administrator creates Security Hub CSPM configuration policies. Configuration policies can be used to define whether Security Hub CSPM is enabled or disabled, and which standards and controls are enabled. The delegated administrator associates configuration policies with specific accounts, OUs, or the root (the entire organization).

The delegated administrator can create and manage configuration policies for the organization only from the home Region. In addition, configuration policies take effect in the home Region and all linked Regions. You can't create a configuration policy that applies only in some linked Regions and not others. For information about cross-Region aggregation, see Cross-Region aggregation.

To use central configuration, you must designate a home Region. Optionally, you can choose one or more Regions as linked Regions. You can also choose to designate a home Region without any linked Regions.

Changing your cross-Region aggregation settings can impact your configuration policies. When you add a linked Region, your configuration policies take effect in that Region. If the Region is an opt-in Region, the Region must be enabled in order for your configuration policies to take effect there. Conversely, when you remove a linked Region, configuration policies no longer take effect in that Region. In that Region, accounts maintain the settings they had when the linked Region was removed. You can change those settings, but must do so separately in each account and Region.

If you remove or change the home Region, your configuration policies and policy associations are deleted. You can no longer use central configuration or create configuration policies in any Region. Accounts maintain the settings they had before the home Region was changed or removed. You

can change those settings at any time, but since you no longer use central configuration, settings must be modified separately in each account and Region. You can use central configuration and create configuration policies again if you designate a new home Region.

For more information about central configuration, see Understanding central configuration in Security Hub CSPM.

Enabling cross-Region aggregation

> **Note**
>
> The *aggregation Region* is now called the *home Region*. Some Security Hub CSPM API operations still use the older term aggregation Region.

You must enable cross-Region aggregation from the AWS Region that you want to designate as the home Region.

To enable cross-Region aggregation, you create a Security Hub CSPM resource called a finding aggregator. The finding aggregator resource specifies your home Region and linked Regions (if any).

You can't use an AWS Region that is disabled by default as your home Region. For a list of Regions that are disabled by default, see Enabling a Region in the *AWS General Reference*.

When you enable cross-Region aggregation, you choose to specify one or more linked Regions if you wish. You can also choose whether to automatically link new Regions when Security Hub CSPM begins to support them and you have opted into them.

Security Hub CSPM console

To enable cross-Region aggregation

1. Open the AWS Security Hub CSPM console at https://console.aws.amazon.com/securityhub/.
2. Using the AWS Region selector, sign in to the Region that you want to use as the aggregation Region.
3. In the Security Hub CSPM navigation menu, choose **Settings** and then **Regions**.
4. For **Finding aggregation**, choose **Configure finding aggregation**.

By default, the home Region is set to **No aggregation Region**.

5. Under **Aggregation Region**, select the option to designate the current Region as the home Region.
6. Optionally, for **Linked Regions**, select the Regions to aggregate data from.
7. To automatically aggregate data from new Regions in the partition as Security Hub CSPM supports them and you opt into them, select **Link future Regions**.
8. Choose **Save**.

Security Hub CSPM API

From the Region that you want to use as the home Region, use the `CreateFindingAggregator` operation of the Security Hub CSPM API. If you use the AWS CLI, run the create-finding-aggregator command.

For `RegionLinkingMode`, choose one of the following options:

- `ALL_REGIONS` – Security Hub CSPM aggregates data from all Regions. Security Hub CSPM also aggregates data from new Regions as they are supported and you opt into them.
- `ALL_REGIONS_EXCEPT_SPECIFIED` – Security Hub CSPM aggregates data from all Regions except for Regions that you want to exclude. Security Hub CSPM also aggregates data from new Regions as they are supported and you opt into them. Use `Regions` to provide the list of Regions to exclude from aggregation.
- `SPECIFIED_REGIONS` – Security Hub CSPM aggregates data from a selected list of Regions. Security Hub CSPM does not aggregate data automatically from new Regions. Use `Regions` to provide the list of Regions to aggregate from.
- `NO_REGIONS` – Security Hub CSPM doesn't aggregate data because you don't select any linked Regions.

The following example configures cross-Region aggregation. The home Region is US East (N. Virginia). The linked Regions are US West (N. California) and US West (Oregon). This example is formatted for Linux, macOS, or Unix, and it uses the backslash (\) line-continuation character to improve readability.

```
$ aws securityhub create-finding-aggregator --region us-east-1 --region-linking-
mode SPECIFIED_REGIONS --regions us-west-1 us-west-2
```

Reviewing cross-Region aggregation settings

> **Note**
>
> The *aggregation Region* is now called the *home Region*. Some Security Hub CSPM API operations still use the older term aggregation Region.

You can view the current cross-Region aggregation configuration in AWS Security Hub CSPM from any AWS Region. The configuration includes the home Region, the linked Regions (if any), and whether to automatically link new Regions as Security Hub CSPM supports them.

Member accounts can view the cross-Region aggregation settings that the administrator account configured.

Choose your preferred method, and follow the steps to view your current cross-Region aggregation settings.

Security Hub CSPM console

To view cross-Region aggregation settings (console)

1. Open the AWS Security Hub CSPM console at https://console.aws.amazon.com/securityhub/.
2. On the navigation pane, choose **Settings** and then the **Regions** tab.

If cross-Region aggregation is not enabled, then the **Regions** tab displays the option to enable cross-Region aggregation. Only administrator accounts and standalone accounts can enable cross-Region aggregation.

If cross-Region aggregation is enabled, then the **Regions** tab displays the following information:

- The home Region
- Whether to automatically aggregate findings, insights, control statuses, and security scores from new Regions that Security Hub CSPM supports and that you opt into
- The list of linked Regions (if any are selected)

Security Hub CSPM API

To review cross-Region aggregation settings (Security Hub CSPM API)

Use the `GetFindingAggregator` operation of the Security Hub CSPM API. If you use the AWS CLI, run the get-finding-aggregator command.

When you make the request, provide the finding aggregator ARN. To obtain the finding aggregator ARN, use the `ListFindingAggregators` operation or list-finding-aggregators command.

The following example shows the cross-Region aggregation settings for the specified finding aggregator ARN. This example is formatted for Linux, macOS, or Unix, and it uses the backslash (\) line-continuation character to improve readability

```
$aws securityhub get-finding-aggregator --finding-aggregator-
arn arn:aws:securityhub:us-east-1:222222222222:finding-aggregator/123e4567-
e89b-12d3-a456-426652340000
```

Updating cross-Region aggregation settings

> **Note**
>
> The *aggregation Region* is now called the *home Region*. Some Security Hub CSPM API operations still use the older term aggregation Region.

You can update your current cross-Region aggregation settings in AWS Security Hub CSPM by changing the linked Regions or the current home Region. You can also change whether to automatically aggregate data from new AWS Regions that Security Hub CSPM is supported in.

Changes to cross-Region aggregation aren't implemented for an opt-in Region until you enable the Region in your AWS account. Regions that AWS introduced on or after to March 20, 2019 are opt-in Regions.

When you stop aggregating data from a linked Region, AWS Security Hub CSPM doesn't remove any existing aggregated data from that Region that is accessible in the home Region.

You can't use the update procedures in this section to change the home Region. To change the home Region, you must do the following:

1. Stop cross-Region aggregation. For instructions, see the section called “Stopping aggregation”.
2. Change to the Region that you want to be the new home Region.
3. Enable cross-Region aggregation. For instructions, see the section called “Enabling aggregation”.

You must update the cross-Region aggregation configuration from the current home Region.

Security Hub CSPM console

To change the linked Regions

1. Open the AWS Security Hub CSPM console at https://console.aws.amazon.com/securityhub/.

   Sign in to the current aggregation Region.
2. In the Security Hub CSPM navigation menu, choose **Settings**, then choose **Regions**.
3. For **Finding aggregation**, choose **Edit**.
4. For **Linked Regions**, update the selected linked Regions.
5. If needed, change whether **Link future Regions** is selected. This setting determines whether Security Hub CSPM automatically links new Regions as it adds support for them and you opt into them.
6. Choose **Save**.

Security Hub CSPM API

Use the `UpdateFindingAggregator` operation. If you use the AWS CLI, run the update-finding-aggregator command. To identify the finding aggregator, you must provide the finding aggregator ARN. To obtain the finding aggregator ARN, use the `ListFindingAggregators` operation or list-finding-aggregators command..

If the linking mode is `ALL_REGIONS_EXCEPT_SPECIFIED` or `SPECIFIED_REGIONS`, you can change the list of excluded or included Regions. If you want to change the Region linking mode to `NO_REGIONS`, you shouldn't provide a Regions list.

When you change the list of excluded or included Regions, you must provide the full list with the updates. For example, suppose you currently aggregate findings from US East (Ohio), and want to also aggregate findings from US West (Oregon). You must provide a `Regions` list that contains both US East (Ohio) and US West (Oregon).

The following example updates cross-Region aggregation to selected Regions. The command is run from the current home Region, which is US East (N. Virginia). The linked Regions are US West (N. California) and US West (Oregon). This example is formatted for Linux, macOS, or Unix, and it uses the backslash (\) line-continuation character to improve readability.

```
aws securityhub update-finding-aggregator --region us-east-1 --finding-
aggregator-arn arn:aws:securityhub:us-east-1:222222222222:finding-
aggregator/123e4567-e89b-12d3-a456-426652340000 --region-linking-mode
 SPECIFIED_REGIONS --regions us-west-1 us-west-2
```

Stopping cross-Region aggregation

> **Note**
>
> The *aggregation Region* is now called the *home Region*. Some Security Hub CSPM API operations still use the older term aggregation Region.

If you don't want AWS Security Hub CSPM to aggregate data, you can delete your finding aggregator. Alternatively, you can keep your finding aggregator but not link any AWS Regions to the home Region by updating the existing aggregator to the `NO_REGIONS` linking mode.

To change your home Region, you must delete your current finding aggregator and create a new one.

When you delete your finding aggregator, Security Hub CSPM stops aggregating data. It doesn't remove any existing aggregated data from the home Region.

Deleting the finding aggregator (console)

You can delete your finding aggregator from the current home Region only.

In Regions other than the home Region, the **Finding aggregation** panel on the Security Hub CSPM console displays a message that you must edit the configuration in the home Region. Choose this message to display a link to switch to the home Region.

Security Hub CSPM console

To stop cross-Region aggregation (console)

1. Open the AWS Security Hub CSPM console at https://console.aws.amazon.com/securityhub/.
2. Ensure that you're signed in to your current home Region.
3. In the Security Hub CSPM navigation menu, choose **Settings**, then choose **Regions**.
4. Under **Finding aggregation**, choose **Edit**.
5. Under **Aggregation Region**, choose **No aggregation Region**.
6. Choose **Save**.
7. On the confirmation dialog, in the confirmation field, type **`Confirm`**.
8. Choose **Confirm**.

Security Hub CSPM API

Use the `DeleteFindingAggregator` operation of the Security Hub CSPM API. If you're using the AWS CLI, run the `delete-finding-aggregator` command.

To identify the finding aggregator to delete, provide the finding aggregator ARN. To obtain the finding aggregator ARN, use the `ListFindingAggregators` operation or `list-finding-aggregators` command.

The following example deletes the finding aggregator. The command is run from the current home Region, which is US East (N. Virginia). This example is formatted for Linux, macOS, or Unix, and it uses the backslash (\) line-continuation character to improve readability.

```
$aws securityhub delete-finding-aggregator arn:aws:securityhub:us-east-1:222222222222:finding-aggregator/123e4567-e89b-12d3-a456-426652340000 --region us-east-1
```

Understanding security standards in Security Hub CSPM

In AWS Security Hub CSPM, a *security standard* is a set of requirements that's based on regulatory frameworks, industry best practices, or company policies. For details about the standards that Security Hub CSPM currently supports, including the security controls that apply to each one, see the Standards reference for Security Hub CSPM.

When you enable a standard, Security Hub CSPM automatically enables all the controls that apply to the standard. Security Hub CSPM then runs security checks on the controls, which generates Security Hub CSPM findings. You can disable and later re-enable individual controls as necessary. You can also disable a standard completely. If you disable a standard, Security Hub CSPM stops running security checks on controls that apply to the standard. Findings are no longer generated for the controls.

In addition to findings, Security Hub CSPM generates a security score for each standard that you enable. The score is based on the status of the controls that apply to the standard. If you set an aggregation Region, the security score for a standard reflects the status of the controls across all linked Regions. If you're the Security Hub CSPM administrator for an organization, the score reflects the status of the controls for all the accounts in your organization. For more information, see Calculating security scores.

To review and manage standards, you can use the Security Hub CSPM console or the Security Hub CSPM API. On the console, the **Security standards** page shows all the security standards that Security Hub CSPM currently supports. This includes a description of each standard and the current status of the standard. If you enable a standard, you can also use this page to access additional details for the standard. For example, you can review:

- The current security score for the standard.
- Aggregated statistics for controls that apply to the standard.
- A list of controls that apply to the standard and are currently enabled, including the compliance status of each one.
- A list of controls that apply to the standard but are currently disabled.

For deeper analysis, you can filter and sort the data, and drill down to review the details of individual controls that apply to the standard.

You can enable standards individually for a single account and AWS Region. However, to save time and reduce configuration drift in multi-account and multi-Region environments, we recommend using central configuration to enable and manage standards. With central configuration, the delegated Security Hub CSPM administrator can create policies that specify how to configure a standard across multiple accounts and Regions.

- Reviewing the details of a security standard
- Turning off automatically enabled security standards
- Disabling a security standard

Standards reference for Security Hub CSPM

In AWS Security Hub CSPM, a *security standard* is a set of requirements that's based on regulatory frameworks, industry best practices, or company policies. Security Hub CSPM maps these requirements to controls, and runs security checks on the controls to assess whether the requirements of a standard are being met. Each standard includes multiple controls.

Security Hub CSPM currently supports the following standards:

- **AWS Foundational Security Best Practices** – Developed by AWS and industry professionals, this standard is a compilation of security best practices for organizations, regardless of sector or size. It provides a set of controls that detect when your AWS accounts and resources deviate from security best practices. It also provides prescriptive guidance about how to improve and maintain your security posture.
- **AI Security Best Practices** – Developed by AWS security experts, this standard provides a curated set of controls that detect when deployed AI resources do not align with security best practices. It helps you identify areas where your AI workloads deviate from recommended security configurations, covering domains such as network isolation, encryption, VPC placement, and AWS KMS key usage.
- **AWS Resource Tagging** – Developed by Security Hub CSPM, this standard can help you determine whether your AWS resources have tags. A *tag* is a key-value pair that acts as metadata for an AWS resource. Tags can help you identify, categorize, manage, and search for AWS resources. For example, you can use tags to categorize resources by purpose, owner, or environment.
- **CIS AWS Foundations Benchmark** – Developed by the Center for Internet Security (CIS), this standard provides secure configuration guidelines for AWS. It specifies a set of security configuration guidelines and best practices for a subset of AWS services and resources, with an emphasis on foundational, testable, and architecture agnostic settings. The guidelines include clear, step-by-step implementation and assessment procedures.
- **NIST SP 800-53 Revision 5** – This standard aligns with National Institute of Standards and Technology (NIST) requirements for protecting the confidentiality, integrity, and availability of

information systems and critical resources. The associated framework generally applies to U.S. federal agencies or organizations that work with U.S. federal agencies or information systems. However, private organizations can also use the requirements as a guiding framework.

- **NIST SP 800-171 Revision 2** – This standard aligns with NIST security recommendations and requirements for protecting the confidentiality of Controlled Unclassified Information (CUI) in systems and organizations that aren't part of the U.S. federal government. *CUI* is information that doesn't meet government criteria for classification, but is considered sensitive and is created or possessed by the U.S. federal government or other entities on behalf of the U.S. federal government.
- **PCI DSS** – This standard aligns with the Payment Card Industry Data Security Standard (PCI DSS) compliance framework defined by the PCI Security Standards Council (SSC). The framework provides a set of rules and guidelines for safely handling credit and debit card information. The framework generally applies to organizations that store, process, or transmit cardholder data.
- **CRI Profile v2.2** – This standard aligns with the CRI Profile, a compliance framework developed by the Cyber Risk Institute (CRI). The framework harmonizes cybersecurity and regulatory expectations that apply to the financial services sector into a common set of requirements. The framework generally applies to financial institutions and the organizations that serve them.
- **Service-managed standard, AWS Control Tower** – This standard helps you configure the detective controls provided by Security Hub CSPM from AWS Control Tower. AWS Control Tower offers a straightforward way to set up and govern an AWS multi-account environment, following prescriptive best practices.

Security Hub CSPM standards and controls don't guarantee compliance with any regulatory frameworks or audits. Instead, they provide a way to evaluate and monitor the state of your AWS accounts and resources. We recommend enabling each standard that's relevant to your business needs, industry, or use case.

Individual controls can apply to more than one standard. If you enable multiple standards, we recommend that you also enable consolidated control findings. If you do this, Security Hub CSPM generates a single finding for each control, even if the control applies to more than one standard. If you don't turn on consolidated control findings, Security Hub CSPM generates a separate finding for each enabled standard that a control applies to. For example, if you enable two standards and a control applies to both of them, you receive two separate findings for the control, one for each standard. If you enable consolidated control findings, you receive only one finding for the control. For more information, see Consolidated control findings.

AWS Foundational Security Best Practices standard in Security Hub CSPM

Developed by AWS and industry professionals, the AWS Foundational Security Best Practices (FSBP) standard is a compilation of security best practices for organizations, regardless of organization sector or size. It provides a set of controls that detect when AWS accounts and resources deviate from security best practices. It also provides prescriptive guidance about how to improve and maintain your organization's security posture.

In AWS Security Hub CSPM, the AWS Foundational Security Best Practices standard includes controls that continuously evaluate your AWS accounts and workloads, and help you identify areas that deviate from security best practices. The controls include security best practices for resources from multiple AWS services. Each control is assigned a category that reflects the security function that the control applies to. For a list of categories and additional details, see Control categories.

Controls that apply to the standard

The following list specifies which AWS Security Hub CSPM controls apply to the AWS Foundational Security Best Practices standard (v1.0.0). To review the details of a control, choose the control.

[Account.1] Security contact information should be provided for an AWS account

[ACM.1] Imported and ACM-issued certificates should be renewed after a specified time period

[ACM.2] RSA certificates managed by ACM should use a key length of at least 2,048 bits

[APIGateway.1] API Gateway REST and WebSocket API execution logging should be enabled

[APIGateway.2] API Gateway REST API stages should be configured to use SSL certificates for backend authentication

[APIGateway.3] API Gateway REST API stages should have AWS X-Ray tracing enabled

[APIGateway.4] API Gateway should be associated with a WAF Web ACL

[APIGateway.5] API Gateway REST API cache data should be encrypted at rest

[APIGateway.8] API Gateway routes should specify an authorization type

[APIGateway.9] Access logging should be configured for API Gateway V2 Stages

[APIGateway.10] API Gateway V2 integrations should use HTTPS for private connections

[APIGateway.11] API Gateway domain names should use recommended security policies

[AppSync.2] AWS AppSync should have field-level logging enabled

[AppSync.5] AWS AppSync GraphQL APIs should not be authenticated with API keys

[Athena.4] Athena workgroups should have logging enabled

[AutoScaling.1] Auto Scaling groups associated with a load balancer should use ELB health checks

[AutoScaling.2] Amazon EC2 Auto Scaling group should cover multiple Availability Zones

[AutoScaling.3] Auto Scaling group launch configurations should configure EC2 instances to require Instance Metadata Service Version 2 (IMDSv2)

[Autoscaling.5] Amazon EC2 instances launched using Auto Scaling group launch configurations should not have Public IP addresses

[AutoScaling.6] Auto Scaling groups should use multiple instance types in multiple Availability Zones

[AutoScaling.9] Amazon EC2 Auto Scaling groups should use Amazon EC2 launch templates

[Backup.1] AWS Backup recovery points should be encrypted at rest

[BedrockAgentCore.1] Bedrock AgentCore runtimes should be configured with VPC network mode

[BedrockAgentCore.2] Bedrock AgentCore Gateways should require authorization for inbound requests

[BedrockAgentCore.5] Bedrock AgentCore custom browsers should not use public network mode

[BedrockAgentCore.6] Bedrock AgentCore custom browsers should have session recording enabled

[BedrockAgentCore.7] Bedrock AgentCore custom code interpreters should use a private network configuration

[CloudFormation.3] CloudFormation stacks should have termination protection enabled

[CloudFormation.4] CloudFormation stacks should have associated service roles

[CloudFront.1] CloudFront distributions should have a default root object configured

[CloudFront.3] CloudFront distributions should require encryption in transit

[CloudFront.4] CloudFront distributions should have origin failover configured

[CloudFront.5] CloudFront distributions should have logging enabled

[CloudFront.6] CloudFront distributions should have WAF enabled

[CloudFront.7] CloudFront distributions should use custom SSL/TLS certificates

[CloudFront.8] CloudFront distributions should use SNI to serve HTTPS requests

[CloudFront.9] CloudFront distributions should encrypt traffic to custom origins

[CloudFront.10] CloudFront distributions should not use deprecated SSL protocols between edge locations and custom origins

[CloudFront.12] CloudFront distributions should not point to non-existent S3 origins

[CloudFront.13] CloudFront distributions should use origin access control

[CloudFront.15] CloudFront distributions should use the recommended TLS security policy

[CloudFront.16] CloudFront distributions should use origin access control for Lambda function URL origins

[CloudFront.17] CloudFront distributions should use trusted key groups for signed URLs and cookies

[CloudTrail.1] CloudTrail should be enabled and configured with at least one multi-Region trail that includes read and write management events

[CloudTrail.2] CloudTrail should have encryption at-rest enabled

[CloudTrail.4] CloudTrail log file validation should be enabled

[CloudTrail.5] CloudTrail trails should be integrated with Amazon CloudWatch Logs

[CodeBuild.1] CodeBuild Bitbucket source repository URLs should not contain sensitive credentials

[CodeBuild.2] CodeBuild project environment variables should not contain clear text credentials

[CodeBuild.3] CodeBuild S3 logs should be encrypted

[CodeBuild.4] CodeBuild project environments should have a logging AWS Configuration

[CodeBuild.7] CodeBuild report group exports should be encrypted at rest

[Cognito.2] Cognito identity pools should not allow unauthenticated identities

[Cognito.3] Password policies for Cognito user pools should have strong configurations

[Cognito.4] Cognito user pools should have threat protection activated with full function enforcement mode for custom authentication

[Cognito.5] MFA should be enabled for Cognito user pools

[Cognito.6] Cognito user pools should have deletion protection enabled

[Config.1] AWS Config should be enabled and use the service-linked role for resource recording

[Connect.2] Connect Customer instances should have CloudWatch logging enabled

[DataFirehose.1] Firehose delivery streams should be encrypted at rest

[DataSync.1] DataSync tasks should have logging enabled

[DMS.1] Database Migration Service replication instances should not be public

[DMS.6] DMS replication instances should have automatic minor version upgrade enabled

[DMS.7] DMS replication tasks for the target database should have logging enabled

[DMS.8] DMS replication tasks for the source database should have logging enabled

[DMS.9] DMS endpoints should use SSL

[DMS.10] DMS endpoints for Neptune databases should have IAM authorization enabled

[DMS.11] DMS endpoints for MongoDB should have an authentication mechanism enabled

[DMS.12] DMS endpoints for Redis OSS should have TLS enabled

[DMS.13] DMS replication instances should be configured to use multiple Availability Zones

[DocumentDB.1] Amazon DocumentDB clusters should be encrypted at rest

[DocumentDB.2] Amazon DocumentDB clusters should have an adequate backup retention period

[DocumentDB.3] Amazon DocumentDB manual cluster snapshots should not be public

[DocumentDB.4] Amazon DocumentDB clusters should publish audit logs to CloudWatch Logs

[DocumentDB.5] Amazon DocumentDB clusters should have deletion protection enabled

[DocumentDB.6] Amazon DocumentDB clusters should be encrypted in transit

[DynamoDB.1] DynamoDB tables should automatically scale capacity with demand

[DynamoDB.2] DynamoDB tables should have point-in-time recovery enabled

[DynamoDB.3] DynamoDB Accelerator (DAX) clusters should be encrypted at rest

[DynamoDB.6] DynamoDB tables should have deletion protection enabled

[DynamoDB.7] DynamoDB Accelerator clusters should be encrypted in transit

[EC2.1] Amazon EBS snapshots should not be configured to be publicly restorable

[EC2.2] VPC default security groups should not allow inbound or outbound traffic

[EC2.3] Attached Amazon EBS volumes should be encrypted at-rest

[EC2.4] Stopped EC2 instances should be removed after a specified time period

[EC2.6] VPC flow logging should be enabled in all VPCs

[EC2.7] EBS default encryption should be enabled

[EC2.8] EC2 instances should use Instance Metadata Service Version 2 (IMDSv2)

[EC2.9] Amazon EC2 instances should not have a public IPv4 address

[EC2.10] Amazon EC2 should be configured to use VPC endpoints that are created for the Amazon EC2 service

[EC2.15] Amazon EC2 subnets should not automatically assign public IP addresses

[EC2.16] Unused Network Access Control Lists should be removed

[EC2.17] Amazon EC2 instances should not use multiple ENIs

[EC2.18] Security groups should only allow unrestricted incoming traffic for authorized ports

[EC2.19] Security groups should not allow unrestricted access to ports with high risk

[EC2.20] Both VPN tunnels for an AWS Site-to-Site VPN connection should be up

[EC2.21] Network ACLs should not allow ingress from 0.0.0.0/0 to port 22 or port 3389

[EC2.23] Amazon EC2 Transit Gateways should not automatically accept VPC attachment requests

[EC2.24] Amazon EC2 paravirtual instance types should not be used

[EC2.25] Amazon EC2 launch templates should not assign public IPs to network interfaces

[EC2.51] EC2 Client VPN endpoints should have client connection logging enabled

[EC2.55] VPCs should be configured with an interface endpoint for ECR API

[EC2.56] VPCs should be configured with an interface endpoint for Docker Registry

[EC2.57] VPCs should be configured with an interface endpoint for Systems Manager

[EC2.58] VPCs should be configured with an interface endpoint for Systems Manager Incident Manager Contacts

[EC2.60] VPCs should be configured with an interface endpoint for Systems Manager Incident Manager

[EC2.170] EC2 launch templates should use Instance Metadata Service Version 2 (IMDSv2)

[EC2.171] EC2 VPN connections should have logging enabled

[EC2.172] EC2 VPC Block Public Access settings should block internet gateway traffic

[EC2.173] EC2 Spot Fleet requests with launch parameters should enable encryption for attached EBS volumes

[EC2.180] EC2 network interfaces should have source/destination checking enabled

[EC2.181] EC2 launch templates should enable encryption for attached EBS volumes

[EC2.182] Block public access settings should be enabled for Amazon EBS snapshots

[EC2.183] EC2 VPN connections should use IKEv2 protocol

[ECR.1] ECR private repositories should have image scanning configured

[ECR.2] ECR private repositories should have tag immutability configured

[ECR.3] ECR repositories should have at least one lifecycle policy configured

[ECS.2] ECS services should not have public IP addresses assigned to them automatically

[ECS.3] ECS task definitions should not share the host's process namespace

[ECS.4] ECS containers should run as non-privileged

[ECS.5] ECS task definitions should configure containers to be limited to read-only access to root filesystems

[ECS.8] Secrets should not be passed as container environment variables

[ECS.9] ECS task definitions should have a logging configuration

[ECS.10] ECS Fargate services should run on the latest Fargate platform version

[ECS.12] ECS clusters should use Container Insights

[ECS.16] ECS task sets should not automatically assign public IP addresses

[ECS.18] ECS Task Definitions should use in-transit encryption for EFS volumes

[ECS.19] ECS capacity providers should have managed termination protection enabled

[ECS.20] ECS Task Definitions should configure non-root users in Linux container definitions

[ECS.21] ECS Task Definitions should configure non-administrator users in Windows container definitions

[EFS.1] Elastic File System should be configured to encrypt file data at-rest using AWS KMS

[EFS.2] Amazon EFS volumes should be in backup plans

[EFS.3] EFS access points should enforce a root directory

[EFS.4] EFS access points should enforce a user identity

[EFS.7] EFS file systems should have automatic backups enabled

[EFS.8] EFS file systems should be encrypted at rest

[EKS.1] EKS cluster endpoints should not be publicly accessible

[EKS.2] EKS clusters should run on a supported Kubernetes version

[EKS.8] EKS clusters should have audit logging enabled

[EKS.9] EKS node groups should run on a supported Kubernetes version

[ElastiCache.1] ElastiCache (Redis OSS) clusters should have automatic backups enabled

[ElastiCache.2] ElastiCache clusters should have automatic minor version upgrades enabled

[ElastiCache.3] ElastiCache replication groups should have automatic failover enabled

[ElastiCache.4] ElastiCache replication groups should be encrypted at rest

[ElastiCache.5] ElastiCache replication groups should be encrypted in transit

[ElastiCache.6] ElastiCache (Redis OSS) replication groups of earlier versions should have Redis OSS AUTH enabled

[ElastiCache.7] ElastiCache clusters should not use the default subnet group

[ElasticBeanstalk.1] Elastic Beanstalk environments should have enhanced health reporting enabled

[ElasticBeanstalk.2] Elastic Beanstalk managed platform updates should be enabled

[ElasticBeanstalk.3] Elastic Beanstalk should stream logs to CloudWatch

[ELB.1] Application Load Balancer should be configured to redirect all HTTP requests to HTTPS

[ELB.2] Classic Load Balancers with SSL/HTTPS listeners should use a certificate provided by AWS Certificate Manager

[ELB.3] Classic Load Balancer listeners should be configured with HTTPS or TLS termination

[ELB.4] Application Load Balancer should be configured to drop invalid http headers

[ELB.5] Application and Classic Load Balancers logging should be enabled

[ELB.6] Application, Gateway, and Network Load Balancers should have deletion protection enabled

[ELB.7] Classic Load Balancers should have connection draining enabled

[ELB.8] Classic Load Balancers with SSL listeners should use a predefined security policy that has strong AWS Configuration

[ELB.9] Classic Load Balancers should have cross-zone load balancing enabled

[ELB.10] Classic Load Balancer should span multiple Availability Zones

[ELB.12] Application Load Balancer should be configured with defensive or strictest desync mitigation mode

[ELB.13] Application, Network and Gateway Load Balancers should span multiple Availability Zones

[ELB.14] Classic Load Balancer should be configured with defensive or strictest desync mitigation mode

[ELB.17] Application and Network Load Balancers with listeners should use recommended security policies

[ELB.18] Application and Network Load Balancer listeners should use secure protocols to encrypt data in transit

[ELB.21] Application and Network Load Balancer target groups should use encrypted health check protocols

[ELB.22] ELB target groups should use encrypted transport protocols

[EMR.1] Amazon EMR cluster primary nodes should not have public IP addresses

[EMR.2] Amazon EMR block public access setting should be enabled

[EMR.3] Amazon EMR security configurations should be encrypted at rest

[EMR.4] Amazon EMR security configurations should be encrypted in transit

[ES.1] Elasticsearch domains should have encryption at-rest enabled

[ES.2] Elasticsearch domains should not be publicly accessible

[ES.3] Elasticsearch domains should encrypt data sent between nodes

[ES.4] Elasticsearch domain error logging to CloudWatch Logs should be enabled

[ES.5] Elasticsearch domains should have audit logging enabled

[ES.6] Elasticsearch domains should have at least three data nodes

[ES.7] Elasticsearch domains should be configured with at least three dedicated master nodes

[ES.8] Connections to Elasticsearch domains should be encrypted using the latest TLS security policy

[EventBridge.3] EventBridge custom event buses should have a resource-based policy attached

[FSx.1] FSx for OpenZFS file systems should be configured to copy tags to backups and volumes

[FSx.2] FSx for Lustre file systems should be configured to copy tags to backups

[FSx.3] FSx for OpenZFS file systems should be configured for Multi-AZ deployment

[FSx.4] FSx for NetApp ONTAP file systems should be configured for Multi-AZ deployment

[FSx.5] FSx for Windows File Server file systems should be configured for Multi-AZ deployment

[Glue.3] AWS Glue machine learning transforms should be encrypted at rest

[Glue.4] AWS Glue Spark jobs should run on supported versions of AWS Glue

[GuardDuty.1] GuardDuty should be enabled

[GuardDuty.5] GuardDuty EKS Audit Log Monitoring should be enabled

[GuardDuty.6] GuardDuty Lambda Protection should be enabled

[GuardDuty.7] GuardDuty EKS Runtime Monitoring should be enabled

[GuardDuty.8] GuardDuty Malware Protection for EC2 should be enabled

[GuardDuty.9] GuardDuty RDS Protection should be enabled

[GuardDuty.10] GuardDuty S3 Protection should be enabled

[GuardDuty.11] GuardDuty Runtime Monitoring should be enabled

[GuardDuty.12] GuardDuty ECS Runtime Monitoring should be enabled

[GuardDuty.13] GuardDuty EC2 Runtime Monitoring should be enabled

[IAM.1] IAM policies should not allow full "*" administrative privileges

[IAM.2] IAM users should not have IAM policies attached

[IAM.3] IAM users' access keys should be rotated every 90 days or less

[IAM.4] IAM root user access key should not exist

[IAM.5] MFA should be enabled for all IAM users that have a console password

[IAM.6] Hardware MFA should be enabled for the root user

[IAM.7] Password policies for IAM users should have strong configurations

[IAM.8] Unused IAM user credentials should be removed

[IAM.21] IAM customer managed policies that you create should not allow wildcard actions for services

[Inspector.1] Amazon Inspector EC2 scanning should be enabled

[Inspector.2] Amazon Inspector ECR scanning should be enabled

[Inspector.3] Amazon Inspector Lambda code scanning should be enabled

[Inspector.4] Amazon Inspector Lambda standard scanning should be enabled

[Kinesis.1] Kinesis streams should be encrypted at rest

[Kinesis.3] Kinesis streams should have an adequate data retention period

[KMS.1] IAM customer managed policies should not allow decryption actions on all KMS keys

[KMS.2] IAM principals should not have IAM inline policies that allow decryption actions on all KMS keys

[KMS.3] AWS KMS keys should not be deleted unintentionally

[KMS.5] KMS keys should not be publicly accessible

[Lambda.1] Lambda function policies should prohibit public access

[Lambda.2] Lambda functions should use supported runtimes

[Lambda.5] VPC Lambda functions should operate in multiple Availability Zones

[Macie.1] Amazon Macie should be enabled

[Macie.2] Macie automated sensitive data discovery should be enabled

[MQ.2] ActiveMQ brokers should stream audit logs to CloudWatch

[MSK.1] MSK clusters should be encrypted in transit among broker nodes

[MSK.3] MSK Connect connectors should be encrypted in transit

[MSK.4] MSK clusters should have public access disabled

[MSK.5] MSK connectors should have logging enabled

[MSK.6] MSK clusters should disable unauthenticated access

[Neptune.1] Neptune DB clusters should be encrypted at rest

[Neptune.2] Neptune DB clusters should publish audit logs to CloudWatch Logs

[Neptune.3] Neptune DB cluster snapshots should not be public

[Neptune.4] Neptune DB clusters should have deletion protection enabled

[Neptune.5] Neptune DB clusters should have automated backups enabled

[Neptune.6] Neptune DB cluster snapshots should be encrypted at rest

[Neptune.7] Neptune DB clusters should have IAM database authentication enabled

[Neptune.8] Neptune DB clusters should be configured to copy tags to snapshots

[NetworkFirewall.2] Network Firewall logging should be enabled

[NetworkFirewall.3] Network Firewall policies should have at least one rule group associated

[NetworkFirewall.4] The default stateless action for Network Firewall policies should be drop or forward for full packets

[NetworkFirewall.5] The default stateless action for Network Firewall policies should be drop or forward for fragmented packets

[NetworkFirewall.6] Stateless Network Firewall rule group should not be empty

[NetworkFirewall.9] Network Firewall firewalls should have deletion protection enabled

[NetworkFirewall.10] Network Firewall firewalls should have subnet change protection enabled

[Opensearch.1] OpenSearch domains should have encryption at rest enabled

[Opensearch.2] OpenSearch domains should not be publicly accessible

[Opensearch.3] OpenSearch domains should encrypt data sent between nodes

[Opensearch.4] OpenSearch domain error logging to CloudWatch Logs should be enabled

[Opensearch.5] OpenSearch domains should have audit logging enabled

[Opensearch.6] OpenSearch domains should have at least three data nodes

[Opensearch.7] OpenSearch domains should have fine-grained access control enabled

[Opensearch.8] Connections to OpenSearch domains should be encrypted using the latest TLS security policy

[Opensearch.10] OpenSearch domains should have the latest software update installed

[PCA.1] AWS Private CA root certificate authority should be disabled

[Route53.2] Route 53 public hosted zones should log DNS queries

[RDS.1] RDS snapshot should be private

[RDS.2] RDS DB Instances should prohibit public access, as determined by the PubliclyAccessible configuration

[RDS.3] RDS DB instances should have encryption at-rest enabled

[RDS.4] RDS cluster snapshots and database snapshots should be encrypted at rest

[RDS.5] RDS DB instances should be configured with multiple Availability Zones

[RDS.6] Enhanced monitoring should be configured for RDS DB instances

[RDS.7] RDS clusters should have deletion protection enabled

[RDS.8] RDS DB instances should have deletion protection enabled

[RDS.9] RDS DB instances should publish logs to CloudWatch Logs

[RDS.10] IAM authentication should be configured for RDS instances

[RDS.11] RDS instances should have automatic backups enabled

[RDS.12] IAM authentication should be configured for RDS clusters

[RDS.13] RDS automatic minor version upgrades should be enabled

[RDS.14] Amazon Aurora clusters should have backtracking enabled

[RDS.15] RDS DB clusters should be configured for multiple Availability Zones

[RDS.16] Aurora DB clusters should be configured to copy tags to DB snapshots

[RDS.17] RDS DB instances should be configured to copy tags to snapshots

[RDS.19] Existing RDS event notification subscriptions should be configured for critical cluster events

[RDS.20] Existing RDS event notification subscriptions should be configured for critical database instance events

[RDS.21] An RDS event notifications subscription should be configured for critical database parameter group events

[RDS.22] An RDS event notifications subscription should be configured for critical database security group events

[RDS.23] RDS instances should not use a database engine default port

[RDS.24] RDS Database clusters should use a custom administrator username

[RDS.25] RDS database instances should use a custom administrator username

[RDS.27] RDS DB clusters should be encrypted at rest

[RDS.34] Aurora MySQL DB clusters should publish audit logs to CloudWatch Logs

[RDS.35] RDS DB clusters should have automatic minor version upgrade enabled

[RDS.36] RDS for PostgreSQL DB instances should publish logs to CloudWatch Logs

[RDS.37] Aurora PostgreSQL DB clusters should publish logs to CloudWatch Logs

[RDS.40] RDS for SQL Server DB instances should publish logs to CloudWatch Logs

[RDS.41] RDS for SQL Server DB instances should be encrypted in transit

[RDS.42] RDS for MariaDB DB instances should publish logs to CloudWatch Logs

[RDS.43] RDS DB proxies should require TLS encryption for connections

[RDS.44] RDS for MariaDB DB instances should be encrypted in transit

[RDS.45] Aurora MySQL DB clusters should have audit logging enabled

[RDS.46] RDS DB instances should not be deployed in public subnets with routes to internet gateways

[RDS.47] RDS for PostgreSQL DB clusters should be configured to copy tags to DB snapshots

[RDS.48] RDS for MySQL DB clusters should be configured to copy tags to DB snapshots

[RDS.50] RDS DB clusters should have enough backup retention period set

[RDS.51] RDS global clusters should run on a supported Aurora MySQL version

[Redshift.1] Amazon Redshift clusters should prohibit public access

[Redshift.2] Connections to Amazon Redshift clusters should be encrypted in transit

[Redshift.3] Amazon Redshift clusters should have automatic snapshots enabled

[Redshift.4] Amazon Redshift clusters should have audit logging enabled

[Redshift.6] Amazon Redshift should have automatic upgrades to major versions enabled

[Redshift.7] Redshift clusters should use enhanced VPC routing

[Redshift.8] Amazon Redshift clusters should not use the default Admin username

[Redshift.10] Redshift clusters should be encrypted at rest

[Redshift.15] Redshift security groups should allow ingress on the cluster port only from restricted origins

[Redshift.18] Redshift clusters should have Multi-AZ deployments enabled

[RedshiftServerless.1] Amazon Redshift Serverless workgroups should use enhanced VPC routing

[RedshiftServerless.2] Connections to Redshift Serverless workgroups should be required to use SSL

[RedshiftServerless.3] Redshift Serverless workgroups should prohibit public access

[RedshiftServerless.5] Redshift Serverless namespaces should not use the default admin username

[RedshiftServerless.6] Redshift Serverless namespaces should export logs to CloudWatch Logs

[S3.1] S3 general purpose buckets should have block public access settings enabled

[S3.2] S3 general purpose buckets should block public read access

[S3.3] S3 general purpose buckets should block public write access

[S3.5] S3 general purpose buckets should require requests to use TLS

[S3.6] S3 general purpose bucket policies should restrict access to other AWS accounts

[S3.8] S3 general purpose buckets should block public access

[S3.9] S3 general purpose buckets should have server access logging enabled

[S3.12] ACLs should not be used to manage user access to S3 general purpose buckets

[S3.13] S3 general purpose buckets should have Lifecycle configurations

[S3.19] S3 access points should have block public access settings enabled

[S3.24] S3 Multi-Region Access Points should have block public access settings enabled

[S3.25] S3 directory buckets should have lifecycle configurations

[SageMaker.1] Amazon SageMaker notebook instances should not have direct internet access

[SageMaker.2] SageMaker notebook instances should be launched in a custom VPC

[SageMaker.3] Users should not have root access to SageMaker notebook instances

[SageMaker.4] SageMaker endpoint production variants should have an initial instance count greater than 1

[SageMaker.5] SageMaker models should have network isolation enabled

[SageMaker.8] SageMaker notebook instances should run on supported platforms

[SageMaker.9] SageMaker data quality job definitions should have inter-container traffic encryption enabled

[SageMaker.10] SageMaker model explainability job definitions should have inter-container traffic encryption enabled

[SageMaker.11] SageMaker data quality job definitions should have network isolation enabled

[SageMaker.12] SageMaker model bias job definitions should have network isolation enabled

[SageMaker.13] SageMaker model quality job definitions should have inter-container traffic encryption enabled

[SageMaker.14] SageMaker monitoring schedules should have network isolation enabled

[SageMaker.15] SageMaker model bias job definitions should have inter-container traffic encryption enabled

[SageMaker.16] SageMaker models should use private registry in VPC for primary containers

[SageMaker.17] SageMaker feature group offline stores should be encrypted with AWS KMS keys

[SageMaker.19] SageMaker models should use private registry in VPC for multi-container inference pipelines

[SageMaker.20] SageMaker model explainability job definitions should have network isolation enabled

[SageMaker.22] SageMaker monitoring schedules should have inter-container traffic encryption enabled

[SageMaker.25] SageMaker model quality job definitions should have network isolation enabled

[SecretsManager.1] Secrets Manager secrets should have automatic rotation enabled

[SecretsManager.2] Secrets Manager secrets configured with automatic rotation should rotate successfully

[SecretsManager.3] Remove unused Secrets Manager secrets

[SecretsManager.4] Secrets Manager secrets should be rotated within a specified number of days

[ServiceCatalog.1] Service Catalog portfolios should be shared within an AWS organization only

[SES.3] SES configuration sets should have TLS enabled for sending emails

[SNS.4] SNS topic access policies should not allow public access

[SQS.1] Amazon SQS queues should be encrypted at rest

[SQS.3] SQS queue access policies should not allow public access

[SSM.1] Amazon EC2 instances should be managed by AWS Systems Manager

[SSM.2] Amazon EC2 instances managed by Systems Manager should have a patch compliance status of COMPLIANT after a patch installation

[SSM.3] Amazon EC2 instances managed by Systems Manager should have an association compliance status of COMPLIANT

[SSM.4] SSM documents should not be public

[SSM.6] SSM Automation should have CloudWatch logging enabled

[SSM.7] SSM documents should have the block public sharing setting enabled

[StepFunctions.1] Step Functions state machines should have logging turned on

[Transfer.2] Transfer Family servers should not use FTP protocol for endpoint connection

[Transfer.3] Transfer Family connectors should have logging enabled

[WAF.1] AWS WAF Classic Global Web ACL logging should be enabled

[WAF.2] AWS WAF Classic Regional rules should have at least one condition

[WAF.3] AWS WAF Classic Regional rule groups should have at least one rule

[WAF.4] AWS WAF Classic Regional web ACLs should have at least one rule or rule group

[WAF.6] AWS WAF Classic global rules should have at least one condition

[WAF.7] AWS WAF Classic global rule groups should have at least one rule

[WAF.8] AWS WAF Classic global web ACLs should have at least one rule or rule group

[WAF.10] AWS WAF web ACLs should have at least one rule or rule group

[WAF.12] AWS WAF rules should have CloudWatch metrics enabled

[WorkSpaces.1] WorkSpaces user volumes should be encrypted at rest

[WorkSpaces.2] WorkSpaces root volumes should be encrypted at rest

AI Security Best Practices standard in Security Hub CSPM

The AI Security Best Practices standard is a set of automated security checks that detect when deployed AI resources do not align with security best practices. Developed by AWS security experts, this standard provides a curated set of controls that help you identify areas where your AI workloads deviate from recommended security configurations.

In AWS Security Hub CSPM, the AI Security Best Practices standard includes controls that continuously evaluate your resources. The controls cover security domains including but not limited to network isolation, encryption at rest and in transit, VPC placement, AWS KMS key usage, and private registry requirements. Each control is assigned a category that reflects the security function

that the control applies to. For a list of categories and additional details, see Control categories in Security Hub CSPM.

The AI Security Best Practices standard has the following Amazon Resource Name (ARN): `arn:aws:securityhub:region::standards/ai-security-best-practices/v/1.0.0`, where *region* is the Region code for the applicable AWS Region. You can also use the GetEnabledStandards operation of the Security Hub CSPM API to retrieve the ARN of a standard that's currently enabled.

Controls that apply to the standard

The following list specifies which AWS Security Hub CSPM controls apply to the AI Security Best Practices standard (v1.0.0). To review the details of a control, choose the control.

- [Bedrock.1] Amazon Bedrock data sources should be encrypted with customer managed AWS KMS keys
- [BedrockAgentCore.1] Bedrock AgentCore runtimes should be configured with VPC network mode
- [BedrockAgentCore.2] Bedrock AgentCore Gateways should require authorization for inbound requests
- [BedrockAgentCore.3] Bedrock AgentCore Memory should be encrypted with customer managed AWS KMS keys
- [BedrockAgentCore.4] Bedrock AgentCore Gateway should be encrypted with customer managed AWS KMS keys
- [BedrockAgentCore.5] Bedrock AgentCore custom browsers should not use public network mode
- [BedrockAgentCore.6] Bedrock AgentCore custom browsers should have session recording enabled
- [BedrockAgentCore.7] Bedrock AgentCore custom code interpreters should use a private network configuration
- [SageMaker.1] Amazon SageMaker notebook instances should not have direct internet access
- [SageMaker.2] SageMaker notebook instances should be launched in a custom VPC
- [SageMaker.3] Users should not have root access to SageMaker notebook instances
- [SageMaker.4] SageMaker endpoint production variants should have an initial instance count greater than 1
- [SageMaker.5] SageMaker models should have network isolation enabled
- [SageMaker.8] SageMaker notebook instances should run on supported platforms

- [SageMaker.9] SageMaker data quality job definitions should have inter-container traffic encryption enabled
- [SageMaker.10] SageMaker model explainability job definitions should have inter-container traffic encryption enabled
- [SageMaker.11] SageMaker data quality job definitions should have network isolation enabled
- [SageMaker.12] SageMaker model bias job definitions should have network isolation enabled
- [SageMaker.13] SageMaker model quality job definitions should have inter-container traffic encryption enabled
- [SageMaker.14] SageMaker monitoring schedules should have network isolation enabled
- [SageMaker.15] SageMaker model bias job definitions should have inter-container traffic encryption enabled
- [SageMaker.16] SageMaker models should use private registry in VPC for primary containers
- [SageMaker.17] SageMaker feature group offline stores should be encrypted with AWS KMS keys
- [SageMaker.18] SageMaker feature group online stores with standard storage should be encrypted with AWS KMS keys
- [SageMaker.19] SageMaker models should use private registry in VPC for multi-container inference pipelines
- [SageMaker.20] SageMaker model explainability job definitions should have network isolation enabled
- [SageMaker.21] SageMaker notebook instances should be encrypted with customer managed AWS KMS keys
- [SageMaker.22] SageMaker monitoring schedules should have inter-container traffic encryption enabled
- [SageMaker.23] SageMaker inference experiments should have instance storage volume encrypted with customer managed AWS KMS keys
- [SageMaker.24] SageMaker inference experiments should have data storage encrypted with customer managed AWS KMS keys
- [SageMaker.25] SageMaker model quality job definitions should have network isolation enabled

AWS Resource Tagging standard in Security Hub CSPM

The AWS Resource Tagging standard, developed by AWS Security Hub CSPM, helps you determine whether your AWS resources are missing tags. *Tags* are key-value pairs that act as metadata for

organizing AWS resources. With most AWS resources, you have the option of adding tags to a resource when you create the resource or after you create the resource. Examples of resources include Amazon CloudFront distributions, Amazon Elastic Compute Cloud (Amazon EC2) instances, and secrets in AWS Secrets Manager. Tags can help you manage, identify, organize, search for, and filter AWS resources.

Each tag has two parts:

- A tag key—for example, `CostCenter`, `Environment`, or `Project`. Tag keys are case sensitive.
- A tag value—for example, `111122223333` or `Production`. Like tag keys, tag values are case sensitive.

You can use tags to categorize resources by purpose, owner, environment, or other criteria. For information about adding tags to AWS resources, see the Tagging AWS Resources and Tag Editor User Guide.

For each control that applies to the AWS Resource Tagging standard in Security Hub CSPM, you can optionally use the supported parameter to specify tag keys that you want the control to check for. If you don't specify any tag keys, the control checks only for the existence of at least one tag key, and fails if a resource doesn't have any tag keys.

Before you enable the AWS Resource Tagging standard, it's important to enable and configure resource recording in AWS Config. When you configure resource recording, also be sure to enable it for all the types of AWS resources that are checked by controls that apply to the standard. Otherwise, Security Hub CSPM might not be able to evaluate the appropriate resources, and generate accurate findings for controls that apply to the standard. For more information, including a list of the types of resources to record, see Required AWS Config resources for control findings.

After you enable the AWS Resource Tagging standard, you begin receiving findings for controls that apply to the standard. Note that it can take up to 18 hours for Security Hub CSPM to generate findings for controls that use the same AWS Config service-linked rule as controls that apply to other enabled standards. For more information, see Schedule for running security checks.

The AWS Resource Tagging standard has the following Amazon Resource Name (ARN): `arn:aws:securityhub:`*`region`*`::standards/aws-resource-tagging-standard/v/1.0.0`, where *`region`* is the Region code for the applicable AWS Region. You can also use the GetEnabledStandards operation of the Security Hub CSPM API to retrieve the ARN of a standard that's currently enabled.

> **Note**
>
> The AWS Resource Tagging standard isn't available in the Asia Pacific (New Zealand) and Asia Pacific (Taipei) Regions.

Controls that apply to the standard

The following list specifies which AWS Security Hub CSPM controls apply to the AWS Resource Tagging standard (v1.0.0). To review the details of a control, choose the control.

- [ACM.3] ACM certificates should be tagged
- [Amplify.1] Amplify apps should be tagged
- [Amplify.2] Amplify branches should be tagged
- [AppConfig.1] AWS AppConfig applications should be tagged
- [AppConfig.2] AWS AppConfig configuration profiles should be tagged
- [AppConfig.3] AWS AppConfig environments should be tagged
- [AppConfig.4] AWS AppConfig extension associations should be tagged
- [AppFlow.1] Amazon AppFlow flows should be tagged
- [AppRunner.1] App Runner services should be tagged
- [AppRunner.2] App Runner VPC connectors should be tagged
- [AppSync.4] AWS AppSync GraphQL APIs should be tagged
- [Athena.2] Athena data catalogs should be tagged
- [Athena.3] Athena workgroups should be tagged
- [AutoScaling.10] EC2 Auto Scaling groups should be tagged
- [Backup.2] AWS Backup recovery points should be tagged
- [Backup.3] AWS Backup vaults should be tagged
- [Backup.4] AWS Backup report plans should be tagged
- [Backup.5] AWS Backup backup plans should be tagged
- [Batch.1] Batch job queues should be tagged
- [Batch.2] Batch scheduling policies should be tagged
- [Batch.3] Batch compute environments should be tagged

- [Batch.4] Compute resources properties in managed Batch compute environments should be tagged
- [CloudFormation.2] CloudFormation stacks should be tagged
- [CloudFront.14] CloudFront distributions should be tagged
- [CloudTrail.9] CloudTrail trails should be tagged
- [CodeArtifact.1]CodeArtifact repositories should be tagged
- [CodeGuruProfiler.1] CodeGuru Profiler profiling groups should be tagged
- [CodeGuruReviewer.1] CodeGuru Reviewer repository associations should be tagged
- [Connect.1] Amazon Connect Customer Profiles object types should be tagged
- [DataSync.2] DataSync tasks should be tagged
- [Detective.1] Detective behavior graphs should be tagged
- [DMS.2] DMS certificates should be tagged
- [DMS.3] DMS event subscriptions should be tagged
- [DMS.4] DMS replication instances should be tagged
- [DMS.5] DMS replication subnet groups should be tagged
- [DynamoDB.5] DynamoDB tables should be tagged
- [EC2.33] EC2 transit gateway attachments should be tagged
- [EC2.34] EC2 transit gateway route tables should be tagged
- [EC2.35] EC2 network interfaces should be tagged
- [EC2.36] EC2 customer gateways should be tagged
- [EC2.37] EC2 Elastic IP addresses should be tagged
- [EC2.38] EC2 instances should be tagged
- [EC2.39] EC2 internet gateways should be tagged
- [EC2.40] EC2 NAT gateways should be tagged
- [EC2.41] EC2 network ACLs should be tagged
- [EC2.42] EC2 route tables should be tagged
- [EC2.43] EC2 security groups should be tagged
- [EC2.44] EC2 subnets should be tagged
- [EC2.45] EC2 volumes should be tagged
- [EC2.46] Amazon VPCs should be tagged
- [EC2.47] Amazon VPC endpoint services should be tagged

- [EC2.48] Amazon VPC flow logs should be tagged
- [EC2.49] Amazon VPC peering connections should be tagged
- [EC2.50] EC2 VPN gateways should be tagged
- [EC2.52] EC2 transit gateways should be tagged
- [EC2.174] EC2 DHCP option sets should be tagged
- [EC2.175] EC2 launch templates should be tagged
- [EC2.176] EC2 prefix lists should be tagged
- [EC2.177] EC2 traffic mirror sessions should be tagged
- [EC2.178] EC2 traffic mirror filters should be tagged
- [EC2.179] EC2 traffic mirror targets should be tagged
- [ECR.4] ECR public repositories should be tagged
- [ECS.13] ECS services should be tagged
- [ECS.14] ECS clusters should be tagged
- [ECS.15] ECS task definitions should be tagged
- [EFS.5] EFS access points should be tagged
- [EKS.6] EKS clusters should be tagged
- [EKS.7] EKS identity provider configurations should be tagged
- [ES.9] Elasticsearch domains should be tagged
- [EventBridge.2] EventBridge event buses should be tagged
- [FraudDetector.1] Amazon Fraud Detector entity types should be tagged
- [FraudDetector.2] Amazon Fraud Detector labels should be tagged
- [FraudDetector.3] Amazon Fraud Detector outcomes should be tagged
- [FraudDetector.4] Amazon Fraud Detector variables should be tagged
- [GlobalAccelerator.1] Global Accelerator accelerators should be tagged
- [Glue.1] AWS Glue jobs should be tagged
- [GuardDuty.2] GuardDuty filters should be tagged
- [GuardDuty.3] GuardDuty IPSets should be tagged
- [GuardDuty.4] GuardDuty detectors should be tagged
- [IAM.23] IAM Access Analyzer analyzers should be tagged
- [IAM.24] IAM roles should be tagged

- [IAM.25] IAM users should be tagged
- [IoT.1] AWS IoT Device Defender security profiles should be tagged
- [IoT.2] AWS IoT Core mitigation actions should be tagged
- [IoT.3] AWS IoT Core dimensions should be tagged
- [IoT.4] AWS IoT Core authorizers should be tagged
- [IoT.5] AWS IoT Core role aliases should be tagged
- [IoT.6] AWS IoT Core policies should be tagged
- [IoTSiteWise.1] AWS IoT SiteWise asset models should be tagged
- [IoTSiteWise.2] AWS IoT SiteWise dashboards should be tagged
- [IoTSiteWise.3] AWS IoT SiteWise gateways should be tagged
- [IoTSiteWise.4] AWS IoT SiteWise portals should be tagged
- [IoTSiteWise.5] AWS IoT SiteWise projects should be tagged
- [IoTTwinMaker.1] AWS IoT TwinMaker sync jobs should be tagged
- [IoTTwinMaker.2] AWS IoT TwinMaker workspaces should be tagged
- [IoTTwinMaker.3] AWS IoT TwinMaker scenes should be tagged
- [IoTTwinMaker.4] AWS IoT TwinMaker entities should be tagged
- [IoTWireless.1] AWS IoT Wireless multicast groups should be tagged
- [IoTWireless.2] AWS IoT Wireless service profiles should be tagged
- [IoTWireless.3] AWS IoT FUOTA tasks should be tagged
- [IVS.1] IVS playback key pairs should be tagged
- [IVS.2] IVS recording configurations should be tagged
- [IVS.3] IVS channels should be tagged
- [Keyspaces.1] Amazon Keyspaces keyspaces should be tagged
- [Kinesis.2] Kinesis streams should be tagged
- [Lambda.6] Lambda functions should be tagged
- [MQ.4] Amazon MQ brokers should be tagged
- [NetworkFirewall.7] Network Firewall firewalls should be tagged
- [NetworkFirewall.8] Network Firewall firewall policies should be tagged
- [Opensearch.9] OpenSearch domains should be tagged
- [PCA.2] AWS Private CA certificate authorities should be tagged

- [RDS.28] RDS DB clusters should be tagged
- [RDS.29] RDS DB cluster snapshots should be tagged
- [RDS.30] RDS DB instances should be tagged
- [RDS.31] RDS DB security groups should be tagged
- [RDS.32] RDS DB snapshots should be tagged
- [RDS.33] RDS DB subnet groups should be tagged
- [Redshift.11] Redshift clusters should be tagged
- [Redshift.12] Redshift event notification subscriptions should be tagged
- [Redshift.13] Redshift cluster snapshots should be tagged
- [Redshift.14] Redshift cluster subnet groups should be tagged
- [Redshift.17] Redshift cluster parameter groups should be tagged
- [Route53.1] Route 53 health checks should be tagged
- [SageMaker.6] SageMaker app image configurations should be tagged
- [SageMaker.7] SageMaker images should be tagged
- [SecretsManager.5] Secrets Manager secrets should be tagged
- [SES.1] SES contact lists should be tagged
- [SES.2] SES configuration sets should be tagged
- [SNS.3] SNS topics should be tagged
- [SQS.2] SQS queues should be tagged
- [SSM.5] SSM documents should be tagged
- [StepFunctions.2] Step Functions activities should be tagged
- [Transfer.1] AWS Transfer Family workflows should be tagged
- [Transfer.4] Transfer Family agreements should be tagged
- [Transfer.5] Transfer Family certificates should be tagged
- [Transfer.6] Transfer Family connectors should be tagged
- [Transfer.7] Transfer Family profiles should be tagged

CIS AWS Foundations Benchmark in Security Hub CSPM

The Center for Internet Security (CIS) AWS Foundations Benchmark serves as a set of security configuration best practices for AWS. These industry-accepted best practices provide you with

clear, step-by-step implementation and assessment procedures. Ranging from operating systems to cloud services and network devices, the controls in this benchmark help you protect the specific systems that your organization uses.

AWS Security Hub CSPM supports CIS AWS Foundations Benchmark versions 5.0.0, 3.0.0, 1.4.0, and 1.2.0. This page lists the security controls that each version supports. It also provides a comparison of the versions.

CIS AWS Foundations Benchmark version 5.0.0

Security Hub CSPM supports version 5.0.0 (v5.0.0) of the CIS AWS Foundations Benchmark. Security Hub CSPM has satisfied the requirements of CIS Security Software Certification and has been awarded CIS Security Software Certification for the following CIS Benchmarks:

- CIS Benchmark for CIS AWS Foundations Benchmark, v5.0.0, Level 1
- CIS Benchmark for CIS AWS Foundations Benchmark, v5.0.0, Level 2

Controls that apply to CIS AWS Foundations Benchmark version 5.0.0

[Account.1] Security contact information should be provided for an AWS account

[CloudTrail.1] CloudTrail should be enabled and configured with at least one multi-Region trail that includes read and write management events

[CloudTrail.2] CloudTrail should have encryption at-rest enabled

[CloudTrail.4] CloudTrail log file validation should be enabled

[CloudTrail.7] Ensure S3 bucket access logging is enabled on the CloudTrail S3 bucket

[Config.1] AWS Config should be enabled and use the service-linked role for resource recording

[EC2.2] VPC default security groups should not allow inbound or outbound traffic

[EC2.6] VPC flow logging should be enabled in all VPCs

[EC2.7] EBS default encryption should be enabled

[EC2.8] EC2 instances should use Instance Metadata Service Version 2 (IMDSv2)

[EC2.21] Network ACLs should not allow ingress from 0.0.0.0/0 to port 22 or port 3389

[EC2.53] EC2 security groups should not allow ingress from 0.0.0.0/0 to remote server administration ports

[EC2.54] EC2 security groups should not allow ingress from ::/0 to remote server administration ports

[EFS.1] Elastic File System should be configured to encrypt file data at-rest using AWS KMS

[EFS.8] EFS file systems should be encrypted at rest

[IAM.2] IAM users should not have IAM policies attached

[IAM.3] IAM users' access keys should be rotated every 90 days or less

[IAM.4] IAM root user access key should not exist

[IAM.5] MFA should be enabled for all IAM users that have a console password

[IAM.6] Hardware MFA should be enabled for the root user

[IAM.9] MFA should be enabled for the root user

[IAM.15] Ensure IAM password policy requires minimum password length of 14 or greater

[IAM.16] Ensure IAM password policy prevents password reuse

[IAM.18] Ensure a support role has been created to manage incidents with AWS Support

[IAM.22] IAM user credentials unused for 45 days should be removed

[IAM.26] Expired SSL/TLS certificates managed in IAM should be removed

[IAM.27] IAM identities should not have the AWSCloudShellFullAccess policy attached

[IAM.28] IAM Access Analyzer external access analyzer should be enabled

[KMS.4] AWS KMS key rotation should be enabled

[RDS.2] RDS DB Instances should prohibit public access, as determined by the PubliclyAccessible configuration

[RDS.3] RDS DB instances should have encryption at-rest enabled

[RDS.5] RDS DB instances should be configured with multiple Availability Zones

[RDS.13] RDS automatic minor version upgrades should be enabled

[RDS.15] RDS DB clusters should be configured for multiple Availability Zones

[S3.1] S3 general purpose buckets should have block public access settings enabled

[S3.5] S3 general purpose buckets should require requests to use TLS

[S3.8] S3 general purpose buckets should block public access

[S3.20] S3 general purpose buckets should have MFA delete enabled

[S3.22] S3 general purpose buckets should log object-level write events

[S3.23] S3 general purpose buckets should log object-level read events

CIS AWS Foundations Benchmark version 3.0.0

Security Hub CSPM supports version 3.0.0 (v3.0.0) of the CIS AWS Foundations Benchmark. Security Hub CSPM has satisfied the requirements of CIS Security Software Certification and has been awarded CIS Security Software Certification for the following CIS Benchmarks:

- CIS Benchmark for CIS AWS Foundations Benchmark, v3.0.0, Level 1
- CIS Benchmark for CIS AWS Foundations Benchmark, v3.0.0, Level 2

Controls that apply to CIS AWS Foundations Benchmark version 3.0.0

[Account.1] Security contact information should be provided for an AWS account

[CloudTrail.1] CloudTrail should be enabled and configured with at least one multi-Region trail that includes read and write management events

[CloudTrail.2] CloudTrail should have encryption at-rest enabled

[CloudTrail.4] CloudTrail log file validation should be enabled

[CloudTrail.7] Ensure S3 bucket access logging is enabled on the CloudTrail S3 bucket

[Config.1] AWS Config should be enabled and use the service-linked role for resource recording

[EC2.2] VPC default security groups should not allow inbound or outbound traffic

[EC2.6] VPC flow logging should be enabled in all VPCs

[EC2.7] EBS default encryption should be enabled

[EC2.8] EC2 instances should use Instance Metadata Service Version 2 (IMDSv2)

[EC2.21] Network ACLs should not allow ingress from 0.0.0.0/0 to port 22 or port 3389

[EC2.53] EC2 security groups should not allow ingress from 0.0.0.0/0 to remote server administration ports

[EC2.54] EC2 security groups should not allow ingress from ::/0 to remote server administration ports

[EFS.1] Elastic File System should be configured to encrypt file data at-rest using AWS KMS

[IAM.2] IAM users should not have IAM policies attached

[IAM.3] IAM users' access keys should be rotated every 90 days or less

[IAM.4] IAM root user access key should not exist

[IAM.5] MFA should be enabled for all IAM users that have a console password

[IAM.6] Hardware MFA should be enabled for the root user

[IAM.9] MFA should be enabled for the root user

[IAM.15] Ensure IAM password policy requires minimum password length of 14 or greater

[IAM.16] Ensure IAM password policy prevents password reuse

[IAM.18] Ensure a support role has been created to manage incidents with AWS Support

[IAM.22] IAM user credentials unused for 45 days should be removed

[IAM.26] Expired SSL/TLS certificates managed in IAM should be removed

[IAM.27] IAM identities should not have the AWSCloudShellFullAccess policy attached

[IAM.28] IAM Access Analyzer external access analyzer should be enabled

[KMS.4] AWS KMS key rotation should be enabled

[RDS.2] RDS DB Instances should prohibit public access, as determined by the PubliclyAccessible configuration

[RDS.3] RDS DB instances should have encryption at-rest enabled

[RDS.13] RDS automatic minor version upgrades should be enabled

[S3.1] S3 general purpose buckets should have block public access settings enabled

[S3.5] S3 general purpose buckets should require requests to use TLS

[S3.8] S3 general purpose buckets should block public access

[S3.20] S3 general purpose buckets should have MFA delete enabled

[S3.22] S3 general purpose buckets should log object-level write events

[S3.23] S3 general purpose buckets should log object-level read events

CIS AWS Foundations Benchmark version 1.4.0

Security Hub CSPM supports version 1.4.0 (v1.4.0) of the CIS AWS Foundations Benchmark.

Controls that apply to CIS AWS Foundations Benchmark version 1.4.0

[CloudTrail.1] CloudTrail should be enabled and configured with at least one multi-Region trail that includes read and write management events

[CloudTrail.2] CloudTrail should have encryption at-rest enabled

[CloudTrail.4] CloudTrail log file validation should be enabled

[CloudTrail.5] CloudTrail trails should be integrated with Amazon CloudWatch Logs

[CloudTrail.6] Ensure the S3 bucket used to store CloudTrail logs is not publicly accessible

[CloudTrail.7] Ensure S3 bucket access logging is enabled on the CloudTrail S3 bucket

[CloudWatch.1] A log metric filter and alarm should exist for usage of the "root" user

[CloudWatch.4] Ensure a log metric filter and alarm exist for IAM policy changes

[CloudWatch.5] Ensure a log metric filter and alarm exist for CloudTrail configuration changes

[CloudWatch.6] Ensure a log metric filter and alarm exist for AWS Management Console authentication failures

[CloudWatch.7] Ensure a log metric filter and alarm exist for disabling or scheduled deletion of customer managed keys

[CloudWatch.8] Ensure a log metric filter and alarm exist for S3 bucket policy changes

[CloudWatch.9] Ensure a log metric filter and alarm exist for AWS Config configuration changes

[CloudWatch.10] Ensure a log metric filter and alarm exist for security group changes

[CloudWatch.11] Ensure a log metric filter and alarm exist for changes to Network Access Control Lists (NACL)

[CloudWatch.12] Ensure a log metric filter and alarm exist for changes to network gateways

[CloudWatch.13] Ensure a log metric filter and alarm exist for route table changes

[CloudWatch.14] Ensure a log metric filter and alarm exist for VPC changes

[Config.1] AWS Config should be enabled and use the service-linked role for resource recording

[EC2.2] VPC default security groups should not allow inbound or outbound traffic

[EC2.6] VPC flow logging should be enabled in all VPCs

[EC2.7] EBS default encryption should be enabled

[EC2.21] Network ACLs should not allow ingress from 0.0.0.0/0 to port 22 or port 3389

[IAM.1] IAM policies should not allow full "*" administrative privileges

[IAM.3] IAM users' access keys should be rotated every 90 days or less

[IAM.4] IAM root user access key should not exist

[IAM.5] MFA should be enabled for all IAM users that have a console password

[IAM.6] Hardware MFA should be enabled for the root user

[IAM.9] MFA should be enabled for the root user

[IAM.15] Ensure IAM password policy requires minimum password length of 14 or greater

[IAM.16] Ensure IAM password policy prevents password reuse

[IAM.18] Ensure a support role has been created to manage incidents with AWS Support

[IAM.22] IAM user credentials unused for 45 days should be removed

[KMS.4] AWS KMS key rotation should be enabled

[RDS.3] RDS DB instances should have encryption at-rest enabled

[S3.1] S3 general purpose buckets should have block public access settings enabled

[S3.5] S3 general purpose buckets should require requests to use TLS

[S3.8] S3 general purpose buckets should block public access

[S3.20] S3 general purpose buckets should have MFA delete enabled

CIS AWS Foundations Benchmark version 1.2.0

Security Hub CSPM supports version 1.2.0 (v1.2.0) of the CIS AWS Foundations Benchmark. Security Hub CSPM has satisfied the requirements of CIS Security Software Certification and has been awarded CIS Security Software Certification for the following CIS Benchmarks:

- CIS Benchmark for CIS AWS Foundations Benchmark, v1.2.0, Level 1
- CIS Benchmark for CIS AWS Foundations Benchmark, v1.2.0, Level 2

Controls that apply to CIS AWS Foundations Benchmark version 1.2.0

[CloudTrail.1] CloudTrail should be enabled and configured with at least one multi-Region trail that includes read and write management events

[CloudTrail.2] CloudTrail should have encryption at-rest enabled

[CloudTrail.4] CloudTrail log file validation should be enabled

[CloudTrail.5] CloudTrail trails should be integrated with Amazon CloudWatch Logs

[CloudTrail.6] Ensure the S3 bucket used to store CloudTrail logs is not publicly accessible

[CloudTrail.7] Ensure S3 bucket access logging is enabled on the CloudTrail S3 bucket

[CloudWatch.1] A log metric filter and alarm should exist for usage of the "root" user

[CloudWatch.2] Ensure a log metric filter and alarm exist for unauthorized API calls

[CloudWatch.3] Ensure a log metric filter and alarm exist for Management Console sign-in without MFA

[CloudWatch.4] Ensure a log metric filter and alarm exist for IAM policy changes

[CloudWatch.5] Ensure a log metric filter and alarm exist for CloudTrail configuration changes

[CloudWatch.6] Ensure a log metric filter and alarm exist for AWS Management Console authentication failures

[CloudWatch.7] Ensure a log metric filter and alarm exist for disabling or scheduled deletion of customer managed keys

[CloudWatch.8] Ensure a log metric filter and alarm exist for S3 bucket policy changes

[CloudWatch.9] Ensure a log metric filter and alarm exist for AWS Config configuration changes

[CloudWatch.10] Ensure a log metric filter and alarm exist for security group changes

[CloudWatch.11] Ensure a log metric filter and alarm exist for changes to Network Access Control Lists (NACL)

[CloudWatch.12] Ensure a log metric filter and alarm exist for changes to network gateways

[CloudWatch.13] Ensure a log metric filter and alarm exist for route table changes

[CloudWatch.14] Ensure a log metric filter and alarm exist for VPC changes

[Config.1] AWS Config should be enabled and use the service-linked role for resource recording

[EC2.2] VPC default security groups should not allow inbound or outbound traffic

[EC2.6] VPC flow logging should be enabled in all VPCs

[EC2.13] Security groups should not allow ingress from 0.0.0.0/0 or ::/0 to port 22

[EC2.14] Security groups should not allow ingress from 0.0.0.0/0 or ::/0 to port 3389

[IAM.1] IAM policies should not allow full "*" administrative privileges

[IAM.2] IAM users should not have IAM policies attached

[IAM.3] IAM users' access keys should be rotated every 90 days or less

[IAM.4] IAM root user access key should not exist

[IAM.5] MFA should be enabled for all IAM users that have a console password

[IAM.6] Hardware MFA should be enabled for the root user

[IAM.8] Unused IAM user credentials should be removed

[IAM.9] MFA should be enabled for the root user

[IAM.11] Ensure IAM password policy requires at least one uppercase letter

[IAM.12] Ensure IAM password policy requires at least one lowercase letter

[IAM.13] Ensure IAM password policy requires at least one symbol

[IAM.14] Ensure IAM password policy requires at least one number

[IAM.15] Ensure IAM password policy requires minimum password length of 14 or greater

[IAM.16] Ensure IAM password policy prevents password reuse

[IAM.17] Ensure IAM password policy expires passwords within 90 days or less

[IAM.18] Ensure a support role has been created to manage incidents with AWS Support

[KMS.4] AWS KMS key rotation should be enabled

Version comparison for CIS AWS Foundations Benchmark

This section summarizes the differences between specific versions of the Center for Internet Security (CIS) AWS Foundations Benchmark—v5.0.0, v3.0.0, v1.4.0, and v1.2.0. AWS Security Hub CSPM supports each of these versions of the CIS AWS Foundations Benchmark. However, we recommend using v5.0.0 to stay current with security best practices. You can have multiple versions of CIS AWS Foundations Benchmark standards enabled at the same time. For information about enabling standards, see Enabling a security standard. If you want to upgrade to v5.0.0, enable it before you disable an older version. This prevents gaps in your security checks. If you use the Security Hub CSPM integration with AWS Organizations and want to batch enable v5.0.0 in multiple accounts, we recommend using central configuration.

Mapping of controls to CIS requirements in each version

Understand which controls each version of the CIS AWS Foundations Benchmark supports.

Control ID and title	CIS v5.0.0 requirement	CIS v3.0.0 requirement	CIS v1.4.0 requirement	CIS v1.2.0 requirement
[Account.1] Security contact information should be provided for an AWS account	1.2	1.2	1.2	1.18
[CloudTrail.1] CloudTrail should be enabled and configured with at least one multi-Region trail that includes read and write management events	3.1	3.1	3.1	2.1
[CloudTrail.2] CloudTrail should have encryption at-rest enabled	3.5	3.5	3.7	2.7
[CloudTrail.4] CloudTrail log file validation should be enabled	3.2	3.2	3.2	2.2
[CloudTrail.5] CloudTrail trails should be integrated with Amazon CloudWatch Logs	Not supported – CIS removed this requirement	Not supported – CIS removed this requirement	3.4	2.4
[CloudTrail.6] Ensure the S3 bucket used to store CloudTrail logs is not publicly accessible	Not supported – CIS removed this requirement	Not supported – CIS removed this requirement	3.3	2.3
[CloudTrail.7] Ensure S3 bucket access logging is enabled on the CloudTrail S3 bucket	3.4	3.4	3.6	2.6

Control ID and title	CIS v5.0.0 requirement	CIS v3.0.0 requirement	CIS v1.4.0 requirement	CIS v1.2.0 requirement
[CloudWatch.1] A log metric filter and alarm should exist for usage of the "root" user	Not supported – manual check	Not supported – manual check	4.3	3.3
[CloudWatch.2] Ensure a log metric filter and alarm exist for unauthorized API calls	Not supported – manual check	Not supported – manual check	Not supported – manual check	3.1
[CloudWatch.3] Ensure a log metric filter and alarm exist for Management Console sign-in without MFA	Not supported – manual check	Not supported – manual check	Not supported – manual check	3.2
[CloudWatch.4] Ensure a log metric filter and alarm exist for IAM policy changes	Not supported – manual check	Not supported – manual check	4.4	3.4
[CloudWatch.5] Ensure a log metric filter and alarm exist for CloudTrail configuration changes	Not supported – manual check	Not supported – manual check	4.5	3.5
[CloudWatch.6] Ensure a log metric filter and alarm exist for AWS Management Console authentication failures	Not supported – manual check	Not supported – manual check	4.6	3.6

Control ID and title	CIS v5.0.0 requirement	CIS v3.0.0 requirement	CIS v1.4.0 requirement	CIS v1.2.0 requirement
[CloudWatch.7] Ensure a log metric filter and alarm exist for disabling or scheduled deletion of customer managed keys	Not supported – manual check	Not supported – manual check	4.7	3.7
[CloudWatch.8] Ensure a log metric filter and alarm exist for S3 bucket policy changes	Not supported – manual check	Not supported – manual check	4.8	3.8
[CloudWatch.9] Ensure a log metric filter and alarm exist for AWS Config configuration changes	Not supported – manual check	Not supported – manual check	4.9	3.9
[CloudWatch.10] Ensure a log metric filter and alarm exist for security group changes	Not supported – manual check	Not supported – manual check	4.10	3.10
[CloudWatch.11] Ensure a log metric filter and alarm exist for changes to Network Access Control Lists (NACL)	Not supported – manual check	Not supported – manual check	4.11	3.11
[CloudWatch.12] Ensure a log metric filter and alarm exist for changes to network gateways	Not supported – manual check	Not supported – manual check	4.12	3.12
[CloudWatch.13] Ensure a log metric filter and alarm exist for route table changes	Not supported – manual check	Not supported – manual check	4.13	3.13

Control ID and title	CIS v5.0.0 requirement	CIS v3.0.0 requirement	CIS v1.4.0 requirement	CIS v1.2.0 requirement
[CloudWatch.14] Ensure a log metric filter and alarm exist for VPC changes	Not supported – manual check	Not supported – manual check	4.14	3.14
[Config.1] AWS Config should be enabled and use the service-linked role for resource recording	3.3	3.3	3.5	2.5
[EC2.2] VPC default security groups should not allow inbound or outbound traffic	5.5	5.4	5.3	4.3
[EC2.6] VPC flow logging should be enabled in all VPCs	3.7	3.7	3.9	2.9
[EC2.7] EBS default encryption should be enabled	5.1.1	2.2.1	2.2.1	Not supported
[EC2.8] EC2 instances should use Instance Metadata Service Version 2 (IMDSv2)	5.7	5.6	Not supported	Not supported
[EC2.13] Security groups should not allow ingress from 0.0.0.0/0 or ::/0 to port 22	Not supported – replaced by requirements 5.3 and 5.4	Not supported – replaced by requirements 5.2 and 5.3	Not supported – replaced by requirements 5.2 and 5.3	4.1
[EC2.14] Security groups should not allow ingress from 0.0.0.0/0 or ::/0 to port 3389	Not supported – replaced by requirements 5.3 and 5.4	Not supported – replaced by requirements 5.2 and 5.3	Not supported – replaced by requirements 5.2 and 5.3	4.2

Control ID and title	CIS v5.0.0 requirement	CIS v3.0.0 requirement	CIS v1.4.0 requirement	CIS v1.2.0 requirement
[EC2.21] Network ACLs should not allow ingress from 0.0.0.0/0 to port 22 or port 3389	5.2	5.1	5.1	Not supported
[EC2.53] EC2 security groups should not allow ingress from 0.0.0.0/0 to remote server administration ports	5.3	5.2	Not supported	Not supported
[EC2.54] EC2 security groups should not allow ingress from ::/0 to remote server administration ports	5.4	5.3	Not supported	Not supported
[EFS.1] Elastic File System should be configured to encrypt file data at-rest using AWS KMS	2.3.1	2.4.1	Not supported	Not supported
[EFS.8] EFS file systems should be encrypted at rest	2.3.1	Not supported	Not supported	Not supported
[IAM.1] IAM policies should not allow full "*" administrative privileges	Not supported	Not supported	1.16	1.22
[IAM.2] IAM users should not have IAM policies attached	1.14	1.15	Not supported	1.16
[IAM.3] IAM users' access keys should be rotated every 90 days or less	1.13	1.14	1.14	1.4
[IAM.4] IAM root user access key should not exist	1.3	1.4	1.4	1.12

Control ID and title	CIS v5.0.0 requirement	CIS v3.0.0 requirement	CIS v1.4.0 requirement	CIS v1.2.0 requirement
[IAM.5] MFA should be enabled for all IAM users that have a console password	1.9	1.10	1.10	1.2
[IAM.6] Hardware MFA should be enabled for the root user	1.5	1.6	1.6	1.14
[IAM.8] Unused IAM user credentials should be removed	Not supported – see [IAM.22] IAM user credentials unused for 45 days should be removed instead	Not supported – see [IAM.22] IAM user credentials unused for 45 days should be removed instead	Not supported – see [IAM.22] IAM user credentials unused for 45 days should be removed instead	1.3
[IAM.9] MFA should be enabled for the root user	1.4	1.5	1.5	1.13
[IAM.11] Ensure IAM password policy requires at least one uppercase letter	Not supported – CIS removed this requirement	Not supported – CIS removed this requirement	Not supported – CIS removed this requirement	1.5
[IAM.12] Ensure IAM password policy requires at least one lowercase letter	Not supported – CIS removed this requirement	Not supported – CIS removed this requirement	Not supported – CIS removed this requirement	1.6

Control ID and title	CIS v5.0.0 requirement	CIS v3.0.0 requirement	CIS v1.4.0 requirement	CIS v1.2.0 requirement
[IAM.13] Ensure IAM password policy requires at least one symbol	Not supported – CIS removed this requirement	Not supported – CIS removed this requirement	Not supported – CIS removed this requirement	1.7
[IAM.14] Ensure IAM password policy requires at least one number	Not supported – CIS removed this requirement	Not supported – CIS removed this requirement	Not supported – CIS removed this requirement	1.8
[IAM.15] Ensure IAM password policy requires minimum password length of 14 or greater	1.7	1.8	1.8	1.9
[IAM.16] Ensure IAM password policy prevents password reuse	1.8	1.9	1.9	1.10
[IAM.17] Ensure IAM password policy expires passwords within 90 days or less	Not supported – CIS removed this requirement	Not supported – CIS removed this requirement	Not supported – CIS removed this requirement	1.11
[IAM.18] Ensure a support role has been created to manage incidents with AWS Support	1.16	1.17	1.17	1.2

Control ID and title	CIS v5.0.0 requirement	CIS v3.0.0 requirement	CIS v1.4.0 requirement	CIS v1.2.0 requirement
[IAM.20] Avoid the use of the root user	Not supported – CIS removed this requirement	Not supported – CIS removed this requirement	Not supported – CIS removed this requirement	1.1
[IAM.22] IAM user credentials unused for 45 days should be removed	1.11	1.12	1.12	Not supported – CIS added this requirement in later versions
[IAM.26] Expired SSL/TLS certificates managed in IAM should be removed	1.18	1.19	Not supported – CIS added this requirement in later versions	Not supported – CIS added this requirement in later versions
[IAM.27] IAM identities should not have the AWSCloudShellFullAccess policy attached	1.21	1.22	Not supported – CIS added this requirement in later versions	Not supported – CIS added this requirement in later versions

Control ID and title	CIS v5.0.0 requirement	CIS v3.0.0 requirement	CIS v1.4.0 requirement	CIS v1.2.0 requirement
[IAM.28] IAM Access Analyzer external access analyzer should be enabled	1.19	1.20	Not supported – CIS added this requirement in later versions	Not supported – CIS added this requirement in later versions
[KMS.4] AWS KMS key rotation should be enabled	3.6	3.6	3.8	2.8
[Macie.1] Amazon Macie should be enabled	Not supported – manual check	Not supported – manual check	Not supported – manual check	Not supported – manual check
[RDS.2] RDS DB Instances should prohibit public access, as determined by the PubliclyAccessible configuration	2.2.3	2.3.3	Not supported – CIS added this requirement in later versions	Not supported – CIS added this requirement in later versions
[RDS.3] RDS DB instances should have encryption at-rest enabled	2.2.1	2.3.1	2.3.1	Not supported – CIS added this requirement in later versions

Control ID and title	CIS v5.0.0 requirement	CIS v3.0.0 requirement	CIS v1.4.0 requirement	CIS v1.2.0 requirement
[RDS.5] RDS DB instances should be configured with multiple Availability Zones	2.2.4	Not supported – CIS added this requirement in later versions	Not supported – CIS added this requirement in later versions	Not supported – CIS added this requirement in later versions
[RDS.13] RDS automatic minor version upgrades should be enabled	2.2.2	2.3.2	Not supported – CIS added this requirement in later versions	Not supported – CIS added this requirement in later versions
[RDS.15] RDS DB clusters should be configured for multiple Availability Zones	2.2.4	Not supported – CIS added this requirement in later versions	Not supported – CIS added this requirement in later versions	Not supported – CIS added this requirement in later versions
[S3.1] S3 general purpose buckets should have block public access settings enabled	2.1.4	2.1.4	2.1.5	Not supported – CIS added this requirement in later versions

Control ID and title	CIS v5.0.0 requirement	CIS v3.0.0 requirement	CIS v1.4.0 requirement	CIS v1.2.0 requirement
[S3.5] S3 general purpose buckets should require requests to use TLS	2.1.1	2.1.1	2.1.2	Not supported – CIS added this requirement in later versions
[S3.8] S3 general purpose buckets should block public access	2.1.4	2.1.4	2.1.5	Not supported – CIS added this requirement in later versions
[S3.20] S3 general purpose buckets should have MFA delete enabled	2.1.2	2.1.2	2.1.3	Not supported – CIS added this requirement in later versions

ARNs for CIS AWS Foundations Benchmarks

When you enable one or more versions of the CIS AWS Foundations Benchmark, you begin receiving findings in the AWS Security Finding Format (ASFF). In ASFF, each version uses the following Amazon Resource Name (ARN):

CIS AWS Foundations Benchmark v5.0.0

```
arn:aws:securityhub:region::standards/cis-aws-foundations-benchmark/
v/5.0.0
```

CIS AWS Foundations Benchmark v3.0.0

```
arn:aws:securityhub:region::standards/cis-aws-foundations-benchmark/
v/3.0.0
```

CIS AWS Foundations Benchmark v1.4.0

```
arn:aws:securityhub:region::standards/cis-aws-foundations-benchmark/
v/1.4.0
```

CIS AWS Foundations Benchmark v1.2.0

```
arn:aws:securityhub:::ruleset/cis-aws-foundations-benchmark/v/1.2.0
```

You can use the GetEnabledStandards operation of the Security Hub CSPM API to find the ARN of an enabled standard.

The preceding values are for `StandardsArn`. However, `StandardsSubscriptionArn` refers to the standard subscription resource that Security Hub CSPM creates when you subscribe to a standard by calling BatchEnableStandards in a Region.

> **Note**
>
> When you enable a version of the CIS AWS Foundations Benchmark, it can take up to 18 hours for Security Hub CSPM to generate findings for controls that use the same AWS Config service-linked rule as enabled controls in other enabled standards. For more information about the schedule for generating control findings, see Schedule for running security checks.

Finding fields differ if you turn on consolidated control findings. For information about these differences, see Impact of consolidation on ASFF fields and values. For sample control findings, see Samples of control findings.

CIS requirements that aren't supported in Security Hub CSPM

As noted in the preceding table, Security Hub CSPM doesn't support every CIS requirement in every version of the CIS AWS Foundations Benchmark. Many of the unsupported requirements can be evaluated only by manually reviewing the state of your AWS resources.

NIST SP 800-53 Revision 5 in Security Hub CSPM

NIST Special Publication 800-53 Revision 5 (NIST SP 800-53 Rev. 5) is a cybersecurity and compliance framework developed by the National Institute of Standards and Technology (NIST), an agency that's part of the U.S. Department of Commerce. This compliance framework provides a catalog of security and privacy requirements for protecting the confidentiality, integrity, and availability of information systems and critical resources. U.S. federal government agencies and contractors must comply with these requirements to protect their systems and organizations. Private organizations can also voluntarily use the requirements as a guiding framework for reducing cybersecurity risk. For more information about the framework and its requirements, see NIST SP 800-53 Rev. 5 in the *NIST Computer Security Resource Center*.

AWS Security Hub CSPM provides security controls that support a subset of NIST SP 800-53 Revision 5 requirements. The controls perform automated security checks for certain AWS services and resources. To enable and manage these controls, you can enable the NIST SP 800-53 Revision 5 framework as a standard in Security Hub CSPM. Note that the controls don't support NIST SP 800-53 Revision 5 requirements that require manual checks.

Unlike other frameworks, the NIST SP 800-53 Revision 5 framework isn't prescriptive about how its requirements should be evaluated. Instead, the framework provides guidelines. In Security Hub CSPM, the NIST SP 800-53 Revision 5 standard and controls represent the service's understanding of these guidelines.

Topics

- Configuring resource recording for controls that apply to the standard
- Determining which controls apply to the standard

Configuring resource recording for controls that apply to the standard

To optimize coverage and the accuracy of findings, it's important to enable and configure resource recording in AWS Config before you enable the NIST SP 800-53 Revision 5 standard in AWS Security Hub CSPM. When you configure resource recording, also be sure to enable it for all the types of AWS resources that are checked by controls that apply to the standard. This is primarily for controls that have a *change triggered* schedule type. However, some controls with a *periodic* schedule type also require resource recording. If resource recording isn't enabled or configured correctly, Security Hub CSPM might not be able to evaluate the appropriate resources, and generate accurate findings for controls that apply to the standard.

For information about how Security Hub CSPM uses resource recording in AWS Config, see Enabling and configuring AWS Config for Security Hub CSPM. For information about configuring resource recording in AWS Config, see Working with the configuration recorder in the *AWS Config Developer Guide*.

The following table specifies the types of resources to record for controls that apply to the NIST SP 800-53 Revision 5 standard in Security Hub CSPM.

AWS service	Resource types
Amazon API Gateway	`AWS::ApiGateway::Stage` , `AWS::ApiGatewayV2::Stage`
AWS AppSync	`AWS::AppSync::GraphQLApi`
AWS Backup	`AWS::Backup::RecoveryPoint`
Amazon Bedrock AgentCore	`AWS::BedrockAgentCore::Gateway` , `AWS::BedrockAgentCore::Memory`
AWS Certificate Manager (ACM)	`AWS::ACM::Certificate`
AWS CloudFormation	`AWS::CloudFormation::Stack`
Amazon CloudFront	`AWS::CloudFront::Distribution`
Amazon CloudWatch	`AWS::CloudWatch::Alarm`
AWS CodeBuild	`AWS::CodeBuild::Project`
AWS Database Migration Service (AWS DMS)	`AWS::DMS::Endpoint` , `AWS::DMS::ReplicationInstance` , `AWS::DMS::ReplicationTask`
Amazon DynamoDB	`AWS::DynamoDB::Table`
Amazon Elastic Compute Cloud (Amazon EC2)	`AWS::EC2::ClientVpnEndpoint` , `AWS::EC2::EIP` , `AWS::EC2::Instance` , `AWS::EC2::LaunchTemplate` , `AWS::EC2::NetworkAcl` , `AWS::EC2:`

AWS service	Resource types
	:NetworkInterface ,AWS::EC2::SecurityGroup ,AWS::EC2::Subnet ,AWS::EC2::TransitGateway ,AWS::EC2::VPNConnection ,AWS::EC2::Volume
Amazon EC2 Auto Scaling	AWS::AutoScaling::AutoScalingGroup ,AWS::AutoScaling::LaunchConfiguration
Amazon Elastic Container Registry (Amazon ECR)	AWS::ECR::Repository
Amazon Elastic Container Service (Amazon ECS)	AWS::ECS::Cluster ,AWS::ECS::Service ,AWS::ECS::TaskDefinition
Amazon Elastic File System (Amazon EFS)	AWS::EFS::AccessPoint
Amazon Elastic Kubernetes Service (Amazon EKS)	AWS::EKS::Cluster
AWS Elastic Beanstalk	AWS::ElasticBeanstalk::Environment
Elastic Load Balancing	AWS::ElasticLoadBalancing::LoadBalancer ,AWS::ElasticLoadBalancingV2::Listener ,AWS::ElasticLoadBalancingV2::LoadBalancer
Amazon ElasticSearch	AWS::Elasticsearch::Domain
Amazon EMR	AWS::EMR::SecurityConfiguration
Amazon EventBridge	AWS::Events::Endpoint ,AWS::Events::EventBus

AWS service	Resource types
AWS Glue	AWS::Glue::Job
AWS Identity and Access Management (IAM)	AWS::IAM::Group , AWS::IAM::Policy , AWS::IAM::Role , AWS::IAM::User
AWS Key Management Service (AWS KMS)	AWS::KMS::Alias , AWS::KMS::Key
Amazon Kinesis	AWS::Kinesis::Stream
AWS Lambda	AWS::Lambda::Function
Amazon Managed Streaming for Apache Kafka (Amazon MSK)	AWS::MSK::Cluster
Amazon MQ	AWS::AmazonMQ::Broker
AWS Network Firewall	AWS::NetworkFirewall::Firewall , AWS::NetworkFirewall::FirewallPolicy , AWS::NetworkFirewall::RuleGroup
Amazon OpenSearch Service	AWS::OpenSearch::Domain
Amazon Relational Database Service (Amazon RDS)	AWS::RDS::DBCluster , AWS::RDS::DBClusterSnapshot , AWS::RDS::DBInstance , AWS::RDS::DBSnapshot , AWS::RDS::EventSubscription
Amazon Redshift	AWS::Redshift::Cluster , AWS::Redshift::ClusterSubnetGroup
Amazon Route 53	AWS::Route53::HostedZone
Amazon Simple Storage Service (Amazon S3)	AWS::S3::AccessPoint , AWS::S3::AccountPublicAccessBlock , AWS::S3::Bucket
AWS Service Catalog	AWS::ServiceCatalog::Portfolio

AWS service	Resource types
Amazon Simple Notification Service (Amazon SNS)	`AWS::SNS::Topic`
Amazon Simple Queue Service (Amazon SQS)	`AWS::SQS::Queue`
Amazon EC2 Systems Manager (SSM)	`AWS::SSM::AssociationCompliance` , `AWS::SSM::ManagedInstanceInventory` , `AWS::SSM::PatchCompliance`
Amazon SageMaker AI	`AWS::SageMaker::FeatureGroup` , `AWS::SageMaker::NotebookInstance`
AWS Secrets Manager	`AWS::SecretsManager::Secret`
AWS Transfer Family	`AWS::Transfer::Connector`
AWS WAF	`AWS::WAF::Rule` , `AWS::WAF::RuleGroup` , `AWS::WAF::WebACL` , `AWS::WAFRegional::Rule` , `AWS::WAFRegional::RuleGroup` , `AWS::WAFRegional::WebACL` , `AWS::WAFv2::RuleGroup` , `AWS::WAFv2::WebACL`

Determining which controls apply to the standard

The following list specifies the controls that support NIST SP 800-53 Revision 5 requirements and apply to the NIST SP 800-53 Revision 5 standard in AWS Security Hub CSPM. For details about specific requirements that a control supports, choose the control. Then refer to the **Related requirements** field in the details for the control. This field specifies each NIST requirement that the control supports. If the field doesn't specify a particular NIST requirement, the control doesn't support the requirement.

- [Account.1] Security contact information should be provided for an AWS account
- [Account.2] AWS accounts should be part of an AWS Organizations organization
- [ACM.1] Imported and ACM-issued certificates should be renewed after a specified time period

- [APIGateway.1] API Gateway REST and WebSocket API execution logging should be enabled
- [APIGateway.2] API Gateway REST API stages should be configured to use SSL certificates for backend authentication
- [APIGateway.3] API Gateway REST API stages should have AWS X-Ray tracing enabled
- [APIGateway.4] API Gateway should be associated with a WAF Web ACL
- [APIGateway.5] API Gateway REST API cache data should be encrypted at rest
- [APIGateway.8] API Gateway routes should specify an authorization type
- [APIGateway.9] Access logging should be configured for API Gateway V2 Stages
- [AppSync.5] AWS AppSync GraphQL APIs should not be authenticated with API keys
- [AutoScaling.1] Auto Scaling groups associated with a load balancer should use ELB health checks
- [AutoScaling.2] Amazon EC2 Auto Scaling group should cover multiple Availability Zones
- [AutoScaling.3] Auto Scaling group launch configurations should configure EC2 instances to require Instance Metadata Service Version 2 (IMDSv2)
- [Autoscaling.5] Amazon EC2 instances launched using Auto Scaling group launch configurations should not have Public IP addresses
- [AutoScaling.6] Auto Scaling groups should use multiple instance types in multiple Availability Zones
- [AutoScaling.9] Amazon EC2 Auto Scaling groups should use Amazon EC2 launch templates
- [Backup.1] AWS Backup recovery points should be encrypted at rest
- [Bedrock.1] Amazon Bedrock data sources should be encrypted with customer managed AWS KMS keys
- [BedrockAgentCore.3] Bedrock AgentCore Memory should be encrypted with customer managed AWS KMS keys
- [BedrockAgentCore.4] Bedrock AgentCore Gateway should be encrypted with customer managed AWS KMS keys
- [CloudFront.1] CloudFront distributions should have a default root object configured
- [CloudFront.3] CloudFront distributions should require encryption in transit
- [CloudFront.4] CloudFront distributions should have origin failover configured
- [CloudFront.5] CloudFront distributions should have logging enabled
- [CloudFront.6] CloudFront distributions should have WAF enabled
- [CloudFront.7] CloudFront distributions should use custom SSL/TLS certificates

- [CloudFront.8] CloudFront distributions should use SNI to serve HTTPS requests
- [CloudFront.9] CloudFront distributions should encrypt traffic to custom origins
- [CloudFront.10] CloudFront distributions should not use deprecated SSL protocols between edge locations and custom origins
- [CloudFront.12] CloudFront distributions should not point to non-existent S3 origins
- [CloudTrail.1] CloudTrail should be enabled and configured with at least one multi-Region trail that includes read and write management events
- [CloudTrail.2] CloudTrail should have encryption at-rest enabled
- [CloudTrail.4] CloudTrail log file validation should be enabled
- [CloudTrail.5] CloudTrail trails should be integrated with Amazon CloudWatch Logs
- [CloudTrail.10] CloudTrail Lake event data stores should be encrypted with customer managed AWS KMS keys
- [CloudWatch.15] CloudWatch alarms should have specified actions configured
- [CloudWatch.16] CloudWatch log groups should be retained for a specified time period
- [CloudWatch.17] CloudWatch alarm actions should be activated
- [CodeBuild.1] CodeBuild Bitbucket source repository URLs should not contain sensitive credentials
- [CodeBuild.2] CodeBuild project environment variables should not contain clear text credentials
- [CodeBuild.3] CodeBuild S3 logs should be encrypted
- [CodeBuild.4] CodeBuild project environments should have a logging AWS Configuration
- [Config.1] AWS Config should be enabled and use the service-linked role for resource recording
- [DataFirehose.1] Firehose delivery streams should be encrypted at rest
- [DMS.1] Database Migration Service replication instances should not be public
- [DMS.6] DMS replication instances should have automatic minor version upgrade enabled
- [DMS.7] DMS replication tasks for the target database should have logging enabled
- [DMS.8] DMS replication tasks for the source database should have logging enabled
- [DMS.9] DMS endpoints should use SSL
- [DMS.10] DMS endpoints for Neptune databases should have IAM authorization enabled
- [DMS.11] DMS endpoints for MongoDB should have an authentication mechanism enabled
- [DMS.12] DMS endpoints for Redis OSS should have TLS enabled
- [DocumentDB.1] Amazon DocumentDB clusters should be encrypted at rest

- [DocumentDB.2] Amazon DocumentDB clusters should have an adequate backup retention period
- [DocumentDB.3] Amazon DocumentDB manual cluster snapshots should not be public
- [DocumentDB.4] Amazon DocumentDB clusters should publish audit logs to CloudWatch Logs
- [DocumentDB.5] Amazon DocumentDB clusters should have deletion protection enabled
- [DynamoDB.1] DynamoDB tables should automatically scale capacity with demand
- [DynamoDB.2] DynamoDB tables should have point-in-time recovery enabled
- [DynamoDB.3] DynamoDB Accelerator (DAX) clusters should be encrypted at rest
- [DynamoDB.4] DynamoDB tables should be present in a backup plan
- [DynamoDB.6] DynamoDB tables should have deletion protection enabled
- [DynamoDB.7] DynamoDB Accelerator clusters should be encrypted in transit
- [EC2.1] Amazon EBS snapshots should not be configured to be publicly restorable
- [EC2.2] VPC default security groups should not allow inbound or outbound traffic
- [EC2.3] Attached Amazon EBS volumes should be encrypted at-rest
- [EC2.4] Stopped EC2 instances should be removed after a specified time period
- [EC2.6] VPC flow logging should be enabled in all VPCs
- [EC2.7] EBS default encryption should be enabled
- [EC2.8] EC2 instances should use Instance Metadata Service Version 2 (IMDSv2)
- [EC2.9] Amazon EC2 instances should not have a public IPv4 address
- [EC2.10] Amazon EC2 should be configured to use VPC endpoints that are created for the Amazon EC2 service
- [EC2.12] Unused Amazon EC2 EIPs should be removed
- [EC2.13] Security groups should not allow ingress from 0.0.0.0/0 or ::/0 to port 22
- [EC2.15] Amazon EC2 subnets should not automatically assign public IP addresses
- [EC2.16] Unused Network Access Control Lists should be removed
- [EC2.17] Amazon EC2 instances should not use multiple ENIs
- [EC2.18] Security groups should only allow unrestricted incoming traffic for authorized ports
- [EC2.19] Security groups should not allow unrestricted access to ports with high risk
- [EC2.20] Both VPN tunnels for an AWS Site-to-Site VPN connection should be up
- [EC2.21] Network ACLs should not allow ingress from 0.0.0.0/0 to port 22 or port 3389

- [EC2.23] Amazon EC2 Transit Gateways should not automatically accept VPC attachment requests
- [EC2.24] Amazon EC2 paravirtual instance types should not be used
- [EC2.25] Amazon EC2 launch templates should not assign public IPs to network interfaces
- [EC2.28] EBS volumes should be covered by a backup plan
- [EC2.51] EC2 Client VPN endpoints should have client connection logging enabled
- [EC2.55] VPCs should be configured with an interface endpoint for ECR API
- [EC2.56] VPCs should be configured with an interface endpoint for Docker Registry
- [EC2.57] VPCs should be configured with an interface endpoint for Systems Manager
- [EC2.58] VPCs should be configured with an interface endpoint for Systems Manager Incident Manager Contacts
- [EC2.60] VPCs should be configured with an interface endpoint for Systems Manager Incident Manager
- [ECR.1] ECR private repositories should have image scanning configured
- [ECR.2] ECR private repositories should have tag immutability configured
- [ECR.3] ECR repositories should have at least one lifecycle policy configured
- [ECR.5] ECR repositories should be encrypted with customer managed AWS KMS keys
- [ECS.2] ECS services should not have public IP addresses assigned to them automatically
- [ECS.3] ECS task definitions should not share the host's process namespace
- [ECS.4] ECS containers should run as non-privileged
- [ECS.5] ECS task definitions should configure containers to be limited to read-only access to root filesystems
- [ECS.8] Secrets should not be passed as container environment variables
- [ECS.9] ECS task definitions should have a logging configuration
- [ECS.10] ECS Fargate services should run on the latest Fargate platform version
- [ECS.12] ECS clusters should use Container Insights
- [ECS.17] ECS task definitions should not use host network mode
- [EFS.1] Elastic File System should be configured to encrypt file data at-rest using AWS KMS
- [EFS.2] Amazon EFS volumes should be in backup plans
- [EFS.3] EFS access points should enforce a root directory
- [EFS.4] EFS access points should enforce a user identity

- [EFS.6] EFS mount targets should not be associated with subnets that assign public IP addresses on launch
- [EKS.1] EKS cluster endpoints should not be publicly accessible
- [EKS.2] EKS clusters should run on a supported Kubernetes version
- [EKS.8] EKS clusters should have audit logging enabled
- [ElastiCache.1] ElastiCache (Redis OSS) clusters should have automatic backups enabled
- [ElastiCache.2] ElastiCache clusters should have automatic minor version upgrades enabled
- [ElastiCache.3] ElastiCache replication groups should have automatic failover enabled
- [ElastiCache.4] ElastiCache replication groups should be encrypted at rest
- [ElastiCache.5] ElastiCache replication groups should be encrypted in transit
- [ElastiCache.6] ElastiCache (Redis OSS) replication groups of earlier versions should have Redis OSS AUTH enabled
- [ElastiCache.7] ElastiCache clusters should not use the default subnet group
- [ElasticBeanstalk.1] Elastic Beanstalk environments should have enhanced health reporting enabled
- [ElasticBeanstalk.2] Elastic Beanstalk managed platform updates should be enabled
- [ELB.1] Application Load Balancer should be configured to redirect all HTTP requests to HTTPS
- [ELB.2] Classic Load Balancers with SSL/HTTPS listeners should use a certificate provided by AWS Certificate Manager
- [ELB.3] Classic Load Balancer listeners should be configured with HTTPS or TLS termination
- [ELB.4] Application Load Balancer should be configured to drop invalid http headers
- [ELB.5] Application and Classic Load Balancers logging should be enabled
- [ELB.6] Application, Gateway, and Network Load Balancers should have deletion protection enabled
- [ELB.7] Classic Load Balancers should have connection draining enabled
- [ELB.8] Classic Load Balancers with SSL listeners should use a predefined security policy that has strong AWS Configuration
- [ELB.9] Classic Load Balancers should have cross-zone load balancing enabled
- [ELB.10] Classic Load Balancer should span multiple Availability Zones
- [ELB.12] Application Load Balancer should be configured with defensive or strictest desync mitigation mode

- [ELB.13] Application, Network and Gateway Load Balancers should span multiple Availability Zones
- [ELB.14] Classic Load Balancer should be configured with defensive or strictest desync mitigation mode
- [ELB.16] Application Load Balancers should be associated with an AWS WAF web ACL
- [ELB.17] Application and Network Load Balancers with listeners should use recommended security policies
- [EMR.1] Amazon EMR cluster primary nodes should not have public IP addresses
- [EMR.2] Amazon EMR block public access setting should be enabled
- [EMR.3] Amazon EMR security configurations should be encrypted at rest
- [EMR.4] Amazon EMR security configurations should be encrypted in transit
- [ES.1] Elasticsearch domains should have encryption at-rest enabled
- [ES.2] Elasticsearch domains should not be publicly accessible
- [ES.3] Elasticsearch domains should encrypt data sent between nodes
- [ES.4] Elasticsearch domain error logging to CloudWatch Logs should be enabled
- [ES.5] Elasticsearch domains should have audit logging enabled
- [ES.6] Elasticsearch domains should have at least three data nodes
- [ES.7] Elasticsearch domains should be configured with at least three dedicated master nodes
- [ES.8] Connections to Elasticsearch domains should be encrypted using the latest TLS security policy
- [EventBridge.3] EventBridge custom event buses should have a resource-based policy attached
- [EventBridge.4] EventBridge global endpoints should have event replication enabled
- [FSx.1] FSx for OpenZFS file systems should be configured to copy tags to backups and volumes
- [FSx.2] FSx for Lustre file systems should be configured to copy tags to backups
- [Glue.4] AWS Glue Spark jobs should run on supported versions of AWS Glue
- [GuardDuty.1] GuardDuty should be enabled
- [IAM.1] IAM policies should not allow full "*" administrative privileges
- [IAM.2] IAM users should not have IAM policies attached
- [IAM.3] IAM users' access keys should be rotated every 90 days or less
- [IAM.4] IAM root user access key should not exist
- [IAM.5] MFA should be enabled for all IAM users that have a console password

- [IAM.6] Hardware MFA should be enabled for the root user
- [IAM.7] Password policies for IAM users should have strong configurations
- [IAM.8] Unused IAM user credentials should be removed
- [IAM.9] MFA should be enabled for the root user
- [IAM.19] MFA should be enabled for all IAM users
- [IAM.21] IAM customer managed policies that you create should not allow wildcard actions for services
- [Kinesis.1] Kinesis streams should be encrypted at rest
- [KMS.1] IAM customer managed policies should not allow decryption actions on all KMS keys
- [KMS.2] IAM principals should not have IAM inline policies that allow decryption actions on all KMS keys
- [KMS.3] AWS KMS keys should not be deleted unintentionally
- [KMS.4] AWS KMS key rotation should be enabled
- [Lambda.1] Lambda function policies should prohibit public access
- [Lambda.2] Lambda functions should use supported runtimes
- [Lambda.3] Lambda functions should be in a VPC
- [Lambda.5] VPC Lambda functions should operate in multiple Availability Zones
- [Lambda.7] Lambda functions should have AWS X-Ray active tracing enabled
- [Macie.1] Amazon Macie should be enabled
- [Macie.2] Macie automated sensitive data discovery should be enabled
- [MSK.1] MSK clusters should be encrypted in transit among broker nodes
- [MSK.2] MSK clusters should have enhanced monitoring configured
- [MQ.2] ActiveMQ brokers should stream audit logs to CloudWatch
- [MQ.5] ActiveMQ brokers should use active/standby deployment mode
- [MQ.6] RabbitMQ brokers should use cluster deployment mode
- [Neptune.1] Neptune DB clusters should be encrypted at rest
- [Neptune.2] Neptune DB clusters should publish audit logs to CloudWatch Logs
- [Neptune.3] Neptune DB cluster snapshots should not be public
- [Neptune.4] Neptune DB clusters should have deletion protection enabled
- [Neptune.5] Neptune DB clusters should have automated backups enabled

- [Neptune.6] Neptune DB cluster snapshots should be encrypted at rest
- [Neptune.7] Neptune DB clusters should have IAM database authentication enabled
- [Neptune.8] Neptune DB clusters should be configured to copy tags to snapshots
- [Neptune.9] Neptune DB clusters should be deployed across multiple Availability Zones
- [NetworkFirewall.1] Network Firewall firewalls should be deployed across multiple Availability Zones
- [NetworkFirewall.2] Network Firewall logging should be enabled
- [NetworkFirewall.3] Network Firewall policies should have at least one rule group associated
- [NetworkFirewall.4] The default stateless action for Network Firewall policies should be drop or forward for full packets
- [NetworkFirewall.5] The default stateless action for Network Firewall policies should be drop or forward for fragmented packets
- [NetworkFirewall.6] Stateless Network Firewall rule group should not be empty
- [NetworkFirewall.9] Network Firewall firewalls should have deletion protection enabled
- [NetworkFirewall.10] Network Firewall firewalls should have subnet change protection enabled
- [Opensearch.1] OpenSearch domains should have encryption at rest enabled
- [Opensearch.2] OpenSearch domains should not be publicly accessible
- [Opensearch.3] OpenSearch domains should encrypt data sent between nodes
- [Opensearch.4] OpenSearch domain error logging to CloudWatch Logs should be enabled
- [Opensearch.5] OpenSearch domains should have audit logging enabled
- [Opensearch.6] OpenSearch domains should have at least three data nodes
- [Opensearch.7] OpenSearch domains should have fine-grained access control enabled
- [Opensearch.8] Connections to OpenSearch domains should be encrypted using the latest TLS security policy
- [Opensearch.10] OpenSearch domains should have the latest software update installed
- [Opensearch.11] OpenSearch domains should have at least three dedicated primary nodes
- [PCA.1] AWS Private CA root certificate authority should be disabled
- [RDS.1] RDS snapshot should be private
- [RDS.2] RDS DB Instances should prohibit public access, as determined by the PubliclyAccessible configuration
- [RDS.3] RDS DB instances should have encryption at-rest enabled

- [RDS.4] RDS cluster snapshots and database snapshots should be encrypted at rest
- [RDS.5] RDS DB instances should be configured with multiple Availability Zones
- [RDS.6] Enhanced monitoring should be configured for RDS DB instances
- [RDS.7] RDS clusters should have deletion protection enabled
- [RDS.8] RDS DB instances should have deletion protection enabled
- [RDS.9] RDS DB instances should publish logs to CloudWatch Logs
- [RDS.10] IAM authentication should be configured for RDS instances
- [RDS.11] RDS instances should have automatic backups enabled
- [RDS.12] IAM authentication should be configured for RDS clusters
- [RDS.13] RDS automatic minor version upgrades should be enabled
- [RDS.14] Amazon Aurora clusters should have backtracking enabled
- [RDS.15] RDS DB clusters should be configured for multiple Availability Zones
- [RDS.16] Aurora DB clusters should be configured to copy tags to DB snapshots
- [RDS.17] RDS DB instances should be configured to copy tags to snapshots
- [RDS.19] Existing RDS event notification subscriptions should be configured for critical cluster events
- [RDS.20] Existing RDS event notification subscriptions should be configured for critical database instance events
- [RDS.21] An RDS event notifications subscription should be configured for critical database parameter group events
- [RDS.22] An RDS event notifications subscription should be configured for critical database security group events
- [RDS.23] RDS instances should not use a database engine default port
- [RDS.24] RDS Database clusters should use a custom administrator username
- [RDS.25] RDS database instances should use a custom administrator username
- [RDS.26] RDS DB instances should be protected by a backup plan
- [RDS.27] RDS DB clusters should be encrypted at rest
- [RDS.34] Aurora MySQL DB clusters should publish audit logs to CloudWatch Logs
- [RDS.35] RDS DB clusters should have automatic minor version upgrade enabled
- [RDS.40] RDS for SQL Server DB instances should publish logs to CloudWatch Logs
- [RDS.42] RDS for MariaDB DB instances should publish logs to CloudWatch Logs

- [RDS.45] Aurora MySQL DB clusters should have audit logging enabled
- [Redshift.1] Amazon Redshift clusters should prohibit public access
- [Redshift.2] Connections to Amazon Redshift clusters should be encrypted in transit
- [Redshift.3] Amazon Redshift clusters should have automatic snapshots enabled
- [Redshift.4] Amazon Redshift clusters should have audit logging enabled
- [Redshift.6] Amazon Redshift should have automatic upgrades to major versions enabled
- [Redshift.7] Redshift clusters should use enhanced VPC routing
- [Redshift.8] Amazon Redshift clusters should not use the default Admin username
- [Redshift.10] Redshift clusters should be encrypted at rest
- [RedshiftServerless.4] Redshift Serverless namespaces should be encrypted with customer managed AWS KMS keys
- [Route53.2] Route 53 public hosted zones should log DNS queries
- [S3.1] S3 general purpose buckets should have block public access settings enabled
- [S3.2] S3 general purpose buckets should block public read access
- [S3.3] S3 general purpose buckets should block public write access
- [S3.5] S3 general purpose buckets should require requests to use TLS
- [S3.6] S3 general purpose bucket policies should restrict access to other AWS accounts
- [S3.7] S3 general purpose buckets should use cross-Region replication
- [S3.8] S3 general purpose buckets should block public access
- [S3.9] S3 general purpose buckets should have server access logging enabled
- [S3.10] S3 general purpose buckets with versioning enabled should have Lifecycle configurations
- [S3.11] S3 general purpose buckets should have event notifications enabled
- [S3.12] ACLs should not be used to manage user access to S3 general purpose buckets
- [S3.13] S3 general purpose buckets should have Lifecycle configurations
- [S3.14] S3 general purpose buckets should have versioning enabled
- [S3.15] S3 general purpose buckets should have Object Lock enabled
- [S3.17] S3 general purpose buckets should be encrypted at rest with AWS KMS keys
- [S3.19] S3 access points should have block public access settings enabled
- [S3.20] S3 general purpose buckets should have MFA delete enabled
- [SageMaker.1] Amazon SageMaker notebook instances should not have direct internet access

- [SageMaker.2] SageMaker notebook instances should be launched in a custom VPC
- [SageMaker.3] Users should not have root access to SageMaker notebook instances
- [SageMaker.4] SageMaker endpoint production variants should have an initial instance count greater than 1
- [SageMaker.18] SageMaker feature group online stores with standard storage should be encrypted with AWS KMS keys
- [SageMaker.21] SageMaker notebook instances should be encrypted with customer managed AWS KMS keys
- [SageMaker.23] SageMaker inference experiments should have instance storage volume encrypted with customer managed AWS KMS keys
- [SageMaker.24] SageMaker inference experiments should have data storage encrypted with customer managed AWS KMS keys
- [SecretsManager.1] Secrets Manager secrets should have automatic rotation enabled
- [SecretsManager.2] Secrets Manager secrets configured with automatic rotation should rotate successfully
- [SecretsManager.3] Remove unused Secrets Manager secrets
- [SecretsManager.4] Secrets Manager secrets should be rotated within a specified number of days
- [ServiceCatalog.1] Service Catalog portfolios should be shared within an AWS organization only
- [SNS.1] SNS topics should be encrypted at-rest using AWS KMS
- [SQS.1] Amazon SQS queues should be encrypted at rest
- [SSM.1] Amazon EC2 instances should be managed by AWS Systems Manager
- [SSM.2] Amazon EC2 instances managed by Systems Manager should have a patch compliance status of COMPLIANT after a patch installation
- [SSM.3] Amazon EC2 instances managed by Systems Manager should have an association compliance status of COMPLIANT
- [SSM.4] SSM documents should not be public
- [Transfer.2] Transfer Family servers should not use FTP protocol for endpoint connection
- [Transfer.3] Transfer Family connectors should have logging enabled
- [WAF.1] AWS WAF Classic Global Web ACL logging should be enabled
- [WAF.2] AWS WAF Classic Regional rules should have at least one condition
- [WAF.3] AWS WAF Classic Regional rule groups should have at least one rule
- [WAF.4] AWS WAF Classic Regional web ACLs should have at least one rule or rule group

- [WAF.6] AWS WAF Classic global rules should have at least one condition
- [WAF.7] AWS WAF Classic global rule groups should have at least one rule
- [WAF.8] AWS WAF Classic global web ACLs should have at least one rule or rule group
- [WAF.10] AWS WAF web ACLs should have at least one rule or rule group
- [WAF.11] AWS WAF web ACL logging should be enabled
- [WAF.12] AWS WAF rules should have CloudWatch metrics enabled

NIST SP 800-171 Revision 2 in Security Hub CSPM

NIST Special Publication 800-171 Revision 2 (NIST SP 800-171 Rev. 2) is a cybersecurity and compliance framework developed by the National Institute of Standards and Technology (NIST), an agency that's part of the U.S. Department of Commerce. This compliance framework provides recommended security requirements for protecting the confidentiality of Controlled Unclassified Information in systems and organizations that aren't part of the U.S. federal government. *Controlled Unclassified Information*, also referred to as *CUI*, is sensitive information that doesn't meet government criteria for classification but must be protected. It's information that is considered sensitive and is created or possessed by the U.S. federal government or other entities on behalf of the U.S. federal government.

NIST SP 800-171 Rev. 2 provides recommended security requirements for protecting the confidentiality of CUI when:

- The information resides in non-federal systems and organizations,
- The non-federal organization is not collecting or maintaining information on behalf of a federal agency or using or operating a system on behalf of an agency, and
- There are no specific safeguarding requirements for protecting the confidentiality of CUI prescribed by the authorizing law, regulation, or government-wide policy for the CUI category listed in the CUI Registry.

The requirements apply to all components of non-federal systems and organizations that process, store, or transmit CUI, or provide security protection for the components. For more information, see NIST SP 800-171 Rev. 2 in the *NIST Computer Security Resource Center*.

AWS Security Hub CSPM provides security controls that support a subset of NIST SP 800-171 Revision 2 requirements. The controls perform automated security checks for certain AWS services and resources. To enable and manage these controls, you can enable the NIST SP 800-171 Revision

2 framework as a standard in Security Hub CSPM. Note that the controls don't support NIST SP 800-171 Revision 2 requirements that require manual checks.

Topics

- Configuring resource recording for controls that apply to the standard
- Determining which controls apply to the standard

Configuring resource recording for controls that apply to the standard

To optimize coverage and the accuracy of findings, it's important to enable and configure resource recording in AWS Config before you enable the NIST SP 800-171 Revision 2 standard in AWS Security Hub CSPM. When you configure resource recording, also be sure to enable it for all the types of AWS resources that are checked by controls that apply to the standard. Otherwise, Security Hub CSPM might not be able to evaluate the appropriate resources, and generate accurate findings for controls that apply to the standard.

For information about how Security Hub CSPM uses resource recording in AWS Config, see Enabling and configuring AWS Config for Security Hub CSPM. For information about configuring resource recording in AWS Config, see Working with the configuration recorder in the *AWS Config Developer Guide*.

The following table specifies the types of resources to record for controls that apply to the NIST SP 800-171 Revision 2 standard in Security Hub CSPM.

AWS service	Resource types
AWS Certificate Manager (ACM)	`AWS::ACM::Certificate`
Amazon API Gateway	`AWS::ApiGateway::Stage`
Amazon CloudFront	`AWS::CloudFront::Distribution`
Amazon CloudWatch	`AWS::CloudWatch::Alarm`
Amazon Elastic Compute Cloud (Amazon EC2)	`AWS::EC2::ClientVpnEndpoint` , `AWS::EC2::NetworkAcl` , `AWS::EC2::SecurityGroup` , `AWS::EC2::VPC` , `AWS::EC2::VPNConnection`

AWS service	Resource types
Elastic Load Balancing	`AWS::ElasticLoadBalancing::LoadBalancer`
AWS Identity and Access Management (IAM)	`AWS::IAM::Policy` , `AWS::IAM::User`
AWS Key Management Service (AWS KMS)	`AWS::KMS::Alias` , `AWS::KMS::Key`
AWS Network Firewall	`AWS::NetworkFirewall::FirewallPolicy` , `AWS::NetworkFirewall::RuleGroup`
Amazon Simple Storage Service (Amazon S3)	`AWS::S3::Bucket`
Amazon Simple Notification Service (Amazon SNS)	`AWS::SNS::Topic`
AWS Systems Manager (SSM)	`AWS::SSM::PatchCompliance`
AWS WAF	`AWS::WAFv2::RuleGroup`

Determining which controls apply to the standard

The following list specifies the controls that support NIST SP 800-171 Revision 2 requirements and apply to the NIST SP 800-171 Revision 2 standard in AWS Security Hub CSPM. For details about specific requirements that a control supports, choose the control. Then refer to the **Related requirements** field in the details for the control. This field specifies each NIST requirement that the control supports. If the field doesn't specify a particular NIST requirement, the control doesn't support the requirement.

- [ACM.1] Imported and ACM-issued certificates should be renewed after a specified time period
- [APIGateway.2] API Gateway REST API stages should be configured to use SSL certificates for backend authentication
- [CloudFront.7] CloudFront distributions should use custom SSL/TLS certificates
- [CloudFront.10] CloudFront distributions should not use deprecated SSL protocols between edge locations and custom origins
- [CloudTrail.2] CloudTrail should have encryption at-rest enabled

- [CloudTrail.3] At least one CloudTrail trail should be enabled
- [CloudTrail.4] CloudTrail log file validation should be enabled
- [CloudWatch.1] A log metric filter and alarm should exist for usage of the "root" user
- [CloudWatch.2] Ensure a log metric filter and alarm exist for unauthorized API calls
- [CloudWatch.4] Ensure a log metric filter and alarm exist for IAM policy changes
- [CloudWatch.5] Ensure a log metric filter and alarm exist for CloudTrail configuration changes
- [CloudWatch.6] Ensure a log metric filter and alarm exist for AWS Management Console authentication failures
- [CloudWatch.7] Ensure a log metric filter and alarm exist for disabling or scheduled deletion of customer managed keys
- [CloudWatch.8] Ensure a log metric filter and alarm exist for S3 bucket policy changes
- [CloudWatch.9] Ensure a log metric filter and alarm exist for AWS Config configuration changes
- [CloudWatch.10] Ensure a log metric filter and alarm exist for security group changes
- [CloudWatch.11] Ensure a log metric filter and alarm exist for changes to Network Access Control Lists (NACL)
- [CloudWatch.12] Ensure a log metric filter and alarm exist for changes to network gateways
- [CloudWatch.13] Ensure a log metric filter and alarm exist for route table changes
- [CloudWatch.14] Ensure a log metric filter and alarm exist for VPC changes
- [CloudWatch.15] CloudWatch alarms should have specified actions configured
- [EC2.6] VPC flow logging should be enabled in all VPCs
- [EC2.10] Amazon EC2 should be configured to use VPC endpoints that are created for the Amazon EC2 service
- [EC2.13] Security groups should not allow ingress from 0.0.0.0/0 or ::/0 to port 22
- [EC2.16] Unused Network Access Control Lists should be removed
- [EC2.18] Security groups should only allow unrestricted incoming traffic for authorized ports
- [EC2.19] Security groups should not allow unrestricted access to ports with high risk
- [EC2.20] Both VPN tunnels for an AWS Site-to-Site VPN connection should be up
- [EC2.21] Network ACLs should not allow ingress from 0.0.0.0/0 to port 22 or port 3389
- [EC2.51] EC2 Client VPN endpoints should have client connection logging enabled
- [EFS.6] EFS mount targets should not be associated with subnets that assign public IP addresses on launch

- [ELB.2] Classic Load Balancers with SSL/HTTPS listeners should use a certificate provided by AWS Certificate Manager
- [ELB.3] Classic Load Balancer listeners should be configured with HTTPS or TLS termination
- [ELB.8] Classic Load Balancers with SSL listeners should use a predefined security policy that has strong AWS Configuration
- [GuardDuty.1] GuardDuty should be enabled
- [IAM.1] IAM policies should not allow full "*" administrative privileges
- [IAM.2] IAM users should not have IAM policies attached
- [IAM.7] Password policies for IAM users should have strong configurations
- [IAM.8] Unused IAM user credentials should be removed
- [IAM.10] Password policies for IAM users should have strong configurations
- [IAM.11] Ensure IAM password policy requires at least one uppercase letter
- [IAM.12] Ensure IAM password policy requires at least one lowercase letter
- [IAM.13] Ensure IAM password policy requires at least one symbol
- [IAM.14] Ensure IAM password policy requires at least one number
- [IAM.15] Ensure IAM password policy requires minimum password length of 14 or greater
- [IAM.16] Ensure IAM password policy prevents password reuse
- [IAM.18] Ensure a support role has been created to manage incidents with AWS Support
- [IAM.19] MFA should be enabled for all IAM users
- [IAM.21] IAM customer managed policies that you create should not allow wildcard actions for services
- [IAM.22] IAM user credentials unused for 45 days should be removed
- [NetworkFirewall.2] Network Firewall logging should be enabled
- [NetworkFirewall.3] Network Firewall policies should have at least one rule group associated
- [NetworkFirewall.5] The default stateless action for Network Firewall policies should be drop or forward for fragmented packets
- [NetworkFirewall.6] Stateless Network Firewall rule group should not be empty
- [S3.5] S3 general purpose buckets should require requests to use TLS
- [S3.6] S3 general purpose bucket policies should restrict access to other AWS accounts
- [S3.9] S3 general purpose buckets should have server access logging enabled

- [S3.11] S3 general purpose buckets should have event notifications enabled
- [S3.14] S3 general purpose buckets should have versioning enabled
- [S3.17] S3 general purpose buckets should be encrypted at rest with AWS KMS keys
- [SNS.1] SNS topics should be encrypted at-rest using AWS KMS
- [SSM.2] Amazon EC2 instances managed by Systems Manager should have a patch compliance status of COMPLIANT after a patch installation
- [WAF.12] AWS WAF rules should have CloudWatch metrics enabled

PCI DSS in Security Hub CSPM

The Payment Card Industry Data Security Standard (PCI DSS) is a third-party compliance framework that provides a set of rules and guidelines for safely handling credit and debit card information. The PCI Security Standards Council (SSC) creates and updates this framework.

AWS Security Hub CSPM provides a PCI DSS standard that can help you stay compliant with this third-party framework. You can use this standard to discover security vulnerabilities in AWS resources that handle cardholder data. We recommend enabling this standard in AWS accounts that have resources that store, process, or transmit cardholder data or sensitive authentication data. Assessments by the PCI SSC validated this standard.

Security Hub CSPM offers support for both PCI DSS v3.2.1 and PCI DSS v4.0.1. We recommend using v4.0.1 to stay current with security best practices. You can have both versions of the standard enabled at the same time. For information about enabling standards, see Enabling a security standard. If you currently use v3.2.1 but want to use only v4.0.1, enable the newer version before disabling the older version. This prevents gaps in your security checks. If you use the Security Hub CSPM integration with AWS Organizations and want to batch enable v4.0.1 in multiple accounts, we recommend using central configuration to do so.

The following sections specify which controls apply to PCI DSS v3.2.1 and PCI DSS v4.0.1.

Controls that apply to PCI DSS v3.2.1

The following list specifies which Security Hub CSPM controls apply to PCI DSS v3.2.1. To review the details of a control, choose the control.

[AutoScaling.1] Auto Scaling groups associated with a load balancer should use ELB health checks

[CloudTrail.2] CloudTrail should have encryption at-rest enabled

[CloudTrail.3] At least one CloudTrail trail should be enabled

[CloudTrail.4] CloudTrail log file validation should be enabled

[CloudTrail.5] CloudTrail trails should be integrated with Amazon CloudWatch Logs

[CloudWatch.1] A log metric filter and alarm should exist for usage of the "root" user

[CodeBuild.1] CodeBuild Bitbucket source repository URLs should not contain sensitive credentials

[CodeBuild.2] CodeBuild project environment variables should not contain clear text credentials

[Config.1] AWS Config should be enabled and use the service-linked role for resource recording

[DMS.1] Database Migration Service replication instances should not be public

[EC2.1] Amazon EBS snapshots should not be configured to be publicly restorable

[EC2.2] VPC default security groups should not allow inbound or outbound traffic

[EC2.6] VPC flow logging should be enabled in all VPCs

[EC2.12] Unused Amazon EC2 EIPs should be removed

[EC2.13] Security groups should not allow ingress from 0.0.0.0/0 or ::/0 to port 22

[ELB.1] Application Load Balancer should be configured to redirect all HTTP requests to HTTPS

[ES.1] Elasticsearch domains should have encryption at-rest enabled

[ES.2] Elasticsearch domains should not be publicly accessible

[GuardDuty.1] GuardDuty should be enabled

[IAM.1] IAM policies should not allow full "*" administrative privileges

[IAM.2] IAM users should not have IAM policies attached

[IAM.4] IAM root user access key should not exist

[IAM.6] Hardware MFA should be enabled for the root user

[IAM.8] Unused IAM user credentials should be removed

[IAM.9] MFA should be enabled for the root user

[IAM.10] Password policies for IAM users should have strong configurations

[IAM.19] MFA should be enabled for all IAM users

[KMS.4] AWS KMS key rotation should be enabled

[Lambda.1] Lambda function policies should prohibit public access

[Lambda.3] Lambda functions should be in a VPC

[Opensearch.1] OpenSearch domains should have encryption at rest enabled

[Opensearch.2] OpenSearch domains should not be publicly accessible

[RDS.1] RDS snapshot should be private

[RDS.2] RDS DB Instances should prohibit public access, as determined by the PubliclyAccessible configuration

[Redshift.1] Amazon Redshift clusters should prohibit public access

[S3.1] S3 general purpose buckets should have block public access settings enabled

[S3.2] S3 general purpose buckets should block public read access

[S3.3] S3 general purpose buckets should block public write access

[S3.5] S3 general purpose buckets should require requests to use TLS

[S3.7] S3 general purpose buckets should use cross-Region replication

[SageMaker.1] Amazon SageMaker notebook instances should not have direct internet access

[SSM.1] Amazon EC2 instances should be managed by AWS Systems Manager

[SSM.2] Amazon EC2 instances managed by Systems Manager should have a patch compliance status of COMPLIANT after a patch installation

[SSM.3] Amazon EC2 instances managed by Systems Manager should have an association compliance status of COMPLIANT

Controls that apply to PCI DSS v4.0.1

The following list specifies which Security Hub CSPM controls apply to PCI DSS v4.0.1. To review the details of a control, choose the control.

[ACM.1] Imported and ACM-issued certificates should be renewed after a specified time period

[ACM.2] RSA certificates managed by ACM should use a key length of at least 2,048 bits

[APIGateway.9] Access logging should be configured for API Gateway V2 Stages

[AppSync.2] AWS AppSync should have field-level logging enabled

[AutoScaling.3] Auto Scaling group launch configurations should configure EC2 instances to require Instance Metadata Service Version 2 (IMDSv2)

[Autoscaling.5] Amazon EC2 instances launched using Auto Scaling group launch configurations should not have Public IP addresses

[CloudFront.1] CloudFront distributions should have a default root object configured

[CloudFront.10] CloudFront distributions should not use deprecated SSL protocols between edge locations and custom origins

[CloudFront.12] CloudFront distributions should not point to non-existent S3 origins

[CloudFront.3] CloudFront distributions should require encryption in transit

[CloudFront.5] CloudFront distributions should have logging enabled

[CloudFront.6] CloudFront distributions should have WAF enabled

[CloudFront.9] CloudFront distributions should encrypt traffic to custom origins

[CloudTrail.2] CloudTrail should have encryption at-rest enabled

[CloudTrail.3] At least one CloudTrail trail should be enabled

[CloudTrail.4] CloudTrail log file validation should be enabled

[CloudTrail.6] Ensure the S3 bucket used to store CloudTrail logs is not publicly accessible

[CloudTrail.7] Ensure S3 bucket access logging is enabled on the CloudTrail S3 bucket

[CodeBuild.1] CodeBuild Bitbucket source repository URLs should not contain sensitive credentials

[CodeBuild.2] CodeBuild project environment variables should not contain clear text credentials

[CodeBuild.3] CodeBuild S3 logs should be encrypted

[DMS.1] Database Migration Service replication instances should not be public

[DMS.10] DMS endpoints for Neptune databases should have IAM authorization enabled

[DMS.11] DMS endpoints for MongoDB should have an authentication mechanism enabled

[DMS.12] DMS endpoints for Redis OSS should have TLS enabled

[DMS.6] DMS replication instances should have automatic minor version upgrade enabled

[DMS.7] DMS replication tasks for the target database should have logging enabled

[DMS.8] DMS replication tasks for the source database should have logging enabled

[DMS.9] DMS endpoints should use SSL

[DocumentDB.2] Amazon DocumentDB clusters should have an adequate backup retention period

[DocumentDB.3] Amazon DocumentDB manual cluster snapshots should not be public

[DocumentDB.4] Amazon DocumentDB clusters should publish audit logs to CloudWatch Logs

[DynamoDB.7] DynamoDB Accelerator clusters should be encrypted in transit

[EC2.13] Security groups should not allow ingress from 0.0.0.0/0 or ::/0 to port 22

[EC2.14] Security groups should not allow ingress from 0.0.0.0/0 or ::/0 to port 3389

[EC2.15] Amazon EC2 subnets should not automatically assign public IP addresses

[EC2.16] Unused Network Access Control Lists should be removed

[EC2.170] EC2 launch templates should use Instance Metadata Service Version 2 (IMDSv2)

[EC2.171] EC2 VPN connections should have logging enabled

[EC2.21] Network ACLs should not allow ingress from 0.0.0.0/0 to port 22 or port 3389

[EC2.25] Amazon EC2 launch templates should not assign public IPs to network interfaces

[EC2.51] EC2 Client VPN endpoints should have client connection logging enabled

[EC2.53] EC2 security groups should not allow ingress from 0.0.0.0/0 to remote server administration ports

[EC2.54] EC2 security groups should not allow ingress from ::/0 to remote server administration ports

[EC2.8] EC2 instances should use Instance Metadata Service Version 2 (IMDSv2)

[ECR.1] ECR private repositories should have image scanning configured

[ECS.10] ECS Fargate services should run on the latest Fargate platform version

[ECS.16] ECS task sets should not automatically assign public IP addresses

[ECS.2] ECS services should not have public IP addresses assigned to them automatically

[ECS.8] Secrets should not be passed as container environment variables

[EFS.4] EFS access points should enforce a user identity

[EKS.1] EKS cluster endpoints should not be publicly accessible

[EKS.2] EKS clusters should run on a supported Kubernetes version

[EKS.8] EKS clusters should have audit logging enabled

[ElastiCache.2] ElastiCache clusters should have automatic minor version upgrades enabled

[ElastiCache.5] ElastiCache replication groups should be encrypted in transit

[ElastiCache.6] ElastiCache (Redis OSS) replication groups of earlier versions should have Redis OSS AUTH enabled

[ElasticBeanstalk.2] Elastic Beanstalk managed platform updates should be enabled

[ElasticBeanstalk.3] Elastic Beanstalk should stream logs to CloudWatch

[ELB.12] Application Load Balancer should be configured with defensive or strictest desync mitigation mode

[ELB.14] Classic Load Balancer should be configured with defensive or strictest desync mitigation mode

[ELB.3] Classic Load Balancer listeners should be configured with HTTPS or TLS termination

[ELB.4] Application Load Balancer should be configured to drop invalid http headers

[ELB.8] Classic Load Balancers with SSL listeners should use a predefined security policy that has strong AWS Configuration

[EMR.1] Amazon EMR cluster primary nodes should not have public IP addresses

[EMR.2] Amazon EMR block public access setting should be enabled

[ES.2] Elasticsearch domains should not be publicly accessible

[ES.3] Elasticsearch domains should encrypt data sent between nodes

[ES.5] Elasticsearch domains should have audit logging enabled

[ES.8] Connections to Elasticsearch domains should be encrypted using the latest TLS security policy

[EventBridge.3] EventBridge custom event buses should have a resource-based policy attached

[GuardDuty.1] GuardDuty should be enabled

[GuardDuty.10] GuardDuty S3 Protection should be enabled

[GuardDuty.6] GuardDuty Lambda Protection should be enabled

[GuardDuty.7] GuardDuty EKS Runtime Monitoring should be enabled

[GuardDuty.9] GuardDuty RDS Protection should be enabled

[IAM.3] IAM users' access keys should be rotated every 90 days or less

[IAM.5] MFA should be enabled for all IAM users that have a console password

[IAM.6] Hardware MFA should be enabled for the root user

[IAM.7] Password policies for IAM users should have strong configurations

[IAM.8] Unused IAM user credentials should be removed

[IAM.9] MFA should be enabled for the root user

[IAM.11] Ensure IAM password policy requires at least one uppercase letter

[IAM.12] Ensure IAM password policy requires at least one lowercase letter

[IAM.14] Ensure IAM password policy requires at least one number

[IAM.16] Ensure IAM password policy prevents password reuse

[IAM.17] Ensure IAM password policy expires passwords within 90 days or less

[IAM.18] Ensure a support role has been created to manage incidents with AWS Support

[IAM.19] MFA should be enabled for all IAM users

[Inspector.1] Amazon Inspector EC2 scanning should be enabled

[Inspector.2] Amazon Inspector ECR scanning should be enabled

[Inspector.3] Amazon Inspector Lambda code scanning should be enabled

[Inspector.4] Amazon Inspector Lambda standard scanning should be enabled

[KMS.4] AWS KMS key rotation should be enabled

[Lambda.1] Lambda function policies should prohibit public access

[Lambda.2] Lambda functions should use supported runtimes

[MQ.2] ActiveMQ brokers should stream audit logs to CloudWatch

[MSK.1] MSK clusters should be encrypted in transit among broker nodes

[MSK.3] MSK Connect connectors should be encrypted in transit

[Neptune.2] Neptune DB clusters should publish audit logs to CloudWatch Logs

[Neptune.3] Neptune DB cluster snapshots should not be public

[Opensearch.10] OpenSearch domains should have the latest software update installed

[Opensearch.5] OpenSearch domains should have audit logging enabled

[RDS.13] RDS automatic minor version upgrades should be enabled

[RDS.2] RDS DB Instances should prohibit public access, as determined by the PubliclyAccessible configuration

[RDS.20] Existing RDS event notification subscriptions should be configured for critical database instance events

[RDS.21] An RDS event notifications subscription should be configured for critical database parameter group events

[RDS.22] An RDS event notifications subscription should be configured for critical database security group events

[RDS.24] RDS Database clusters should use a custom administrator username

[RDS.25] RDS database instances should use a custom administrator username

[RDS.34] Aurora MySQL DB clusters should publish audit logs to CloudWatch Logs

[RDS.35] RDS DB clusters should have automatic minor version upgrade enabled

[RDS.36] RDS for PostgreSQL DB instances should publish logs to CloudWatch Logs

[RDS.37] Aurora PostgreSQL DB clusters should publish logs to CloudWatch Logs

[RDS.9] RDS DB instances should publish logs to CloudWatch Logs

[Redshift.1] Amazon Redshift clusters should prohibit public access

[Redshift.15] Redshift security groups should allow ingress on the cluster port only from restricted origins

[Redshift.2] Connections to Amazon Redshift clusters should be encrypted in transit

[Redshift.4] Amazon Redshift clusters should have audit logging enabled

[Route53.2] Route 53 public hosted zones should log DNS queries

[S3.1] S3 general purpose buckets should have block public access settings enabled

[S3.15] S3 general purpose buckets should have Object Lock enabled

[S3.17] S3 general purpose buckets should be encrypted at rest with AWS KMS keys

[S3.19] S3 access points should have block public access settings enabled

[S3.22] S3 general purpose buckets should log object-level write events

[S3.23] S3 general purpose buckets should log object-level read events

[S3.24] S3 Multi-Region Access Points should have block public access settings enabled

[S3.5] S3 general purpose buckets should require requests to use TLS

[S3.8] S3 general purpose buckets should block public access

[S3.9] S3 general purpose buckets should have server access logging enabled

[SageMaker.1] Amazon SageMaker notebook instances should not have direct internet access

[SecretsManager.1] Secrets Manager secrets should have automatic rotation enabled

[SecretsManager.2] Secrets Manager secrets configured with automatic rotation should rotate successfully

[SecretsManager.4] Secrets Manager secrets should be rotated within a specified number of days

[SSM.2] Amazon EC2 instances managed by Systems Manager should have a patch compliance status of COMPLIANT after a patch installation

[SSM.3] Amazon EC2 instances managed by Systems Manager should have an association compliance status of COMPLIANT

[StepFunctions.1] Step Functions state machines should have logging turned on

[Transfer.2] Transfer Family servers should not use FTP protocol for endpoint connection

[WAF.1] AWS WAF Classic Global Web ACL logging should be enabled

[WAF.11] AWS WAF web ACL logging should be enabled

CRI Profile v2.2 in Security Hub CSPM

The CRI Profile is a cybersecurity framework developed by the Cyber Risk Institute (CRI), a non-profit coalition of financial institutions and trade associations. The framework harmonizes

cybersecurity and regulatory expectations for the financial services sector into a common set of requirements. This lets an organization assess itself once and report against multiple regulations. For more information about the framework and its requirements, see CRI Profile overview on the Cyber Risk Institute website.

AWS Security Hub CSPM provides security controls that support a subset of CRI Profile v2.2 requirements. The controls perform automated security checks for certain AWS services and resources. To enable and manage these controls, you can enable CRI Profile v2.2 as a standard in Security Hub CSPM. Note that the controls don't support CRI Profile v2.2 requirements that require manual checks.

Enabling this standard, and passing the checks for its controls, doesn't by itself establish or certify compliance with CRI Profile v2.2. Compliance depends on organizational and operational practices that Security Hub CSPM can't evaluate.

Topics

- Controls that apply to the standard

Controls that apply to the standard

The following list specifies which Security Hub CSPM controls apply to CRI Profile v2.2. To review the details of a control, choose the control.

- [Account.1] Security contact information should be provided for an AWS account
- [Account.2] AWS accounts should be part of an AWS Organizations organization
- [ACM.1] Imported and ACM-issued certificates should be renewed after a specified time period
- [ACM.2] RSA certificates managed by ACM should use a key length of at least 2,048 bits
- [Amplify.2] Amplify branches should be tagged
- [APIGateway.1] API Gateway REST and WebSocket API execution logging should be enabled
- [APIGateway.2] API Gateway REST API stages should be configured to use SSL certificates for backend authentication
- [APIGateway.3] API Gateway REST API stages should have AWS X-Ray tracing enabled
- [APIGateway.4] API Gateway should be associated with a WAF Web ACL
- [APIGateway.5] API Gateway REST API cache data should be encrypted at rest
- [APIGateway.8] API Gateway routes should specify an authorization type

- [APIGateway.9] Access logging should be configured for API Gateway V2 Stages
- [AppFlow.1] Amazon AppFlow flows should be tagged
- [AppRunner.1] App Runner services should be tagged
- [AppSync.2] AWS AppSync should have field-level logging enabled
- [AppSync.5] AWS AppSync GraphQL APIs should not be authenticated with API keys
- [Athena.4] Athena workgroups should have logging enabled
- [AutoScaling.1] Auto Scaling groups associated with a load balancer should use ELB health checks
- [AutoScaling.2] Amazon EC2 Auto Scaling group should cover multiple Availability Zones
- [AutoScaling.3] Auto Scaling group launch configurations should configure EC2 instances to require Instance Metadata Service Version 2 (IMDSv2)
- [Autoscaling.5] Amazon EC2 instances launched using Auto Scaling group launch configurations should not have Public IP addresses
- [AutoScaling.6] Auto Scaling groups should use multiple instance types in multiple Availability Zones
- [AutoScaling.9] Amazon EC2 Auto Scaling groups should use Amazon EC2 launch templates
- [Backup.1] AWS Backup recovery points should be encrypted at rest
- [Batch.2] Batch scheduling policies should be tagged
- [Batch.4] Compute resources properties in managed Batch compute environments should be tagged
- [CloudFront.1] CloudFront distributions should have a default root object configured
- [CloudFront.3] CloudFront distributions should require encryption in transit
- [CloudFront.4] CloudFront distributions should have origin failover configured
- [CloudFront.5] CloudFront distributions should have logging enabled
- [CloudFront.6] CloudFront distributions should have WAF enabled
- [CloudFront.7] CloudFront distributions should use custom SSL/TLS certificates
- [CloudFront.8] CloudFront distributions should use SNI to serve HTTPS requests
- [CloudFront.9] CloudFront distributions should encrypt traffic to custom origins
- [CloudFront.10] CloudFront distributions should not use deprecated SSL protocols between edge locations and custom origins
- [CloudFront.12] CloudFront distributions should not point to non-existent S3 origins

- [CloudFront.13] CloudFront distributions should use origin access control
- [CloudFront.15] CloudFront distributions should use the recommended TLS security policy
- [CloudTrail.1] CloudTrail should be enabled and configured with at least one multi-Region trail that includes read and write management events
- [CloudTrail.2] CloudTrail should have encryption at-rest enabled
- [CloudTrail.3] At least one CloudTrail trail should be enabled
- [CloudTrail.4] CloudTrail log file validation should be enabled
- [CloudTrail.5] CloudTrail trails should be integrated with Amazon CloudWatch Logs
- [CloudTrail.6] Ensure the S3 bucket used to store CloudTrail logs is not publicly accessible
- [CloudTrail.7] Ensure S3 bucket access logging is enabled on the CloudTrail S3 bucket
- [CloudWatch.1] A log metric filter and alarm should exist for usage of the "root" user
- [CloudWatch.2] Ensure a log metric filter and alarm exist for unauthorized API calls
- [CloudWatch.3] Ensure a log metric filter and alarm exist for Management Console sign-in without MFA
- [CloudWatch.4] Ensure a log metric filter and alarm exist for IAM policy changes
- [CloudWatch.5] Ensure a log metric filter and alarm exist for CloudTrail configuration changes
- [CloudWatch.6] Ensure a log metric filter and alarm exist for AWS Management Console authentication failures
- [CloudWatch.7] Ensure a log metric filter and alarm exist for disabling or scheduled deletion of customer managed keys
- [CloudWatch.8] Ensure a log metric filter and alarm exist for S3 bucket policy changes
- [CloudWatch.9] Ensure a log metric filter and alarm exist for AWS Config configuration changes
- [CloudWatch.10] Ensure a log metric filter and alarm exist for security group changes
- [CloudWatch.11] Ensure a log metric filter and alarm exist for changes to Network Access Control Lists (NACL)
- [CloudWatch.12] Ensure a log metric filter and alarm exist for changes to network gateways
- [CloudWatch.13] Ensure a log metric filter and alarm exist for route table changes
- [CloudWatch.14] Ensure a log metric filter and alarm exist for VPC changes
- [CloudWatch.15] CloudWatch alarms should have specified actions configured
- [CloudWatch.16] CloudWatch log groups should be retained for a specified time period
- [CloudWatch.17] CloudWatch alarm actions should be activated

- [CodeBuild.1] CodeBuild Bitbucket source repository URLs should not contain sensitive credentials
- [CodeBuild.2] CodeBuild project environment variables should not contain clear text credentials
- [CodeBuild.3] CodeBuild S3 logs should be encrypted
- [CodeBuild.4] CodeBuild project environments should have a logging AWS Configuration
- [CodeBuild.7] CodeBuild report group exports should be encrypted at rest
- [CodeGuruProfiler.1] CodeGuru Profiler profiling groups should be tagged
- [CodeGuruReviewer.1] CodeGuru Reviewer repository associations should be tagged
- [Cognito.2] Cognito identity pools should not allow unauthenticated identities
- [Cognito.3] Password policies for Cognito user pools should have strong configurations
- [Config.1] AWS Config should be enabled and use the service-linked role for resource recording
- [Connect.2] Connect Customer instances should have CloudWatch logging enabled
- [DataFirehose.1] Firehose delivery streams should be encrypted at rest
- [DataSync.1] DataSync tasks should have logging enabled
- [DataSync.2] DataSync tasks should be tagged
- [DMS.1] Database Migration Service replication instances should not be public
- [DMS.6] DMS replication instances should have automatic minor version upgrade enabled
- [DMS.7] DMS replication tasks for the target database should have logging enabled
- [DMS.8] DMS replication tasks for the source database should have logging enabled
- [DMS.9] DMS endpoints should use SSL
- [DMS.10] DMS endpoints for Neptune databases should have IAM authorization enabled
- [DMS.11] DMS endpoints for MongoDB should have an authentication mechanism enabled
- [DMS.12] DMS endpoints for Redis OSS should have TLS enabled
- [DocumentDB.1] Amazon DocumentDB clusters should be encrypted at rest
- [DocumentDB.2] Amazon DocumentDB clusters should have an adequate backup retention period
- [DocumentDB.3] Amazon DocumentDB manual cluster snapshots should not be public
- [DocumentDB.4] Amazon DocumentDB clusters should publish audit logs to CloudWatch Logs
- [DocumentDB.5] Amazon DocumentDB clusters should have deletion protection enabled
- [DocumentDB.6] Amazon DocumentDB clusters should be encrypted in transit

- [DynamoDB.1] DynamoDB tables should automatically scale capacity with demand
- [DynamoDB.2] DynamoDB tables should have point-in-time recovery enabled
- [DynamoDB.3] DynamoDB Accelerator (DAX) clusters should be encrypted at rest
- [DynamoDB.4] DynamoDB tables should be present in a backup plan
- [DynamoDB.6] DynamoDB tables should have deletion protection enabled
- [DynamoDB.7] DynamoDB Accelerator clusters should be encrypted in transit
- [EC2.1] Amazon EBS snapshots should not be configured to be publicly restorable
- [EC2.2] VPC default security groups should not allow inbound or outbound traffic
- [EC2.3] Attached Amazon EBS volumes should be encrypted at-rest
- [EC2.4] Stopped EC2 instances should be removed after a specified time period
- [EC2.6] VPC flow logging should be enabled in all VPCs
- [EC2.7] EBS default encryption should be enabled
- [EC2.8] EC2 instances should use Instance Metadata Service Version 2 (IMDSv2)
- [EC2.9] Amazon EC2 instances should not have a public IPv4 address
- [EC2.10] Amazon EC2 should be configured to use VPC endpoints that are created for the Amazon EC2 service
- [EC2.12] Unused Amazon EC2 EIPs should be removed
- [EC2.13] Security groups should not allow ingress from 0.0.0.0/0 or ::/0 to port 22
- [EC2.14] Security groups should not allow ingress from 0.0.0.0/0 or ::/0 to port 3389
- [EC2.15] Amazon EC2 subnets should not automatically assign public IP addresses
- [EC2.16] Unused Network Access Control Lists should be removed
- [EC2.17] Amazon EC2 instances should not use multiple ENIs
- [EC2.18] Security groups should only allow unrestricted incoming traffic for authorized ports
- [EC2.19] Security groups should not allow unrestricted access to ports with high risk
- [EC2.20] Both VPN tunnels for an AWS Site-to-Site VPN connection should be up
- [EC2.21] Network ACLs should not allow ingress from 0.0.0.0/0 to port 22 or port 3389
- [EC2.22] Unused Amazon EC2 security groups should be removed
- [EC2.23] Amazon EC2 Transit Gateways should not automatically accept VPC attachment requests
- [EC2.24] Amazon EC2 paravirtual instance types should not be used

- [EC2.25] Amazon EC2 launch templates should not assign public IPs to network interfaces
- [EC2.28] EBS volumes should be covered by a backup plan
- [EC2.51] EC2 Client VPN endpoints should have client connection logging enabled
- [EC2.53] EC2 security groups should not allow ingress from 0.0.0.0/0 to remote server administration ports
- [EC2.54] EC2 security groups should not allow ingress from ::/0 to remote server administration ports
- [EC2.170] EC2 launch templates should use Instance Metadata Service Version 2 (IMDSv2)
- [EC2.171] EC2 VPN connections should have logging enabled
- [EC2.173] EC2 Spot Fleet requests with launch parameters should enable encryption for attached EBS volumes
- [EC2.174] EC2 DHCP option sets should be tagged
- [EC2.176] EC2 prefix lists should be tagged
- [EC2.177] EC2 traffic mirror sessions should be tagged
- [EC2.178] EC2 traffic mirror filters should be tagged
- [EC2.180] EC2 network interfaces should have source/destination checking enabled
- [EC2.181] EC2 launch templates should enable encryption for attached EBS volumes
- [ECR.1] ECR private repositories should have image scanning configured
- [ECR.2] ECR private repositories should have tag immutability configured
- [ECR.3] ECR repositories should have at least one lifecycle policy configured
- [ECS.2] ECS services should not have public IP addresses assigned to them automatically
- [ECS.3] ECS task definitions should not share the host's process namespace
- [ECS.4] ECS containers should run as non-privileged
- [ECS.5] ECS task definitions should configure containers to be limited to read-only access to root filesystems
- [ECS.8] Secrets should not be passed as container environment variables
- [ECS.9] ECS task definitions should have a logging configuration
- [ECS.10] ECS Fargate services should run on the latest Fargate platform version
- [ECS.12] ECS clusters should use Container Insights
- [ECS.16] ECS task sets should not automatically assign public IP addresses

- [ECS.17] ECS task definitions should not use host network mode
- [EFS.1] Elastic File System should be configured to encrypt file data at-rest using AWS KMS
- [EFS.2] Amazon EFS volumes should be in backup plans
- [EFS.3] EFS access points should enforce a root directory
- [EFS.4] EFS access points should enforce a user identity
- [EFS.6] EFS mount targets should not be associated with subnets that assign public IP addresses on launch
- [EFS.7] EFS file systems should have automatic backups enabled
- [EFS.8] EFS file systems should be encrypted at rest
- [EKS.1] EKS cluster endpoints should not be publicly accessible
- [EKS.2] EKS clusters should run on a supported Kubernetes version
- [EKS.8] EKS clusters should have audit logging enabled
- [ElastiCache.1] ElastiCache (Redis OSS) clusters should have automatic backups enabled
- [ElastiCache.2] ElastiCache clusters should have automatic minor version upgrades enabled
- [ElastiCache.3] ElastiCache replication groups should have automatic failover enabled
- [ElastiCache.4] ElastiCache replication groups should be encrypted at rest
- [ElastiCache.5] ElastiCache replication groups should be encrypted in transit
- [ElastiCache.6] ElastiCache (Redis OSS) replication groups of earlier versions should have Redis OSS AUTH enabled
- [ElastiCache.7] ElastiCache clusters should not use the default subnet group
- [ElasticBeanstalk.1] Elastic Beanstalk environments should have enhanced health reporting enabled
- [ElasticBeanstalk.2] Elastic Beanstalk managed platform updates should be enabled
- [ElasticBeanstalk.3] Elastic Beanstalk should stream logs to CloudWatch
- [ELB.1] Application Load Balancer should be configured to redirect all HTTP requests to HTTPS
- [ELB.2] Classic Load Balancers with SSL/HTTPS listeners should use a certificate provided by AWS Certificate Manager
- [ELB.3] Classic Load Balancer listeners should be configured with HTTPS or TLS termination
- [ELB.4] Application Load Balancer should be configured to drop invalid http headers
- [ELB.5] Application and Classic Load Balancers logging should be enabled

- [ELB.6] Application, Gateway, and Network Load Balancers should have deletion protection enabled
- [ELB.7] Classic Load Balancers should have connection draining enabled
- [ELB.8] Classic Load Balancers with SSL listeners should use a predefined security policy that has strong AWS Configuration
- [ELB.9] Classic Load Balancers should have cross-zone load balancing enabled
- [ELB.10] Classic Load Balancer should span multiple Availability Zones
- [ELB.12] Application Load Balancer should be configured with defensive or strictest desync mitigation mode
- [ELB.13] Application, Network and Gateway Load Balancers should span multiple Availability Zones
- [ELB.14] Classic Load Balancer should be configured with defensive or strictest desync mitigation mode
- [ELB.16] Application Load Balancers should be associated with an AWS WAF web ACL
- [ELB.17] Application and Network Load Balancers with listeners should use recommended security policies
- [ELB.18] Application and Network Load Balancer listeners should use secure protocols to encrypt data in transit
- [ELB.21] Application and Network Load Balancer target groups should use encrypted health check protocols
- [ELB.22] ELB target groups should use encrypted transport protocols
- [EMR.1] Amazon EMR cluster primary nodes should not have public IP addresses
- [EMR.2] Amazon EMR block public access setting should be enabled
- [EMR.3] Amazon EMR security configurations should be encrypted at rest
- [EMR.4] Amazon EMR security configurations should be encrypted in transit
- [ES.1] Elasticsearch domains should have encryption at-rest enabled
- [ES.2] Elasticsearch domains should not be publicly accessible
- [ES.3] Elasticsearch domains should encrypt data sent between nodes
- [ES.4] Elasticsearch domain error logging to CloudWatch Logs should be enabled
- [ES.5] Elasticsearch domains should have audit logging enabled
- [ES.6] Elasticsearch domains should have at least three data nodes

- [ES.7] Elasticsearch domains should be configured with at least three dedicated master nodes
- [ES.8] Connections to Elasticsearch domains should be encrypted using the latest TLS security policy
- [EventBridge.3] EventBridge custom event buses should have a resource-based policy attached
- [EventBridge.4] EventBridge global endpoints should have event replication enabled
- [FSx.1] FSx for OpenZFS file systems should be configured to copy tags to backups and volumes
- [FSx.2] FSx for Lustre file systems should be configured to copy tags to backups
- [FSx.3] FSx for OpenZFS file systems should be configured for Multi-AZ deployment
- [FSx.5] FSx for Windows File Server file systems should be configured for Multi-AZ deployment
- [Glue.3] AWS Glue machine learning transforms should be encrypted at rest
- [Glue.4] AWS Glue Spark jobs should run on supported versions of AWS Glue
- [GuardDuty.1] GuardDuty should be enabled
- [GuardDuty.5] GuardDuty EKS Audit Log Monitoring should be enabled
- [GuardDuty.6] GuardDuty Lambda Protection should be enabled
- [GuardDuty.7] GuardDuty EKS Runtime Monitoring should be enabled
- [GuardDuty.8] GuardDuty Malware Protection for EC2 should be enabled
- [GuardDuty.9] GuardDuty RDS Protection should be enabled
- [GuardDuty.10] GuardDuty S3 Protection should be enabled
- [GuardDuty.11] GuardDuty Runtime Monitoring should be enabled
- [GuardDuty.12] GuardDuty ECS Runtime Monitoring should be enabled
- [GuardDuty.13] GuardDuty EC2 Runtime Monitoring should be enabled
- [IAM.1] IAM policies should not allow full "*" administrative privileges
- [IAM.2] IAM users should not have IAM policies attached
- [IAM.3] IAM users' access keys should be rotated every 90 days or less
- [IAM.4] IAM root user access key should not exist
- [IAM.5] MFA should be enabled for all IAM users that have a console password
- [IAM.6] Hardware MFA should be enabled for the root user
- [IAM.7] Password policies for IAM users should have strong configurations
- [IAM.8] Unused IAM user credentials should be removed
- [IAM.9] MFA should be enabled for the root user

- [IAM.10] Password policies for IAM users should have strong configurations
- [IAM.11] Ensure IAM password policy requires at least one uppercase letter
- [IAM.12] Ensure IAM password policy requires at least one lowercase letter
- [IAM.13] Ensure IAM password policy requires at least one symbol
- [IAM.14] Ensure IAM password policy requires at least one number
- [IAM.15] Ensure IAM password policy requires minimum password length of 14 or greater
- [IAM.16] Ensure IAM password policy prevents password reuse
- [IAM.17] Ensure IAM password policy expires passwords within 90 days or less
- [IAM.18] Ensure a support role has been created to manage incidents with AWS Support
- [IAM.19] MFA should be enabled for all IAM users
- [IAM.21] IAM customer managed policies that you create should not allow wildcard actions for services
- [IAM.22] IAM user credentials unused for 45 days should be removed
- [IAM.26] Expired SSL/TLS certificates managed in IAM should be removed
- [IAM.27] IAM identities should not have the AWSCloudShellFullAccess policy attached
- [IAM.28] IAM Access Analyzer external access analyzer should be enabled
- [Inspector.1] Amazon Inspector EC2 scanning should be enabled
- [Inspector.2] Amazon Inspector ECR scanning should be enabled
- [Inspector.3] Amazon Inspector Lambda code scanning should be enabled
- [Inspector.4] Amazon Inspector Lambda standard scanning should be enabled
- [IoTTwinMaker.2] AWS IoT TwinMaker workspaces should be tagged
- [IVS.1] IVS playback key pairs should be tagged
- [IVS.2] IVS recording configurations should be tagged
- [Keyspaces.1] Amazon Keyspaces keyspaces should be tagged
- [Kinesis.1] Kinesis streams should be encrypted at rest
- [KMS.1] IAM customer managed policies should not allow decryption actions on all KMS keys
- [KMS.2] IAM principals should not have IAM inline policies that allow decryption actions on all KMS keys
- [KMS.3] AWS KMS keys should not be deleted unintentionally
- [KMS.4] AWS KMS key rotation should be enabled

- [KMS.5] KMS keys should not be publicly accessible
- [Lambda.1] Lambda function policies should prohibit public access
- [Lambda.2] Lambda functions should use supported runtimes
- [Lambda.3] Lambda functions should be in a VPC
- [Lambda.5] VPC Lambda functions should operate in multiple Availability Zones
- [Lambda.7] Lambda functions should have AWS X-Ray active tracing enabled
- [Macie.1] Amazon Macie should be enabled
- [Macie.2] Macie automated sensitive data discovery should be enabled
- [MQ.2] ActiveMQ brokers should stream audit logs to CloudWatch
- [MQ.5] ActiveMQ brokers should use active/standby deployment mode
- [MQ.6] RabbitMQ brokers should use cluster deployment mode
- [MSK.1] MSK clusters should be encrypted in transit among broker nodes
- [MSK.2] MSK clusters should have enhanced monitoring configured
- [MSK.3] MSK Connect connectors should be encrypted in transit
- [MSK.4] MSK clusters should have public access disabled
- [MSK.5] MSK connectors should have logging enabled
- [MSK.6] MSK clusters should disable unauthenticated access
- [Neptune.1] Neptune DB clusters should be encrypted at rest
- [Neptune.2] Neptune DB clusters should publish audit logs to CloudWatch Logs
- [Neptune.3] Neptune DB cluster snapshots should not be public
- [Neptune.4] Neptune DB clusters should have deletion protection enabled
- [Neptune.5] Neptune DB clusters should have automated backups enabled
- [Neptune.6] Neptune DB cluster snapshots should be encrypted at rest
- [Neptune.7] Neptune DB clusters should have IAM database authentication enabled
- [Neptune.8] Neptune DB clusters should be configured to copy tags to snapshots
- [Neptune.9] Neptune DB clusters should be deployed across multiple Availability Zones
- [NetworkFirewall.1] Network Firewall firewalls should be deployed across multiple Availability Zones
- [NetworkFirewall.2] Network Firewall logging should be enabled
- [NetworkFirewall.3] Network Firewall policies should have at least one rule group associated

- [NetworkFirewall.4] The default stateless action for Network Firewall policies should be drop or forward for full packets
- [NetworkFirewall.5] The default stateless action for Network Firewall policies should be drop or forward for fragmented packets
- [NetworkFirewall.6] Stateless Network Firewall rule group should not be empty
- [NetworkFirewall.9] Network Firewall firewalls should have deletion protection enabled
- [NetworkFirewall.10] Network Firewall firewalls should have subnet change protection enabled
- [Opensearch.1] OpenSearch domains should have encryption at rest enabled
- [Opensearch.2] OpenSearch domains should not be publicly accessible
- [Opensearch.3] OpenSearch domains should encrypt data sent between nodes
- [Opensearch.4] OpenSearch domain error logging to CloudWatch Logs should be enabled
- [Opensearch.5] OpenSearch domains should have audit logging enabled
- [Opensearch.6] OpenSearch domains should have at least three data nodes
- [Opensearch.7] OpenSearch domains should have fine-grained access control enabled
- [Opensearch.8] Connections to OpenSearch domains should be encrypted using the latest TLS security policy
- [Opensearch.10] OpenSearch domains should have the latest software update installed
- [Opensearch.11] OpenSearch domains should have at least three dedicated primary nodes
- [PCA.1] AWS Private CA root certificate authority should be disabled
- [RDS.1] RDS snapshot should be private
- [RDS.2] RDS DB Instances should prohibit public access, as determined by the PubliclyAccessible configuration
- [RDS.3] RDS DB instances should have encryption at-rest enabled
- [RDS.4] RDS cluster snapshots and database snapshots should be encrypted at rest
- [RDS.5] RDS DB instances should be configured with multiple Availability Zones
- [RDS.6] Enhanced monitoring should be configured for RDS DB instances
- [RDS.7] RDS clusters should have deletion protection enabled
- [RDS.8] RDS DB instances should have deletion protection enabled
- [RDS.9] RDS DB instances should publish logs to CloudWatch Logs
- [RDS.10] IAM authentication should be configured for RDS instances

- [RDS.11] RDS instances should have automatic backups enabled
- [RDS.12] IAM authentication should be configured for RDS clusters
- [RDS.13] RDS automatic minor version upgrades should be enabled
- [RDS.14] Amazon Aurora clusters should have backtracking enabled
- [RDS.15] RDS DB clusters should be configured for multiple Availability Zones
- [RDS.16] Aurora DB clusters should be configured to copy tags to DB snapshots
- [RDS.17] RDS DB instances should be configured to copy tags to snapshots
- [RDS.19] Existing RDS event notification subscriptions should be configured for critical cluster events
- [RDS.20] Existing RDS event notification subscriptions should be configured for critical database instance events
- [RDS.21] An RDS event notifications subscription should be configured for critical database parameter group events
- [RDS.22] An RDS event notifications subscription should be configured for critical database security group events
- [RDS.23] RDS instances should not use a database engine default port
- [RDS.24] RDS Database clusters should use a custom administrator username
- [RDS.25] RDS database instances should use a custom administrator username
- [RDS.26] RDS DB instances should be protected by a backup plan
- [RDS.27] RDS DB clusters should be encrypted at rest
- [RDS.34] Aurora MySQL DB clusters should publish audit logs to CloudWatch Logs
- [RDS.35] RDS DB clusters should have automatic minor version upgrade enabled
- [RDS.36] RDS for PostgreSQL DB instances should publish logs to CloudWatch Logs
- [RDS.37] Aurora PostgreSQL DB clusters should publish logs to CloudWatch Logs
- [RDS.38] RDS for PostgreSQL DB instances should be encrypted in transit
- [RDS.39] RDS for MySQL DB instances should be encrypted in transit
- [RDS.41] RDS for SQL Server DB instances should be encrypted in transit
- [RDS.44] RDS for MariaDB DB instances should be encrypted in transit
- [RDS.45] Aurora MySQL DB clusters should have audit logging enabled
- [Redshift.1] Amazon Redshift clusters should prohibit public access

- [Redshift.2] Connections to Amazon Redshift clusters should be encrypted in transit
- [Redshift.3] Amazon Redshift clusters should have automatic snapshots enabled
- [Redshift.4] Amazon Redshift clusters should have audit logging enabled
- [Redshift.6] Amazon Redshift should have automatic upgrades to major versions enabled
- [Redshift.7] Redshift clusters should use enhanced VPC routing
- [Redshift.8] Amazon Redshift clusters should not use the default Admin username
- [Redshift.10] Redshift clusters should be encrypted at rest
- [Redshift.15] Redshift security groups should allow ingress on the cluster port only from restricted origins
- [Redshift.16] Redshift cluster subnet groups should have subnets from multiple Availability Zones
- [Redshift.18] Redshift clusters should have Multi-AZ deployments enabled
- [RedshiftServerless.1] Amazon Redshift Serverless workgroups should use enhanced VPC routing
- [RedshiftServerless.2] Connections to Redshift Serverless workgroups should be required to use SSL
- [RedshiftServerless.3] Redshift Serverless workgroups should prohibit public access
- [RedshiftServerless.6] Redshift Serverless namespaces should export logs to CloudWatch Logs
- [Route53.2] Route 53 public hosted zones should log DNS queries
- [S3.1] S3 general purpose buckets should have block public access settings enabled
- [S3.2] S3 general purpose buckets should block public read access
- [S3.3] S3 general purpose buckets should block public write access
- [S3.5] S3 general purpose buckets should require requests to use TLS
- [S3.6] S3 general purpose bucket policies should restrict access to other AWS accounts
- [S3.7] S3 general purpose buckets should use cross-Region replication
- [S3.8] S3 general purpose buckets should block public access
- [S3.9] S3 general purpose buckets should have server access logging enabled
- [S3.10] S3 general purpose buckets with versioning enabled should have Lifecycle configurations
- [S3.11] S3 general purpose buckets should have event notifications enabled
- [S3.12] ACLs should not be used to manage user access to S3 general purpose buckets
- [S3.13] S3 general purpose buckets should have Lifecycle configurations

- [S3.14] S3 general purpose buckets should have versioning enabled
- [S3.15] S3 general purpose buckets should have Object Lock enabled
- [S3.17] S3 general purpose buckets should be encrypted at rest with AWS KMS keys
- [S3.19] S3 access points should have block public access settings enabled
- [S3.20] S3 general purpose buckets should have MFA delete enabled
- [S3.22] S3 general purpose buckets should log object-level write events
- [S3.23] S3 general purpose buckets should log object-level read events
- [S3.24] S3 Multi-Region Access Points should have block public access settings enabled
- [SageMaker.1] Amazon SageMaker notebook instances should not have direct internet access
- [SageMaker.2] SageMaker notebook instances should be launched in a custom VPC
- [SageMaker.3] Users should not have root access to SageMaker notebook instances
- [SageMaker.4] SageMaker endpoint production variants should have an initial instance count greater than 1
- [SageMaker.5] SageMaker models should have network isolation enabled
- [SageMaker.8] SageMaker notebook instances should run on supported platforms
- [SecretsManager.1] Secrets Manager secrets should have automatic rotation enabled
- [SecretsManager.2] Secrets Manager secrets configured with automatic rotation should rotate successfully
- [SecretsManager.3] Remove unused Secrets Manager secrets
- [SecretsManager.4] Secrets Manager secrets should be rotated within a specified number of days
- [ServiceCatalog.1] Service Catalog portfolios should be shared within an AWS organization only
- [SNS.1] SNS topics should be encrypted at-rest using AWS KMS
- [SNS.4] SNS topic access policies should not allow public access
- [SQS.1] Amazon SQS queues should be encrypted at rest
- [SQS.3] SQS queue access policies should not allow public access
- [SSM.1] Amazon EC2 instances should be managed by AWS Systems Manager
- [SSM.2] Amazon EC2 instances managed by Systems Manager should have a patch compliance status of COMPLIANT after a patch installation
- [SSM.3] Amazon EC2 instances managed by Systems Manager should have an association compliance status of COMPLIANT
- [SSM.4] SSM documents should not be public

- [SSM.6] SSM Automation should have CloudWatch logging enabled
- [SSM.7] SSM documents should have the block public sharing setting enabled
- [StepFunctions.1] Step Functions state machines should have logging turned on
- [Transfer.2] Transfer Family servers should not use FTP protocol for endpoint connection
- [Transfer.3] Transfer Family connectors should have logging enabled
- [Transfer.4] Transfer Family agreements should be tagged
- [Transfer.6] Transfer Family connectors should be tagged
- [WAF.1] AWS WAF Classic Global Web ACL logging should be enabled
- [WAF.2] AWS WAF Classic Regional rules should have at least one condition
- [WAF.3] AWS WAF Classic Regional rule groups should have at least one rule
- [WAF.4] AWS WAF Classic Regional web ACLs should have at least one rule or rule group
- [WAF.6] AWS WAF Classic global rules should have at least one condition
- [WAF.7] AWS WAF Classic global rule groups should have at least one rule
- [WAF.8] AWS WAF Classic global web ACLs should have at least one rule or rule group
- [WAF.10] AWS WAF web ACLs should have at least one rule or rule group
- [WAF.11] AWS WAF web ACL logging should be enabled
- [WAF.12] AWS WAF rules should have CloudWatch metrics enabled
- [WorkSpaces.1] WorkSpaces user volumes should be encrypted at rest
- [WorkSpaces.2] WorkSpaces root volumes should be encrypted at rest

Service-managed standards in Security Hub CSPM

A service-managed standard is a security standard that another AWS service manages but that you can view in Security Hub CSPM. For example, Service-Managed Standard: AWS Control Tower is a service-managed standard that AWS Control Tower manages. Service-Managed Standard: AWS Organizations is a service-managed standard that Security Hub CSPM creates and manages for the controls that your Security Hub CSPM policies in AWS Organizations enable. A service-managed standard differs from a security standard that AWS Security Hub CSPM manages in the following ways:

- **Standard creation and deletion** – You create and delete a service-managed standard with the managing service's console or API, or with the AWS CLI. Until you create the standard in the managing service in one of those ways, the standard doesn't appear in the Security Hub CSPM

console and isn't accessible by the Security Hub CSPM API or AWS CLI. You don't create Service-Managed Standard: AWS Organizations directly. Security Hub CSPM creates it when an account's effective Security Hub CSPM declarative policy requires it.

- **No automatic enablement of controls** – When you create a service-managed standard, Security Hub CSPM and the managing service don't automatically enable the controls that apply to the standard. In addition, when Security Hub CSPM releases new controls for the standard, they're not automatically enabled. This is a departure from standards that Security Hub CSPM manages. For more information about the usual way of configuring controls in Security Hub CSPM, see Understanding security controls in Security Hub CSPM.
- **Enabling and disabling controls** – We recommend enabling and disabling controls in the managing service to avoid drift. For Service-Managed Standard: AWS Organizations, you enable and disable controls by updating your Security Hub CSPM policies. While a policy governs an account in a Region, you can't enable or disable the standard or its controls through Security Hub CSPM.
- **Availability of controls** – The managing service chooses which controls are available as part of the service-managed standard. Available controls may include all, or a subset of, the existing Security Hub CSPM controls.

After the managing service creates the service-managed standard and makes controls available for it, you can access your control findings, control statuses, and standard security score in the Security Hub CSPM console, Security Hub CSPM API, or AWS CLI. Some or all of this information may also be available in the managing service.

Select a service-managed standard from the following list to view more details about it.

Service-managed standards

- Service-Managed Standard: AWS Control Tower
- Service-Managed Standard: AWS Organizations

Service-Managed Standard: AWS Control Tower

This section provides information about Service-Managed Standard: AWS Control Tower.

What is Service-Managed Standard: AWS Control Tower?

Service-Managed Standard: AWS Control Tower is a service-managed standard which AWS Control Tower manages that supports a subset of Security Hub controls. This standard is designed for users

of AWS Security Hub CSPM and AWS Control Tower. It lets you configure the detective controls of Security Hub CSPM from the AWS Control Tower service.

Detective controls detect noncompliance of resources (for example, misconfigurations) within your AWS accounts.

> **Tip**
>
> Service-managed standards differ from standards that AWS Security Hub CSPM manages. For example, you must create and delete a service-managed standard in the managing service. For more information, see Service-managed standards in Security Hub CSPM.

When you enable a Security Hub CSPM control through AWS Control Tower, Control Tower also enables Security Hub CSPM for you in those specific accounts and Regions, if not already enabled. In the Security Hub CSPM console and API, you can view Service-Managed Standard: AWS Control Tower alongside other Security Hub CSPM standards, once the standard is enabled from AWS Control Tower.

For more information about this standard, see Security Hub CSPM controls in the *AWS Control Tower User Guide*.

Creating the standard

This standard is available in Security Hub CSPM only if you enable Security Hub CSPM controls from AWS Control Tower. AWS Control Tower creates the standard when you first enable an applicable control by using one of the following methods:

- AWS Control Tower console
- AWS Control Tower API (call the `EnableControl` API)
- AWS CLI (run the `enable-control` command)

When you enable a Security Hub CSPM control through AWS Control Tower, if you haven't already enabled Security Hub CSPM, AWS Control Tower also enables Security Hub CSPM for you in those specific accounts and Regions.

To identify an Security Hub CSPM control by control ID in Control Catalog, you can use the field `Implementation.Identifier` in AWS Control Tower. This field maps to Security Hub CSPM control ID and can be used to filter for a specific control ID. To retrieve control metadata for a

specific Security Hub CSPM control (say, "CodeBuild.1") in AWS Control Tower, you can use the `ListControls` API:

```
aws controlcatalog list-controls --filter '{"Implementations":
{"Identifiers":["CodeBuild.1"],"Types":
["AWS::SecurityHub::SecurityControl"]}}'
```

You can't view or access this standard in the Security Hub CSPM console, Security Hub CSPM API, or AWS CLI without first setting up AWS Control Tower and enabling Security Hub CSPM controls from AWS Control Tower using one of the preceding methods.

This standard is only available in the AWS Regions where AWS Control Tower is available.

Enabling and disabling controls in the standard

After you've enabled Security Hub CSPM controls through AWS Control Tower and the Service-Managed Standard: AWS Control Tower standard has been created, you can view the standard and its available controls in Security Hub CSPM.

When Security Hub CSPM adds new controls to the Service-Managed Standard: AWS Control Tower standard, they aren't automatically enabled for customers who have the standard enabled. You should enable and disable controls for the standard from AWS Control Tower by using one of the following methods:

- AWS Control Tower console
- AWS Control Tower API (call the `EnableControl` and `DisableControl` APIs)
- AWS CLI (run the `enable-control` and `disable-control` commands)

When you change the enablement status of a control in AWS Control Tower, the change is also reflected in Security Hub CSPM.

However, disabling a control in Security Hub CSPM that's enabled in AWS Control Tower results in control drift. The control status in AWS Control Tower shows as `Drifted`. You can resolve this drift by using the ResetEnabledControl API to reset the control which is in drift, or by selecting Re-register OU in the AWS Control Tower console, or by disabling and re-enabling the control in AWS Control Tower using one of the preceding methods.

Completing enablement and disablement actions in AWS Control Tower helps you avoid control drift.

When you enable or disable controls in AWS Control Tower, the action applies across accounts and Regions governed by AWS Control Tower. If you enable and disable controls in Security Hub CSPM (not recommended for this standard), the action applies only to the current account and region.

> **Note**
>
> Central configuration can't be used to manage Service-Managed Standard: AWS Control Tower. You can use *only* the AWS Control Tower service to enable and disable controls in this standard.

Viewing enablement status and control status

You can view the enablement status of a control by using one of the following methods:

- Security Hub CSPM console, Security Hub CSPM API, or AWS CLI
- AWS Control Tower console
- AWS Control Tower API to see a list of enabled controls (call the `ListEnabledControls` API)
- AWS CLI to see a list of enabled controls (run the `list-enabled-controls` command)

A control that you disable in AWS Control Tower has an enablement status of `Disabled` in Security Hub CSPM unless you explicitly enable that control in Security Hub CSPM.

Security Hub CSPM calculates control status based on the workflow status and compliance status of the control findings. For more information about enablement status and control status, see Reviewing the details of controls in Security Hub CSPM.

Based on control statuses, Security Hub CSPM calculates a security score for Service-Managed Standard: AWS Control Tower. This score is only available in Security Hub CSPM. In addition, you can only view control findings in Security Hub CSPM. The standard security score and control findings aren't available in AWS Control Tower.

> **Note**
>
> When you enable controls for Service-Managed Standard: AWS Control Tower, Security Hub CSPM may take up to 18 hours to generate findings for controls that use an existing AWS Config service-linked rule. You may have existing service-linked rules if you've enabled

other standards and controls in Security Hub CSPM. For more information, see Schedule for running security checks.

Deleting the standard

You can delete this service managed standard in AWS Control Tower by disabling all applicable controls using one of the following methods:

- AWS Control Tower console
- AWS Control Tower API (call the `DisableControl` API)
- AWS CLI (run the `disable-control` command)

Disabling all controls deletes the standard in all managed accounts and governed Regions in AWS Control Tower. Deleting the standard in AWS Control Tower removes it from the **Standards** page of the Security Hub CSPM console, and you can no longer access it by using the Security Hub CSPM API or AWS CLI.

Note

Disabling all controls from the standard in Security Hub CSPM doesn't disable or delete the standard.

Disabling the Security Hub CSPM service removes Service-Managed Standard: AWS Control Tower and any other standards that you've enabled.

Finding field format for Service-Managed Standard: AWS Control Tower

When you create Service-Managed Standard: AWS Control Tower and enable controls for it, you'll start to receive control findings in Security Hub CSPM. Security Hub CSPM reports control findings in the AWS Security Finding Format (ASFF). These are the ASFF values for this standard's Amazon Resource Name (ARN) and `GeneratorId`:

- **Standard ARN** – `arn:aws:us-east-1:securityhub:::standards/service-managed-aws-control-tower/v/1.0.0`
- **GeneratorId** – `service-managed-aws-control-tower/v/1.0.0/CodeBuild.1`

For a sample finding for Service-Managed Standard: AWS Control Tower, see Samples of control findings.

Controls that apply to Service-Managed Standard: AWS Control Tower

Service-Managed Standard: AWS Control Tower supports a subset of controls that are part of the AWS Foundational Security Best Practices (FSBP) standard. Choose a control to view information about it, including remediation steps for failed findings.

To see what Security Hub CSPM controls are supported by AWS Control Tower, you can use one of the following methods:

- AWS Control Catalog console where you can filter for "`Control owner = AWS Security Hub`"
- AWS Control Catalog API (call the `ListControls` API) with filter for `Implementations` to check for `Types` is `AWS::SecurityHub::SecurityControl`
- AWS CLI (run the `list-controls` command) with filter for `Implementations`. Example CLI command:

```
aws controlcatalog list-controls --filter '{"Implementations":{"Types":
["AWS::SecurityHub::SecurityControl"]}}'
```

Regional limits on Security Hub CSPM controls when enabled through Control Tower standard may not match Regional limits on the underlying controls.

In Security Hub CSPM, if consolidated control findings is turned off in your account, the `ProductFields.ControlId` field in the generated findings uses the standard-based control ID. The standard-based control ID is formatted as **CT.*`ControlId`*** (for example, **CT.CodeBuild.1**).

For more information about this standard, see Security Hub CSPM controls in the *AWS Control Tower User Guide*.

Service-Managed Standard: AWS Organizations

Service-Managed Standard: AWS Organizations holds controls that your AWS Security Hub CSPM declarative policies enable when no enabled standard contains them. This section explains how Security Hub CSPM creates and manages the standard, and how to view its controls and findings.

What is Service-Managed Standard: AWS Organizations?

Service-Managed Standard: AWS Organizations is a service-managed standard that Security Hub CSPM creates and manages for accounts that a Security Hub CSPM policy governs. The standard includes all Security Hub CSPM controls for AWS. Security Hub CSPM uses this standard to enable a control when the account's effective policy enables the control but doesn't enable any standard that contains it.

This situation can occur only in an effective policy. When you create or update a Security Hub CSPM policy, Organizations rejects the policy if a control in `enabled_controls` doesn't belong to a standard that the same policy enables. When Organizations merges several policies that are each valid on their own, the resulting effective policy can still enable a control without enabling a standard that contains it. For example:

- A policy attached to the organization root enables standard A and lists control X in `enabled_controls`.
- A policy attached to an organizational unit (OU) uses `@@assign` to replace the list of enabled standards with standard B, which doesn't include control X.

The effective policy for accounts in that OU enables control X, but no enabled standard contains it. Instead of failing the policy, Security Hub CSPM enables control X through Service-Managed Standard: AWS Organizations.

> **Tip**
>
> Service-managed standards differ from other standards in AWS Security Hub CSPM. For example, you can't create, delete, or configure this standard directly in Security Hub CSPM. For more information, see Service-managed standards in Security Hub CSPM.

For more information about Security Hub CSPM policies and effective policies, see Managing accounts with declarative policies in Security Hub CSPM in this guide and Security Hub CSPM policies in the *AWS Organizations User Guide*.

Creating the standard

You don't create this standard yourself. Security Hub CSPM creates the standard in an account and AWS Region the first time that the account's effective policy enables a control that isn't in any

enabled standard. Security Hub CSPM creates the standard only in Regions where the effective policy enables Security Hub CSPM.

Until Security Hub CSPM creates the standard in an account and Region, you can't see the standard in the Security Hub CSPM console. You also can't access it through the Security Hub CSPM API or AWS CLI in that account and Region.

You can't specify this standard in the `enabled_standards` list of a Security Hub CSPM policy. Security Hub CSPM policies don't configure service-managed standards. For more information, see Security Hub CSPM policy syntax and examples in the *AWS Organizations User Guide*.

This standard is available only in the Regions where Security Hub CSPM policies are available.

Enabling and disabling controls in the standard

Security Hub CSPM enables a control in this standard only when the account's effective policy enables that control and no other enabled standard contains it. When Security Hub CSPM adds new controls to the standard, it doesn't automatically enable them.

While a Security Hub CSPM policy governs an account in a Region, the account can't directly disable this standard or change the enablement status of its controls through the Security Hub CSPM console, Security Hub CSPM API, or AWS CLI. For example, Security Hub CSPM denies BatchDisableStandards, UpdateStandardsControl, and BatchUpdateStandardsControlAssociations requests from governed accounts and Regions.

If a policy no longer governs an account in a Region, you can disable the standard or its controls in that Region. You can't enable the standard or its controls yourself.

> **Note**
>
> You can't use central configuration to manage Service-Managed Standard: AWS Organizations. You can manage this standard only through Security Hub CSPM policies in AWS Organizations.

Viewing enablement status and control status

You can view the enablement status of this standard and its controls by using one of the following methods:

- Security Hub CSPM console

- Security Hub CSPM API (call the GetEnabledStandards and ListStandardsControlAssociations operations)
- AWS CLI (run the get-enabled-standards and list-standards-control-associations commands)

To see the configuration that Security Hub CSPM applies, view the account's effective policy in Organizations. For example, call the DescribeEffectivePolicy API with the `SECURITYHUB_CSPM_POLICY` policy type.

Security Hub CSPM calculates control status based on the workflow status and compliance status of the control findings. For more information about enablement status and control status, see Reviewing the details of controls in Security Hub CSPM.

> **Note**
>
> When Security Hub CSPM enables controls for this standard, it can take up to 18 hours to generate findings for controls that use an existing AWS Config service-linked rule. For more information, see Schedule for running security checks.

Deleting the standard

While a policy governs an account in a Region, you can't delete or disable this standard in that account and Region. If an account's effective Security Hub CSPM policy no longer enables any control that's missing from the enabled standards, Security Hub CSPM automatically disables this standard.

Disabling Security Hub CSPM removes Service-Managed Standard: AWS Organizations and any other standards that you've enabled. This also applies when a Security Hub CSPM policy disables Security Hub CSPM in a Region.

Finding field format for Service-Managed Standard: AWS Organizations

When Security Hub CSPM enables controls for this standard, you start to receive control findings in Security Hub CSPM. Security Hub CSPM reports control findings in the AWS Security Finding Format (ASFF). These are the ASFF values for this standard's Amazon Resource Name (ARN) and `GeneratorId`:

- **Standard ARN** – `arn:aws:securityhub:us-east-1::standards/service-managed-aws-organizations-cspm/v/1.0.0`

- **GeneratorId** – `service-managed-aws-organizations-cspm/v/1.0.0/ACM.1`

For a sample control finding, see Samples of control findings.

Controls that apply to Service-Managed Standard: AWS Organizations

Service-Managed Standard: AWS Organizations supports all Security Hub CSPM controls. For information about each control, including remediation steps for failed findings, see Control reference for Security Hub CSPM.

Regional limits on controls apply to this standard. If a control isn't available in a Region, Security Hub CSPM doesn't enable it in that Region. For more information, see Regional limits on Security Hub CSPM controls.

Enabling a security standard

When you enable a security standard in AWS Security Hub CSPM, Security Hub CSPM automatically creates and enables all the controls that apply to the standard. Security Hub CSPM also starts running security checks and generating findings for the controls.

To optimize coverage and the accuracy of findings, enable and configure resource recording in AWS Config before you enable a standard. When you configure resource recording, also be sure to enable it for all the types of resources that are checked by controls that apply to the standard. Otherwise, Security Hub CSPM might not be able to evaluate the appropriate resources, and generate accurate findings for controls that apply to the standard. For more information, see Enabling and configuring AWS Config for Security Hub CSPM.

Multicloud security standards, such as CIS Azure Foundations Benchmark v4.0.0, have different requirements than AWS standards. Multicloud standards require a Security Hub CSPM connector for the external cloud provider and do not require you to configure AWS Config or manually create a configuration recorder. The Security Hub CSPM multicloud connector automatically sets up a service-linked recorder to evaluate resources in the external cloud environment.

After you enable a standard, you can disable or later re-enable individual controls that apply to the standard. If you disable a control for a standard, Security Hub CSPM stops generating findings for the control. In addition, Security Hub CSPM ignores the control when it calculates the security score for the standard. The security score is the percentage of controls that passed evaluation, relative to the total number of controls that apply to the standard, are enabled, and have evaluation data.

When you enable a standard, Security Hub CSPM generates a preliminary security score for the standard, typically within 30 minutes of your first visit to the **Summary** or **Security standards** page on the Security Hub CSPM console. Security scores are generated only for standards that are enabled when you visit those pages on the console. In addition, resource recording must be configured in AWS Config for the scores to appear. In the China Regions and AWS GovCloud (US) Regions, it can take up to 24 hours for Security Hub CSPM to generate a preliminary security score for a standard. After Security Hub CSPM generates a preliminary score, it updates the score every 24 hours. To determine when a security score was last updated, you can refer to a timestamp that Security Hub CSPM provides for the score. For more information, see Calculating security scores.

How you enable a standard depends on whether you use central configuration to manage Security Hub CSPM for multiple accounts and AWS Regions. We recommend using central configuration if you want to enable standards in multi-account, multi-Region environments. You can use central configuration if you integrate Security Hub CSPM with AWS Organizations. If you don't use central configuration, you must enable each standard separately in each account and each Region.

Topics

- Enabling a standard in multiple accounts and AWS Regions
- Enabling a standard in a single account and AWS Region
- Checking the status of a standard

Enabling a standard in multiple accounts and AWS Regions

To enable and configure a security standard across multiple accounts and AWS Regions, use central configuration. With central configuration, the delegated Security Hub CSPM administrator can create Security Hub CSPM configuration policies that enable one or more standards. The administrator can then associate a configuration policy with individual accounts, organizational units (OUs), or the root. A configuration policy affects the home Region, also referred to as an *aggregation Region*, and all linked Regions.

Configuration policies offer customization options. For example, you might choose to enable only the AWS Foundational Security Best Practices (FSBP) standard for one OU. For another OU, you might choose to enable both the FSBP standard and the Center for Internet Security (CIS) AWS Foundations Benchmark v1.4.0 standard. For information about creating a configuration policy that enables particular standards that you specify, see Creating and associating configuration policies.

If you use central configuration, Security Hub CSPM doesn't automatically enable any standards in new or existing accounts. Instead, the Security Hub CSPM administrator specifies which standards

to enable in different accounts when they create Security Hub CSPM configuration policies for their organization. Security Hub CSPM offers a recommended configuration policy in which only the FSBP standard is enabled. For more information, see Types of configuration policies.

> **Note**
>
> The Security Hub CSPM administrator can use configuration policies to enable any standard except the AWS Control Tower service-managed standard. To enable this standard, the administrator must use AWS Control Tower directly. They must also use AWS Control Tower to enable or disable individual controls in this standard for a centrally managed account.

If you want some accounts to enable and configure standards for their own accounts, the Security Hub CSPM administrator can designate those accounts as *self-managed accounts*. Self-managed accounts must enable and configure standards separately in each Region.

Enabling a standard in a single account and AWS Region

If you don't use central configuration or you have a self-managed account, you can't use configuration policies to centrally enable security standards in multiple accounts or AWS Regions. However, you can enable a standard in a single account and Region. You can do this by using the Security Hub CSPM console or the Security Hub CSPM API.

Security Hub CSPM console

Follow these steps to enable a standard in one account and Region by using the Security Hub CSPM console.

To enable a standard in one account and Region

1. Open the AWS Security Hub CSPM console at https://console.aws.amazon.com/securityhub/.
2. By using the AWS Region selector in the upper-right corner of the page, choose the Region in which you want to enable the standard.
3. In the navigation pane, choose **Security standards**. The **Security standards** page lists all the standards that Security Hub CSPM currently supports. If you already enabled a standard, the section for the standard includes the current security score and additional details for the standard.
4. In the section for the standard that you want to enable, choose **Enable standard**.

To enable the standard in additional Regions, repeat the preceding steps in each additional Region.

Security Hub CSPM API

To enable a standard programmatically in a single account and Region, use the BatchEnableStandards operation. Or, if you're using the AWS Command Line Interface (AWS CLI), run the batch-enable-standards command.

In your request, use the `StandardsArn` parameter to specify the Amazon Resource Name (ARN) of the standard that you want to enable. Also specify the Region that your request applies to. For example, the following command enables the AWS Foundational Security Best Practices (FSBP) standard:

```
$ aws securityhub batch-enable-standards \
--standards-subscription-requests '{"StandardsArn":"arn:aws:securityhub:us-east-1::standards/aws-foundational-security-best-practices/v/1.0.0"}' \
--region us-east-1
```

Where *arn:aws:securityhub:us-east-1::standards/aws-foundational-security-best-practices/v/1.0.0* is the ARN of the FSBP standard in the US East (N. Virginia) Region, and *us-east-1* is the Region in which to enable it.

To obtain the ARN for a standard, use the DescribeStandards operation or, if you're using the AWS CLI, run the describe-standards command.

To first review a list of standards that are currently enabled in your account, you can use the GetEnabledStandards operation. If you're using the AWS CLI, you can run the get-enabled-standards command to retrieve this list.

After you enable a standard, Security Hub CSPM begins performing tasks to enable the standard in the account and the specified Region. This includes creating all the controls that apply to the standard. To monitor the status of these tasks, you can check the status of the standard for the account and Region.

Checking the status of a standard

When you enable a security standard for an account, Security Hub CSPM begins creating all the controls that apply to the standard in the account. Security Hub CSPM also performs additional tasks to enable the standard for the account, such as generating a preliminary security score for

the standard. While Security Hub CSPM performs these tasks, the status of the standard is *Pending* for the account. The status of the standard then passes through additional states, which you can monitor and check.

> **Note**
>
> Changes to individual controls for a standard don't affect the overall status of the standard. For example, if you enable a control that you previously disabled, your change doesn't affect the status of the standard. Similarly, if you change a parameter value for an enabled control, your change doesn't affect the status of the standard.

To check the status of a standard by using the Security Hub CSPM console, choose **Security standards** in the navigation pane. The **Security standards** page lists all the standards that Security Hub CSPM currently supports. If Security Hub CSPM is currently performing tasks to enable the standard, the section for the standard indicates that Security Hub CSPM is still generating a security score for the standard. If a standard is enabled, the section for the standard includes the current score. Choose **View results** to review additional details, including the status of individual controls that apply to the standard. For more information, see Schedule for running security checks.

To check the status of a standard programmatically with the Security Hub CSPM API, use the GetEnabledStandards operation. In your request, optionally use the `StandardsSubscriptionArns` parameter to specify the Amazon Resource Name (ARN) of the standard whose status you want to check. If you're using the AWS Command Line Interface (AWS CLI), you can run the get-enabled-standards command to check the status of a standard. To specify the ARN of the standard to check, use the `standards-subscription-arns` parameter. To determine which ARN to specify, you can use the DescribeStandards operation or, for the AWS CLI, run the describe-standards command.

If your request succeeds, Security Hub CSPM responds with an array of `StandardsSubscription` objects. A *standard subscription* is an AWS resource that Security Hub CSPM creates in an account when a standard is enabled for the account. Each `StandardsSubscription` object provides details about a standard that is currently enabled or is being enabled or disabled for the account. Within each object, the `StandardsStatus` field specifies the current status of the standard for the account.

The status of a standard (`StandardsStatus`) can be one of the following.

PENDING

Security Hub CSPM is currently performing tasks to enable the standard for the account. This includes creating the controls that apply to the standard, and generating a preliminary security score for the standard. It can take several minutes for Security Hub CSPM to complete all the tasks. A standard can also have this status if it's already enabled for the account and Security Hub CSPM is currently adding new controls to the standard.

If a standard has this status, you might not be able to retrieve the details of individual controls that apply to the standard. In addition, you might not be able to configure or disable individual controls for the standard. For example, if you try to disable a control by using the UpdateStandardsControl operation, an error occurs.

To determine whether you can configure or otherwise manage individual controls for the standard, refer to the value for the `StandardsControlsUpdatable` field. If the value for this field is `READY_FOR_UPDATES`, you can start managing individual controls for the standard. Otherwise, wait until Security Hub CSPM completes additional processing tasks to enable the standard.

READY

The standard is currently enabled for the account. Security Hub CSPM can run security checks and generate findings for all the controls that apply to the standard and are currently enabled. Security Hub CSPM can also calculate a security score for the standard.

If a standard has this status, you can retrieve the details of individual controls that apply to the standard. In addition, you can configure, disable, or re-enable the controls. You can also disable the standard.

INCOMPLETE

Security Hub CSPM wasn't able to enable the standard completely for the account. Security Hub CSPM can't run security checks and generate findings for all the controls that apply to the standard and are currently enabled. In addition, Security Hub CSPM can't calculate a security score for the standard.

For multicloud standards, the subscription enters `INCOMPLETE` with a status reason of `NO_AVAILABLE_MULTICLOUD_CONNECTOR` if you enable the standard without a CSPM connector. The subscription automatically transitions to `READY` when a connector becomes available.

To determine why the standard wasn't able to be enabled completely, refer to the information in the `StandardsStatusReason` array. This array specifies issues that prevented Security Hub CSPM from enabling the standard. If an internal error occurred, try enabling the standard for the account again. For other types of issues, check your AWS Config settings. You can also disable individual controls that you don't want to check, or disable the standard completely.

DELETING

Security Hub CSPM is currently processing a request to disable the standard for the account. This includes disabling the controls that apply to the standard, and removing the associated security score. It can take several minutes for Security Hub CSPM to finish processing the request.

If a standard has this status, you can't re-enable the standard or try to disable it again for the account. Security Hub CSPM must finish processing the current request first. In addition, you can't retrieve the details of individual controls that apply to the standard or manage the controls.

FAILED

Security Hub CSPM wasn't able to disable the standard for the account. One or more errors occurred when Security Hub CSPM attempted to disable the standard. In addition, Security Hub CSPM can't calculate a security score for the standard.

To determine why the standard wasn't disabled completely, refer to the information in the `StandardsStatusReason` array. This array specifies issues that prevented Security Hub CSPM from disabling the standard.

If a standard has this status, you can't retrieve the details of individual controls that apply to the standard or manage the controls. You can, however, re-enable the standard for the account. If you address the issues that prevented Security Hub CSPM from disabling the standard, you can also try to disable the standard again.

If the status of a standard is `READY`, Security Hub CSPM runs security checks and generates findings for all the controls that apply to the standard and are currently enabled. For other statuses, Security Hub CSPM might run checks and generate findings for some, but not all, enabled controls. It can take up to 24 hours to generate or update control findings. For more information, see Schedule for running security checks.

Reviewing the details of a security standard

After you enable a security standard in AWS Security Hub CSPM, you can use the console to review the details of the standard. On the console, the details page for a standard includes the following information:

- The current security score for the standard.
- A table of controls that apply to the standard.
- Aggregated statistics for controls that apply to the standard.
- A visual summary of the status of the controls that apply to the standard.
- A visual summary of security checks for controls that are enabled and apply to the standard. If you integrate with AWS Organizations, controls that are enabled in at least one organization account are considered enabled.

To review these details, choose **Security standards** in the navigation pane on the console. Then, in the section for the standard, choose **View results**. For deeper analysis, you can filter and sort the data, and drill down to review the details of individual controls that apply to the standard.

Topics

- Understanding the standard security score
- Reviewing the controls for a standard

Understanding the standard security score

On the AWS Security Hub CSPM console, the details page for a standard displays the security score for the standard. The score is the percentage of controls that passed evaluation, relative to the total number of controls that apply to the standard, are enabled, and have evaluation data. Under the score is a chart that summarizes security checks for controls that are enabled for the standard. This includes the number of passed and failed security checks. For administrator accounts, the standard score and chart are aggregated across the administrator account and all member accounts. To review failed security checks for controls that have a specific severity, choose the severity.

When you enable a standard, Security Hub CSPM generates a preliminary security score for the standard, typically within 30 minutes of your first visit to the **Summary** page or the **Security standards** page on the Security Hub CSPM console. Scores are generated only for standards that

are enabled when you visit those pages. In addition, AWS Config resource recording must be configured for the scores to appear. In the China Regions and AWS GovCloud (US) Regions, it can take up to 24 hours for Security Hub CSPM to generate a preliminary score. After Security Hub CSPM generates a preliminary score for a standard, it updates the score every 24 hours. For more information, see Calculating security scores.

All the data on **Security standards** detail pages is specific to the current AWS Region unless you set an aggregation Region. If you set an aggregation Region, security scores apply across Regions and include findings for all linked Regions. In addition, the compliance status of controls reflects findings from linked Regions, and the number of security checks includes findings from linked Regions.

Reviewing the controls for a standard

When you use the AWS Security Hub CSPM console to review the details of a standard that you enabled, you can review a table of security controls that apply to the standard. For each control, the table includes the following information:

- The control ID and title.
- The status of the control. For more information, see Evaluating compliance status and control status.
- The severity assigned to the control.
- The number of failed checks and the total number of checks. If applicable, the **Failed checks** field also specifies the number of findings with a status of **Unknown**.
- Whether the control supports custom parameters. For more information, see Understanding control parameters in Security Hub CSPM.

Security Hub CSPM updates control statuses and the count of security checks every 24 hours. A timestamp at the top of the page indicates when Security Hub CSPM most recently updated this data.

For administrator accounts, control statuses and the number of security checks are aggregated across the administrator account and all member accounts. The count of enabled controls includes controls that are enabled for the standard in the administrator account or at least one member account. The count of disabled controls includes controls that are disabled for the standard in the administrator account and all member accounts.

You can filter the table of controls that apply to the standard. Using the **Filter by** options next to the table, you can choose to view only enabled or only disabled controls for the standard. If you display only enabled controls, you can further filter the table by control status. You can then focus on controls that have a specific control status. In addition to the **Filter by** options, you can enter filter criteria in the **Filter controls** box. For example, you can filter by control ID or title.

Choose your preferred access method. Then follow the steps to review the controls that apply to a standard that you enabled.

Security Hub CSPM console

To review the controls for an enabled standard

1. Open the AWS Security Hub CSPM console at https://console.aws.amazon.com/securityhub/.
2. Choose **Security standards** in the navigation pane.
3. In the section for the standard, choose **View results**.

The table at the bottom of the page lists all the controls that apply to the standard. You can filter and sort the table. You can also download the current page of the table as a CSV file. To do this, choose **Download** above the table. If you filter the table, the downloaded file includes only the controls that match your current filter settings.

Security Hub CSPM API

To review the controls for an enabled standard

1. Use the ListSecurityControlDefinitions operation of the Security Hub CSPM API. If you're using the AWS CLI, run the list-security-control-definitions command.

   Specify the Amazon Resource Name (ARN) of the standard that you want to review controls for. To obtain ARNs for standards, use the DescribeStandards operation or run the describe-standards command. If you don't specify the ARN for a standard, Security Hub CSPM returns all security control IDs.
2. Use the ListStandardsControlAssociations operation of the Security Hub CSPM API, or run the list-standards-control-associations command. This operation tells you which standards a control is enabled in.

Identify the control by providing the security control ID or ARN. Pagination parameters are optional.

The following example tells you which standards the Config.1 control is enabled in.

```
$ aws securityhub list-standards-control-associations --region us-east-1 --security-control-id Config.1
```

Turning off automatically enabled security standards

If your organization doesn't use central configuration, it uses a configuration type called *local configuration*. With local configuration, AWS Security Hub CSPM can automatically enable default security standards for new member accounts when the accounts join your organization. All the controls that apply to these default standards are also enabled automatically.

Currently, the default security standards are the AWS Foundational Security Best Practices standard and the Center for Internet Security (CIS) AWS Foundations Benchmark v1.2.0 standard. For information about these standards, see the Standards reference for Security Hub CSPM.

If you prefer to manually enable security standards for new member accounts, you can turn off automatic enablement of the default standards. You can do this only if you integrate with AWS Organizations and use local configuration. If you use central configuration, you can instead create a configuration policy that enables the default standards and associate the policy with the root. All of your organization accounts and OUs then inherit this configuration policy unless they are associated with a different policy or are self-managed. If you don't integrate with AWS Organizations, you can disable a default standard when you initially enable Security Hub CSPM or later. To learn how, see Disabling a standard.

To turn off automatic enablement of the default standards for new member accounts, you can use the Security Hub CSPM console or the Security Hub CSPM API.

Security Hub CSPM console

Follow these steps to turn off automatic enablement of the default standards by using the Security Hub CSPM console.

To turn off automatic enablement of default standards

1. Open the AWS Security Hub CSPM console at https://console.aws.amazon.com/securityhub/.

   Sign in using the credentials of the administrator account.
2. In the navigation pane, under **Settings**, choose **Configuration**.
3. In the **Overview** section, choose **Edit**.
4. Under **New account settings**, clear the **Enable the default security standards** checkbox.
5. Choose **Confirm**.

Security Hub CSPM API

To turn off automatic enablement of the default standards programmatically, from the Security Hub CSPM administrator account, use the UpdateOrganizationConfiguration operation of the Security Hub CSPM API. In your request, specify `NONE` for the `AutoEnableStandards` parameter.

If you're using the AWS CLI, run the update-organization-configuration command to turn off automatic enablement of the default standards. For the `auto-enable-standards` parameter, specify `NONE`. For example, the following command automatically enables Security Hub CSPM for new member accounts, and turns off automatic enablement of the default standards for the accounts.

```
$ aws securityhub update-organization-configuration --auto-enable --auto-enable-standards NONE
```

Disabling a security standard

When you disable a security standard in AWS Security Hub CSPM, the following occurs:

- All the controls that apply to the standard are disabled, unless they're associated with another standard that's currently enabled.
- Security checks for the disabled controls are no longer performed, and no additional findings are generated for the disabled controls.
- Existing findings for the disabled controls are archived automatically after approximately 3-5 days.

- AWS Config rules that Security Hub CSPM created for the disabled controls are deleted.

Deletion of the appropriate AWS Config rules typically occurs within a few minutes of disabling a standard. However, it might take longer. If the first request fails to delete the rules, Security Hub CSPM tries again every 12 hours. However, if you disabled Security Hub CSPM or don't have any other standards enabled, Security Hub CSPM can't try again, which means that it can't delete the rules. If this occurs and you need to delete the rules, contact AWS Support.

> **Note**
>
> Disabling a standard can increase AWS Config costs related to disabling the associated rules. Before you disable any standards, we recommend that you review the Considerations for deleting AWS Config rules documentation. Also review how to exclude Resource Compliance configuration items from being recorded when rules tied to an Security Hub CSPM standard are disabled.

Topics

- Disabling a standard in multiple accounts and AWS Regions
- Disabling a standard in a single account and AWS Region

Disabling a standard in multiple accounts and AWS Regions

To disable a security standard across multiple accounts and AWS Regions, use central configuration. With central configuration, the delegated Security Hub CSPM administrator can create Security Hub CSPM configuration policies that disable one or more standards. The administrator can then associate a configuration policy with individual accounts, organizational units (OUs), or the root. A configuration policy affects the home Region, also referred to as an *aggregation Region*, and all linked Regions.

Configuration policies offer customization options. For example, you might choose to disable the Payment Card Industry Data Security Standard (PCI DSS) in one OU. For another OU, you might choose to disable both the PCI DSS and the National Institute of Standards and Technology (NIST) SP 800-53 Rev. 5 standard. For information about creating a configuration policy that enables or disables individual standards that you specify, see Creating and associating configuration policies.

> **Note**
>
> The Security Hub CSPM administrator can use configuration policies to disable any standard except the AWS Control Tower service-managed standard. To disable this standard, the administrator must use AWS Control Tower directly. They must also use AWS Control Tower to disable or enable individual controls in this standard for a centrally managed account.

If you want some accounts to configure or disable standards for their own accounts, the Security Hub CSPM administrator can designate those accounts as *self-managed accounts*. Self-managed accounts must disable standards separately in each Region.

Disabling a standard in a single account and AWS Region

If you don't use central configuration or you have a self-managed account, you can't use configuration policies to centrally disable security standards in multiple accounts or AWS Regions. However, you can disable a standard in a single account and Region. You can do this by using the Security Hub CSPM console or the Security Hub CSPM API.

Security Hub CSPM console

Follow these steps to disable a standard in one account and Region by using the Security Hub CSPM console.

To disable a standard in one account and Region

1. Open the AWS Security Hub CSPM console at https://console.aws.amazon.com/securityhub/.
2. By using the AWS Region selector in the upper-right corner of the page, choose the Region in which you want to disable the standard.
3. In the navigation pane, choose **Security standards**.
4. In the section for the standard that you want to disable, choose **Disable standard**.

To disable the standard in additional Regions, repeat the preceding steps in each additional Region.

Security Hub CSPM API

To disable a standard programmatically in a single account and Region, use the BatchDisableStandards operation. Or, if you're using the AWS Command Line Interface (AWS CLI), run the batch-disable-standards command.

In your request, use the `StandardsSubscriptionArns` parameter to specify the Amazon Resource Name (ARN) of the standard that you want to disable. If you're using the AWS CLI, use the `standards-subscription-arns` parameter to specify the ARN. Also specify the Region that your request applies to. For example, the following command disables the AWS Foundational Security Best Practices (FSBP) standard for an account (*123456789012*):

```
$ aws securityhub batch-disable-standards \
--standards-subscription-arns "arn:aws:securityhub:us-
east-1:123456789012:subscription/aws-foundational-security-best-practices/v/1.0.0" \
--region us-east-1
```

Where *arn:aws:securityhub:us-east-1:123456789012:subscription/aws-foundational-security-best-practices/v/1.0.0* is the ARN of the FSBP standard for the account in the US East (N. Virginia) Region, and *us-east-1* is the Region in which to disable it.

To obtain the ARN for a standard, you can use the GetEnabledStandards operation. This operation retrieves information about the standards that are currently enabled in your account. If you're using the AWS CLI, you can run the get-enabled-standards command to retrieve this information.

After you disable a standard, Security Hub CSPM begins performing tasks to disable the standard in the account and the specified Region. This includes disabling all the controls that apply to the standard. To monitor the status of these tasks, you can check the status of the standard for the account and Region.

Understanding security controls in Security Hub CSPM

In AWS Security Hub CSPM, a *security control*, also referred to as a *control*, is a safeguard within a security standard that helps an organization protect the confidentiality, integrity, and availability of its information. In Security Hub CSPM, a control is related to a specific AWS resource.

When you enable a control in one or more standards, Security Hub CSPM begins running security checks on it. The security checks result in Security Hub CSPM findings. When you disable a control, Security Hub CSPM stops running security checks on it, and findings are no longer generated.

You can enable or disable controls individually for a single account and AWS Region. To save time and reduce configuration drift in multi-account environments, we recommend using central configuration to enable or disable controls. With central configuration, the delegated Security Hub CSPM administrator can create policies that specify how a control should be configured across multiple accounts and Regions. For more information about enabling and disabling controls, see Enabling controls in Security Hub CSPM.

Consolidated controls view

The **Controls** page of the Security Hub CSPM console displays all of the controls available in the current AWS Region (you can view controls in the context of a standard by visiting the **Security standards** page and choosing an enabled standard). Security Hub CSPM assigns controls a consistent security control ID, title, and description across standards. Controls IDs include the relevant AWS service and a unique number (for example, CodeBuild.3).

The following information is available on the **Controls** page of the Security Hub CSPM console:

- An overall security score based on the proportion of passed controls compared to the total number of enabled controls with data
- Breakdown of control statuses across all supported Security Hub CSPM controls
- The number of total passed and failed security checks.
- The number of failed security checks for controls of varying severity, and links to view more details about those failed checks.
- A list of Security Hub CSPM controls, with filters to view specific subsets of controls.

From the **Controls** page, you can choose a control to view its details and take action on the findings generated by the control. From this page, you can also enable or disable a security control in your current AWS account and AWS Region. Enablement and disablement actions from the **Controls** page apply across standards. For more information, see Enabling controls in Security Hub CSPM.

For administrator accounts, the **Controls** page reflects the status of controls across the member accounts. If a control check fails in at least one member account, the control status is **Failed**. If you

have set an aggregation Region, the **Controls** page reflects the status of controls across all linked Regions. If a control check fails in at least one linked Region, the control status is **Failed**.

Consolidated controls view causes changes to control finding fields in the AWS Security Finding Format (ASFF) that may affect workflows. For more information, see Consolidated controls view – ASFF changes.

Summary security score for controls

The **Controls** page displays a summary security score from 0–100 percent. The summary security score is calculated based on the proportion of passed controls compared to the total number of enabled controls with data across standards.

> **Note**
>
> To view the overall security score for controls, you must add permission to call **`BatchGetControlEvaluations`** to the IAM role that you use to access Security Hub CSPM. This permission isn't required to view security scores for specific standards.

When you enable Security Hub CSPM, Security Hub CSPM calculates the initial security score within 30 minutes after your first visit to the **Summary** page or **Security standards** page on the Security Hub CSPM console. It can take up to 24 hours for first-time security scores to be generated in the China Regions and AWS GovCloud (US) Regions.

In addition to the overall security score, Security Hub CSPM calculates a standard security score for each enabled standard within 30 minutes after your first visit to the **Summary** page or **Security standards** page. To view a list of standards that are currently enabled, use the `GetEnabledStandards` API operation.

AWS Config must be enabled with resource recording for scores to appear. For information about how Security Hub CSPM calculates security scores, see Calculating security scores.

After first-time score generation, Security Hub CSPM updates security scores every 24 hours. Security Hub CSPM displays a timestamp to indicate when a security score was last updated.

If you have set an aggregation Region, the overall security score reflects control findings across linked Regions.

Control reference for Security Hub CSPM

This control reference provides a table of available AWS Security Hub CSPM controls with links to more information about each control. In the table, controls are listed in alphabetical order by control ID. Only controls in active use by Security Hub CSPM are included here. Retired controls are excluded from the table.

The table provides the following information for each control:

- **Security control ID** – This ID applies across standards and indicates the AWS service and resource that the control relates to. The Security Hub CSPM console displays security control IDs, regardless of whether consolidated control findings is turned on or off in your account. However, Security Hub CSPM findings reference security control IDs only if consolidated control findings is turned on in your account. If consolidated control findings is turned off in your account, some control IDs vary by standard in your control findings. For a mapping of standard-specific control IDs to security control IDs, see How consolidation impacts control IDs and titles.

  If you want to set up automations for security controls, we recommend filtering based on control ID rather than title or description. Whereas Security Hub CSPM may occasionally update control titles or descriptions, control IDs stay the same.

  Control IDs may skip numbers. These are placeholders for future controls.
- **Security control title** – This title applies across standards. The Security Hub CSPM console displays security control titles, regardless of whether consolidated control findings is turned on or off in your account. However, Security Hub CSPM findings reference security control titles only if consolidated control findings is turned on in your account. If consolidated control findings is turned off in your account, some control titles vary by standard in your control findings. For a mapping of standard-specific control IDs to security control IDs, see How consolidation impacts control IDs and titles.
- **Applicable standards** – Indicates which standards a control applies to. Choose a control to review specific requirements from third-party compliance frameworks.
- **Severity** – The severity of a control identifies its importance from a security standpoint. For information about how Security Hub CSPM determines control severity, see Severity levels for control findings.
- **Supports custom parameters** – Indicates whether the control supports custom values for one or more parameters. Choose a control to review the parameter details. For more information, see Understanding control parameters in Security Hub CSPM.

- **Schedule type** – Indicates when the control is evaluated. For more information, see Schedule for running security checks.

Choose a control to review additional details. Controls are listed in alphabetical order by security control ID.

Security control ID	Security control title	Applicable standards	Severity	Supports custom parameters	Schedule type
Account.1	Security contact information should be provided for an AWS account	CIS AWS Foundations Benchmark v5.0.0, CIS AWS Foundations Benchmark v3.0.0, AWS Foundational Security Best Practices v1.0.0, NIST SP 800-53 Rev. 5, CRI Profile v2.2	MEDIUM	⊗ No	Periodic
Account.2	AWS account should be part of an AWS Organizations organization	NIST SP 800-53 Rev. 5, CRI Profile v2.2	HIGH	⊗ No	Periodic
ACM.1	Imported and ACM-issued certificates should be renewed after a specified time period	AWS Foundational Security Best Practices v1.0.0, NIST SP 800-53 Rev. 5, NIST SP 800-171 Rev. 2, PCI DSS v4.0.1, CRI Profile v2.2	MEDIUM	✓ Yes	Change triggered and periodic
ACM.2	RSA certificates managed by ACM should use a key	AWS Foundational Security Best Practices v1.0.0,	HIGH	⊗ No	Change triggered

Security control ID	Security control title	Applicable standards	Severity	Supports custom parameters	Schedule type
	length of at least 2,048 bits	PCI DSS v4.0.1, CRI Profile v2.2			
ACM.3	ACM certificates should be tagged	AWS Resource Tagging Standard	LOW	Yes	Change triggered
Amplify.1	Amplify apps should be tagged	AWS Resource Tagging Standard	LOW	Yes	Change triggered
Amplify.2	Amplify branches should be tagged	AWS Resource Tagging Standard, CRI Profile v2.2	LOW	Yes	Change triggered
APIGateway.1	API Gateway REST and WebSocket API execution logging should be enabled	AWS Foundational Security Best Practices v1.0.0, NIST SP 800-53 Rev. 5, CRI Profile v2.2	MEDIUM	Yes	Change triggered
APIGateway.2	API Gateway REST API stages should be configured to use SSL certificates for backend authentication	AWS Foundational Security Best Practices v1.0.0, NIST SP 800-53 Rev. 5, NIST SP 800-171 Rev. 2, CRI Profile v2.2	MEDIUM	No	Change triggered
APIGateway.3	API Gateway REST API stages should have AWS X-Ray tracing enabled	AWS Foundational Security Best Practices v1.0.0, NIST SP 800-53 Rev. 5, CRI Profile v2.2	LOW	No	Change triggered

Security control ID	Security control title	Applicable standards	Severity	Supports custom parameters	Schedule type
APIGateway.4	API Gateway should be associated with a WAF Web ACL	AWS Foundational Security Best Practices v1.0.0, NIST SP 800-53 Rev. 5, CRI Profile v2.2	MEDIUM	⊗ No	Change triggered
APIGateway.5	API Gateway REST API cache data should be encrypted at rest	AWS Foundational Security Best Practices v1.0.0, NIST SP 800-53 Rev. 5, CRI Profile v2.2	MEDIUM	⊗ No	Change triggered
APIGateway.8	API Gateway routes should specify an authorization type	AWS Foundational Security Best Practices v1.0.0, NIST SP 800-53 Rev. 5, CRI Profile v2.2	MEDIUM	⊙ Yes	Periodic
APIGateway.9	Access logging should be configured for API Gateway V2 Stages	AWS Foundational Security Best Practices v1.0.0, NIST SP 800-53 Rev. 5, PCI DSS v4.0.1, CRI Profile v2.2	MEDIUM	⊗ No	Change triggered
APIGateway.10	API Gateway V2 integrations should use HTTPS for private connections	AWS Foundational Security Best Practices v1.0.0	MEDIUM	⊗ No	Change triggered

Security control ID	Security control title	Applicable standards	Severity	Supports custom parameters	Schedule type
APIGateway.11	API Gateway domain names should use recommended security policies	AWS Foundational Security Best Practices	MEDIUM	No	Change triggered
AppConfig.1	AWS AppConfig applications should be tagged	AWS Resource Tagging Standard	LOW	Yes	Change triggered
AppConfig.2	AWS AppConfig configuration profiles should be tagged	AWS Resource Tagging Standard	LOW	Yes	Change triggered
AppConfig.3	AWS AppConfig environments should be tagged	AWS Resource Tagging Standard	LOW	Yes	Change triggered
AppConfig.4	AWS AppConfig extension associations should be tagged	AWS Resource Tagging Standard	LOW	Yes	Change triggered
AppFlow.1	Amazon AppFlow flows should be tagged	AWS Resource Tagging Standard, CRI Profile v2.2	LOW	Yes	Change triggered
AppRunner.1	App Runner services should be tagged	AWS Resource Tagging Standard, CRI Profile v2.2	LOW	Yes	Change triggered
AppRunner.2	App Runner VPC connectors should be tagged	AWS Resource Tagging Standard	LOW	Yes	Change triggered

Security control ID	Security control title	Applicable standards	Severity	Supports custom parameters	Schedule type
AppSync.2	AWS AppSync should have field-level logging enabled	AWS Foundational Security Best Practices v1.0.0, PCI DSS v4.0.1, CRI Profile v2.2	MEDIUM	Yes	Change triggered
AppSync.4	AWS AppSync GraphQL APIs should be tagged	AWS Resource Tagging Standard	LOW	Yes	Change triggered
AppSync.5	AWS AppSync GraphQL APIs should not be authenticated with API keys	AWS Foundational Security Best Practices v1.0.0, NIST SP 800-53 Rev. 5, CRI Profile v2.2	HIGH	No	Change triggered
Athena.2	Athena data catalogs should be tagged	AWS Resource Tagging Standard	LOW	Yes	Change triggered
Athena.3	Athena workgroups should be tagged	AWS Resource Tagging Standard	LOW	Yes	Change triggered
Athena.4	Athena workgroups should have logging enabled	AWS Foundational Security Best Practices, CRI Profile v2.2	MEDIUM	No	Change triggered
AutoScaling.1	Auto Scaling groups associated with a load balancer should use ELB health checks	AWS Foundational Security Best Practices, PCI DSS v3.2.1, NIST SP 800-53 Rev. 5, CRI Profile v2.2	LOW	No	Change triggered

Security control ID	Security control title	Applicable standards	Severity	Supports custom parameters	Schedule type
AutoScaling.2	Amazon EC2 Auto Scaling group should cover multiple Availability Zones	AWS Foundational Security Best Practices v1.0.0, NIST SP 800-53 Rev. 5, CRI Profile v2.2	MEDIUM	Yes	Change triggered
AutoScaling.3	Auto Scaling group launch configurations should configure EC2 instances to require Instance Metadata Service Version 2 (IMDSv2)	AWS Foundational Security Best Practices v1.0.0, NIST SP 800-53 Rev. 5, PCI DSS v4.0.1, CRI Profile v2.2	HIGH	No	Change triggered
Autoscaling.5	Amazon EC2 instances launched using Auto Scaling group launch configurations should not have Public IP addresses	AWS Foundational Security Best Practices v1.0.0, NIST SP 800-53 Rev. 5, PCI DSS v4.0.1, CRI Profile v2.2	HIGH	No	Change triggered
AutoScaling.6	Auto Scaling groups should use multiple instance types in multiple Availability Zones	AWS Foundational Security Best Practices v1.0.0, NIST SP 800-53 Rev. 5, CRI Profile v2.2	MEDIUM	No	Change triggered

Security control ID	Security control title	Applicable standards	Severity	Supports custom parameters	Schedule type
AutoScaling.9	EC2 Auto Scaling groups should use EC2 launch templates	AWS Foundational Security Best Practices v1.0.0, NIST SP 800-53 Rev. 5, CRI Profile v2.2	MEDIUM	⊗ No	Change triggered
AutoScaling.10	EC2 Auto Scaling groups should be tagged	AWS Resource Tagging Standard	LOW	⊙ Yes	Change triggered
Backup.1	AWS Backup recovery points should be encrypted at rest	AWS Foundational Security Best Practices v1.0.0, NIST SP 800-53 Rev. 5, CRI Profile v2.2	MEDIUM	⊗ No	Change triggered
Backup.2	AWS Backup recovery points should be tagged	AWS Resource Tagging Standard	LOW	⊙ Yes	Change triggered
Backup.3	AWS Backup vaults should be tagged	AWS Resource Tagging Standard	LOW	⊙ Yes	Change triggered
Backup.4	AWS Backup report plans should be tagged	AWS Resource Tagging Standard	LOW	⊙ Yes	Change triggered
Backup.5	AWS Backup backup plans should be tagged	AWS Resource Tagging Standard	LOW	⊙ Yes	Change triggered
Batch.1	Batch job queues should be tagged	AWS Resource Tagging Standard	LOW	⊙ Yes	Change triggered

Security control ID	Security control title	Applicable standards	Severity	Supports custom parameters	Schedule type
Batch.2	Batch scheduling policies should be tagged	AWS Resource Tagging Standard, CRI Profile v2.2	LOW	✓ Yes	Change triggered
Batch.3	Batch compute environments should be tagged	AWS Resource Tagging Standard	LOW	✓ Yes	Change triggered
Batch.4	Compute resources properties in managed Batch compute environments should be tagged	AWS Resource Tagging Standard, CRI Profile v2.2	LOW	✓ Yes	Change triggered
Bedrock.1	Amazon Bedrock data sources should be encrypted with customer managed AWS KMS keys	NIST SP 800-53 Rev. 5	MEDIUM	✗ No	Change triggered
BedrockAgentCore.1	Bedrock AgentCore runtimes should be configured with VPC network mode	AWS Foundational Security Best Practices	HIGH	✗ No	Change triggered
BedrockAgentCore.2	Bedrock AgentCore Gateways should require authorization for inbound requests	AWS Foundational Security Best Practices	HIGH	✗ No	Change triggered

Security control ID	Security control title	Applicable standards	Severity	Supports custom parameters	Schedule type
BedrockAgentCore.3	Bedrock AgentCore Memory should be encrypted with customer managed AWS KMS keys	NIST SP 800-53 Rev. 5	MEDIUM	⊗ No	Change triggered
BedrockAgentCore.4	Bedrock AgentCore Gateway should be encrypted with customer managed AWS KMS keys	NIST SP 800-53 Rev. 5	MEDIUM	⊗ No	Change triggered
BedrockAgentCore.5	Bedrock AgentCore custom browsers should not use public network mode	AWS Foundational Security Best Practices	HIGH	⊗ No	Change triggered
BedrockAgentCore.6	Bedrock AgentCore custom browsers should have session recording enabled	AWS Foundational Security Best Practices	MEDIUM	⊗ No	Change triggered
BedrockAgentCore.7	Bedrock AgentCore custom code interpreters should use a private network configuration	AWS Foundational Security Best Practices	HIGH	⊗ No	Change triggered
CloudFormation.2	CloudFormation stacks should be tagged	AWS Resource Tagging Standard	LOW	✓ Yes	Change triggered

Security control ID	Security control title	Applicable standards	Severity	Supports custom parameters	Schedule type
CloudFormation.3	CloudFormation stacks should have termination protection enabled	AWS Foundational Security Best Practices	MEDIUM	⊗ No	Change triggered
CloudFormation.4	CloudFormation stacks should have associated service roles	AWS Foundational Security Best Practices	MEDIUM	⊗ No	Change triggered
CloudFront.1	CloudFront distributions should have a default root object configured	AWS Foundational Security Best Practices v1.0.0, NIST SP 800-53 Rev. 5, PCI DSS v4.0.1, CRI Profile v2.2	HIGH	⊗ No	Change triggered
CloudFront.3	CloudFront distributions should require encryption in transit	AWS Foundational Security Best Practices v1.0.0, NIST SP 800-53 Rev. 5, PCI DSS v4.0.1, CRI Profile v2.2	MEDIUM	⊗ No	Change triggered
CloudFront.4	CloudFront distributions should have origin failover configured	AWS Foundational Security Best Practices v1.0.0, NIST SP 800-53 Rev. 5, CRI Profile v2.2	LOW	⊗ No	Change triggered

Security control ID	Security control title	Applicable standards	Severity	Supports custom parameters	Schedule type
CloudFront.5	CloudFront distributions should have logging enabled	AWS Foundational Security Best Practices v1.0.0, NIST SP 800-53 Rev. 5, PCI DSS v4.0.1, CRI Profile v2.2	MEDIUM	⊗ No	Change triggered
CloudFront.6	CloudFront distributions should have WAF enabled	AWS Foundational Security Best Practices v1.0.0, NIST SP 800-53 Rev. 5, PCI DSS v4.0.1, CRI Profile v2.2	MEDIUM	⊗ No	Change triggered
CloudFront.7	CloudFront distributions should use custom SSL/TLS certificates	AWS Foundational Security Best Practices v1.0.0, NIST SP 800-53 Rev. 5, NIST SP 800-171 Rev. 2, CRI Profile v2.2	LOW	⊗ No	Change triggered
CloudFront.8	CloudFront distributions should use SNI to serve HTTPS requests	AWS Foundational Security Best Practices v1.0.0, NIST SP 800-53 Rev. 5, CRI Profile v2.2	LOW	⊗ No	Change triggered

Security control ID	Security control title	Applicable standards	Severity	Supports custom parameters	Schedule type
CloudFront.9	CloudFront distributions should encrypt traffic to custom origins	AWS Foundational Security Best Practices v1.0.0, NIST SP 800-53 Rev. 5, PCI DSS v4.0.1, CRI Profile v2.2	MEDIUM	⊗ No	Change triggered
CloudFront.10	CloudFront distributions should not use deprecated SSL protocols between edge locations and custom origins	AWS Foundational Security Best Practices v1.0.0, NIST SP 800-53 Rev. 5, NIST SP 800-171 Rev. 2, PCI DSS v4.0.1, CRI Profile v2.2	MEDIUM	⊗ No	Change triggered
CloudFront.12	CloudFront distributions should not point to non-existent S3 origins	AWS Foundational Security Best Practices v1.0.0, NIST SP 800-53 Rev. 5, PCI DSS v4.0.1, CRI Profile v2.2	HIGH	⊗ No	Periodic
CloudFront.13	CloudFront distributions should use origin access control	AWS Foundational Security Best Practices v1.0.0, CRI Profile v2.2	MEDIUM	⊗ No	Change triggered
CloudFront.14	CloudFront distributions should be tagged	AWS Resource Tagging Standard	LOW	⊘ Yes	Change triggered

Security control ID	Security control title	Applicable standards	Severity	Supports custom parameters	Schedule type
CloudFront.15	CloudFront distributions should use the recommended TLS security policy	AWS Foundational Security Best Practices v1.0.0, CRI Profile v2.2	MEDIUM	⊗ No	Change triggered
CloudFront.16	CloudFront distributions should use origin access control for Lambda function URL origins	AWS Foundational Security Best Practices v1.0.0	MEDIUM	⊗ No	Change triggered
CloudFront.17	CloudFront distributions should use trusted key groups for signed URLs and cookies	AWS Foundational Security Best Practices v1.0.0	MEDIUM	⊗ No	Change triggered
CloudTrail.1	CloudTrail should be enabled and configured with at least one multi-Region trail that includes read and write management events	CIS AWS Foundations Benchmark v5.0.0, CIS AWS Foundations Benchmark v3.0.0, CIS AWS Foundations Benchmark v1.4.0, CIS AWS Foundations Benchmark v1.2.0, AWS Foundational Security Best Practices, NIST SP 800-53 Rev. 5, CRI Profile v2.2	HIGH	⊗ No	Periodic

Security control ID	Security control title	Applicable standards	Severity	Supports custom parameters	Schedule type
CloudTrail.2	CloudTrail should have encryption at-rest enabled	CIS AWS Foundations Benchmark v5.0.0, CIS AWS Foundations Benchmark v3.0.0, CIS AWS Foundations Benchmark v1.2.0, CIS AWS Foundations Benchmark v1.4.0 AWS Foundational Security Best Practices v1.0.0, NIST SP 800-53 Rev. 5, NIST SP 800-171 Rev. 2, PCI DSS v3.2.1, PCI DSS v4.0.1, CRI Profile v2.2	MEDIUM	⊗ No	Periodic
CloudTrail.3	At least one CloudTrail trail should be enabled	NIST SP 800-171 Rev. 2, PCI DSS v4.0.1, PCI DSS v3.2.1, CRI Profile v2.2	HIGH	⊗ No	Periodic

Security control ID	Security control title	Applicable standards	Severity	Supports custom parameters	Schedule type
CloudTrail.4	CloudTrail log file validation should be enabled	CIS AWS Foundations Benchmark v5.0.0, CIS AWS Foundations Benchmark v3.0.0, CIS AWS Foundations Benchmark v1.4.0, CIS AWS Foundations Benchmark v1.2.0, AWS Foundational Security Best Practices v1.0.0, NIST SP 800-53 Rev. 5, NIST SP 800-171 Rev. 2, PCI DSS v4.0.1, PCI DSS v3.2.1, CRI Profile v2.2	LOW	⊗ No	Periodic
CloudTrail.5	CloudTrail trails should be integrated with Amazon CloudWatch Logs	CIS AWS Foundations Benchmark v1.2.0, CIS AWS Foundations Benchmark v1.4.0, AWS Foundational Security Best Practices v1.0.0, NIST SP 800-53 Rev. 5, PCI DSS v3.2.1, PCI DSS v4.0.1, CRI Profile v2.2	MEDIUM	⊗ No	Periodic

Security control ID	Security control title	Applicable standards	Severity	Supports custom parameters	Schedule type
CloudTrail.6	Ensure the S3 bucket used to store CloudTrail logs is not publicly accessible	CIS AWS Foundations Benchmark v1.2.0, CIS AWS Foundations Benchmark v1.4.0, PCI DSS v4.0.1, CRI Profile v2.2	CRITICAL	No	Change triggered and periodic
CloudTrail.7	Ensure S3 bucket access logging is enabled on the CloudTrail S3 bucket	CIS AWS Foundations Benchmark v5.0.0, CIS AWS Foundations Benchmark v3.0.0, CIS AWS Foundations Benchmark v1.2.0, CIS AWS Foundations Benchmark v1.4.0, CIS AWS Foundations Benchmark v3.0.0, PCI DSS v4.0.1, CRI Profile v2.2	LOW	No	Periodic
CloudTrail.9	CloudTrail trails should be tagged	AWS Resource Tagging Standard	LOW	Yes	Change triggered
CloudTrail.10	CloudTrail Lake event data stores should be encrypted with customer managed AWS KMS keys	NIST SP 800-53 Rev. 5	MEDIUM	Yes	Periodic

Security control ID	Security control title	Applicable standards	Severity	Supports custom parameters	Schedule type
CloudWatch.1	A log metric filter and alarm should exist for usage of the "root" user	CIS AWS Foundations Benchmark v1.4.0, CIS AWS Foundations Benchmark v1.2.0, NIST SP 800-171 Rev. 2, PCI DSS v3.2.1, CRI Profile v2.2	LOW	⊗ No	Periodic
CloudWatch.2	Ensure a log metric filter and alarm exist for unauthorized API calls	CIS AWS Foundations Benchmark v1.2.0, NIST SP 800-171 Rev. 2, CRI Profile v2.2	LOW	⊗ No	Periodic
CloudWatch.3	Ensure a log metric filter and alarm exist for Management Console sign-in without MFA	CIS AWS Foundations Benchmark v1.2.0, CRI Profile v2.2	LOW	⊗ No	Periodic
CloudWatch.4	Ensure a log metric filter and alarm exist for IAM policy changes	CIS AWS Foundations Benchmark v1.4.0, CIS AWS Foundations Benchmark v1.2.0, NIST SP 800-171 Rev. 2, CRI Profile v2.2	LOW	⊗ No	Periodic
CloudWatch.5	Ensure a log metric filter and alarm exist for CloudTrail configuration changes	CIS AWS Foundations Benchmark v1.4.0, CIS AWS Foundations Benchmark v1.2.0, NIST SP 800-171 Rev. 2, CRI Profile v2.2	LOW	⊗ No	Periodic

Security control ID	Security control title	Applicable standards	Severity	Supports custom parameters	Schedule type
CloudWatch.6	Ensure a log metric filter and alarm exist for AWS Management Console authentication failures	CIS AWS Foundations Benchmark v1.4.0, CIS AWS Foundations Benchmark v1.2.0, NIST SP 800-171 Rev. 2, CRI Profile v2.2	LOW	⊗ No	Periodic
CloudWatch.7	Ensure a log metric filter and alarm exist for disabling or scheduled deletion of customer created CMKs	CIS AWS Foundations Benchmark v1.4.0, CIS AWS Foundations Benchmark v1.2.0, NIST SP 800-171 Rev. 2, CRI Profile v2.2	LOW	⊗ No	Periodic
CloudWatch.8	Ensure a log metric filter and alarm exist for S3 bucket policy changes	CIS AWS Foundations Benchmark v1.4.0, CIS AWS Foundations Benchmark v1.2.0, NIST SP 800-171 Rev. 2, CRI Profile v2.2	LOW	⊗ No	Periodic
CloudWatch.9	Ensure a log metric filter and alarm exist for AWS Config configuration changes	CIS AWS Foundations Benchmark v1.4.0, CIS AWS Foundations Benchmark v1.2.0, NIST SP 800-171 Rev. 2, CRI Profile v2.2	LOW	⊗ No	Periodic

Security control ID	Security control title	Applicable standards	Severity	Supports custom parameters	Schedule type
CloudWatch.10	Ensure a log metric filter and alarm exist for security group changes	CIS AWS Foundations Benchmark v1.4.0, CIS AWS Foundations Benchmark v1.2.0, NIST SP 800-171 Rev. 2, CRI Profile v2.2	LOW	⊗ No	Periodic
CloudWatch.11	Ensure a log metric filter and alarm exist for changes to Network Access Control Lists (NACL)	CIS AWS Foundations Benchmark v1.4.0, CIS AWS Foundations Benchmark v1.2.0, NIST SP 800-171 Rev. 2, CRI Profile v2.2	LOW	⊗ No	Periodic
CloudWatch.12	Ensure a log metric filter and alarm exist for changes to network gateways	CIS AWS Foundations Benchmark v1.4.0, CIS AWS Foundations Benchmark v1.2.0, NIST SP 800-171 Rev. 2, CRI Profile v2.2	LOW	⊗ No	Periodic
CloudWatch.13	Ensure a log metric filter and alarm exist for route table changes	CIS AWS Foundations Benchmark v1.4.0, CIS AWS Foundations Benchmark v1.2.0, NIST SP 800-171 Rev. 2, CRI Profile v2.2	LOW	⊗ No	Periodic

Security control ID	Security control title	Applicable standards	Severity	Supports custom parameters	Schedule type
CloudWatch.14	Ensure a log metric filter and alarm exist for VPC changes	CIS AWS Foundations Benchmark v1.4.0, CIS AWS Foundations Benchmark v1.2.0, NIST SP 800-171 Rev. 2, CRI Profile v2.2	LOW	No	Periodic
CloudWatch.15	CloudWatch alarms should have specified actions configured	NIST SP 800-53 Rev. 5, NIST SP 800-171 Rev. 2, CRI Profile v2.2	HIGH	Yes	Change triggered
CloudWatch.16	CloudWatch log groups should be retained for a specified time period	NIST SP 800-53 Rev. 5, CRI Profile v2.2	MEDIUM	Yes	Periodic
CloudWatch.17	CloudWatch alarm actions should be enabled	NIST SP 800-53 Rev. 5, CRI Profile v2.2	HIGH	No	Change triggered
CodeArtifact.1	CodeArtifact repositories should be tagged	AWS Resource Tagging Standard	LOW	Yes	Change triggered
CodeBuild.1	CodeBuild Bitbucket source repository URLs should not contain sensitive credentials	AWS Foundational Security Best Practices, NIST SP 800-53 Rev. 5, PCI DSS v3.2.1, PCI DSS v4.0.1, CRI Profile v2.2	CRITICAL	No	Change triggered

Security control ID	Security control title	Applicable standards	Severity	Supports custom parameters	Schedule type
CodeBuild.2	CodeBuild project environment variables should not contain clear text credentials	AWS Foundational Security Best Practices, NIST SP 800-53 Rev. 5, PCI DSS v3.2.1, PCI DSS v4.0.1, CRI Profile v2.2	CRITICAL	⊗ No	Change triggered
CodeBuild.3	CodeBuild S3 logs should be encrypted	AWS Foundational Security Best Practices, NIST SP 800-53 Rev. 5, PCI DSS v4.0.1, CRI Profile v2.2	LOW	⊗ No	Change triggered
CodeBuild.4	CodeBuild project environments should have a logging configuration	AWS Foundational Security Best Practices v1.0.0, NIST SP 800-53 Rev. 5, CRI Profile v2.2	MEDIUM	⊗ No	Change triggered
CodeBuild.7	CodeBuild report group exports should be encrypted at rest	AWS Foundational Security Best Practices, CRI Profile v2.2	MEDIUM	⊗ No	Change triggered
CodeGuruProfiler.1	CodeGuru Profiler profiling groups should be tagged	AWS Resource Tagging Standard, CRI Profile v2.2	LOW	⊙ Yes	Change triggered
CodeGuruReviewer.1	CodeGuru Reviewer repository associations should be tagged	AWS Resource Tagging Standard, CRI Profile v2.2	LOW	⊙ Yes	Change triggered

Security control ID	Security control title	Applicable standards	Severity	Supports custom parameters	Schedule type
Cognito.1	Cognito user pools should have threat protection activated with full function enforcement mode for standard authentication	AWS Foundational Security Best Practices	MEDIUM	Yes	Change triggered
Cognito.2	Cognito identity pools should not allow unauthenticated identities	AWS Foundational Security Best Practices, CRI Profile v2.2	MEDIUM	No	Change triggered
Cognito.3	Password policies for Cognito user pools should have strong configurations	AWS Foundational Security Best Practices, CRI Profile v2.2	MEDIUM	Yes	Change triggered
Cognito.4	Cognito user pools should have threat protection activated with full function enforcement mode for custom authentication	AWS Foundational Security Best Practices	MEDIUM	No	Change triggered
Cognito.5	MFA should be enabled for Cognito user pools	AWS Foundational Security Best Practices	MEDIUM	No	Change triggered
Cognito.6	Cognito user pools should have deletion protection enabled	AWS Foundational Security Best Practices	MEDIUM	No	Change triggered

Security control ID	Security control title	Applicable standards	Severity	Supports custom parameters	Schedule type
Config.1	AWS Config should be enabled and use the service-linked role for resource recording	CIS AWS Foundations Benchmark v5.0.0, CIS AWS Foundations Benchmark v3.0.0, CIS AWS Foundations Benchmark v1.4.0, CIS AWS Foundations Benchmark v1.2.0, AWS Foundational Security Best Practices, NIST SP 800-53 Rev. 5, PCI DSS v3.2.1, CRI Profile v2.2	CRITICAL	Yes	Periodic
Connect.1	Connect Customer Customer Profiles object types should be tagged	AWS Resource Tagging Standard	LOW	Yes	Change triggered
Connect.2	Connect Customer instances should have CloudWatch logging enabled	AWS Foundational Security Best Practices, CRI Profile v2.2	MEDIUM	No	Change triggered
DataFirehose.1	Firehose delivery streams should be encrypted at rest	AWS Foundational Security Best Practices, NIST SP 800-53 Rev. 5, CRI Profile v2.2	MEDIUM	No	Periodic

Security control ID	Security control title	Applicable standards	Severity	Supports custom parameters	Schedule type
DataSync.1	DataSync tasks should have logging enabled	AWS Foundational Security Best Practices, CRI Profile v2.2	MEDIUM	⊗ No	Change triggered
DataSync.2	DataSync tasks should be tagged	AWS Resource Tagging Standard, CRI Profile v2.2	LOW	⊙ Yes	Change triggered
Detective.1	Detective behavior graphs should be tagged	AWS Resource Tagging Standard	LOW	⊙ Yes	Change triggered
DMS.1	Database Migration Service replication instances should not be public	AWS Foundational Security Best Practices, NIST SP 800-53 Rev. 5, PCI DSS v3.2.1, PCI DSS v4.0.1, CRI Profile v2.2	CRITICAL	⊗ No	Periodic
DMS.2	DMS certificates should be tagged	AWS Resource Tagging Standard	LOW	⊙ Yes	Change triggered
DMS.3	DMS event subscriptions should be tagged	AWS Resource Tagging Standard	LOW	⊙ Yes	Change triggered
DMS.4	DMS replication instances should be tagged	AWS Resource Tagging Standard	LOW	⊙ Yes	Change triggered

Security control ID	Security control title	Applicable standards	Severity	Supports custom parameters	Schedule type
DMS.5	DMS replication subnet groups should be tagged	AWS Resource Tagging Standard	LOW	Yes	Change triggered
DMS.6	DMS replication instances should have automatic minor version upgrade enabled	AWS Foundational Security Best Practices, NIST SP 800-53 Rev. 5, PCI DSS v4.0.1, CRI Profile v2.2	MEDIUM	No	Change triggered
DMS.7	DMS replication tasks for the target database should have logging enabled	AWS Foundational Security Best Practices, NIST SP 800-53 Rev. 5, PCI DSS v4.0.1, CRI Profile v2.2	MEDIUM	No	Change triggered
DMS.8	DMS replication tasks for the source database should have logging enabled	AWS Foundational Security Best Practices, NIST SP 800-53 Rev. 5, PCI DSS v4.0.1, CRI Profile v2.2	MEDIUM	No	Change triggered
DMS.9	DMS endpoints should use SSL	AWS Foundational Security Best Practices, NIST SP 800-53 Rev. 5, PCI DSS v4.0.1, CRI Profile v2.2	MEDIUM	No	Change triggered

Security control ID	Security control title	Applicable standards	Severity	Supports custom parameters	Schedule type
DMS.10	DMS endpoints for Neptune databases should have IAM authorization enabled	AWS Foundational Security Best Practices, NIST SP 800-53 Rev. 5, PCI DSS v4.0.1, CRI Profile v2.2	MEDIUM	⊗ No	Change triggered
DMS.11	DMS endpoints for MongoDB should have an authentication mechanism enabled	AWS Foundational Security Best Practices, NIST SP 800-53 Rev. 5, PCI DSS v4.0.1, CRI Profile v2.2	MEDIUM	⊗ No	Change triggered
DMS.12	DMS endpoints for Redis OSS should have TLS enabled	AWS Foundational Security Best Practices, NIST SP 800-53 Rev. 5, PCI DSS v4.0.1, CRI Profile v2.2	MEDIUM	⊗ No	Change triggered
DMS.13	DMS replication instances should be configured to use multiple Availability Zones	AWS Foundational Security Best Practices	MEDIUM	⊗ No	Change triggered
DocumentDB.1	Amazon DocumentDB clusters should be encrypted at rest	AWS Foundational Security Best Practices v1.0.0, NIST SP 800-53 Rev. 5, CRI Profile v2.2	MEDIUM	⊗ No	Change triggered

Security control ID	Security control title	Applicable standards	Severity	Supports custom parameters	Schedule type
DocumentDB.2	Amazon DocumentDB clusters should have an adequate backup retention period	AWS Foundational Security Best Practices, NIST SP 800-53 Rev. 5, PCI DSS v4.0.1, CRI Profile v2.2	MEDIUM	Yes	Change triggered
DocumentDB.3	Amazon DocumentDB manual cluster snapshots should not be public	AWS Foundational Security Best Practices, NIST SP 800-53 Rev. 5, PCI DSS v4.0.1, CRI Profile v2.2	CRITICAL	No	Change triggered
DocumentDB.4	Amazon DocumentDB clusters should publish audit logs to CloudWatch Logs	AWS Foundational Security Best Practices, NIST SP 800-53 Rev. 5, PCI DSS v4.0.1, CRI Profile v2.2	MEDIUM	No	Change triggered
DocumentDB.5	Amazon DocumentDB clusters should have deletion protection enabled	AWS Foundational Security Best Practices v1.0.0, NIST SP 800-53 Rev. 5, CRI Profile v2.2	MEDIUM	No	Change triggered
DocumentDB.6	Amazon DocumentDB clusters should be encrypted in transit	AWS Foundational Security Best Practices, CRI Profile v2.2	MEDIUM	No	Periodic

Security control ID	Security control title	Applicable standards	Severity	Supports custom parameters	Schedule type
DynamoDB 1	DynamoDB tables should automatically scale capacity with demand	AWS Foundational Security Best Practices v1.0.0, NIST SP 800-53 Rev. 5, CRI Profile v2.2	MEDIUM	Yes	Periodic
DynamoDB 2	DynamoDB tables should have point-in-time recovery enabled	AWS Foundational Security Best Practices v1.0.0, NIST SP 800-53 Rev. 5, CRI Profile v2.2	MEDIUM	No	Change triggered
DynamoDB 3	DynamoDB Accelerator (DAX) clusters should be encrypted at rest	AWS Foundational Security Best Practices v1.0.0, NIST SP 800-53 Rev. 5, CRI Profile v2.2	MEDIUM	No	Periodic
DynamoDB 4	DynamoDB tables should be present in a backup plan	NIST SP 800-53 Rev. 5, CRI Profile v2.2	MEDIUM	Yes	Periodic
DynamoDB 5	DynamoDB tables should be tagged	AWS Resource Tagging Standard	LOW	Yes	Change triggered
DynamoDB 6	DynamoDB tables should have deletion protection enabled	AWS Foundational Security Best Practices v1.0.0, NIST SP 800-53 Rev. 5, CRI Profile v2.2	MEDIUM	No	Change triggered

Security control ID	Security control title	Applicable standards	Severity	Supports custom parameters	Schedule type
DynamoDB 7	DynamoDB Accelerator clusters should be encrypted in transit	AWS Foundational Security Best Practices, NIST SP 800-53 Rev. 5, PCI DSS v4.0.1, CRI Profile v2.2	MEDIUM	⊗ No	Periodic
EC2.1	EBS snapshots should not be publicly restorable	AWS Foundational Security Best Practices v1.0.0, PCI DSS v3.2.1, NIST SP 800-53 Rev. 5, CRI Profile v2.2	CRITICAL	⊗ No	Periodic
EC2.2	VPC default security groups should not allow inbound or outbound traffic	CIS AWS Foundations Benchmark v5.0.0, CIS AWS Foundations Benchmark v3.0.0, CIS AWS Foundations Benchmark v1.2.0, AWS Foundational Security Best Practices v1.0.0, PCI DSS v3.2.1, CIS AWS Foundations Benchmark v1.4.0, NIST SP 800-53 Rev. 5, CRI Profile v2.2	HIGH	⊗ No	Change triggered

Security control ID	Security control title	Applicable standards	Severity	Supports custom parameters	Schedule type
EC2.3	Attached EBS volumes should be encrypted at-rest	AWS Foundational Security Best Practices v1.0.0, NIST SP 800-53 Rev. 5, CRI Profile v2.2	MEDIUM	⊗ No	Change triggered
EC2.4	Stopped EC2 instances should be removed after a specified time period	AWS Foundational Security Best Practices v1.0.0, NIST SP 800-53 Rev. 5, CRI Profile v2.2	MEDIUM	⊙ Yes	Periodic
EC2.6	VPC flow logging should be enabled in all VPCs	CIS AWS Foundations Benchmark v5.0.0, CIS AWS Foundations Benchmark v3.0.0, CIS AWS Foundations Benchmark v1.2.0, AWS Foundational Security Best Practices v1.0.0, PCI DSS v3.2.1, CIS AWS Foundations Benchmark v1.4.0, NIST SP 800-53 Rev. 5, NIST SP 800-171 Rev. 2, CRI Profile v2.2	MEDIUM	⊗ No	Periodic

Security control ID	Security control title	Applicable standards	Severity	Supports custom parameters	Schedule type
EC2.7	EBS default encryption should be enabled	CIS AWS Foundations Benchmark v5.0.0, CIS AWS Foundations Benchmark v3.0.0, AWS Foundational Security Best Practices v1.0.0, CIS AWS Foundations Benchmark v1.4.0, NIST SP 800-53 Rev. 5, CRI Profile v2.2	MEDIUM	⊗ No	Periodic
EC2.8	EC2 instances should use Instance Metadata Service Version 2 (IMDSv2)	CIS AWS Foundations Benchmark v5.0.0, CIS AWS Foundations Benchmark v3.0.0, AWS Foundational Security Best Practices, NIST SP 800-53 Rev. 5, PCI DSS v4.0.1, CRI Profile v2.2	HIGH	⊗ No	Change triggered
EC2.9	EC2 instances should not have a public IPv4 address	AWS Foundational Security Best Practices v1.0.0, NIST SP 800-53 Rev. 5, CRI Profile v2.2	HIGH	⊗ No	Change triggered

Security control ID	Security control title	Applicable standards	Severity	Supports custom parameters	Schedule type
EC2.10	Amazon EC2 should be configured to use VPC endpoints that are created for the Amazon EC2 service	AWS Foundational Security Best Practices v1.0.0, NIST SP 800-53 Rev. 5, NIST SP 800-171 Rev. 2, CRI Profile v2.2	MEDIUM	⊗ No	Periodic
EC2.12	Unused EC2 EIPs should be removed	PCI DSS v3.2.1, NIST SP 800-53 Rev. 5, CRI Profile v2.2	LOW	⊗ No	Change triggered
EC2.13	Security groups should not allow ingress from 0.0.0.0/0 or ::/0 to port 22	CIS AWS Foundations Benchmark v1.2.0, PCI DSS v3.2.1, PCI DSS v4.0.1, NIST SP 800-53 Rev. 5, NIST SP 800-171 Rev. 2, CRI Profile v2.2	HIGH	⊗ No	Change triggered and periodic
EC2.14	Security groups should not allow ingress from 0.0.0.0/0 or ::/0 to port 3389	CIS AWS Foundations Benchmark v1.2.0, PCI DSS v4.0.1, CRI Profile v2.2	HIGH	⊗ No	Change triggered and periodic
EC2.15	EC2 subnets should not automatically assign public IP addresses	AWS Foundational Security Best Practices, NIST SP 800-53 Rev. 5, PCI DSS v4.0.1, CRI Profile v2.2	MEDIUM	⊗ No	Change triggered

Security control ID	Security control title	Applicable standards	Severity	Supports custom parameters	Schedule type
EC2.16	Unused Network Access Control Lists should be removed	AWS Foundational Security Best Practices, NIST SP 800-53 Rev. 5, NIST SP 800-171 Rev. 2, PCI DSS v4.0.1, CRI Profile v2.2	LOW	No	Change triggered
EC2.17	EC2 instances should not use multiple ENIs	AWS Foundational Security Best Practices v1.0.0, NIST SP 800-53 Rev. 5, CRI Profile v2.2	LOW	No	Change triggered
EC2.18	Security groups should only allow unrestricted incoming traffic for authorized ports	AWS Foundational Security Best Practices v1.0.0, NIST SP 800-53 Rev. 5, NIST SP 800-171 Rev. 2, CRI Profile v2.2	HIGH	Yes	Change triggered
EC2.19	Security groups should not allow unrestricted access to ports with high risk	AWS Foundational Security Best Practices, NIST SP 800-53 Rev. 5, NIST SP 800-171 Rev. 2, CRI Profile v2.2	CRITICAL	No	Change triggered and periodic

Security control ID	Security control title	Applicable standards	Severity	Supports custom parameters	Schedule type
EC2.20	Both VPN tunnels for an AWS Site-to-Site VPN connection should be up	AWS Foundational Security Best Practices v1.0.0, NIST SP 800-53 Rev. 5, NIST SP 800-171 Rev. 2, CRI Profile v2.2	MEDIUM	⊗ No	Change triggered
EC2.21	Network ACLs should not allow ingress from 0.0.0.0/0 to port 22 or port 3389	CIS AWS Foundations Benchmark v5.0.0, CIS AWS Foundations Benchmark v3.0.0, CIS AWS Foundations Benchmark v1.4.0, AWS Foundational Security Best Practices, NIST SP 800-53 Rev. 5, NIST SP 800-171 Rev. 2, PCI DSS v4.0.1, CRI Profile v2.2	MEDIUM	⊗ No	Change triggered
EC2.22	Unused EC2 security groups should be removed	CRI Profile v2.2	MEDIUM	⊗ No	Periodic
EC2.23	EC2 Transit Gateways should not automatically accept VPC attachment requests	AWS Foundational Security Best Practices v1.0.0, NIST SP 800-53 Rev. 5, CRI Profile v2.2	HIGH	⊗ No	Change triggered

Security control ID	Security control title	Applicable standards	Severity	Supports custom parameters	Schedule type
EC2.24	EC2 paravirtual instance types should not be used	AWS Foundational Security Best Practices v1.0.0, NIST SP 800-53 Rev. 5, CRI Profile v2.2	MEDIUM	No	Change triggered
EC2.25	EC2 launch templates should not assign public IPs to network interfaces	AWS Foundational Security Best Practices, NIST SP 800-53 Rev. 5, PCI DSS v4.0.1, CRI Profile v2.2	HIGH	No	Change triggered
EC2.28	EBS volumes should be in a backup plan	NIST SP 800-53 Rev. 5, CRI Profile v2.2	LOW	Yes	Periodic
EC2.33	EC2 transit gateway attachments should be tagged	AWS Resource Tagging Standard	LOW	Yes	Change triggered
EC2.34	EC2 transit gateway route tables should be tagged	AWS Resource Tagging Standard	LOW	Yes	Change triggered
EC2.35	EC2 network interfaces should be tagged	AWS Resource Tagging Standard	LOW	Yes	Change triggered
EC2.36	EC2 customer gateways should be tagged	AWS Resource Tagging Standard	LOW	Yes	Change triggered

Security control ID	Security control title	Applicable standards	Severity	Supports custom parameters	Schedule type
EC2.37	EC2 Elastic IP addresses should be tagged	AWS Resource Tagging Standard	LOW	Yes	Change triggered
EC2.38	EC2 instances should be tagged	AWS Resource Tagging Standard	LOW	Yes	Change triggered
EC2.39	EC2 internet gateways should be tagged	AWS Resource Tagging Standard	LOW	Yes	Change triggered
EC2.40	EC2 NAT gateways should be tagged	AWS Resource Tagging Standard	LOW	Yes	Change triggered
EC2.41	EC2 network ACLs should be tagged	AWS Resource Tagging Standard	LOW	Yes	Change triggered
EC2.42	EC2 route tables should be tagged	AWS Resource Tagging Standard	LOW	Yes	Change triggered
EC2.43	EC2 security groups should be tagged	AWS Resource Tagging Standard	LOW	Yes	Change triggered
EC2.44	EC2 subnets should be tagged	AWS Resource Tagging Standard	LOW	Yes	Change triggered
EC2.45	EC2 volumes should be tagged	AWS Resource Tagging Standard	LOW	Yes	Change triggered
EC2.46	Amazon VPCs should be tagged	AWS Resource Tagging Standard	LOW	Yes	Change triggered

Security control ID	Security control title	Applicable standards	Severity	Supports custom parameters	Schedule type
EC2.47	Amazon VPC endpoint services should be tagged	AWS Resource Tagging Standard	LOW	Yes	Change triggered
EC2.48	Amazon VPC flow logs should be tagged	AWS Resource Tagging Standard	LOW	Yes	Change triggered
EC2.49	Amazon VPC peering connections should be tagged	AWS Resource Tagging Standard	LOW	Yes	Change triggered
EC2.50	EC2 VPN gateways should be tagged	AWS Resource Tagging Standard	LOW	Yes	Change triggered
EC2.51	EC2 Client VPN endpoints should have client connection logging enabled	AWS Foundational Security Best Practices, NIST SP 800-53 Rev. 5, NIST SP 800-171 Rev. 2, PCI DSS v4.0.1, CRI Profile v2.2	LOW	No	Change triggered
EC2.52	EC2 transit gateways should be tagged	AWS Resource Tagging Standard	LOW	Yes	Change triggered
EC2.53	EC2 security groups should not allow ingress from 0.0.0.0/0 to remote server administration ports	CIS AWS Foundations Benchmark v5.0.0, CIS AWS Foundations Benchmark v3.0.0, PCI DSS v4.0.1, CRI Profile v2.2	HIGH	No	Periodic

Security control ID	Security control title	Applicable standards	Severity	Supports custom parameters	Schedule type
EC2.54	EC2 security groups should not allow ingress from ::/0 to remote server administration ports	CIS AWS Foundations Benchmark v5.0.0, CIS AWS Foundations Benchmark v3.0.0, PCI DSS v4.0.1, CRI Profile v2.2	HIGH	No	Periodic
EC2.55	VPCs should be configured with an interface endpoint for ECR API	AWS Foundational Security Best Practices, NIST SP 800-53 Rev. 5	MEDIUM	Yes	Periodic
EC2.56	VPCs should be configured with an interface endpoint for Docker Registry	AWS Foundational Security Best Practices, NIST SP 800-53 Rev. 5	MEDIUM	Yes	Periodic
EC2.57	VPCs should be configured with an interface endpoint for Systems Manager	AWS Foundational Security Best Practices, NIST SP 800-53 Rev. 5	MEDIUM	Yes	Periodic
EC2.58	VPCs should be configured with an interface endpoint for Systems Manager Incident Manager Contacts	AWS Foundational Security Best Practices, NIST SP 800-53 Rev. 5	MEDIUM	Yes	Periodic

Security control ID	Security control title	Applicable standards	Severity	Supports custom parameters	Schedule type
EC2.60	VPCs should be configured with an interface endpoint for Systems Manager Incident Manager	AWS Foundational Security Best Practices, NIST SP 800-53 Rev. 5	MEDIUM	Yes	Periodic
EC2.170	EC2 launch templates should use Instance Metadata Service Version 2 (IMDSv2)	AWS Foundational Security Best Practices, PCI DSS v4.0.1, CRI Profile v2.2	LOW	No	Change triggered
EC2.171	EC2 VPN connections should have logging enabled	AWS Foundational Security Best Practices, PCI DSS v4.0.1, CRI Profile v2.2	MEDIUM	No	Change triggered
EC2.172	EC2 VPC Block Public Access settings should block internet gateway traffic	AWS Foundational Security Best Practices	MEDIUM	Yes	Change triggered
EC2.173	EC2 Spot Fleet requests with launch parameters should enable encryption for attached EBS volumes	AWS Foundational Security Best Practices, CRI Profile v2.2	MEDIUM	No	Change triggered
EC2.174	EC2 DHCP option sets should be tagged	AWS Resource Tagging Standard, CRI Profile v2.2	LOW	Yes	Change triggered

Security control ID	Security control title	Applicable standards	Severity	Supports custom parameters	Schedule type
EC2.175	EC2 launch templates should be tagged	AWS Resource Tagging Standard	LOW	Yes	Change triggered
EC2.176	EC2 prefix lists should be tagged	AWS Resource Tagging Standard, CRI Profile v2.2	LOW	Yes	Change triggered
EC2.177	EC2 traffic mirror sessions should be tagged	AWS Resource Tagging Standard, CRI Profile v2.2	LOW	Yes	Change triggered
EC2.178	EC2 traffic mirror filters should be tagged	AWS Resource Tagging Standard, CRI Profile v2.2	LOW	Yes	Change triggered
EC2.179	EC2 traffic mirror targets should be tagged	AWS Resource Tagging Standard	LOW	Yes	Change triggered
EC2.180	EC2 network interfaces should have source/destination checking enabled	AWS Foundational Security Best Practices v1.0.0, CRI Profile v2.2	MEDIUM	No	Change triggered
EC2.181	EC2 launch templates should enable encryption for attached EBS volumes	AWS Foundational Security Best Practices v1.0.0, CRI Profile v2.2	MEDIUM	No	Change triggered

Security control ID	Security control title	Applicable standards	Severity	Supports custom parameters	Schedule type
EC2.182	EBS Snapshots should not be publicly accessible	AWS Foundational Security Best Practices	HIGH	⊗ No	Change triggered
EC2.183	EC2 VPN connections should use IKEv2 protocol	AWS Foundational Security Best Practices	MEDIUM	⊗ No	Change triggered
ECR.1	ECR private repositories should have image scanning configured	AWS Foundational Security Best Practices v1.0.0, NIST SP 800-53 Rev. 5, PCI DSS v4.0.1, CRI Profile v2.2	HIGH	⊗ No	Periodic
ECR.2	ECR private repositories should have tag immutability configured	AWS Foundational Security Best Practices v1.0.0, NIST SP 800-53 Rev. 5, CRI Profile v2.2	MEDIUM	⊗ No	Change triggered
ECR.3	ECR repositories should have at least one lifecycle policy configured	AWS Foundational Security Best Practices v1.0.0, NIST SP 800-53 Rev. 5, CRI Profile v2.2	MEDIUM	⊗ No	Change triggered
ECR.4	ECR public repositories should be tagged	AWS Resource Tagging Standard	LOW	⊙ Yes	Change triggered

Security control ID	Security control title	Applicable standards	Severity	Supports custom parameters	Schedule type
ECR.5	ECR repositories should be encrypted with customer managed AWS KMS keys	NIST SP 800-53 Rev. 5	MEDIUM	Yes	Change triggered
ECS.2	ECS services should not have public IP addresses assigned to them automatically	AWS Foundational Security Best Practices, NIST SP 800-53 Rev. 5, PCI DSS v4.0.1, CRI Profile v2.2	HIGH	No	Change triggered
ECS.3	ECS task definitions should not share the host's process namespace	AWS Foundational Security Best Practices v1.0.0, NIST SP 800-53 Rev. 5, CRI Profile v2.2	HIGH	No	Change triggered
ECS.4	ECS containers should run as non-privileged	AWS Foundational Security Best Practices v1.0.0, NIST SP 800-53 Rev. 5, CRI Profile v2.2	HIGH	No	Change triggered
ECS.5	ECS containers should be limited to read-only access to root filesystems	AWS Foundational Security Best Practices v1.0.0, NIST SP 800-53 Rev. 5, CRI Profile v2.2	HIGH	No	Change triggered

Security control ID	Security control title	Applicable standards	Severity	Supports custom parameters	Schedule type
ECS.8	Secrets should not be passed as container environment variables	AWS Foundational Security Best Practices, NIST SP 800-53 Rev. 5, PCI DSS v4.0.1, CRI Profile v2.2	HIGH	⊗ No	Change triggered
ECS.9	ECS task definitions should have a logging configuration	AWS Foundational Security Best Practices v1.0.0, NIST SP 800-53 Rev. 5, CRI Profile v2.2	HIGH	⊗ No	Change triggered
ECS.10	ECS Fargate services should run on the latest Fargate platform version	AWS Foundational Security Best Practices, NIST SP 800-53 Rev. 5, PCI DSS v4.0.1, CRI Profile v2.2	MEDIUM	⊗ No	Change triggered
ECS.12	ECS clusters should use Container Insights	AWS Foundational Security Best Practices v1.0.0, NIST SP 800-53 Rev. 5, CRI Profile v2.2	MEDIUM	⊗ No	Change triggered
ECS.13	ECS services should be tagged	AWS Resource Tagging Standard	LOW	⊙ Yes	Change triggered
ECS.14	ECS clusters should be tagged	AWS Resource Tagging Standard	LOW	⊙ Yes	Change triggered

Security control ID	Security control title	Applicable standards	Severity	Supports custom parameters	Schedule type
ECS.15	ECS task definitions should be tagged	AWS Resource Tagging Standard	LOW	Yes	Change triggered
ECS.16	ECS task sets should not automatically assign public IP addresses	AWS Foundational Security Best Practices, PCI DSS v4.0.1, CRI Profile v2.2	HIGH	No	Change triggered
ECS.17	ECS task definitions should not use host network mode	NIST SP 800-53 Rev. 5, CRI Profile v2.2	MEDIUM	No	Change triggered
ECS.18	ECS Task Definitions should use in-transit encryption for EFS volumes	AWS Foundational Security Best Practices	MEDIUM	No	Change triggered
ECS.19	ECS capacity providers should have managed termination protection enabled	AWS Foundational Security Best Practices	MEDIUM	No	Change triggered
ECS.20	ECS Task Definitions should configure non-root users in Linux container definitions	AWS Foundational Security Best Practices	MEDIUM	No	Change triggered

Security control ID	Security control title	Applicable standards	Severity	Supports custom parameters	Schedule type
ECS.21	ECS Task Definitions should configure non-administrator users in Windows container definitions	AWS Foundational Security Best Practices	MEDIUM	⊗ No	Change triggered
EFS.1	Elastic File System should be configured to encrypt file data at-rest using AWS KMS	CIS AWS Foundations Benchmark v5.0.0, CIS AWS Foundations Benchmark v3.0.0, AWS Foundational Security Best Practices v1.0.0, NIST SP 800-53 Rev. 5, CRI Profile v2.2	MEDIUM	⊗ No	Periodic
EFS.2	Amazon EFS volumes should be in backup plans	AWS Foundational Security Best Practices v1.0.0, NIST SP 800-53 Rev. 5, CRI Profile v2.2	MEDIUM	⊗ No	Periodic
EFS.3	EFS access points should enforce a root directory	AWS Foundational Security Best Practices v1.0.0, NIST SP 800-53 Rev. 5, CRI Profile v2.2	MEDIUM	⊗ No	Change triggered

Security control ID	Security control title	Applicable standards	Severity	Supports custom parameters	Schedule type
EFS.4	EFS access points should enforce a user identity	AWS Foundational Security Best Practices, NIST SP 800-53 Rev. 5, PCI DSS v4.0.1, CRI Profile v2.2	MEDIUM	⊗ No	Change triggered
EFS.5	EFS access points should be tagged	AWS Resource Tagging Standard	LOW	⊙ Yes	Change triggered
EFS.6	EFS mount targets should not be associated with subnets that assign public IP addresses on launch	NIST SP 800-53 Rev. 5, NIST SP 800-171 Rev. 2, PCI DSS v4.0.1, CRI Profile v2.2	MEDIUM	⊗ No	Periodic
EFS.7	EFS file systems should have automatic backups enabled	AWS Foundational Security Best Practices, CRI Profile v2.2	MEDIUM	⊗ No	Change triggered
EFS.8	EFS file systems should be encrypted at rest	CIS AWS Foundations Benchmark v5.0.0, AWS Foundational Security Best Practices, CRI Profile v2.2	MEDIUM	⊙ Yes	Change triggered

Security control ID	Security control title	Applicable standards	Severity	Supports custom parameters	Schedule type
EKS.1	EKS cluster endpoints should not be publicly accessible	AWS Foundational Security Best Practices, NIST SP 800-53 Rev. 5, PCI DSS v4.0.1, CRI Profile v2.2	HIGH	⊗ No	Periodic
EKS.2	EKS clusters should run on a supported Kubernetes version	AWS Foundational Security Best Practices, NIST SP 800-53 Rev. 5, PCI DSS v4.0.1, CRI Profile v2.2	HIGH	⊗ No	Change triggered
EKS.6	EKS clusters should be tagged	AWS Resource Tagging Standard	LOW	⊙ Yes	Change triggered
EKS.7	EKS identity provider configurations should be tagged	AWS Resource Tagging Standard	LOW	⊙ Yes	Change triggered
EKS.8	EKS clusters should have audit logging enabled	AWS Foundational Security Best Practices, NIST SP 800-53 Rev. 5, PCI DSS v4.0.1, CRI Profile v2.2	MEDIUM	⊗ No	Change triggered
EKS.9	EKS node groups should run on a supported Kubernetes version	AWS Foundational Security Best Practices	HIGH	⊗ No	Change triggered

Security control ID	Security control title	Applicable standards	Severity	Supports custom parameters	Schedule type
ElastiCache.1	ElastiCache (Redis OSS) clusters should have automatic backups enabled	AWS Foundational Security Best Practices v1.0.0, NIST SP 800-53 Rev. 5, CRI Profile v2.2	HIGH	Yes	Periodic
ElastiCache.2	ElastiCache clusters should have automatic minor version upgrades enabled	AWS Foundational Security Best Practices, NIST SP 800-53 Rev. 5, PCI DSS v4.0.1, CRI Profile v2.2	HIGH	No	Periodic
ElastiCache.3	ElastiCache replication groups should have automatic failover enabled	AWS Foundational Security Best Practices v1.0.0, NIST SP 800-53 Rev. 5, CRI Profile v2.2	MEDIUM	No	Periodic
ElastiCache.4	ElastiCache replication groups should be encrypted-at-rest	AWS Foundational Security Best Practices v1.0.0, NIST SP 800-53 Rev. 5, CRI Profile v2.2	MEDIUM	No	Periodic
ElastiCache.5	ElastiCache replication groups should be encrypted-in-transit	AWS Foundational Security Best Practices, NIST SP 800-53 Rev. 5, PCI DSS v4.0.1, CRI Profile v2.2	MEDIUM	No	Periodic

Security control ID	Security control title	Applicable standards	Severity	Supports custom parameters	Schedule type
ElastiCache.6	ElastiCache (Redis OSS) replication groups of earlier versions should have Redis OSS AUTH enabled	AWS Foundational Security Best Practices, NIST SP 800-53 Rev. 5, PCI DSS v4.0.1, CRI Profile v2.2	MEDIUM	No	Periodic
ElastiCache.7	ElastiCache clusters should not use the default subnet group	AWS Foundational Security Best Practices v1.0.0, NIST SP 800-53 Rev. 5, CRI Profile v2.2	HIGH	No	Periodic
ElasticBeanstalk.1	Elastic Beanstalk environments should have enhanced health reporting enabled	AWS Foundational Security Best Practices v1.0.0, NIST SP 800-53 Rev. 5, CRI Profile v2.2	LOW	No	Change triggered
ElasticBeanstalk.2	Elastic Beanstalk managed platform updates should be enabled	AWS Foundational Security Best Practices, NIST SP 800-53 Rev. 5, PCI DSS v4.0.1, CRI Profile v2.2	HIGH	Yes	Change triggered
ElasticBeanstalk.3	Elastic Beanstalk should stream logs to CloudWatch	AWS Foundational Security Best Practices, PCI DSS v4.0.1, CRI Profile v2.2	HIGH	Yes	Change triggered

Security control ID	Security control title	Applicable standards	Severity	Supports custom parameters	Schedule type
ELB.1	Application Load Balancer should be configured to redirect all HTTP requests to HTTPS	AWS Foundational Security Best Practices v1.0.0, PCI DSS v3.2.1, NIST SP 800-53 Rev. 5, CRI Profile v2.2	MEDIUM	⊗ No	Periodic
ELB.2	Classic Load Balancers with SSL/HTTPS listeners should use a certificate provided by AWS Certificate Manager	AWS Foundational Security Best Practices v1.0.0, NIST SP 800-53 Rev. 5, NIST SP 800-171 Rev. 2, CRI Profile v2.2	MEDIUM	⊗ No	Change triggered
ELB.3	Classic Load Balancer listeners should be configured with HTTPS or TLS termination	AWS Foundational Security Best Practices, NIST SP 800-53 Rev. 5, NIST SP 800-171 Rev. 2, PCI DSS v4.0.1, CRI Profile v2.2	MEDIUM	⊗ No	Change triggered
ELB.4	Application Load Balancer should be configured to drop http headers	AWS Foundational Security Best Practices, NIST SP 800-53 Rev. 5, PCI DSS v4.0.1, CRI Profile v2.2	MEDIUM	⊗ No	Change triggered

Security control ID	Security control title	Applicable standards	Severity	Supports custom parameters	Schedule type
ELB.5	Application and Classic Load Balancers logging should be enabled	AWS Foundational Security Best Practices v1.0.0, NIST SP 800-53 Rev. 5, CRI Profile v2.2	MEDIUM	⊗ No	Change triggered
ELB.6	Application, Gateway, and Network Load Balancers should have deletion protection enabled	AWS Foundational Security Best Practices, NIST SP 800-53 Rev. 5, CRI Profile v2.2	MEDIUM	⊗ No	Change triggered
ELB.7	Classic Load Balancers should have connection draining enabled	AWS Foundational Security Best Practices v1.0.0, NIST SP 800-53 Rev. 5, CRI Profile v2.2	LOW	⊗ No	Change triggered
ELB.8	Classic Load Balancers with SSL listeners should use a predefined security policy that has strong configuration	AWS Foundational Security Best Practices, NIST SP 800-53 Rev. 5, NIST SP 800-171 Rev. 2, PCI DSS v4.0.1, CRI Profile v2.2	MEDIUM	⊗ No	Change triggered
ELB.9	Classic Load Balancers should have cross-zone load balancing enabled	AWS Foundational Security Best Practices v1.0.0, NIST SP 800-53 Rev. 5, CRI Profile v2.2	MEDIUM	⊗ No	Change triggered

Security control ID	Security control title	Applicable standards	Severity	Supports custom parameters	Schedule type
ELB.10	Classic Load Balancer should span multiple Availability Zones	AWS Foundational Security Best Practices v1.0.0, NIST SP 800-53 Rev. 5, CRI Profile v2.2	MEDIUM	Yes	Change triggered
ELB.12	Application Load Balancer should be configured with defensive or strictest desync mitigation mode	AWS Foundational Security Best Practices, NIST SP 800-53 Rev. 5, PCI DSS v4.0.1, CRI Profile v2.2	MEDIUM	No	Change triggered
ELB.13	Application, Network and Gateway Load Balancers should span multiple Availability Zones	AWS Foundational Security Best Practices v1.0.0, NIST SP 800-53 Rev. 5, CRI Profile v2.2	MEDIUM	Yes	Change triggered
ELB.14	Classic Load Balancer should be configured with defensive or strictest desync mitigation mode	AWS Foundational Security Best Practices, NIST SP 800-53 Rev. 5, PCI DSS v4.0.1, CRI Profile v2.2	MEDIUM	No	Change triggered
ELB.16	Application Load Balancers should be associated with an AWS WAF web ACL	NIST SP 800-53 Rev. 5, CRI Profile v2.2	MEDIUM	No	Change triggered

Security control ID	Security control title	Applicable standards	Severity	Supports custom parameters	Schedule type
ELB.17	Application and Network Load Balancers with listeners should use recommended security policies	AWS Foundational Security Best Practices v1.0.0, NIST SP 800-53 Rev. 5, CRI Profile v2.2	MEDIUM	⊗ No	Change triggered
ELB.18	Application and Network Load Balancer listeners should use secure protocols to encrypt data in transit	AWS Foundational Security Best Practices v1.0.0, CRI Profile v2.2	MEDIUM	⊗ No	Change triggered
ELB.21	Application and Network Load Balancer target groups should use encrypted health check protocols	AWS Foundational Security Best Practices v1.0.0, CRI Profile v2.2	MEDIUM	⊗ No	Change triggered
ELB.22	ELB target groups should use encrypted transport protocols	AWS Foundational Security Best Practices v1.0.0, CRI Profile v2.2	MEDIUM	⊗ No	Change triggered
EMR.1	Amazon EMR cluster primary nodes should not have public IP addresses	AWS Foundational Security Best Practices, NIST SP 800-53 Rev. 5, PCI DSS v4.0.1, CRI Profile v2.2	HIGH	⊗ No	Periodic

Security control ID	Security control title	Applicable standards	Severity	Supports custom parameters	Schedule type
EMR.2	Amazon EMR block public access setting should be enabled	AWS Foundational Security Best Practices, NIST SP 800-53 Rev. 5, PCI DSS v4.0.1, CRI Profile v2.2	CRITICAL	⊗ No	Periodic
EMR.3	Amazon EMR security configurations should be encrypted at rest	AWS Foundational Security Best Practices, NIST SP 800-53 Rev. 5, CRI Profile v2.2	MEDIUM	⊗ No	Change triggered
EMR.4	Amazon EMR security configurations should be encrypted in transit	AWS Foundational Security Best Practices, NIST SP 800-53 Rev. 5, CRI Profile v2.2	MEDIUM	⊗ No	Change triggered
ES.1	Elasticsearch domains should have encryption at-rest enabled	AWS Foundational Security Best Practices v1.0.0, PCI DSS v3.2.1, NIST SP 800-53 Rev. 5, CRI Profile v2.2	MEDIUM	⊗ No	Periodic

Security control ID	Security control title	Applicable standards	Severity	Supports custom parameters	Schedule type
ES.2	Elasticsearch domains should not be publicly accessible	AWS Foundational Security Best Practices, PCI DSS v3.2.1, PCI DSS v4.0.1, NIST SP 800-53 Rev. 5, CRI Profile v2.2	CRITICAL	⊗ No	Periodic
ES.3	Elasticsearch domains should encrypt data sent between nodes	AWS Foundational Security Best Practices, NIST SP 800-53 Rev. 5, PCI DSS v4.0.1, CRI Profile v2.2	MEDIUM	⊗ No	Change triggered
ES.4	Elasticsearch domain error logging to CloudWatch Logs should be enabled	AWS Foundational Security Best Practices v1.0.0, NIST SP 800-53 Rev. 5, CRI Profile v2.2	MEDIUM	⊗ No	Change triggered
ES.5	Elasticsearch domains should have audit logging enabled	AWS Foundational Security Best Practices, NIST SP 800-53 Rev. 5, CRI Profile v2.2	MEDIUM	⊗ No	Change triggered
ES.6	Elasticsearch domains should have at least three data nodes	AWS Foundational Security Best Practices v1.0.0, NIST SP 800-53 Rev. 5, CRI Profile v2.2	MEDIUM	⊗ No	Change triggered

Security control ID	Security control title	Applicable standards	Severity	Supports custom parameters	Schedule type
ES.7	Elasticsearch domains should be configured with at least three dedicated master nodes	AWS Foundational Security Best Practices v1.0.0, NIST SP 800-53 Rev. 5, CRI Profile v2.2	MEDIUM	⊗ No	Change triggered
ES.8	Connections to Elasticsearch domains should be encrypted using the latest TLS security policy	AWS Foundational Security Best Practices, NIST SP 800-53 Rev. 5, PCI DSS v4.0.1, CRI Profile v2.2	MEDIUM	⊗ No	Change triggered
ES.9	Elasticsearch domains should be tagged	AWS Resource Tagging Standard	LOW	⊙ Yes	Change triggered
EventBridge.2	EventBridge event buses should be tagged	AWS Resource Tagging Standard	LOW	⊙ Yes	Change triggered
EventBridge.3	EventBridge custom event buses should have a resource-based policy attached	AWS Foundational Security Best Practices, NIST SP 800-53 Rev. 5, PCI DSS v4.0.1, CRI Profile v2.2	LOW	⊗ No	Change triggered
EventBridge.4	EventBridge global endpoints should have event replication enabled	NIST SP 800-53 Rev. 5, CRI Profile v2.2	MEDIUM	⊗ No	Change triggered

Security control ID	Security control title	Applicable standards	Severity	Supports custom parameters	Schedule type
FraudDetector.1	Amazon Fraud Detector entity types should be tagged	AWS Resource Tagging Standard	LOW	Yes	Change triggered
FraudDetector.2	Amazon Fraud Detector labels should be tagged	AWS Resource Tagging Standard	LOW	Yes	Change triggered
FraudDetector.3	Amazon Fraud Detector outcomes should be tagged	AWS Resource Tagging Standard	LOW	Yes	Change triggered
FraudDetector.4	Amazon Fraud Detector variables should be tagged	AWS Resource Tagging Standard	LOW	Yes	Change triggered
FSx.1	FSx for OpenZFS file systems should be configured to copy tags to backups and volumes	AWS Foundational Security Best Practices v1.0.0, NIST SP 800-53 Rev. 5, CRI Profile v2.2	LOW	No	Periodic
FSx.2	FSx for Lustre file systems should be configured to copy tags to backups	AWS Foundational Security Best Practices, NIST SP 800-53 Rev. 5, CRI Profile v2.2	LOW	No	Periodic
FSx.3	FSx for OpenZFS file systems should be configured for Multi-AZ deployment	AWS Foundational Security Best Practices, CRI Profile v2.2	MEDIUM	No	Periodic

Security control ID	Security control title	Applicable standards	Severity	Supports custom parameters	Schedule type
FSx.4	FSx for NetApp ONTAP file systems should be configured for Multi-AZ deployment	AWS Foundational Security Best Practices	MEDIUM	Yes	Periodic
FSx.5	FSx for Windows File Server file systems should be configured for Multi-AZ deployment	AWS Foundational Security Best Practices, CRI Profile v2.2	MEDIUM	No	Periodic
Glue.1	AWS Glue jobs should be tagged	AWS Resource Tagging Standard	LOW	Yes	Change triggered
Glue.3	AWS Glue machine learning transforms should be encrypted at rest	AWS Foundational Security Best Practices, CRI Profile v2.2	MEDIUM	No	Change triggered
Glue.4	AWS Glue Spark jobs should run on supported versions of AWS Glue	AWS Foundational Security Best Practices, NIST SP 800-53 Rev. 5, CRI Profile v2.2	MEDIUM	No	Change triggered
GlobalAccelerator.1	Global Accelerator accelerators should be tagged	AWS Resource Tagging Standard	LOW	Yes	Change triggered

Security control ID	Security control title	Applicable standards	Severity	Supports custom parameters	Schedule type
GuardDuty.1	GuardDuty should be enabled	AWS Foundational Security Best Practices, NIST SP 800-53 Rev. 5, NIST SP 800-171 Rev. 2, PCI DSS v3.2.1, PCI DSS v4.0.1, CRI Profile v2.2	HIGH	No	Periodic
GuardDuty.2	GuardDuty filters should be tagged	AWS Resource Tagging Standard	LOW	Yes	Change triggered
GuardDuty.3	GuardDuty IPSets should be tagged	AWS Resource Tagging Standard	LOW	Yes	Change triggered
GuardDuty.4	GuardDuty detectors should be tagged	AWS Resource Tagging Standard	LOW	Yes	Change triggered
GuardDuty.5	GuardDuty EKS Audit Log Monitoring should be enabled	AWS Foundational Security Best Practices, CRI Profile v2.2	HIGH	No	Periodic
GuardDuty.6	GuardDuty Lambda Protection should be enabled	AWS Foundational Security Best Practices, PCI DSS v4.0.1, CRI Profile v2.2	HIGH	No	Periodic

Security control ID	Security control title	Applicable standards	Severity	Supports custom parameters	Schedule type
GuardDuty.7	GuardDuty EKS Runtime Monitoring should be enabled	AWS Foundational Security Best Practices, PCI DSS v4.0.1, CRI Profile v2.2	HIGH	⊗ No	Periodic
GuardDuty.8	GuardDuty Malware Protection for EC2 should be enabled	AWS Foundational Security Best Practices, CRI Profile v2.2	HIGH	⊗ No	Periodic
GuardDuty.9	GuardDuty RDS Protection should be enabled	AWS Foundational Security Best Practices, PCI DSS v4.0.1, CRI Profile v2.2	HIGH	⊗ No	Periodic
GuardDuty.10	GuardDuty S3 Protection should be enabled	AWS Foundational Security Best Practices, PCI DSS v4.0.1, CRI Profile v2.2	HIGH	⊗ No	Periodic
GuardDuty.11	GuardDuty Runtime Monitoring should be enabled	AWS Foundational Security Best Practices, CRI Profile v2.2	HIGH	⊗ No	Periodic
GuardDuty.12	GuardDuty ECS Runtime Monitoring should be enabled	AWS Foundational Security Best Practices, CRI Profile v2.2	MEDIUM	⊗ No	Periodic

Security control ID	Security control title	Applicable standards	Severity	Supports custom parameters	Schedule type
GuardDuty.13	GuardDuty EC2 Runtime Monitoring should be enabled	AWS Foundational Security Best Practices, CRI Profile v2.2	MEDIUM	⊗ No	Periodic
IAM.1	IAM policies should not allow full "*" administrative privileges	CIS AWS Foundations Benchmark v1.2.0, AWS Foundational Security Best Practices v1.0.0, PCI DSS v3.2.1, CIS AWS Foundations Benchmark v1.4.0, NIST SP 800-53 Rev. 5, NIST SP 800-171 Rev. 2, CRI Profile v2.2	HIGH	⊗ No	Change triggered
IAM.2	IAM users should not have IAM policies attached	CIS AWS Foundations Benchmark v5.0.0, CIS AWS Foundations Benchmark v3.0.0, CIS AWS Foundations Benchmark v1.2.0, AWS Foundational Security Best Practices v1.0.0, PCI DSS v3.2.1, NIST SP 800-53 Rev. 5, NIST SP 800-171 Rev. 2, CRI Profile v2.2	LOW	⊗ No	Change triggered

Security control ID	Security control title	Applicable standards	Severity	Supports custom parameters	Schedule type
IAM.3	IAM users' access keys should be rotated every 90 days or less	CIS AWS Foundations Benchmark v5.0.0, CIS AWS Foundations Benchmark v3.0.0, CIS AWS Foundations Benchmark v1.4.0, CIS AWS Foundations Benchmark v1.2.0, AWS Foundational Security Best Practices, NIST SP 800-53 Rev. 5, PCI DSS v4.0.1, CRI Profile v2.2	MEDIUM	⊗ No	Periodic
IAM.4	IAM root user access key should not exist	CIS AWS Foundations Benchmark v5.0.0, CIS AWS Foundations Benchmark v3.0.0, CIS AWS Foundations Benchmark v1.4.0, CIS AWS Foundations Benchmark v1.2.0, AWS Foundational Security Best Practices v1.0.0, PCI DSS v3.2.1, NIST SP 800-53 Rev. 5, CRI Profile v2.2	CRITICAL	⊗ No	Periodic

Security control ID	Security control title	Applicable standards	Severity	Supports custom parameters	Schedule type
IAM.5	MFA should be enabled for all IAM users that have a console password	CIS AWS Foundations Benchmark v5.0.0, CIS AWS Foundations Benchmark v3.0.0, CIS AWS Foundations Benchmark v1.4.0, CIS AWS Foundations Benchmark v1.2.0, AWS Foundational Security Best Practices, NIST SP 800-53 Rev. 5, PCI DSS v4.0.1, CRI Profile v2.2	MEDIUM	⊗ No	Periodic
IAM.6	Hardware MFA should be enabled for the root user	CIS AWS Foundations Benchmark v5.0.0, CIS AWS Foundations Benchmark v3.0.0, CIS AWS Foundations Benchmark v1.4.0, CIS AWS Foundations Benchmark v1.2.0, AWS Foundational Security Best Practices, NIST SP 800-53 Rev. 5, PCI DSS v3.2.1, PCI DSS v4.0.1, CRI Profile v2.2	CRITICAL	⊗ No	Periodic

Security control ID	Security control title	Applicable standards	Severity	Supports custom parameters	Schedule type
IAM.7	Password policies for IAM users should have strong configurations	AWS Foundational Security Best Practices, NIST SP 800-53 Rev. 5, NIST SP 800-171 Rev. 2, PCI DSS v4.0.1, CRI Profile v2.2	MEDIUM	Yes	Periodic
IAM.8	Unused IAM user credentials should be removed	CIS AWS Foundations Benchmark v1.2.0, AWS Foundational Security Best Practices, NIST SP 800-53 Rev. 5, NIST SP 800-171 Rev. 2, PCI DSS v3.2.1, PCI DSS v4.0.1, CRI Profile v2.2	MEDIUM	No	Periodic
IAM.9	MFA should be enabled for the root user	CIS AWS Foundations Benchmark v5.0.0, CIS AWS Foundations Benchmark v3.0.0, CIS AWS Foundations Benchmark v1.4.0, CIS AWS Foundations Benchmark v1.2.0, NIST SP 800-53 Rev. 5, PCI DSS v3.2.1, PCI DSS v4.0.1, CRI Profile v2.2	CRITICAL	No	Periodic

Security control ID	Security control title	Applicable standards	Severity	Supports custom parameters	Schedule type
IAM.10	Password policies for IAM users should have strong configurations	NIST SP 800-171 Rev. 2, PCI DSS v3.2.1, CRI Profile v2.2	MEDIUM	⊗ No	Periodic
IAM.11	Ensure IAM password policy requires at least one uppercase letter	CIS AWS Foundations Benchmark v1.2.0, NIST SP 800-171 Rev. 2, PCI DSS v4.0.1, CRI Profile v2.2	MEDIUM	⊗ No	Periodic
IAM.12	Ensure IAM password policy requires at least one lowercase letter	CIS AWS Foundations Benchmark v1.2.0, NIST SP 800-171 Rev. 2, PCI DSS v4.0.1, CRI Profile v2.2	MEDIUM	⊗ No	Periodic
IAM.13	Ensure IAM password policy requires at least one symbol	CIS AWS Foundations Benchmark v1.2.0, NIST SP 800-171 Rev. 2, CRI Profile v2.2	MEDIUM	⊗ No	Periodic
IAM.14	Ensure IAM password policy requires at least one number	CIS AWS Foundations Benchmark v1.2.0, NIST SP 800-171 Rev. 2, PCI DSS v4.0.1, CRI Profile v2.2	MEDIUM	⊗ No	Periodic

Security control ID	Security control title	Applicable standards	Severity	Supports custom parameters	Schedule type
IAM.15	Ensure IAM password policy requires minimum password length of 14 or greater	CIS AWS Foundations Benchmark v5.0.0, CIS AWS Foundations Benchmark v3.0.0, CIS AWS Foundations Benchmark v1.4.0, CIS AWS Foundations Benchmark v1.2.0, NIST SP 800-171 Rev. 2, CRI Profile v2.2	MEDIUM	⊗ No	Periodic
IAM.16	Ensure IAM password policy prevents password reuse	CIS AWS Foundations Benchmark v5.0.0, CIS AWS Foundations Benchmark v3.0.0, CIS AWS Foundations Benchmark v1.4.0, CIS AWS Foundations Benchmark v1.2.0, NIST SP 800-171 Rev. 2, PCI DSS v4.0.1, CRI Profile v2.2	LOW	⊗ No	Periodic
IAM.17	Ensure IAM password policy expires passwords within 90 days or less	CIS AWS Foundations Benchmark v1.2.0, PCI DSS v4.0.1, CRI Profile v2.2	LOW	⊗ No	Periodic

Security control ID	Security control title	Applicable standards	Severity	Supports custom parameters	Schedule type
IAM.18	Ensure a support role has been created to manage incidents with AWS Support	CIS AWS Foundations Benchmark v5.0.0, CIS AWS Foundations Benchmark v3.0.0, CIS AWS Foundations Benchmark v1.4.0, CIS AWS Foundations Benchmark v1.2.0, NIST SP 800-171 Rev. 2, PCI DSS v4.0.1, CRI Profile v2.2	LOW	⊗ No	Periodic
IAM.19	MFA should be enabled for all IAM users	NIST SP 800-53 Rev. 5, NIST SP 800-171 Rev. 2, PCI DSS v3.2.1, PCI DSS v4.0.1, CRI Profile v2.2	MEDIUM	⊗ No	Periodic
IAM.21	IAM customer managed policies that you create should not allow wildcard actions for services	AWS Foundational Security Best Practices v1.0.0, NIST SP 800-53 Rev. 5, NIST SP 800-171 Rev. 2, CRI Profile v2.2	LOW	⊗ No	Change triggered

Security control ID	Security control title	Applicable standards	Severity	Supports custom parameters	Schedule type
IAM.22	IAM user credentials unused for 45 days should be removed	CIS AWS Foundations Benchmark v5.0.0, CIS AWS Foundations Benchmark v3.0.0, CIS AWS Foundations Benchmark v1.4.0, NIST SP 800-171 Rev. 2, CRI Profile v2.2	MEDIUM	No	Periodic
IAM.23	IAM Access Analyzer analyzers should be tagged	AWS Resource Tagging Standard	LOW	Yes	Change triggered
IAM.24	IAM roles should be tagged	AWS Resource Tagging Standard	LOW	Yes	Change triggered
IAM.25	IAM users should be tagged	AWS Resource Tagging Standard	LOW	Yes	Change triggered
IAM.26	Expired SSL/TLS certificates managed in IAM should be removed	CIS AWS Foundations Benchmark v5.0.0, CIS AWS Foundations Benchmark v3.0.0, CRI Profile v2.2	MEDIUM	No	Periodic
IAM.27	IAM identities should not have the AWSCloudShellFullAccess policy attached	CIS AWS Foundations Benchmark v5.0.0, CIS AWS Foundations Benchmark v3.0.0, CRI Profile v2.2	MEDIUM	No	Change triggered

Security control ID	Security control title	Applicable standards	Severity	Supports custom parameters	Schedule type
IAM.28	IAM Access Analyzer external access analyzer should be enabled	CIS AWS Foundations Benchmark v5.0.0, CIS AWS Foundations Benchmark v3.0.0, CRI Profile v2.2	HIGH	⊗ No	Periodic
Inspector.1	Amazon Inspector EC2 scanning should be enabled	AWS Foundational Security Best Practices, PCI DSS v4.0.1, CRI Profile v2.2	HIGH	⊗ No	Periodic
Inspector.2	Amazon Inspector ECR scanning should be enabled	AWS Foundational Security Best Practices, PCI DSS v4.0.1, CRI Profile v2.2	HIGH	⊗ No	Periodic
Inspector.3	Amazon Inspector Lambda code scanning should be enabled	AWS Foundational Security Best Practices, PCI DSS v4.0.1, CRI Profile v2.2	HIGH	⊗ No	Periodic
Inspector.4	Amazon Inspector Lambda standard scanning should be enabled	AWS Foundational Security Best Practices, PCI DSS v4.0.1, CRI Profile v2.2	HIGH	⊗ No	Periodic

Security control ID	Security control title	Applicable standards	Severity	Supports custom parameters	Schedule type
IoT.1	AWS IoT Device Defender security profiles should be tagged	AWS Resource Tagging Standard	LOW	Yes	Change triggered
IoT.2	AWS IoT Core mitigation actions should be tagged	AWS Resource Tagging Standard	LOW	Yes	Change triggered
IoT.3	AWS IoT Core dimensions should be tagged	AWS Resource Tagging Standard	LOW	Yes	Change triggered
IoT.4	AWS IoT Core authorizers should be tagged	AWS Resource Tagging Standard	LOW	Yes	Change triggered
IoT.5	AWS IoT Core role aliases should be tagged	AWS Resource Tagging Standard	LOW	Yes	Change triggered
IoT.6	AWS IoT Core policies should be tagged	AWS Resource Tagging Standard	LOW	Yes	Change triggered
IoTSiteWise.1	AWS IoT SiteWise asset models should be tagged	AWS Resource Tagging Standard	LOW	Yes	Change triggered
IoTSiteWise.2	AWS IoT SiteWise dashboards should be tagged	AWS Resource Tagging Standard	LOW	Yes	Change triggered

Security control ID	Security control title	Applicable standards	Severity	Supports custom parameters	Schedule type
IoTSiteWise.3	AWS IoT SiteWise gateways should be tagged	AWS Resource Tagging Standard	LOW	Yes	Change triggered
IoTSiteWise.4	AWS IoT SiteWise portals should be tagged	AWS Resource Tagging Standard	LOW	Yes	Change triggered
IoTSiteWise.5	AWS IoT SiteWise projects should be tagged	AWS Resource Tagging Standard	LOW	Yes	Change triggered
IoTTwinMaker.1	AWS IoT TwinMaker sync jobs should be tagged	AWS Resource Tagging Standard	LOW	Yes	Change triggered
IoTTwinMaker.2	AWS IoT TwinMaker workspaces should be tagged	AWS Resource Tagging Standard, CRI Profile v2.2	LOW	Yes	Change triggered
IoTTwinMaker.3	AWS IoT TwinMaker scenes should be tagged	AWS Resource Tagging Standard	LOW	Yes	Change triggered
IoTTwinMaker.4	AWS IoT TwinMaker entities should be tagged	AWS Resource Tagging Standard	LOW	Yes	Change triggered
IoTWireless.1	AWS IoT Wireless multicast groups should be tagged	AWS Resource Tagging Standard	LOW	Yes	Change triggered

Security control ID	Security control title	Applicable standards	Severity	Supports custom parameters	Schedule type
IoTWireless.2	AWS IoT Wireless service profiles should be tagged	AWS Resource Tagging Standard	LOW	Yes	Change triggered
IoTWireless.3	AWS IoT Wireless FUOTA tasks should be tagged	AWS Resource Tagging Standard	LOW	Yes	Change triggered
IVS.1	IVS playback key pairs should be tagged	AWS Resource Tagging Standard, CRI Profile v2.2	LOW	Yes	Change triggered
IVS.2	IVS recording configurations should be tagged	AWS Resource Tagging Standard, CRI Profile v2.2	LOW	Yes	Change triggered
IVS.3	IVS channels should be tagged	AWS Resource Tagging Standard	LOW	Yes	Change triggered
Keyspaces.1	Amazon Keyspaces keyspaces should be tagged	AWS Resource Tagging Standard, CRI Profile v2.2	LOW	Yes	Change triggered
Kinesis.1	Kinesis streams should be encrypted at rest	AWS Foundational Security Best Practices v1.0.0, NIST SP 800-53 Rev. 5, CRI Profile v2.2	MEDIUM	No	Change triggered
Kinesis.2	Kinesis streams should be tagged	AWS Resource Tagging Standard	LOW	Yes	Change triggered

Security control ID	Security control title	Applicable standards	Severity	Supports custom parameters	Schedule type
Kinesis.3	Kinesis streams should have an adequate data retention period	AWS Foundational Security Best Practices	MEDIUM	Yes	Change triggered
KMS.1	IAM customer managed policies should not allow decryption actions on all KMS keys	AWS Foundational Security Best Practices v1.0.0, NIST SP 800-53 Rev. 5, CRI Profile v2.2	MEDIUM	No	Change triggered
KMS.2	IAM principals should not have IAM inline policies that allow decryption actions on all KMS keys	AWS Foundational Security Best Practices v1.0.0, NIST SP 800-53 Rev. 5, CRI Profile v2.2	MEDIUM	No	Change triggered
KMS.3	AWS KMS keys should not be deleted unintentionally	AWS Foundational Security Best Practices v1.0.0, NIST SP 800-53 Rev. 5, CRI Profile v2.2	CRITICAL	No	Change triggered

Security control ID	Security control title	Applicable standards	Severity	Supports custom parameters	Schedule type
KMS.4	AWS KMS key rotation should be enabled	CIS AWS Foundations Benchmark v5.0.0, CIS AWS Foundations Benchmark v3.0.0, CIS AWS Foundations Benchmark v1.4.0, CIS AWS Foundations Benchmark v1.2.0, NIST SP 800-53 Rev. 5, PCI DSS v3.2.1, PCI DSS v4.0.1, CRI Profile v2.2	MEDIUM	⊗ No	Periodic
KMS.5	KMS keys should not be publicly accessible	AWS Foundational Security Best Practices, CRI Profile v2.2	CRITICAL	⊗ No	Change triggered
Lambda.1	Lambda function policies should prohibit public access	AWS Foundational Security Best Practices, NIST SP 800-53 Rev. 5, PCI DSS v3.2.1, PCI DSS v4.0.1, CRI Profile v2.2	CRITICAL	⊗ No	Change triggered
Lambda.2	Lambda functions should use supported runtimes	AWS Foundational Security Best Practices, NIST SP 800-53 Rev. 5, PCI DSS v4.0.1, CRI Profile v2.2	MEDIUM	⊗ No	Change triggered

Security control ID	Security control title	Applicable standards	Severity	Supports custom parameters	Schedule type
Lambda.3	Lambda functions should be in a VPC	PCI DSS v3.2.1, NIST SP 800-53 Rev. 5, CRI Profile v2.2	LOW	⊗ No	Change triggered
Lambda.5	VPC Lambda functions should operate in multiple Availability Zones	AWS Foundational Security Best Practices v1.0.0, NIST SP 800-53 Rev. 5, CRI Profile v2.2	MEDIUM	⊙ Yes	Change triggered
Lambda.6	Lambda functions should be tagged	AWS Resource Tagging Standard	LOW	⊙ Yes	Change triggered
Lambda.7	Lambda functions should have AWS X-Ray active tracing enabled	NIST SP 800-53 Rev. 5, CRI Profile v2.2	LOW	⊗ No	Change triggered
Macie.1	Amazon Macie should be enabled	AWS Foundational Security Best Practices v1.0.0, NIST SP 800-53 Rev. 5, CRI Profile v2.2	MEDIUM	⊗ No	Periodic
Macie.2	Macie automated sensitive data discovery should be enabled	AWS Foundational Security Best Practices v1.0.0, NIST SP 800-53 Rev. 5, CRI Profile v2.2	HIGH	⊗ No	Periodic

Security control ID	Security control title	Applicable standards	Severity	Supports custom parameters	Schedule type
MSK.1	MSK clusters should be encrypted in transit among broker nodes	AWS Foundational Security Best Practices, NIST SP 800-53 Rev. 5, PCI DSS v4.0.1, CRI Profile v2.2	MEDIUM	⊗ No	Change triggered
MSK.2	MSK clusters should have enhanced monitoring configured	NIST SP 800-53 Rev. 5, CRI Profile v2.2	LOW	⊗ No	Change triggered
MSK.3	MSK Connect connectors should be encrypted in transit	AWS Foundational Security Best Practices, PCI DSS v4.0.1, CRI Profile v2.2	MEDIUM	⊗ No	Change triggered
MSK.4	MSK clusters should have public access disabled	AWS Foundational Security Best Practices, CRI Profile v2.2	CRITICAL	⊗ No	Change triggered
MSK.5	MSK connectors should have logging enabled	AWS Foundational Security Best Practices, CRI Profile v2.2	MEDIUM	⊗ No	Change triggered
MSK.6	MSK clusters should disable unauthenticated access	AWS Foundational Security Best Practices, CRI Profile v2.2	MEDIUM	⊗ No	Change triggered

Security control ID	Security control title	Applicable standards	Severity	Supports custom parameters	Schedule type
MQ.2	ActiveMQ brokers should stream audit logs to CloudWatch	AWS Foundational Security Best Practices, NIST SP 800-53 Rev. 5, PCI DSS v4.0.1, CRI Profile v2.2	MEDIUM	⊗ No	Change triggered
MQ.4	Amazon MQ brokers should be tagged	AWS Resource Tagging Standard	LOW	⊙ Yes	Change triggered
MQ.5	ActiveMQ brokers should use active/standby deployment mode	NIST SP 800-53 Rev. 5, CRI Profile v2.2	LOW	⊗ No	Change triggered
MQ.6	RabbitMQ brokers should use cluster deployment mode	NIST SP 800-53 Rev. 5, CRI Profile v2.2	LOW	⊗ No	Change triggered
Neptune.1	Neptune DB clusters should be encrypted at rest	AWS Foundational Security Best Practices v1.0.0, NIST SP 800-53 Rev. 5, CRI Profile v2.2	MEDIUM	⊗ No	Change triggered
Neptune.2	Neptune DB clusters should publish audit logs to CloudWatch Logs	AWS Foundational Security Best Practices, NIST SP 800-53 Rev. 5, PCI DSS v4.0.1, CRI Profile v2.2	MEDIUM	⊗ No	Change triggered

Security control ID	Security control title	Applicable standards	Severity	Supports custom parameters	Schedule type
Neptune.3	Neptune DB cluster snapshots should not be public	AWS Foundational Security Best Practices, NIST SP 800-53 Rev. 5, PCI DSS v4.0.1, CRI Profile v2.2	CRITICAL	⊗ No	Change triggered
Neptune.4	Neptune DB clusters should have deletion protection enabled	AWS Foundational Security Best Practices v1.0.0, NIST SP 800-53 Rev. 5, CRI Profile v2.2	LOW	⊗ No	Change triggered
Neptune.5	Neptune DB clusters should have automated backups enabled	AWS Foundational Security Best Practices v1.0.0, NIST SP 800-53 Rev. 5, CRI Profile v2.2	MEDIUM	⊙ Yes	Change triggered
Neptune.6	Neptune DB cluster snapshots should be encrypted at rest	AWS Foundational Security Best Practices v1.0.0, NIST SP 800-53 Rev. 5, CRI Profile v2.2	MEDIUM	⊗ No	Change triggered
Neptune.7	Neptune DB clusters should have IAM database authentication enabled	AWS Foundational Security Best Practices v1.0.0, NIST SP 800-53 Rev. 5, CRI Profile v2.2	MEDIUM	⊗ No	Change triggered

Security control ID	Security control title	Applicable standards	Severity	Supports custom parameters	Schedule type
Neptune.8	Neptune DB clusters should be configured to copy tags to snapshots	AWS Foundational Security Best Practices v1.0.0, NIST SP 800-53 Rev. 5, CRI Profile v2.2	LOW	⊗ No	Change triggered
Neptune.9	Neptune DB clusters should be deployed across multiple Availability Zones	NIST SP 800-53 Rev. 5, CRI Profile v2.2	MEDIUM	⊗ No	Change triggered
NetworkFirewall.1	Network Firewall firewalls should be deployed across multiple Availability Zones	NIST SP 800-53 Rev. 5, CRI Profile v2.2	MEDIUM	⊗ No	Change triggered
NetworkFirewall.2	Network Firewall logging should be enabled	AWS Foundational Security Best Practices v1.0.0, NIST SP 800-53 Rev. 5, NIST SP 800-171 Rev. 2, CRI Profile v2.2	MEDIUM	⊗ No	Periodic
NetworkFirewall.3	Network Firewall policies should have at least one rule group associated	AWS Foundational Security Best Practices v1.0.0, NIST SP 800-53 Rev. 5, NIST SP 800-171 Rev. 2, CRI Profile v2.2	MEDIUM	⊗ No	Change triggered

Security control ID	Security control title	Applicable standards	Severity	Supports custom parameters	Schedule type
NetworkFirewall.4	The default stateless action for Network Firewall policies should be drop or forward for full packets	AWS Foundational Security Best Practices v1.0.0, NIST SP 800-53 Rev. 5, CRI Profile v2.2	MEDIUM	No	Change triggered
NetworkFirewall.5	The default stateless action for Network Firewall policies should be drop or forward for fragmented packets	AWS Foundational Security Best Practices v1.0.0, NIST SP 800-53 Rev. 5, NIST SP 800-171 Rev. 2, CRI Profile v2.2	MEDIUM	No	Change triggered
NetworkFirewall.6	Stateless network firewall rule group should not be empty	AWS Foundational Security Best Practices v1.0.0, NIST SP 800-53 Rev. 5, NIST SP 800-171 Rev. 2, CRI Profile v2.2	MEDIUM	No	Change triggered
NetworkFirewall.7	Network Firewall firewalls should be tagged	AWS Resource Tagging Standard	LOW	Yes	Change triggered
NetworkFirewall.8	Network Firewall firewall policies should be tagged	AWS Resource Tagging Standard	LOW	Yes	Change triggered

Security control ID	Security control title	Applicable standards	Severity	Supports custom parameters	Schedule type
NetworkFirewall.9	Network Firewall firewalls should have deletion protection enabled	AWS Foundational Security Best Practices v1.0.0, NIST SP 800-53 Rev. 5, CRI Profile v2.2	MEDIUM	⊗ No	Change triggered
NetworkFirewall.10	Network Firewall firewalls should have subnet change protection enabled	AWS Foundational Security Best Practices, NIST SP 800-53 Rev. 5, CRI Profile v2.2	MEDIUM	⊗ No	Change triggered
Opensearch.1	OpenSearch domains should have encryption at rest enabled	AWS Foundational Security Best Practices v1.0.0, PCI DSS v3.2.1, NIST SP 800-53 Rev. 5, CRI Profile v2.2	MEDIUM	⊗ No	Change triggered
Opensearch.2	OpenSearch domains should not be publicly accessible	AWS Foundational Security Best Practices v1.0.0, PCI DSS v3.2.1, NIST SP 800-53 Rev. 5, CRI Profile v2.2	CRITICAL	⊗ No	Change triggered
Opensearch.3	OpenSearch domains should encrypt data sent between nodes	AWS Foundational Security Best Practices v1.0.0, NIST SP 800-53 Rev. 5, CRI Profile v2.2	MEDIUM	⊗ No	Change triggered

Security control ID	Security control title	Applicable standards	Severity	Supports custom parameters	Schedule type
Opensearch.4	OpenSearch domain error logging to CloudWatch Logs should be enabled	AWS Foundational Security Best Practices v1.0.0, NIST SP 800-53 Rev. 5, CRI Profile v2.2	MEDIUM	⊗ No	Change triggered
Opensearch.5	OpenSearch domains should have audit logging enabled	AWS Foundational Security Best Practices, NIST SP 800-53 Rev. 5, PCI DSS v4.0.1, CRI Profile v2.2	MEDIUM	⊗ No	Change triggered
Opensearch.6	OpenSearch domains should have at least three data nodes	AWS Foundational Security Best Practices v1.0.0, NIST SP 800-53 Rev. 5, CRI Profile v2.2	MEDIUM	⊗ No	Change triggered
Opensearch.7	OpenSearch domains should have fine-grained access control enabled	AWS Foundational Security Best Practices v1.0.0, NIST SP 800-53 Rev. 5, CRI Profile v2.2	HIGH	⊗ No	Change triggered
Opensearch.8	Connections to OpenSearch domains should be encrypted using the latest TLS security policy	AWS Foundational Security Best Practices, NIST SP 800-53 Rev. 5, CRI Profile v2.2	MEDIUM	⊗ No	Change triggered
Opensearch.9	OpenSearch domains should be tagged	AWS Resource Tagging Standard	LOW	⊙ Yes	Change triggered

Security control ID	Security control title	Applicable standards	Severity	Supports custom parameters	Schedule type
Opensearch.10	OpenSearch domains should have the latest software update installed	AWS Foundational Security Best Practices, NIST SP 800-53 Rev. 5, PCI DSS v4.0.1, CRI Profile v2.2	MEDIUM	No	Change triggered
Opensearch.11	OpenSearch domains should have at least three dedicated primary nodes	NIST SP 800-53 Rev. 5, CRI Profile v2.2	LOW	No	Periodic
PCA.1	AWS Private CA root certificate authority should be disabled	AWS Foundational Security Best Practices v1.0.0, NIST SP 800-53 Rev. 5, CRI Profile v2.2	LOW	No	Periodic
PCA.2	AWS Private CA certificate authorities should be tagged	AWS Resource Tagging Standard	LOW	Yes	Change triggered
RDS.1	RDS snapshot should be private	AWS Foundational Security Best Practices v1.0.0, PCI DSS v3.2.1, NIST SP 800-53 Rev. 5, CRI Profile v2.2	CRITICAL	No	Change triggered

Security control ID	Security control title	Applicable standards	Severity	Supports custom parameters	Schedule type
RDS.2	RDS DB Instances should prohibit public access, as determined by the PubliclyAccessible configuration	CIS AWS Foundations Benchmark v5.0.0, CIS AWS Foundations Benchmark v3.0.0, AWS Foundational Security Best Practices, NIST SP 800-53 Rev. 5, PCI DSS v3.2.1, PCI DSS v4.0.1, CRI Profile v2.2	CRITICAL	⊗ No	Change triggered
RDS.3	RDS DB instances should have encryption at-rest enabled	CIS AWS Foundations Benchmark v5.0.0, CIS AWS Foundations Benchmark v3.0.0, CIS AWS Foundations Benchmark v1.4.0, AWS Foundational Security Best Practices v1.0.0, NIST SP 800-53 Rev. 5, CRI Profile v2.2	MEDIUM	⊗ No	Change triggered
RDS.4	RDS cluster snapshots and database snapshots should be encrypted at rest	AWS Foundational Security Best Practices v1.0.0, NIST SP 800-53 Rev. 5, CRI Profile v2.2	MEDIUM	⊗ No	Change triggered

Security control ID	Security control title	Applicable standards	Severity	Supports custom parameters	Schedule type
RDS.5	RDS DB instances should be configured with multiple Availability Zones	CIS AWS Foundations Benchmark v5.0.0, AWS Foundational Security Best Practices v1.0.0, NIST SP 800-53 Rev. 5, CRI Profile v2.2	MEDIUM	⊗ No	Change triggered
RDS.6	Enhanced monitoring should be configured for RDS DB instances	AWS Foundational Security Best Practices v1.0.0, NIST SP 800-53 Rev. 5, CRI Profile v2.2	LOW	⊙ Yes	Change triggered
RDS.7	RDS clusters should have deletion protection enabled	AWS Foundational Security Best Practices v1.0.0, NIST SP 800-53 Rev. 5, CRI Profile v2.2	MEDIUM	⊗ No	Change triggered
RDS.8	RDS DB instances should have deletion protection enabled	AWS Foundational Security Best Practices v1.0.0, NIST SP 800-53 Rev. 5, CRI Profile v2.2	LOW	⊗ No	Change triggered
RDS.9	RDS DB instances should publish logs to CloudWatch Logs	AWS Foundational Security Best Practices, NIST SP 800-53 Rev. 5, PCI DSS v4.0.1, CRI Profile v2.2	MEDIUM	⊗ No	Change triggered

Security control ID	Security control title	Applicable standards	Severity	Supports custom parameters	Schedule type
RDS.10	IAM authentication should be configured for RDS instances	AWS Foundational Security Best Practices v1.0.0, NIST SP 800-53 Rev. 5, CRI Profile v2.2	MEDIUM	⊗ No	Change triggered
RDS.11	RDS instances should have automatic backups enabled	AWS Foundational Security Best Practices v1.0.0, NIST SP 800-53 Rev. 5, CRI Profile v2.2	MEDIUM	⊙ Yes	Change triggered
RDS.12	IAM authentication should be configured for RDS clusters	AWS Foundational Security Best Practices v1.0.0, NIST SP 800-53 Rev. 5, CRI Profile v2.2	MEDIUM	⊗ No	Change triggered
RDS.13	RDS automatic minor version upgrades should be enabled	CIS AWS Foundations Benchmark v5.0.0, CIS AWS Foundations Benchmark v3.0.0, AWS Foundational Security Best Practices, NIST SP 800-53 Rev. 5, PCI DSS v4.0.1, CRI Profile v2.2	HIGH	⊗ No	Change triggered

Security control ID	Security control title	Applicable standards	Severity	Supports custom parameters	Schedule type
RDS.14	Amazon Aurora clusters should have backtracking enabled	AWS Foundational Security Best Practices v1.0.0, NIST SP 800-53 Rev. 5, CRI Profile v2.2	MEDIUM	Yes	Change triggered
RDS.15	RDS DB clusters should be configured for multiple Availability Zones	CIS AWS Foundations Benchmark v5.0.0, AWS Foundational Security Best Practices v1.0.0, NIST SP 800-53 Rev. 5, CRI Profile v2.2	MEDIUM	No	Change triggered
RDS.16	Aurora DB clusters should be configured to copy tags to DB snapshots	AWS Foundational Security Best Practices v1.0.0, NIST SP 800-53 Rev. 5, CRI Profile v2.2	LOW	No	Change triggered
RDS.17	RDS DB instances should be configured to copy tags to snapshots	AWS Foundational Security Best Practices v1.0.0, NIST SP 800-53 Rev. 5, CRI Profile v2.2	LOW	No	Change triggered
RDS.19	Existing RDS event notification subscriptions should be configured for critical cluster events	AWS Foundational Security Best Practices v1.0.0, NIST SP 800-53 Rev. 5, CRI Profile v2.2	LOW	No	Change triggered

Security control ID	Security control title	Applicable standards	Severity	Supports custom parameters	Schedule type
RDS.20	Existing RDS event notification subscriptions should be configured for critical database instance events	AWS Foundational Security Best Practices, NIST SP 800-53 Rev. 5, PCI DSS v4.0.1, CRI Profile v2.2	LOW	⊗ No	Change triggered
RDS.21	An RDS event notifications subscription should be configured for critical database parameter group events	AWS Foundational Security Best Practices, NIST SP 800-53 Rev. 5, PCI DSS v4.0.1, CRI Profile v2.2	LOW	⊗ No	Change triggered
RDS.22	An RDS event notifications subscription should be configured for critical database security group events	AWS Foundational Security Best Practices, NIST SP 800-53 Rev. 5, PCI DSS v4.0.1, CRI Profile v2.2	LOW	⊗ No	Change triggered
RDS.23	RDS instances should not use a database engine default port	AWS Foundational Security Best Practices v1.0.0, NIST SP 800-53 Rev. 5, CRI Profile v2.2	LOW	⊗ No	Change triggered

Security control ID	Security control title	Applicable standards	Severity	Supports custom parameters	Schedule type
RDS.24	RDS Database Clusters should use a custom administrator username	AWS Foundational Security Best Practices, NIST SP 800-53 Rev. 5, PCI DSS v4.0.1, CRI Profile v2.2	MEDIUM	⊗ No	Change triggered
RDS.25	RDS database instances should use a custom administrator username	AWS Foundational Security Best Practices, NIST SP 800-53 Rev. 5, PCI DSS v4.0.1, CRI Profile v2.2	MEDIUM	⊗ No	Change triggered
RDS.26	RDS DB instances should be protected by a backup plan	NIST SP 800-53 Rev. 5, CRI Profile v2.2	MEDIUM	✓ Yes	Periodic
RDS.27	RDS DB clusters should be encrypted at rest	AWS Foundational Security Best Practices v1.0.0, NIST SP 800-53 Rev. 5, CRI Profile v2.2	MEDIUM	⊗ No	Change triggered
RDS.28	RDS DB clusters should be tagged	AWS Resource Tagging Standard	LOW	✓ Yes	Change triggered
RDS.29	RDS DB cluster snapshots should be tagged	AWS Resource Tagging Standard	LOW	✓ Yes	Change triggered
RDS.30	RDS DB instances should be tagged	AWS Resource Tagging Standard	LOW	✓ Yes	Change triggered

Security control ID	Security control title	Applicable standards	Severity	Supports custom parameters	Schedule type
RDS.31	RDS DB security groups should be tagged	AWS Resource Tagging Standard	LOW	Yes	Change triggered
RDS.32	RDS DB snapshots should be tagged	AWS Resource Tagging Standard	LOW	Yes	Change triggered
RDS.33	RDS DB subnet groups should be tagged	AWS Resource Tagging Standard	LOW	Yes	Change triggered
RDS.34	Aurora MySQL DB clusters should publish audit logs to CloudWatch Logs	AWS Foundational Security Best Practices, NIST SP 800-53 Rev. 5, PCI DSS v4.0.1, CRI Profile v2.2	MEDIUM	No	Change triggered
RDS.35	RDS DB clusters should have automatic minor version upgrade enabled	AWS Foundational Security Best Practices, NIST SP 800-53 Rev. 5, PCI DSS v4.0.1, CRI Profile v2.2	MEDIUM	No	Change triggered
RDS.36	RDS for PostgreSQL DB instances should publish logs to CloudWatch Logs	AWS Foundational Security Best Practices, PCI DSS v4.0.1, CRI Profile v2.2	MEDIUM	Yes	Change triggered

Security control ID	Security control title	Applicable standards	Severity	Supports custom parameters	Schedule type
RDS.37	Aurora PostgreSQL DB clusters should publish logs to CloudWatch Logs	AWS Foundational Security Best Practices, PCI DSS v4.0.1, CRI Profile v2.2	MEDIUM	⊗ No	Change triggered
RDS.38	RDS for PostgreSQL DB instances should be encrypted in transit	AWS Foundational Security Best Practices, CRI Profile v2.2	MEDIUM	⊗ No	Periodic
RDS.39	RDS for MySQL DB instances should be encrypted in transit	AWS Foundational Security Best Practices, CRI Profile v2.2	MEDIUM	⊗ No	Periodic
RDS.40	RDS for SQL Server DB instances should publish logs to CloudWatch Logs	AWS Foundational Security Best Practices, NIST SP 800-53 Rev. 5	MEDIUM	✓ Yes	Change triggered
RDS.41	RDS for SQL Server DB instances should be encrypted in transit	AWS Foundational Security Best Practices, CRI Profile v2.2	MEDIUM	⊗ No	Periodic
RDS.42	RDS for MariaDB DB instances should publish logs to CloudWatch Logs	AWS Foundational Security Best Practices, NIST SP 800-53 Rev. 5	MEDIUM	✓ Yes	Periodic

Security control ID	Security control title	Applicable standards	Severity	Supports custom parameters	Schedule type
RDS.43	RDS DB proxies should require TLS encryption for connections	AWS Foundational Security Best Practices	MEDIUM	⊗ No	Periodic
RDS.44	RDS for MariaDB DB instances should be encrypted in transit	AWS Foundational Security Best Practices, CRI Profile v2.2	MEDIUM	⊗ No	Periodic
RDS.45	Aurora MySQL DB clusters should have audit logging enabled	AWS Foundational Security Best Practices, NIST SP 800-53 Rev. 5, CRI Profile v2.2	MEDIUM	⊗ No	Periodic
RDS.46	RDS DB instances should not be deployed in public subnets with routes to internet gateways	AWS Foundational Security Best Practices	HIGH	⊗ No	Periodic
RDS.47	RDS for PostgreSQL DB clusters should be configured to copy tags to DB snapshots	AWS Foundational Security Best Practices	LOW	⊗ No	Change triggered
RDS.48	RDS for MySQL DB clusters should be configured to copy tags to DB snapshots	AWS Foundational Security Best Practices	LOW	⊗ No	Change triggered

Security control ID	Security control title	Applicable standards	Severity	Supports custom parameters	Schedule type
RDS.50	RDS DB clusters should have enough backup retention period set	AWS Foundational Security Best Practices v1.0.0	MEDIUM	⊗ Yes	Change triggered
RDS.51	RDS global clusters should run on a supported Aurora MySQL version	AWS Foundational Security Best Practices	HIGH	⊗ No	Change triggered
Redshift.1	Amazon Redshift clusters should prohibit public access	AWS Foundational Security Best Practices, NIST SP 800-53 Rev. 5, PCI DSS v3.2.1, PCI DSS v4.0.1, CRI Profile v2.2	CRITICAL	⊗ No	Change triggered
Redshift.2	Connections to Amazon Redshift clusters should be encrypted in transit	AWS Foundational Security Best Practices, NIST SP 800-53 Rev. 5, PCI DSS v4.0.1, CRI Profile v2.2	MEDIUM	⊗ No	Change triggered
Redshift.3	Amazon Redshift clusters should have automatic snapshots enabled	AWS Foundational Security Best Practices v1.0.0, NIST SP 800-53 Rev. 5, CRI Profile v2.2	MEDIUM	⊘ Yes	Change triggered

Security control ID	Security control title	Applicable standards	Severity	Supports custom parameters	Schedule type
Redshift.4	Amazon Redshift clusters should have audit logging enabled	AWS Foundational Security Best Practices, NIST SP 800-53 Rev. 5, PCI DSS v4.0.1, CRI Profile v2.2	MEDIUM	⊗ No	Change triggered
Redshift.6	Amazon Redshift should have automatic upgrades to major versions enabled	AWS Foundational Security Best Practices v1.0.0, NIST SP 800-53 Rev. 5, CRI Profile v2.2	MEDIUM	⊗ No	Change triggered
Redshift.7	Redshift clusters should use enhanced VPC routing	AWS Foundational Security Best Practices v1.0.0, NIST SP 800-53 Rev. 5, CRI Profile v2.2	MEDIUM	⊗ No	Change triggered
Redshift.8	Amazon Redshift clusters should not use the default Admin username	AWS Foundational Security Best Practices v1.0.0, NIST SP 800-53 Rev. 5, CRI Profile v2.2	MEDIUM	⊗ No	Change triggered
Redshift.10	Redshift clusters should be encrypted at rest	AWS Foundational Security Best Practices v1.0.0, NIST SP 800-53 Rev. 5, CRI Profile v2.2	MEDIUM	⊗ No	Change triggered
Redshift.11	Redshift clusters should be tagged	AWS Resource Tagging Standard	LOW	✓ Yes	Change triggered

Security control ID	Security control title	Applicable standards	Severity	Supports custom parameters	Schedule type
Redshift.12	Redshift event subscription notifications should be tagged	AWS Resource Tagging Standard	LOW	✓ Yes	Change triggered
Redshift.13	Redshift cluster snapshots should be tagged	AWS Resource Tagging Standard	LOW	✓ Yes	Change triggered
Redshift.14	Redshift cluster subnet groups should be tagged	AWS Resource Tagging Standard	LOW	✓ Yes	Change triggered
Redshift.15	Redshift security groups should allow ingress on the cluster port only from restricted origins	AWS Foundational Security Best Practices, PCI DSS v4.0.1, CRI Profile v2.2	HIGH	✗ No	Periodic
Redshift.16	Redshift cluster subnet groups should have subnets from multiple Availability Zones	NIST SP 800-53 Rev. 5, CRI Profile v2.2	MEDIUM	✗ No	Change triggered
Redshift.17	Redshift cluster parameter groups should be tagged	AWS Resource Tagging Standard	LOW	✓ Yes	Change triggered
Redshift.18	Redshift clusters should have Multi-AZ deployments enabled	AWS Foundational Security Best Practices, CRI Profile v2.2	MEDIUM	✗ No	Change triggered

Security control ID	Security control title	Applicable standards	Severity	Supports custom parameters	Schedule type
RedshiftServerless.1	Amazon Redshift Serverless workgroups should use enhanced VPC routing	AWS Foundational Security Best Practices, CRI Profile v2.2	HIGH	⊗ No	Periodic
RedshiftServerless.2	Connections to Redshift Serverless workgroups should be required to use SSL	AWS Foundational Security Best Practices, CRI Profile v2.2	MEDIUM	⊗ No	Periodic
RedshiftServerless.3	Redshift Serverless workgroups should prohibit public access	AWS Foundational Security Best Practices, CRI Profile v2.2	HIGH	⊗ No	Periodic
RedshiftServerless.4	Redshift Serverless namespaces should be encrypted with customer managed AWS KMS keys	NIST SP 800-53 Rev. 5	MEDIUM	✓ Yes	Periodic
RedshiftServerless.5	Redshift Serverless namespaces should not use the default admin username	AWS Foundational Security Best Practices	MEDIUM	⊗ No	Periodic
RedshiftServerless.6	Redshift Serverless namespaces should export logs to CloudWatch Logs	AWS Foundational Security Best Practices, CRI Profile v2.2	MEDIUM	⊗ No	Periodic

Security control ID	Security control title	Applicable standards	Severity	Supports custom parameters	Schedule type
Route53.1	Route 53 health checks should be tagged	AWS Resource Tagging Standard	LOW	Yes	Change triggered
Route53.2	Route 53 public hosted zones should log DNS queries	AWS Foundational Security Best Practices, NIST SP 800-53 Rev. 5, PCI DSS v4.0.1, CRI Profile v2.2	MEDIUM	No	Change triggered
S3.1	S3 general purpose buckets should have block public access settings enabled	CIS AWS Foundations Benchmark v5.0.0, CIS AWS Foundations Benchmark v3.0.0, CIS AWS Foundations Benchmark v1.4.0, AWS Foundational Security Best Practices, NIST SP 800-53 Rev. 5, PCI DSS v3.2.1, PCI DSS v4.0.1, CRI Profile v2.2	MEDIUM	No	Periodic
S3.2	S3 general purpose buckets should block public read access	AWS Foundational Security Best Practices, PCI DSS v3.2.1, NIST SP 800-53 Rev. 5, CRI Profile v2.2	CRITICAL	No	Change triggered and periodic

Security control ID	Security control title	Applicable standards	Severity	Supports custom parameters	Schedule type
S3.3	S3 general purpose buckets should block public write access	AWS Foundational Security Best Practices, PCI DSS v3.2.1, NIST SP 800-53 Rev. 5, CRI Profile v2.2	CRITICAL	⊗ No	Change triggered and periodic
S3.5	S3 general purpose buckets should require requests to use SSL	CIS AWS Foundations Benchmark v5.0.0, CIS AWS Foundations Benchmark v3.0.0, CIS AWS Foundations Benchmark v1.4.0, AWS Foundational Security Best Practices, NIST SP 800-53 Rev. 5, NIST SP 800-171 Rev. 2, PCI DSS v3.2.1, PCI DSS v4.0.1, CRI Profile v2.2	MEDIUM	⊗ No	Change triggered
S3.6	S3 general purpose bucket policies should restrict access to other AWS accounts	AWS Foundational Security Best Practices, NIST SP 800-53 Rev. 5, NIST SP 800-171 Rev. 2, CRI Profile v2.2	HIGH	⊗ No	Change triggered

Security control ID	Security control title	Applicable standards	Severity	Supports custom parameters	Schedule type
S3.7	S3 general purpose buckets should use cross-Region replication	PCI DSS v3.2.1, NIST SP 800-53 Rev. 5, CRI Profile v2.2	LOW	⊗ No	Change triggered
S3.8	S3 general purpose buckets should block public access	CIS AWS Foundations Benchmark v5.0.0, CIS AWS Foundations Benchmark v3.0.0, CIS AWS Foundations Benchmark v1.4.0, AWS Foundational Security Best Practices, NIST SP 800-53 Rev. 5, PCI DSS v4.0.1, CRI Profile v2.2	HIGH	⊗ No	Change triggered
S3.9	S3 general purpose buckets should have server access logging enabled	AWS Foundational Security Best Practices, NIST SP 800-53 Rev. 5, NIST SP 800-171 Rev. 2, PCI DSS v4.0.1, CRI Profile v2.2	MEDIUM	⊗ No	Change triggered
S3.10	S3 general purpose buckets with versioning enabled should have Lifecycle configurations	NIST SP 800-53 Rev. 5, CRI Profile v2.2	MEDIUM	⊗ No	Change triggered

Security control ID	Security control title	Applicable standards	Severity	Supports custom parameters	Schedule type
S3.11	S3 general purpose buckets should have event notifications enabled	NIST SP 800-53 Rev. 5, NIST SP 800-171 Rev. 2, CRI Profile v2.2	MEDIUM	Yes	Change triggered
S3.12	ACLs should not be used to manage user access to S3 general purpose buckets	AWS Foundational Security Best Practices, NIST SP 800-53 Rev. 5, CRI Profile v2.2	MEDIUM	No	Change triggered
S3.13	S3 general purpose buckets should have Lifecycle configurations	AWS Foundational Security Best Practices, NIST SP 800-53 Rev. 5, CRI Profile v2.2	LOW	Yes	Change triggered
S3.14	S3 general purpose buckets should have versioning enabled	NIST SP 800-53 Rev. 5, NIST SP 800-171 Rev. 2, CRI Profile v2.2	LOW	No	Change triggered
S3.15	S3 general purpose buckets should have Object Lock enabled	NIST SP 800-53 Rev. 5, PCI DSS v4.0.1, CRI Profile v2.2	MEDIUM	Yes	Change triggered
S3.17	S3 general purpose buckets should be encrypted at rest with AWS KMS keys	NIST SP 800-53 Rev. 5, NIST SP 800-171 Rev. 2, PCI DSS v4.0.1, CRI Profile v2.2	MEDIUM	No	Change triggered

Security control ID	Security control title	Applicable standards	Severity	Supports custom parameters	Schedule type
S3.19	S3 access points should have block public access settings enabled	AWS Foundational Security Best Practices, NIST SP 800-53 Rev. 5, PCI DSS v4.0.1, CRI Profile v2.2	CRITICAL	⊗ No	Change triggered
S3.20	S3 general purpose buckets should have MFA delete enabled	CIS AWS Foundations Benchmark v5.0.0, CIS AWS Foundations Benchmark v3.0.0, CIS AWS Foundations Benchmark v1.4.0, NIST SP 800-53 Rev. 5, CRI Profile v2.2	LOW	⊗ No	Change triggered
S3.22	S3 general purpose buckets should log object-level write events	CIS AWS Foundations Benchmark v5.0.0, CIS AWS Foundations Benchmark v3.0.0, PCI DSS v4.0.1, CRI Profile v2.2	MEDIUM	⊗ No	Periodic
S3.23	S3 general purpose buckets should log object-level read events	CIS AWS Foundations Benchmark v5.0.0, CIS AWS Foundations Benchmark v3.0.0, PCI DSS v4.0.1, CRI Profile v2.2	MEDIUM	⊗ No	Periodic

Security control ID	Security control title	Applicable standards	Severity	Supports custom parameters	Schedule type
S3.24	S3 Multi-Region Access Points should have block public access settings enabled	AWS Foundational Security Best Practices, PCI DSS v4.0.1, CRI Profile v2.2	HIGH	⊗ No	Change triggered
S3.25	S3 directory buckets should have lifecycle configurations	AWS Foundational Security Best Practices	LOW	⊙ Yes	Change triggered
SageMaker.1	Amazon SageMaker notebook instances should not have direct internet access	AWS Foundational Security Best Practices, NIST SP 800-53 Rev. 5, PCI DSS v3.2.1, PCI DSS v4.0.1, CRI Profile v2.2	HIGH	⊗ No	Periodic
SageMaker.2	SageMaker notebook instances should be launched in a custom VPC	AWS Foundational Security Best Practices v1.0.0, NIST SP 800-53 Rev. 5, CRI Profile v2.2	HIGH	⊗ No	Change triggered
SageMaker.3	Users should not have root access to SageMaker notebook instances	AWS Foundational Security Best Practices v1.0.0, NIST SP 800-53 Rev. 5, CRI Profile v2.2	HIGH	⊗ No	Change triggered

Security control ID	Security control title	Applicable standards	Severity	Supports custom parameters	Schedule type
SageMaker.4	SageMaker endpoint production variants should have an initial instance count greater than 1	AWS Foundational Security Best Practices, NIST SP 800-53 Rev. 5, CRI Profile v2.2	MEDIUM	⊗ No	Periodic
SageMaker.5	SageMaker models should have network isolation enabled	AWS Foundational Security Best Practices, CRI Profile v2.2	MEDIUM	⊗ No	Change triggered
SageMaker.6	SageMaker app image configurations should be tagged	AWS Resource Tagging Standard	LOW	⊙ Yes	Change triggered
SageMaker.7	SageMaker images should be tagged	AWS Resource Tagging Standard	LOW	⊙ Yes	Change triggered
SageMaker.8	SageMaker notebook instances should run on supported platforms	AWS Foundational Security Best Practices, CRI Profile v2.2	MEDIUM	⊗ No	Periodic
SageMaker.9	SageMaker data quality job definitions should have inter-container traffic encryption enabled	AWS Foundational Security Best Practices v1.0.0	MEDIUM	⊗ No	Change triggered

Security control ID	Security control title	Applicable standards	Severity	Supports custom parameters	Schedule type
SageMaker.10	SageMaker model explainability job definitions should have inter-container traffic encryption enabled	AWS Foundational Security Best Practices v1.0.0	MEDIUM	⊗ No	Change triggered
SageMaker.11	SageMaker data quality job definitions should have network isolation enabled	AWS Foundational Security Best Practices v1.0.0	MEDIUM	⊗ No	Change triggered
SageMaker.12	SageMaker model bias job definitions should have network isolation enabled	AWS Foundational Security Best Practices v1.0.0	MEDIUM	⊗ No	Change triggered
SageMaker.13	SageMaker model quality job definitions should have inter-container traffic encryption enabled	AWS Foundational Security Best Practices v1.0.0	MEDIUM	⊗ No	Change triggered
SageMaker.14	SageMaker monitoring schedules should have network isolation enabled	AWS Foundational Security Best Practices v1.0.0	MEDIUM	⊗ No	Change triggered
SageMaker.15	SageMaker model bias job definitions should have inter-container traffic encryption enabled	AWS Foundational Security Best Practices v1.0.0	MEDIUM	⊗ No	Change triggered

Security control ID	Security control title	Applicable standards	Severity	Supports custom parameters	Schedule type
SageMaker.16	SageMaker models should use private registry in VPC for primary containers	AWS Foundational Security Best Practices	MEDIUM	⊗ No	Change triggered
SageMaker.17	SageMaker feature group offline stores should be encrypted with AWS KMS keys	AWS Foundational Security Best Practices	MEDIUM	⊗ No	Change triggered
SageMaker.18	SageMaker feature group online stores with standard storage should be encrypted with AWS KMS keys	NIST SP 800-53 Rev. 5	MEDIUM	⊗ No	Change triggered
SageMaker.19	SageMaker models should use private registry in VPC for multi-container inference pipelines	AWS Foundational Security Best Practices	MEDIUM	⊗ No	Change triggered
SageMaker.20	SageMaker model explainability job definitions should have network isolation enabled	AWS Foundational Security Best Practices	HIGH	⊗ No	Change triggered
SageMaker.21	SageMaker notebook instances should be encrypted with customer managed AWS KMS keys	NIST SP 800-53 Rev. 5	MEDIUM	⊗ No	Change triggered

Security control ID	Security control title	Applicable standards	Severity	Supports custom parameters	Schedule type
SageMaker.22	SageMaker monitoring schedules should have inter-container traffic encryption enabled	AWS Foundational Security Best Practices	MEDIUM	⊗ No	Change triggered
SageMaker.23	SageMaker inference experiments should have instance storage volume encrypted with customer managed AWS KMS keys	NIST SP 800-53 Rev. 5	MEDIUM	⊗ No	Change triggered
SageMaker.24	SageMaker inference experiments should have data storage encrypted with customer managed AWS KMS keys	NIST SP 800-53 Rev. 5	MEDIUM	⊗ No	Change triggered
SageMaker.25	SageMaker model quality job definitions should have network isolation enabled	AWS Foundational Security Best Practices	HIGH	⊗ No	Change triggered
SecretsManager.1	Secrets Manager secrets should have automatic rotation enabled	AWS Foundational Security Best Practices, NIST SP 800-53 Rev. 5, PCI DSS v4.0.1, CRI Profile v2.2	MEDIUM	⊙ Yes	Change triggered

Security control ID	Security control title	Applicable standards	Severity	Supports custom parameters	Schedule type
SecretsManager.2	Secrets Manager secrets configured with automatic rotation should rotate successfully	AWS Foundational Security Best Practices, NIST SP 800-53 Rev. 5, PCI DSS v4.0.1, CRI Profile v2.2	MEDIUM	No	Change triggered
SecretsManager.3	Remove unused Secrets Manager secrets	AWS Foundational Security Best Practices, NIST SP 800-53 Rev. 5, CRI Profile v2.2	MEDIUM	Yes	Periodic
SecretsManager.4	Secrets Manager secrets should be rotated within a specified number of days	AWS Foundational Security Best Practices, NIST SP 800-53 Rev. 5, PCI DSS v4.0.1, CRI Profile v2.2	MEDIUM	Yes	Periodic
SecretsManager.5	Secrets Manager secrets should be tagged	AWS Resource Tagging Standard	LOW	Yes	Change triggered
ServiceCatalog.1	Service Catalog portfolios should be shared within an AWS organization only	AWS Foundational Security Best Practices, NIST SP 800-53 Rev. 5, CRI Profile v2.2	MEDIUM	No	Periodic
SES.1	SES contact lists should be tagged	AWS Resource Tagging Standard	LOW	Yes	Change triggered

Security control ID	Security control title	Applicable standards	Severity	Supports custom parameters	Schedule type
SES.2	SES configuration sets should be tagged	AWS Resource Tagging Standard	LOW	Yes	Change triggered
SES.3	SES configuration sets should have TLS enabled for sending emails	AWS Foundational Security Best Practices	MEDIUM	No	Change triggered
SNS.1	SNS topics should be encrypted at-rest using AWS KMS	NIST SP 800-53 Rev. 5, NIST SP 800-171 Rev. 2, CRI Profile v2.2	MEDIUM	No	Change triggered
SNS.3	SNS topics should be tagged	AWS Resource Tagging Standard	LOW	Yes	Change triggered
SNS.4	SNS topic access policies should not allow public access	AWS Foundational Security Best Practices, CRI Profile v2.2	CRITICAL	No	Change triggered
SQS.1	Amazon SQS queues should be encrypted at rest	AWS Foundational Security Best Practices v1.0.0, NIST SP 800-53 Rev. 5, CRI Profile v2.2	MEDIUM	No	Change triggered
SQS.2	SQS queues should be tagged	AWS Resource Tagging Standard	LOW	Yes	Change triggered

Security control ID	Security control title	Applicable standards	Severity	Supports custom parameters	Schedule type
SQS.3	SQS queue access policies should not allow public access	AWS Foundational Security Best Practices, CRI Profile v2.2	CRITICAL	⊗ No	Change triggered
SSM.1	EC2 instances should be managed by AWS Systems Manager	AWS Foundational Security Best Practices v1.0.0, PCI DSS v3.2.1, NIST SP 800-53 Rev. 5, CRI Profile v2.2	MEDIUM	⊗ No	Change triggered
SSM.2	EC2 instances managed by Systems Manager should have a patch compliance status of COMPLIANT after a patch installation	AWS Foundational Security Best Practices v1.0.0, NIST SP 800-53 Rev. 5, NIST SP 800-171 Rev. 2, PCI DSS v3.2.1, PCI DSS v4.0.1, CRI Profile v2.2	HIGH	⊗ No	Change triggered
SSM.3	EC2 instances managed by Systems Manager should have an association compliance status of COMPLIANT	AWS Foundational Security Best Practices v1.0.0, NIST SP 800-53 Rev. 5, PCI DSS v3.2.1, PCI DSS v4.0.1, CRI Profile v2.2	LOW	⊗ No	Change triggered

Security control ID	Security control title	Applicable standards	Severity	Supports custom parameters	Schedule type
SSM.4	SSM documents should not be public	AWS Foundational Security Best Practices v1.0.0, NIST SP 800-53 Rev. 5, CRI Profile v2.2	CRITICAL	⊗ No	Periodic
SSM.5	SSM documents should be tagged	AWS Resource Tagging Standard	LOW	⊙ Yes	Change triggered
SSM.6	SSM Automation should have CloudWatch logging enabled	AWS Foundational Security Best Practices v1.0.0, CRI Profile v2.2	MEDIUM	⊗ No	Periodic
SSM.7	SSM documents should have the block public sharing setting enabled	AWS Foundational Security Best Practices v1.0.0, CRI Profile v2.2	CRITICAL	⊗ No	Periodic
StepFunctions.1	Step Functions state machines should have logging turned on	AWS Foundational Security Best Practices v1.0.0, PCI DSS v4.0.1, CRI Profile v2.2	MEDIUM	⊙ Yes	Change triggered
StepFunctions.2	Step Functions activities should be tagged	AWS Resource Tagging Standard	LOW	⊙ Yes	Change triggered
Transfer.1	Transfer Family workflows should be tagged	AWS Resource Tagging Standard	LOW	⊙ Yes	Change triggered

Security control ID	Security control title	Applicable standards	Severity	Supports custom parameters	Schedule type
Transfer.2	Transfer Family servers should not use FTP protocol for endpoint connection	AWS Foundational Security Best Practices, NIST SP 800-53 Rev. 5, PCI DSS v4.0.1, CRI Profile v2.2	MEDIUM	No	Periodic
Transfer.3	Transfer Family connectors should have logging enabled	AWS Foundational Security Best Practices, NIST SP 800-53 Rev. 5, CRI Profile v2.2	MEDIUM	No	Change triggered
Transfer.4	Transfer Family agreements should be tagged	AWS Resource Tagging Standard, CRI Profile v2.2	LOW	Yes	Change triggered
Transfer.5	Transfer Family certificates should be tagged	AWS Resource Tagging Standard	LOW	Yes	Change triggered
Transfer.6	Transfer Family connectors should be tagged	AWS Resource Tagging Standard, CRI Profile v2.2	LOW	Yes	Change triggered
Transfer.7	Transfer Family profiles should be tagged	AWS Resource Tagging Standard	LOW	Yes	Change triggered

Security control ID	Security control title	Applicable standards	Severity	Supports custom parameters	Schedule type
WAF.1	AWS WAF Classic Global Web ACL logging should be enabled	AWS Foundational Security Best Practices, NIST SP 800-53 Rev. 5, PCI DSS v4.0.1, CRI Profile v2.2	MEDIUM	⊗ No	Periodic
WAF.2	AWS WAF Classic Regional rules should have at least one condition	AWS Foundational Security Best Practices v1.0.0, NIST SP 800-53 Rev. 5, CRI Profile v2.2	MEDIUM	⊗ No	Change triggered
WAF.3	AWS WAF Classic Regional rule groups should have at least one rule	AWS Foundational Security Best Practices v1.0.0, NIST SP 800-53 Rev. 5, CRI Profile v2.2	MEDIUM	⊗ No	Change triggered
WAF.4	AWS WAF Classic Regional web ACLs should have at least one rule or rule group	AWS Foundational Security Best Practices v1.0.0, NIST SP 800-53 Rev. 5, CRI Profile v2.2	MEDIUM	⊗ No	Change triggered
WAF.6	AWS WAF Classic global rules should have at least one condition	AWS Foundational Security Best Practices v1.0.0, NIST SP 800-53 Rev. 5, CRI Profile v2.2	MEDIUM	⊗ No	Change triggered

Security control ID	Security control title	Applicable standards	Severity	Supports custom parameters	Schedule type
WAF.7	AWS WAF Classic global rule groups should have at least one rule	AWS Foundational Security Best Practices v1.0.0, NIST SP 800-53 Rev. 5, CRI Profile v2.2	MEDIUM	⊗ No	Change triggered
WAF.8	AWS WAF Classic global web ACLs should have at least one rule or rule group	AWS Foundational Security Best Practices v1.0.0, NIST SP 800-53 Rev. 5, CRI Profile v2.2	MEDIUM	⊗ No	Change triggered
WAF.10	AWS WAF web ACLs should have at least one rule or rule group	AWS Foundational Security Best Practices v1.0.0, NIST SP 800-53 Rev. 5, CRI Profile v2.2	MEDIUM	⊗ No	Change triggered
WAF.11	AWS WAF web ACL logging should be enabled	NIST SP 800-53 Rev. 5, PCI DSS v4.0.1, CRI Profile v2.2	LOW	⊗ No	Periodic
WAF.12	AWS WAF rules should have CloudWatch metrics enabled	AWS Foundational Security Best Practices v1.0.0, NIST SP 800-53 Rev. 5, NIST SP 800-171 Rev. 2, CRI Profile v2.2	MEDIUM	⊗ No	Change triggered
WorkSpaces.1	WorkSpaces user volumes should be encrypted at rest	AWS Foundational Security Best Practices, CRI Profile v2.2	MEDIUM	⊗ No	Change triggered

Security control ID	Security control title	Applicable standards	Severity	Supports custom parameters	Schedule type
WorkSpaces.2	WorkSpaces root volumes should be encrypted at rest	AWS Foundational Security Best Practices, CRI Profile v2.2	MEDIUM	⊗ No	Change triggered

Change log for Security Hub CSPM controls

The following change log tracks material changes to existing AWS Security Hub CSPM controls, which can result in changes to the overall status of a control and the compliance status of its findings. For information about how Security Hub CSPM evaluates control status, see Evaluating compliance status and control status. Changes can take a few days after their entry in this log to affect all AWS Regions in which the control is available.

This log tracks changes occurring since April 2023. Choose a control to review additional details about it. Title changes are noted in a control's detailed description for 90 days.

Date of change	Control ID and title	Description of change
November 13, 2026	[Lambda.2] Lambda functions should use supported runtimes	Lambda.2 checks whether the AWS Lambda function settings for runtimes match the expected values set for the supported runtimes in each language. Security Hub CSPM now supports `nodejs26.x` and `python3.15` as parameter values

Date of change	Control ID and title	Description of change
		as AWS Lambda has added support for these runtimes. Security Hub CSPM no longer supports `dotnet8` as a parameter value as AWS Lambda no longer supports this runtime.
November 4, 2026	[Lambda.2] Lambda functions should use supported runtimes	Security Hub CSPM no longer supports `python3.10` as a parameter value for this control. AWS Lambda no longer supports this runtime.
November 4, 2026	[Opensearch.8] Connections to OpenSearch domains should be encrypted using the latest TLS security policy	Security Hub CSPM now supports `Policy-Min-TLS-1-2-RFC9151-FIPS-2024-08` as a parameter value for this control. The control now produces a `PASSED` finding for OpenSearch domains that use this TLS security policy.

Date of change	Control ID and title	Description of change
October 29, 2026	[ELB.17] Application and Network Load Balancers with listeners should use recommended security policies	Security Hub CSPM updated the parameter value for this control to reflect recommended security policies.
October 29, 2026	[CloudFront.15] CloudFront distributions should use the recommended TLS security policy	Security Hub CSPM updated the parameter value for this control to reflect recommended security policies.
October 12, 2026	[Bedrock.1] Amazon Bedrock data sources should be encrypted with customer managed AWS KMS keys	Security Hub CSPM updated the control to not evaluate data sources that belong to a managed knowledge base, because server-si de encryption for a managed knowledge base is configured on the knowledge base instead of on its data sources.

Date of change	Control ID and title	Description of change
September 23, 2026	[BedrockAgentCore.1] Bedrock AgentCore runtimes should be configured with VPC network mode	Security Hub CSPM updated the control to not evaluate runtimes that are backed by a capacity provider, because such runtimes define their network configuration on the capacity provider instead of on the runtime.
September 11, 2026	[RDS.35] RDS DB clusters should have automatic minor version upgrade enabled	This control checks whether automatic minor version upgrade is enabled for an Amazon RDS DB cluster. Security Hub CSPM expanded the control to evaluate Aurora DB clusters, which previously returned no findings.
September 11, 2026	[S3.5] S3 general purpose buckets should require requests to use TLS	Security Hub CSPM updated the title and description of this control to refer to TLS instead of SSL as SSL is deprecated.

Date of change	Control ID and title	Description of change
August 27, 2026	[RDS.2] RDS DB Instances should prohibit public access, as determined by the PubliclyAccessible configuration	This control checks whether Amazon RDS instances prohibit public access. Because Neptune DB now supports public endpoints, this control evaluates and generates actionable findings for Neptune DB instances. Security Hub CSPM updated the control description to reflect this change.
August 12, 2026	[EKS.2] EKS clusters should run on a supported Kubernetes version	This control checks whether an Amazon EKS cluster runs on a supported Kubernetes version. Security Hub CSPM changed the parameter value for this control from `1.33` to `1.34`. Standard support for Kubernetes version 1.33 in Amazon EKS ended on July 29, 2026.

Date of change	Control ID and title	Description of change
August 12, 2026	[EKS.9] EKS node groups should run on a supported Kubernetes version	This control checks whether an Amazon EKS node group runs on a supported Kubernetes version. Security Hub CSPM changed the parameter value for this control from `1.33` to `1.34`. Standard support for Kubernetes version 1.33 in Amazon EKS ended on July 29, 2026.
Aug 3, 2026	[Lambda.2] Lambda functions should use supported runtimes	Lambda.2 checks whether the AWS Lambda function settings for runtimes match the expected values set for the supported runtimes in each language. Security Hub CSPM now supports `java17.al2023`, `java11.al2023`, `java8.al2023` as parameter value as AWS Lambda has added support for this runtime.

Date of change	Control ID and title	Description of change
Aug 3, 2026	[EFS.6] EFS mount targets should not be associated with subnets that assign public IP addresses on launch	Security Hub CSPM has removed this control from the AWS Foundational Security Best Practices (FSBP) standard.
July 31, 2026	[SageMaker.8] SageMaker notebook instances should run on supported platforms	Security Hub CSPM changed the parameter value for this control from `notebook-al2-v3` to `notebook-al2023-v1` . SageMaker AI migrated notebook instance platforms from Amazon Linux 2 to AL2023.
July 13, 2026	[EC2.10] Amazon EC2 should be configured to use VPC endpoints that are created for the Amazon EC2 service	Security Hub CSPM changed the backing rule for this control from service-vpc-endpoint-enabled to vpc-endpoint-enabled. The updated rule recognizes FIPS-variant endpoint service names as compliant and generates a PASSED finding for VPCs that use FIPS endpoints.

Date of change	Control ID and title	Description of change
June 29, 2026	[EFS.6] EFS mount targets should not be associated with subnets that assign public IP addresses on launch	Security Hub CSPM has added this control to the following applicable standards – the NIST SP 800-53 Rev. 5 standard, the NIST SP 800-171 Revision 2 standard, and the PCI DSS v4.0.1 standard. On July 30, 2026, this control will be removed from the AWS Foundational Security Best Practices (FSBP) standard.

Date of change	Control ID and title	Description of change
June 5, 2026	[EKS.3] EKS clusters should use encrypted Kubernetes secrets	Security Hub CSPM provided notice that this control will be retired and removed from all applicable Security Hub CSPM standards after August 10, 2026. Starting with Kubernetes version 1.28, Amazon EKS clusters have Kubernetes secrets protected with envelope encryption by default.
June 5, 2026	[IoTEvents.1] AWS IoT Events inputs should be tagged	Security Hub CSPM provided notice that this control will be retired and removed from all applicable Security Hub CSPM standards after July 7, 2026. AWS announced end of support for AWS IoT Events service effective May 20, 2026.

Date of change	Control ID and title	Description of change
June 5, 2026	[IoTEvents.2] AWS IoT Events detector models should be tagged	Security Hub CSPM provided notice that this control will be retired and removed from all applicable Security Hub CSPM standards after July 7, 2026. AWS announced end of support for AWS IoT Events service effective May 20, 2026.
June 5, 2026	[IoTEvents.3] AWS IoT Events alarm models should be tagged	Security Hub CSPM provided notice that this control will be retired and removed from all applicable Security Hub CSPM standards after July 7, 2026. AWS announced end of support for AWS IoT Events service effective May 20, 2026.

Date of change	Control ID and title	Description of change
June 5, 2026	[ECS.1] Amazon ECS task definitions should have secure networking modes and user definitions	Security Hub CSPM retired this control and removed it from all applicable standards. Previously, the control checked whether an active Amazon ECS task definition that used host networking mode also had `privileged` or `user` container definitions.

Date of change	Control ID and title	Description of change
June 5, 2026	[RDS.18] RDS instances should be deployed in a VPC	Security Hub CSPM retired this control and removed it from all applicable standards. Since Amazon EC2-Classic networking was retired, Amazon Relational Database Service (Amazon RDS) instances can no longer be deployed outside a VPC. Previously, the control checked whether an Amazon RDS instance was deployed on an EC2-VPC.

Date of change	Control ID and title	Description of change
May 4, 2026	[Lambda.2] Lambda functions should use supported runtimes	Lambda.2 checks whether the AWS Lambda function settings for runtimes match the expected values set for the supported runtimes in each language. Security Hub CSPM now supports `ruby4.0` as a parameter and no longer includes `nodejs20.x` as AWS Lambda has deprecated this runtime.
April 27, 2026	[EC2.4] Stopped EC2 instances should be removed after a specified time period	Security Hub CSPM changed the backing rule for this control from ec2-stopped-instance to a custom Security Hub CSPM rule, ec2-stopped-instance-days-check to simplify evaluation logic.

Date of change	Control ID and title	Description of change
April 7, 2026	[EC2.1] Amazon EBS snapshots should not be configured to be publicly restorable	Security Hub CSPM changed the title and description of this control. The new title and description more accurately reflect that the control checks whether Amazon EBS snapshots are configured to be publicly restorabl e. Previously, the title of this control was: *Amazon EBS snapshots should not be publicly restorable*.
April 7, 2026	[EC2.182] Block public access settings should be enabled for Amazon EBS snapshots	Security Hub CSPM changed the title and description of this control. The new title and description more accurately reflect that the control checks whether account level block public access is enabled for Amazon EBS snapshots . Previously, the title of this control was: *Amazon EBS Snapshots should not be publicly accessible*.

Date of change	Control ID and title	Description of change
April 6, 2026	[ELB.17] Application and Network Load Balancers with listeners should use recommended security policies	Security Hub CSPM updated the parameter value for this control to reflect recommended security policies.
April 3, 2026	[Cognito.3] Password policies for Cognito user pools should have strong configurations	Security Hub CSPM expanded the range of supported values for the `temporaryPasswordValidity` parameter of this control. You can now specify a value ranging from 1-365 days. Previously, the range was 7-365 days.
April 3, 2026	[EKS.2] EKS clusters should run on a supported Kubernetes version	This control checks whether an Amazon EKS cluster runs on a supported Kubernetes version. Security Hub CSPM changed the parameter value for this control from `1.32` to `1.33`. Standard support for Kubernetes version 1.32 in Amazon EKS ended on March 23, 2026.

Date of change	Control ID and title	Description of change
April 3, 2026	[Lambda.2] Lambda functions should use supported runtimes	Lambda.2 parameter for supported runtimes no longer includes `ruby3.2` as Lambda has deprecated this runtime.
March 24, 2026	[RDS.50] RDS DB clusters should have enough backup retention period set	Security Hub CSPM updated the control title to reflect that the control checks all RDS DB clusters.
March 24, 2026	[ECS.5] ECS task definitions should configure containers to be limited to read-only access to root filesystems	Security Hub CSPM updated the control title and descripti on to reflect that the control checks ECS task definitio ns. Security Hub CSPM also updated the control to not generate findings for task definitions with `runtimePlatform` configured to specify a `WINDOWS_SERVER` OS family.

Date of change	Control ID and title	Description of change
March 9, 2026	[AppSync.1] AWS AppSync API caches should be encrypted at rest	Security Hub CSPM retired this control and removed it from the AWS Foundational Security Best Practices (FSBP) standard. AWS AppSync now provides default encryption on all current and future API caches.
March 9, 2026	[AppSync.6] AWS AppSync API caches should be encrypted in transit	Security Hub CSPM retired this control and removed it from the AWS Foundational Security Best Practices (FSBP) standard. AWS AppSync now provides default encryption on all current and future API caches.

Date of change	Control ID and title	Description of change
March 4, 2026	[ECS.1] Amazon ECS task definitions should have secure networking modes and user definitions	Security Hub CSPM retired this control and removed it from the AWS Foundational Security Best Practices (FSBP) standard and the NIST SP 800-53 Rev. 5 standard.
February 5, 2026	[AppSync.1] AWS AppSync API caches should be encrypted at rest	Security Hub CSPM will retire this control and remove from all applicable Security Hub CSPM standards on March 9, 2026. AWS AppSync is providing default encryption on all current and future API caches.
February 5, 2026	[AppSync.6] AWS AppSync API caches should be encrypted in transit	Security Hub CSPM will retire this control and remove from all applicable Security Hub CSPM standards on March 9, 2026. AWS AppSync is providing default encryption on all current and future API caches.

Date of change	Control ID and title	Description of change
January 16, 2026	[ECS.1] Amazon ECS task definitions should have secure networking modes and user definitions	Security Hub CSPM provided notice that this control will be retired and removed from all applicable Security Hub CSPM standards after February 16, 2026.
January 12, 2026	[Redshift.4] Amazon Redshift clusters should have audit logging enabled	Security Hub CSPM updated this control to remove the `loggingEnabled` parameter.

Date of change	Control ID and title	Description of change
January 12, 2026	[MQ.3] Amazon MQ brokers should have automatic minor version upgrade enabled	Security Hub CSPM retired the control and removed the control from all applicable standards . Security Hub CSPM retired the control due to Amazon MQ requirements for automatic minor version upgrades. Previously, the control applied to the AWS Foundational Security Best Practices (FSBP) standard, the NIST SP 800-53 Rev. 5 standard and the PCI DSS v4.0.1 standard.

Date of change	Control ID and title	Description of change
January 12, 2026	[Lambda.2] Lambda functions should use supported runtimes	This control checks whether the runtime settings for an AWS Lambda function match expected values for supported runtimes in each language. Security Hub CSPM now supports `dotnet10` as a parameter value for this control. AWS Lambda added support for this runtime.
December 15, 2025	[Lambda.2] Lambda functions should use supported runtimes	This control checks whether the runtime settings for an AWS Lambda function match expected values for supported runtimes in each language. Security Hub CSPM no longer supports `python3.9` as a parameter value for this control. AWS Lambda no longer supports this runtime.

Date of change	Control ID and title	Description of change
December 12, 2025	[EKS.2] EKS clusters should run on a supported Kubernetes version	This control checks whether an Amazon EKS cluster runs on a supported Kubernetes version. Security Hub CSPM changed the parameter value for this control from `1.31` to `1.32`. Standard support for Kubernetes version 1.31 in Amazon EKS ended on November 26, 2025.
November 21, 2025	[Lambda.2] Lambda functions should use supported runtimes	This control checks whether the runtime settings for an AWS Lambda function match expected values for supported runtimes in each language. Security Hub CSPM now supports `nodejs24.x` and `python3.14` as parameter values for this control. AWS Lambda added support for these runtimes.

Date of change	Control ID and title	Description of change
November 14, 2025	[EC2.15] Amazon EC2 subnets should not automatically assign public IP addresses	Security Hub CSPM updated the description and rationale for this control. Previously, the control only checked for IPv4 public IP auto-assignment in Amazon VPC subnets using the `MapPublicIpOnLaunch` flag. This control now checks for both IPv4 and IPv6 public IP auto-assignment. The control's description and rationale have been updated to reflect these changes.

Date of change	Control ID and title	Description of change
November 14, 2025	[Lambda.2] Lambda functions should use supported runtimes	This control checks whether the runtime settings for an AWS Lambda function match expected values for supported runtimes in each language. Security Hub CSPM now supports `java25` as a parameter value for this control. AWS Lambda added support for this runtime.
November 13, 2025	[SNS.4] SNS topic access policies should not allow public access	Security Hub CSPM changed the severity of this control from `HIGH` to `CRITICAL`. Allowing public access to Amazon SNS topics poses a significant security risk.

Date of change	Control ID and title	Description of change
November 13, 2025	[SQS.3] SQS queue access policies should not allow public access	Security Hub CSPM changed the severity of this control from `HIGH` to `CRITICAL`. Allowing public access to Amazon SQS queues poses a significant security risk.
November 13, 2025	[GuardDuty.7] GuardDuty EKS Runtime Monitoring should be enabled	Security Hub CSPM changed the severity of this control from `MEDIUM` to `HIGH`. This type of runtime monitoring provides enhanced threat detection for Amazon EKS resources.
November 13, 2025	[MQ.3] Amazon MQ brokers should have automatic minor version upgrade enabled	Security Hub CSPM changed the severity of this control from `LOW` to `MEDIUM`. Minor version upgrades include security patches that are necessary for maintaining Amazon MQ broker security.

Date of change	Control ID and title	Description of change
November 13, 2025	[Opensearch.10] OpenSearch domains should have the latest software update installed	Security Hub CSPM changed the severity of this control from `LOW` to `MEDIUM`. Software updates include security patches that are necessary for maintaining OpenSearch domain security.
November 13, 2025	[RDS.7] RDS clusters should have deletion protection enabled	Security Hub CSPM changed the severity of this control from `LOW` to `MEDIUM`. Deletion protectio n helps prevent accidental deletion of Amazon RDS databases and deletion of RDS databases by unauthorized entities.

Date of change	Control ID and title	Description of change
November 13, 2025	[CloudTrail.5] CloudTrail trails should be integrated with Amazon CloudWatch Logs	Security Hub CSPM changed the severity of this control from `LOW` to `MEDIUM`. AWS CloudTrail logging data in Amazon CloudWatch Logs can be used for audit activities, alarms, and other important security operations.
November 13, 2025	[ServiceCatalog.1] Service Catalog portfolios should be shared within an AWS organization only	Security Hub CSPM changed the severity of this control from `HIGH` to `MEDIUM`. Sharing AWS Service Catalog portfolios with specific accounts could be intentional and doesn't necessarily indicate that a portfolio is publicly accessible.

Date of change	Control ID and title	Description of change
November 13, 2025	[CloudFront.7] CloudFront distributions should use custom SSL/TLS certificates	Security Hub CSPM changed the severity of this control from `MEDIUM` to `LOW`. Default `cloudfront.net` domain names for Amazon CloudFront distributions are generated randomly, which reduces security risk.
November 13, 2025	[ELB.7] Classic Load Balancers should have connection draining enabled	Security Hub CSPM changed the severity of this control from `MEDIUM` to `LOW`. In multi-instance deployments, other healthy instances can handle user sessions when an instance is terminated without connection draining, which reduces operational impact and availability risks.
November 13, 2025	[RedshiftServerless.5] Redshift Serverless namespaces should not use the default admin username	Security Hub CSPM updated this control to remove the optional `validAdminUserNames` parameter.

Date of change	Control ID and title	Description of change
October 23, 2025	[ElastiCache.1] ElastiCache (Redis OSS) clusters should have automatic backups enabled	Security Hub CSPM reverted the changes that were made to the title, descripti on, and rule for this control on October 14, 2025.
October 22, 2025	[CloudFront.1] CloudFront distributions should have a default root object configured	Security Hub CSPM updated this control to not generate findings for Amazon CloudFront distribut ions that use custom origins.
October 16, 2025	[CloudFront.15] CloudFront distributions should use the recommended TLS security policy	This control checks whether an Amazon CloudFront distribut ion is configured to use a recommend ed TLS security policy. Security Hub CSPM now supports `TLSv1.2_2025` and `TLSv1.3_2025` as parameter values for this control.

Date of change	Control ID and title	Description of change
October 14, 2025	[ElastiCache.1] ElastiCache (Redis OSS) clusters should have automatic backups enabled	Security Hub CSPM changed the title, description, and rule for this control. Previously, the control checked Redis OSS clusters and all replication groups, using the elasticache-redis-cluster-automatic-backup-check rule. The title of the control was: *ElastiCache (Redis OSS) clusters should have automatic backups enabled*. This control now checks Valkey clusters in addition to Redis OSS clusters and all replication groups, using the elasticache-automatic-backup-check-enabled rule. The new title and description reflect that the control checks both types of clusters.

Date of change	Control ID and title	Description of change
October 5, 2025	[Opensearch.10] OpenSearch domains should have the latest software update installed	The rule for this control was updated to also generate a PASSED finding if an Amazon OpenSearch Service domain has no software updates available and the update status is ineligible. Previously, this control generated a PASSED finding only if an OpenSearch domain had no software updates available and the update status was complete.

Date of change	Control ID and title	Description of change
September 24, 2025	[Redshift.9] Redshift clusters should not use the default database name [RedshiftServerless.7] Redshift Serverless namespaces should not use the default database name	Security Hub CSPM retired these controls and removed them from all applicable standards. Security Hub CSPM retired these controls due to inherent Amazon Redshift limitations that prevented effective remediation of `FAILED` findings for the controls. Previously, the controls applied to the AWS Foundational Security Best Practices (FSBP) standard and the NIST SP 800-53 Rev. 5 standard. The Redshift.9 control also applied to the AWS Control Tower service-managed standard.

Date of change	Control ID and title	Description of change
September 9, 2025	[Lambda.2] Lambda functions should use supported runtimes	This control checks whether the runtime settings for an AWS Lambda function match expected values for supported runtimes in each language. Security Hub CSPM no longer supports `nodejs18.x` as a parameter value for this control. AWS Lambda no longer supports Node.js 18 runtimes.

Date of change	Control ID and title	Description of change
August 13, 2025	[SageMaker.5] SageMaker models should have network isolation enabled	Security Hub CSPM changed the title and description of this control. The new title and description more accurately reflect that the control checks the setting for the `EnableNetworkIsolation` parameter of Amazon SageMaker AI hosted models. Previously, the title of this control was: *SageMaker models should block inbound traffic*.
August 13, 2025	[EFS.6] EFS mount targets should not be associated with subnets that assign public IP addresses on launch	Security Hub CSPM changed the title and description of this control. The new title and description more precisely reflect the scope and nature of the check that the control performs. Previously, the title of this control was: *EFS mount targets should not be associated with a public subnet*.

Date of change	Control ID and title	Description of change
July 24, 2025	[EKS.2] EKS clusters should run on a supported Kubernetes version	This control checks whether an Amazon EKS cluster runs on a supported Kubernetes version. Security Hub CSPM changed the parameter value for this control from `1.30` to `1.31`. Standard support for Kubernetes version 1.30 in Amazon EKS ended on July 23, 2025.
July 23, 2025	[EC2.173] EC2 Spot Fleet requests with launch parameters should enable encryption for attached EBS volumes	Security Hub CSPM changed the title of this control. The new title more accurately reflects that the control only checks Amazon EC2 Spot Fleet requests that specify launch parameters. Previously, the title of this control was: *EC2 Spot Fleet requests should enable encryption for attached EBS volumes*.

Date of change	Control ID and title	Description of change
June 30, 2025	[IAM.13] Ensure IAM password policy requires at least one symbol	Security Hub CSPM removed this control from the PCI DSS v4.0.1 standard. PCI DSS v4.0.1 doesn't explicitly require the use of symbols in passwords.
June 30, 2025	[IAM.17] Ensure IAM password policy expires passwords within 90 days or less	Security Hub CSPM removed this control from the NIST SP 800-171 Revision 2 standard. NIST SP 800-171 Revision 2 doesn't explicitl y require password expiration periods of 90 days or less.
June 30, 2025	[RDS.16] Aurora DB clusters should be configured to copy tags to DB snapshots	Security Hub CSPM changed the title of this control. The new title more accuratel y reflects that the control only checks Amazon Aurora DB clusters. Previousl y, the title of this control was: *RDS DB clusters should be configured to copy tags to snapshots*.

Date of change	Control ID and title	Description of change
June 30, 2025	[SageMaker.8] SageMaker notebook instances should run on supported platforms	This control checks whether an Amazon SageMaker AI notebook instance is configured to run on a supported platform, based on the platform identifier specified for the notebook instance. Security Hub CSPM no longer supports `notebook-al2-v1` and `notebook-al2-v2` as parameter values for this control. Notebook instances that run on these platforms reached end of support on June 30, 2025.

Date of change	Control ID and title	Description of change
May 30, 2025	[IAM.10] Password policies for IAM users should have strong configurations	Security Hub CSPM removed this control from the PCI DSS v4.0.1 standard. This control checks whether account password policies for IAM users meet minimum requirements, including a minimum password length of 7 characters. PCI DSS v4.0.1 now requires passwords to have a minimum of 8 characters. The control continues to apply to the PCI DSS v3.2.1 standard, which has different password requirements. To evaluate account password policies against PCI DSS v4.0.1 requirements, you can use the IAM.7 control. This control requires passwords to have a minimum of 8 characters. It also supports custom values for password

Date of change	Control ID and title	Description of change
		length and other parameters. The IAM.7 control is part of the PCI DSS v4.0.1 standard in Security Hub CSPM.
May 8, 2025	[RDS.46] RDS DB instances should not be deployed in public subnets with routes to internet gateways	Security Hub CSPM rolled back the release of the RDS.46 control in all AWS Regions. Previousl y, this control supported the AWS Foundational Security Best Practices (FSBP) standard.

Date of change	Control ID and title	Description of change
April 7, 2025	[ELB.17] Application and Network Load Balancers with listeners should use recommended security policies	This control checks whether the HTTPS listener for an Application Load Balancer or the TLS listener for a Network Load Balancer is configured to encrypt data in transit by using a recommend ed security policy. Security Hub CSPM now supports two additional parameter values for this control: `ELBSecuri tyPolicy-TLS13-1-2-Res-2021-06` and `ELBSecuri tyPolicy-TLS13-1-2-Res-FIPS-2023-04` .

Date of change	Control ID and title	Description of change
March 27, 2025	[Lambda.2] Lambda functions should use supported runtimes	This control checks whether the runtime settings for an AWS Lambda function match expected values for supported runtimes in each language. Security Hub CSPM now supports `ruby3.4` as a parameter value for this control. AWS Lambda added support for this runtime.
March 26, 2025	[EKS.2] EKS clusters should run on a supported Kubernetes version	This control checks whether an Amazon Elastic Kubernetes Service (Amazon EKS) cluster runs on a supported Kubernetes version. For the `oldestVersionSupported` parameter, Security Hub CSPM changed the value from `1.29` to `1.30`. The oldest supported Kubernetes version is now `1.30`.

Date of change	Control ID and title	Description of change
March 10, 2025	[Lambda.2] Lambda functions should use supported runtimes	This control checks whether the runtime settings for an AWS Lambda function match expected values for supported runtimes in each language. Security Hub CSPM no longer supports `dotnet6` and `python3.8` as parameter values for this control. AWS Lambda no longer supports these runtimes.

Date of change	Control ID and title	Description of change
March 7, 2025	[RDS.18] RDS instances should be deployed in a VPC	Security Hub CSPM removed this control from the AWS Foundational Security Best Practices standard and automated checks for NIST SP 800-53 Rev. 5 requirements. Since Amazon EC2-Classic networking was retired, Amazon Relational Database Service (Amazon RDS) instances can no longer be deployed outside a VPC.
January 10, 2025	[Glue.2] AWS Glue jobs should have logging enabled	Security Hub CSPM retired this control and removed it from all standards.
December 20, 2024	EC2.61 through EC2.169	Security Hub CSPM rolled back the release of the EC2.61 through EC2.169 controls.

Date of change	Control ID and title	Description of change
December 12, 2024	[RDS.23] RDS instances should not use a database engine default port	RDS.23 checks whether an Amazon Relational Database Service (Amazon RDS) cluster or instance uses a port other than the default port of the database engine. We updated the control so that the underlying AWS Config rule returns a result of `NOT_APPLICABLE` for RDS instances that are part of a cluster.
December 2, 2024	[Lambda.2] Lambda functions should use supported runtimes	Lambda.2 checks whether the AWS Lambda function settings for runtimes match the expected values set for the supported runtimes in each language. Security Hub CSPM now supports `nodejs22.x` as a parameter.

Date of change	Control ID and title	Description of change
November 26, 2024	[EKS.2] EKS clusters should run on a supported Kubernetes version	This control checks whether an Amazon Elastic Kubernetes Service (Amazon EKS) cluster runs on a supported Kubernetes version. The oldest supported version is now 1.29.

Date of change	Control ID and title	Description of change
November 20, 2024	[Config.1] AWS Config should be enabled and use the service-linked role for resource recording	Config.1 checks whether AWS Config is enabled, uses the service-linked role, and records resources for enabled controls. Security Hub CSPM increased the severity of this control from `MEDIUM` to `CRITICAL`. Security Hub CSPM also added new status codes and status reasons for failed Config.1 findings. These changes reflect the importance of Config.1 to the operation of Security Hub CSPM controls. If you have AWS Config or resource recording disabled, you can receive inaccurate control findings. To receive a `PASSED` finding for Config.1, turn on resource recording for resources that correspond to enabled Security

Date of change	Control ID and title	Description of change
		Hub CSPM controls, and disable controls that aren't required in your organizat ion. For instructi ons on configuri ng AWS Config for Security Hub CSPM, see Enabling and configuring AWS Config for Security Hub CSPM. For a list of Security Hub CSPM controls and their correspon ding resources, see Required AWS Config resources for control findings.
November 12, 2024	[Lambda.2] Lambda functions should use supported runtimes	Lambda.2 checks whether the AWS Lambda function settings for runtimes match the expected values set for the supported runtimes in each language. Security Hub CSPM now supports `python3.13` as a parameter.

Date of change	Control ID and title	Description of change
October 11, 2024	ElastiCache controls	Changed control titles for ElastiCache.3, ElastiCache.4, ElastiCache.5, and ElastiCache.7. Titles no longer mention Redis OSS because the controls also apply to ElastiCache for Valkey.
September 27, 2024	[ELB.4] Application Load Balancer should be configured to drop invalid http headers	Changed control title from **Application Load Balancer should be configured to drop http headers** to **Application Load Balancer should be configured to drop invalid http headers**.
August 19, 2024	Title changes to DMS.12 and ElastiCache controls	Changed control titles for DMS.12 and ElastiCache.1 through ElastiCache.7. We changed these titles to reflect a name change in the Amazon ElastiCache (Redis OSS) service.

Date of change	Control ID and title	Description of change
August 15, 2024	[Config.1] AWS Config should be enabled and use the service-linked role for resource recording	Config.1 checks whether AWS Config is enabled, uses the service-linked role, and records resources for enabled controls. Security Hub CSPM added a custom control parameter named `includeConfigServiceLinkedRoleCheck`. By setting this parameter to `false`, you can opt out of checking whether AWS Config uses the service-linked role.
July 31, 2024	[IoT.1] AWS IoT Device Defender security profiles should be tagged	Changed control title from **AWS IoT Core security profiles should be tagged** to **AWS IoT Device Defender security profiles should be tagged**.

Date of change	Control ID and title	Description of change
July 29, 2024	[Lambda.2] Lambda functions should use supported runtimes	Lambda.2 checks whether the AWS Lambda function settings for runtimes match the expected values set for the supported runtimes in each language. Security Hub CSPM no longer supports `nodejs16.x` as a parameter.
July 29, 2024	[EKS.2] EKS clusters should run on a supported Kubernetes version	This control checks whether an Amazon Elastic Kubernetes Service (Amazon EKS) cluster runs on a supported Kubernetes version. The oldest supported version is `1.28`.
June 25, 2024	[Config.1] AWS Config should be enabled and use the service-linked role for resource recording	This control checks whether AWS Config is enabled, uses the service-linked role, and records resources for enabled controls. Security Hub CSPM updated the control title to reflect what the control evaluates.

Date of change	Control ID and title	Description of change
June 14, 2024	[RDS.34] Aurora MySQL DB clusters should publish audit logs to CloudWatch Logs	This control checks whether an Amazon Aurora MySQL DB cluster is configure d to publish audit logs to Amazon CloudWatch Logs. Security Hub CSPM updated the control so that it doesn't generate findings for Aurora Serverless v1 DB clusters.
June 11, 2024	[EKS.2] EKS clusters should run on a supported Kubernetes version	This control checks whether an Amazon Elastic Kubernete s Service (Amazon EKS) cluster runs on a supported Kubernete s version. The oldest supported version is `1.27`.

Date of change	Control ID and title	Description of change
June 10, 2024	[Config.1] AWS Config should be enabled and use the service-linked role for resource recording	This control checks whether AWS Config is enabled and AWS Config resource recording is turned on. Previously, the control produced a PASSED finding only if you configure d recording for all resources. Security Hub CSPM updated the control to produce a PASSED finding when recording is turned on for resources that are required for enabled controls. The control has also been updated to check whether the AWS Config service-linked role is used, which provides permissions to record necessary resources.

Date of change	Control ID and title	Description of change
May 8, 2024	[S3.20] S3 general purpose buckets should have MFA delete enabled	This control checks whether an Amazon S3 general purpose versioned bucket has multi-factor authentication (MFA) delete enabled. Previously, the control produced a `FAILED` finding for buckets that have a Lifecycle configura tion. However, MFA delete with versionin g can't be enabled on a bucket that has a Lifecycle configura tion. Security Hub CSPM updated the control to produce no findings for buckets that have a Lifecycle configuration. The control description has been updated to reflect the current behavior.

Date of change	Control ID and title	Description of change
May 2, 2024	[EKS.2] EKS clusters should run on a supported Kubernetes version	Security Hub CSPM updated the oldest supported version of Kubernetes that the Amazon EKS cluster can run on to produce a passed finding. The current oldest supported version is Kubernetes 1.26.
April 30, 2024	[CloudTrail.3] At least one CloudTrail trail should be enabled	Changed control title from **CloudTrail should be enabled** to **At least one CloudTrail trail should be enabled**. This control currently produces a PASSED finding if an AWS account has at least one CloudTrail trail enabled. The title and description have been changed to accurately reflect the current behavior.

Date of change	Control ID and title	Description of change
April 29, 2024	[AutoScaling.1] Auto Scaling groups associated with a load balancer should use ELB health checks	Changed control title from **Auto Scaling groups associated with a Classic Load Balancer should use load balancer health checks** to **Auto Scaling groups associated with a load balancer should use ELB health checks**. This control currently evaluates Application, Gateway, Network, and Classic Load Balancers. The title and description have been changed to accurately reflect the current behavior.

Date of change	Control ID and title	Description of change
April 19, 2024	[CloudTrail.1] CloudTrail should be enabled and configured with at least one multi-Region trail that includes read and write management events	The control checks whether AWS CloudTrail is enabled and configured with at least one multi-Region trail that includes read and write management events. Previously, the control incorrectly generated PASSED findings when an account had CloudTrail enabled and configured with at least one multi-Region trail, even if no trail captured read and write management events. The control now generates a PASSED finding only when CloudTrail is enabled and configured with at least one multi-Region trail that captures read and write management events.

Date of change	Control ID and title	Description of change
April 10, 2024	[Athena.1] Athena workgroups should be encrypted at rest	Security Hub CSPM retired this control and removed it from all standards. Athena workgroups send logs to Amazon Simple Storage Service (Amazon S3) buckets. Amazon S3 now provides default encryption with S3 managed keys (SS3-S3) on new and existing S3 buckets.
April 10, 2024	[AutoScaling.4] Auto Scaling group launch configuration should not have a metadata response hop limit greater than 1	Security Hub CSPM retired this control and removed it from all standards. Metadata response hop limits for Amazon Elastic Compute Cloud (Amazon EC2) instances are workload dependent.

Date of change	Control ID and title	Description of change
April 10, 2024	[CloudFormation.1] CloudFormation stacks should be integrated with Simple Notification Service (SNS)	Security Hub CSPM retired this control and removed it from all standards . Integrating AWS CloudFormation stacks with Amazon SNS topics is no longer a security best practice. Though integrating important CloudFormation stacks with SNS topics can be useful, it is not required for all stacks.
April 10, 2024	[CodeBuild.5] CodeBuild project environments should not have privileged mode enabled	Security Hub CSPM retired this control and removed it from all standards. Enabling privileged mode in a CodeBuild project does not impose an additiona l risk to the customer environment.

Date of change	Control ID and title	Description of change
April 10, 2024	[IAM.20] Avoid the use of the root user	Security Hub CSPM retired this control and removed it from all standards. The purpose of this control is covered by another control, [CloudWatch.1] A log metric filter and alarm should exist for usage of the "root" user.
April 10, 2024	[SNS.2] Logging of delivery status should be enabled for notification messages sent to a topic	Security Hub CSPM retired this control and removed it from all standards . Logging delivery status for SNS topics is no longer a security best practice. Though logging delivery status for important SNS topics can be useful, it is not required for all topics.

Date of change	Control ID and title	Description of change
April 10, 2024	[S3.10] S3 general purpose buckets with versioning enabled should have Lifecycle configurations	Security Hub CSPM removed this control from AWS Foundational Security Best Practices and Service-Managed Standard: AWS Control Tower. The purpose of this control is covered by two other controls: [S3.13] S3 general purpose buckets should have Lifecycle configurations and [S3.14] S3 general purpose buckets should have versioning enabled. This control is still part of NIST SP 800-53 Rev. 5.

Date of change	Control ID and title	Description of change
April 10, 2024	[S3.11] S3 general purpose buckets should have event notifications enabled	Security Hub CSPM removed this control from AWS Foundational Security Best Practices and Service-Managed Standard: AWS Control Tower. Though there are some cases where event notifications for S3 buckets are useful, this not a universal security best practice. This control is still part of NIST SP 800-53 Rev. 5.

Date of change	Control ID and title	Description of change
April 10, 2024	[SNS.1] SNS topics should be encrypted at-rest using AWS KMS	Security Hub CSPM removed this control from AWS Foundational Security Best Practices and Service-Managed Standard: AWS Control Tower. By default, SNS encrypts topics at rest with disk encryption. For more information, see Data encryption. Using AWS KMS to encrypt topics is no longer recommended as a security best practice. This control is still part of NIST SP 800-53 Rev. 5.

Date of change	Control ID and title	Description of change
April 8, 2024	[ELB.6] Application, Gateway, and Network Load Balancers should have deletion protection enabled	Changed control title from **Application Load Balancer deletion protection should be enabled** to **Application, Gateway, and Network Load Balancers should have deletion protection enabled**. This control currently evaluates Application, Gateway, and Network Load Balancers. The title and description have been changed to accurately reflect the current behavior.

Date of change	Control ID and title	Description of change
March 22, 2024	[Opensearch.8] Connections to OpenSearch domains should be encrypted using the latest TLS security policy	Changed control title from **Connections to OpenSearch domains should be encrypted using TLS 1.2** to **Connections to OpenSearch domains should be encrypted using the latest TLS security policy**. Previously, the control only checked whether connections to OpenSearch domains used TLS 1.2. The control now produces a PASSED finding if OpenSearch domains are encrypted using the latest TLS security policy. The control title and description have been updated to reflect the current behavior.

Date of change	Control ID and title	Description of change
March 22, 2024	[ES.8] Connections to Elasticsearch domains should be encrypted using the latest TLS security policy	Changed control title from **Connections to Elasticsearch domains should be encrypted using TLS 1.2** to **Connections to Elasticsearch domains should be encrypted using the latest TLS security policy**. Previously, the control only checked whether connections to Elasticsearch domains used TLS 1.2. The control now produces a PASSED finding if Elasticsearch domains are encrypted using the latest TLS security policy. The control title and description have been updated to reflect the current behavior.

Date of change	Control ID and title	Description of change
March 12, 2024	[S3.1] S3 general purpose buckets should have block public access settings enabled	Changed title from **S3 Block Public Access setting should be enabled** to **S3 general purpose buckets should have block public access settings enabled**. Security Hub CSPM changed the title to account for a new S3 bucket type.
March 12, 2024	[S3.2] S3 general purpose buckets should block public read access	Changed title from **S3 buckets should prohibit public read access** to **S3 general purpose buckets should block public read access**. Security Hub CSPM changed the title to account for a new S3 bucket type.

Date of change	Control ID and title	Description of change
March 12, 2024	[S3.3] S3 general purpose buckets should block public write access	Changed title from **S3 buckets should prohibit public write access** to **S3 general purpose buckets should block public write access**. Security Hub CSPM changed the title to account for a new S3 bucket type.
March 12, 2024	[S3.5] S3 general purpose buckets should require requests to use TLS	Changed title from **S3 buckets should require requests to use Secure Socket Layer** to **S3 general purpose buckets should require requests to use SSL**. Security Hub CSPM changed the title to account for a new S3 bucket type.

Date of change	Control ID and title	Description of change
March 12, 2024	[S3.6] S3 general purpose bucket policies should restrict access to other AWS accounts	Changed title from **S3 permissions granted to other AWS accounts in bucket policies should be restricte d** to **S3 general purpose bucket policies should restrict access to other AWS accounts**. Security Hub CSPM changed the title to account for a new S3 bucket type.
March 12, 2024	[S3.7] S3 general purpose buckets should use cross-Region replication	Changed title from **S3 buckets should have cross-Region replication enabled** to **S3 general purpose buckets should use cross-Region replication**. Security Hub CSPM changed the title to account for a new S3 bucket type.

Date of change	Control ID and title	Description of change
March 12, 2024	[S3.7] S3 general purpose buckets should use cross-Region replication	Changed title from **S3 buckets should have cross-Region replication enabled** to **S3 general purpose buckets should use cross-Region replication**. Security Hub CSPM changed the title to account for a new S3 bucket type.
March 12, 2024	[S3.8] S3 general purpose buckets should block public access	Changed title from **S3 Block Public Access setting should be enabled at the bucket-level** to **S3 general purpose buckets should block public access**. Security Hub CSPM changed the title to account for a new S3 bucket type.

Date of change	Control ID and title	Description of change
March 12, 2024	[S3.9] S3 general purpose buckets should have server access logging enabled	Changed title from **S3 bucket server access logging should be enabled** to **Server access logging should be enabled for S3 general purpose buckets**. Security Hub CSPM changed the title to account for a new S3 bucket type.
March 12, 2024	[S3.10] S3 general purpose buckets with versioning enabled should have Lifecycle configurations	Changed title from **S3 buckets with versioning enabled should have lifecycle policies configure d** to **S3 general purpose buckets with versioning enabled should have Lifecycle configura tions**. Security Hub CSPM changed the title to account for a new S3 bucket type.

Date of change	Control ID and title	Description of change
March 12, 2024	[S3.11] S3 general purpose buckets should have event notifications enabled	Changed title from **S3 buckets should have event notifications enabled** to **S3 general purpose buckets should have event notifications enabled**. Security Hub CSPM changed the title to account for a new S3 bucket type.
March 12, 2024	[S3.12] ACLs should not be used to manage user access to S3 general purpose buckets	Changed title from **S3 access control lists (ACLs) should not be used to manage user access to buckets** to **ACLs should not be used to manage user access to S3 general purpose buckets**. Security Hub CSPM changed the title to account for a new S3 bucket type.

Date of change	Control ID and title	Description of change
March 12, 2024	[S3.13] S3 general purpose buckets should have Lifecycle configurations	Changed title from **S3 buckets should have lifecycle policies configured** to **S3 general purpose buckets should have Lifecycle configurations**. Security Hub CSPM changed the title to account for a new S3 bucket type.
March 12, 2024	[S3.14] S3 general purpose buckets should have versioning enabled	Changed title from **S3 buckets should use versioning** to **S3 general purpose buckets should have versioning enabled**. Security Hub CSPM changed the title to account for a new S3 bucket type.

Date of change	Control ID and title	Description of change
March 12, 2024	[S3.15] S3 general purpose buckets should have Object Lock enabled	Changed title from **S3 buckets should be configured to use Object Lock** to **S3 general purpose buckets should have Object Lock enabled**. Security Hub CSPM changed the title to account for a new S3 bucket type.
March 12, 2024	[S3.17] S3 general purpose buckets should be encrypted at rest with AWS KMS keys	Changed title from **S3 buckets should be encrypted at rest with AWS KMS keys** to **S3 general purpose buckets should be encrypted at rest with AWS KMS keys**. Security Hub CSPM changed the title to account for a new S3 bucket type.

Date of change	Control ID and title	Description of change
March 7, 2024	[Lambda.2] Lambda functions should use supported runtimes	Lambda.2 checks whether the AWS Lambda function settings for runtimes match the expected values set for the supported runtimes in each language. Security Hub CSPM now supports `nodejs20.x` and `ruby3.3` as parameters.
February 22, 2024	[Lambda.2] Lambda functions should use supported runtimes	Lambda.2 checks whether the AWS Lambda function settings for runtimes match the expected values set for the supported runtimes in each language. Security Hub CSPM now supports `dotnet8` as a parameter.

Date of change	Control ID and title	Description of change
February 5, 2024	[EKS.2] EKS clusters should run on a supported Kubernetes version	Security Hub CSPM updated the oldest supported version of Kubernetes that the Amazon EKS cluster can run on to produce a passed finding. The current oldest supported version is Kubernetes 1.25.

Date of change	Control ID and title	Description of change
January 10, 2024	[CodeBuild.1] CodeBuild Bitbucket source repository URLs should not contain sensitive credentials	Changed title from **CodeBuild GitHub or Bitbucket source repository URLs should use OAuth** to **CodeBuild Bitbucket source repository URLs should not contain sensitive credentials**. Security Hub CSPM removed mention of OAuth because other connection methods can also be secure. Security Hub CSPM removed mention of GitHub because it's no longer possible to have a personal access token or username and password in GitHub source repository URLs.

Date of change	Control ID and title	Description of change
January 8, 2024	[Lambda.2] Lambda functions should use supported runtimes	Lambda.2 checks whether the AWS Lambda function settings for runtimes match the expected values set for the supported runtimes in each language. Security Hub CSPM no longer supports `go1.x` and `java8` as parameters because these are retired runtimes.
December 29, 2023	[RDS.8] RDS DB instances should have deletion protection enabled	RDS.8 checks whether an Amazon RDS DB instance that uses one of the supported database engines has deletion protection enabled. Security Hub CSPM now supports `custom-oracle-ee`, `oracle-ee-cdb`, and `oracle-se2-cdb` as database engines.

Date of change	Control ID and title	Description of change
December 22, 2023	[Lambda.2] Lambda functions should use supported runtimes	Lambda.2 checks whether the AWS Lambda function settings for runtimes match the expected values set for the supported runtimes in each language. Security Hub CSPM now supports `java21` and `python3.12` as parameters. Security Hub CSPM no longer supports `ruby2.7` as a parameter.
December 15, 2023	[CloudFront.1] CloudFront distributions should have a default root object configured	CloudFront.1 checks whether an Amazon CloudFront distribut ion has a default root object configured. Security Hub CSPM lowered the severity of this control from CRITICAL to HIGH because adding the default root object is a recommendation that depends on a user's application and specific requirements.

Date of change	Control ID and title	Description of change
December 5, 2023	[EC2.13] Security groups should not allow ingress from 0.0.0.0/0 or ::/0 to port 22	Changed control title from **Security groups should not allow ingress from 0.0.0.0/0 to port 22** to **Security groups should not allow ingress from 0.0.0.0/0 or ::/0 to port 22**.
December 5, 2023	[EC2.14] Security groups should not allow ingress from 0.0.0.0/0 or ::/0 to port 3389	Changed control title from **Ensure no security groups allow ingress from 0.0.0.0/0 to port 3389** to **Security groups should not allow ingress from 0.0.0.0/0 or ::/0 to port 3389**.

Date of change	Control ID and title	Description of change
December 5, 2023	[RDS.9] RDS DB instances should publish logs to CloudWatch Logs	Changed control title from **Database logging should be enabled** to **RDS DB instances should publish logs to CloudWatch Logs**. Security Hub CSPM identified that this control only checks whether logs are published to Amazon CloudWatch Logs and doesn't check whether RDS logs are enabled. The control produces a PASSED finding if RDS DB instances are configured to publish logs to CloudWatch Logs. The control title has been updated to reflect the current behavior.

Date of change	Control ID and title	Description of change
December 5, 2023	[EKS.8] EKS clusters should have audit logging enabled	This control checks whether Amazon EKS clusters have audit logging enabled. The AWS Config rule that Security Hub CSPM uses to evaluate this control changed from `eks-cluster-logging-enabled` to `eks-cluster-log-enabled` .
November 17, 2023	[EC2.19] Security groups should not allow unrestricted access to ports with high risk	EC2.19 checks whether unrestricted incoming traffic for a security group is accessible to the specified ports that are considered to be high risk. Security Hub CSPM updated this control to account for managed prefix lists when they are supplied as the source for a security group rule. The control produces a `FAILED` finding if the prefix lists contain the strings '0.0.0.0/0' or '::/0'.

Date of change	Control ID and title	Description of change
November 16, 2023	[CloudWatch.15] CloudWatch alarms should have specified actions configured	Changed control title from **CloudWatch alarms should have an action configured for the ALARM state** to **CloudWatch alarms should have specified actions configured**.
November 16, 2023	[CloudWatch.16] CloudWatch log groups should be retained for a specified time period	Changed control title from **CloudWatch log groups should be retained for at least 1 year** to **CloudWatch log groups should be retained for a specified time period**.
November 16, 2023	[Lambda.5] VPC Lambda functions should operate in multiple Availability Zones	Changed control title from **VPC Lambda functions should operate in more than one Availability Zone** to **VPC Lambda functions should operate in multiple Availability Zones**.

Date of change	Control ID and title	Description of change
November 16, 2023	[AppSync.2] AWS AppSync should have field-level logging enabled	Changed control title from **AWS AppSync should have request-level and field-level logging turned on** to **AWS AppSync should have field-level logging enabled**.
November 16, 2023	[EMR.1] Amazon EMR cluster primary nodes should not have public IP addresses	Changed control title from **Amazon Elastic MapReduce cluster master nodes should not have public IP addresses** to **Amazon EMR cluster primary nodes should not have public IP addresses**.
November 16, 2023	[Opensearch.2] OpenSearch domains should not be publicly accessible	Changed control title from **OpenSearch domains should be in a VPC** to **OpenSearch domains should not be publicly accessible**.

Date of change	Control ID and title	Description of change
November 16, 2023	[ES.2] Elasticsearch domains should not be publicly accessible	Changed control title from **Elasticsearch domains should be in a VPC** to **Elasticsearch domains should not be publicly accessible**.

Date of change	Control ID and title	Description of change
October 31, 2023	[ES.4] Elasticsearch domain error logging to CloudWatch Logs should be enabled	ES.4 checks whether Elasticsearch domains are configured to send error logs to Amazon CloudWatch Logs. The control previously produced a PASSED finding for an Elasticsearch domain that has any logs configured to send to CloudWatch Logs. Security Hub CSPM updated the control to produce a PASSED finding only for an Elasticsearch domain that is configured to send error logs to CloudWatch Logs. The control was also updated to exclude Elasticsearch versions that don't support error logs from evaluation.

Date of change	Control ID and title	Description of change
October 16, 2023	[EC2.13] Security groups should not allow ingress from 0.0.0.0/0 or ::/0 to port 22	EC2.13 checks whether security groups allow unrestricted ingress access to port 22. Security Hub CSPM updated this control to account for managed prefix lists when they are supplied as the source for a security group rule. The control produces a `FAILED` finding if the prefix lists contain the strings '0.0.0.0/0' or '::/0'.

Date of change	Control ID and title	Description of change
October 16, 2023	[EC2.14] Security groups should not allow ingress from 0.0.0.0/0 or ::/0 to port 3389	EC2.14 checks whether security groups allow unrestricted ingress access to port 3389. Security Hub CSPM updated this control to account for managed prefix lists when they are supplied as the source for a security group rule. The control produces a `FAILED` finding if the prefix lists contain the strings '0.0.0.0/0' or '::/0'.

Date of change	Control ID and title	Description of change
October 16, 2023	[EC2.18] Security groups should only allow unrestricted incoming traffic for authorized ports	EC2.18 checks whether the security groups that are in use allow unrestric ted incoming traffic. Security Hub CSPM updated this control to account for managed prefix lists when they are supplied as the source for a security group rule. The control produces a `FAILED` finding if the prefix lists contain the strings '0.0.0.0/0' or '::/0'.
October 16, 2023	[Lambda.2] Lambda functions should use supported runtimes	Lambda.2 checks whether the AWS Lambda function settings for runtimes match the expected values set for the supported runtimes in each language. Security Hub CSPM now supports `python3.11` as a parameter.

Date of change	Control ID and title	Description of change
October 4, 2023	[S3.7] S3 general purpose buckets should use cross-Region replication	Security Hub CSPM added the parameter `ReplicationType` with a value of `CROSS-REGION` to ensure that S3 buckets have cross-Region replication enabled rather than same-Region replication.
September 27, 2023	[EKS.2] EKS clusters should run on a supported Kubernetes version	Security Hub CSPM updated the oldest supported version of Kubernetes that the Amazon EKS cluster can run on to produce a passed finding. The current oldest supported version is Kubernetes `1.24`.

Date of change	Control ID and title	Description of change
September 20, 2023	[CloudFront.2] CloudFront distributions should have origin access identity enabled	Security Hub CSPM retired this control and removed it from all standards. Instead, see [CloudFront.13] CloudFront distributions should use origin access control. Origin access control is the current security best practice. This control will be removed from documentation in 90 days.

Date of change	Control ID and title	Description of change
September 20, 2023	[EC2.22] Unused Amazon EC2 security groups should be removed	Security Hub CSPM removed this control from AWS Foundational Security Best Practices (FSBP) and National Institute of Standards and Technology (NIST) SP 800-53 Rev. 5. It is still part of Service-Managed Standard: AWS Control Tower. This control produces a passed finding if security groups are attached to EC2 instances or to an elastic network interface. However, for certain use cases, unattached security groups don't pose a security risk. You can use other EC2 controls—such as EC2.2, EC2.13, EC2.14, EC2.18, and EC2.19—to monitor your security groups.

Date of change	Control ID and title	Description of change
September 20, 2023	[EC2.29] EC2 instances should be launched in a VPC	Security Hub CSPM retired this control and removed it from all standards . Amazon EC2 has migrated EC2-Class ic instances to a VPC. This control will be removed from documentation in 90 days.
September 20, 2023	[S3.4] S3 buckets should have server-side encryption enabled	Security Hub CSPM retired this control and removed it from all standards . Amazon S3 now provides default encryption with S3 managed keys (SS3-S3) on new and existing S3 buckets. The encryptio n settings are unchanged for existing buckets that are encrypted with SS3-S3 or SS3-KMS server-side encryptio n. This control will be removed from documentation in 90 days.

Date of change	Control ID and title	Description of change
September 14, 2023	[EC2.2] VPC default security groups should not allow inbound or outbound traffic	Changed control title from **The VPC default security group should not allow inbound and outbound traffic** to **VPC default security groups should not allow inbound or outbound traffic**.
September 14, 2023	[IAM.9] MFA should be enabled for the root user	Changed control title from **Virtual MFA should be enabled for the root user** to **MFA should be enabled for the root user**.
September 14, 2023	[RDS.19] Existing RDS event notification subscriptions should be configured for critical cluster events	Changed control title from **An RDS event notificat ions subscription should be configure d for critical cluster events** to **Existing RDS event notificat ion subscriptions should be configure d for critical cluster events**.

Date of change	Control ID and title	Description of change
September 14, 2023	[RDS.20] Existing RDS event notification subscriptions should be configured for critical database instance events	Changed control title from **An RDS event notifications subscription should be configured for critical database instance events** to **Existing RDS event notification subscriptions should be configured for critical database instance events**.
September 14, 2023	[WAF.2] AWS WAF Classic Regional rules should have at least one condition	Changed control title from **A WAF Regional rule should have at least one condition** to **AWS WAF Classic Regional rules should have at least one condition**.
September 14, 2023	[WAF.3] AWS WAF Classic Regional rule groups should have at least one rule	Changed control title from **A WAF Regional rule group should have at least one rule** to **AWS WAF Classic Regional rule groups should have at least one rule**.

Date of change	Control ID and title	Description of change
September 14, 2023	[WAF.4] AWS WAF Classic Regional web ACLs should have at least one rule or rule group	Changed control title from **A WAF Regional web ACL should have at least one rule or rule group** to **AWS WAF Classic Regional web ACLs should have at least one rule or rule group**.
September 14, 2023	[WAF.6] AWS WAF Classic global rules should have at least one condition	Changed control title from **A WAF global rule should have at least one condition** to **AWS WAF Classic global rules should have at least one condition**.
September 14, 2023	[WAF.7] AWS WAF Classic global rule groups should have at least one rule	Changed control title from **A WAF global rule group should have at least one rule** to **AWS WAF Classic global rule groups should have at least one rule**.

Date of change	Control ID and title	Description of change
September 14, 2023	[WAF.8] AWS WAF Classic global web ACLs should have at least one rule or rule group	Changed control title from **A WAF global web ACL should have at least one rule or rule group** to **AWS WAF Classic global web ACLs should have at least one rule or rule group**.
September 14, 2023	[WAF.10] AWS WAF web ACLs should have at least one rule or rule group	Changed control title from **A WAFv2 web ACL should have at least one rule or rule group** to **AWS WAF web ACLs should have at least one rule or rule group**.
September 14, 2023	[WAF.11] AWS WAF web ACL logging should be enabled	Changed control title from **AWS WAFv2 web ACL logging should be activated** to **AWS WAF web ACL logging should be enabled**.

Date of change	Control ID and title	Description of change
July 20, 2023	[S3.4] S3 buckets should have server-side encryption enabled	S3.4 checks whether an Amazon S3 bucket either has server-side encryption enabled or that the S3 bucket policy explicitly denies `PutObject` requests without server-side encryption. Security Hub CSPM updated this control to include dual-layer server side encryption with KMS keys (DSSE-KMS). The control produces a passed finding when an S3 bucket is encrypted with SSE-S3, SSE-KMS, or DSSE-KMS.

Date of change	Control ID and title	Description of change
July 17, 2023	[S3.17] S3 general purpose buckets should be encrypted at rest with AWS KMS keys	S3.17 checks whether an Amazon S3 bucket is encrypted with an AWS KMS key. Security Hub CSPM updated this control to include dual-layer server side encryptio n with KMS keys (DSSE-KMS). The control produces a passed finding when an S3 bucket is encrypted with SSE-KMS or DSSE-KMS.
June 9, 2023	[EKS.2] EKS clusters should run on a supported Kubernetes version	EKS.2 checks whether an Amazon EKS cluster is running on a supported Kubernetes version.T he oldest supported version is now 1.23.

Date of change	Control ID and title	Description of change
June 9, 2023	[Lambda.2] Lambda functions should use supported runtimes	Lambda.2 checks whether the AWS Lambda function settings for runtimes match the expected values set for the supported runtimes in each language. Security Hub CSPM now supports `ruby3.2` as a parameter.
June 5, 2023	[APIGateway.5] API Gateway REST API cache data should be encrypted at rest	APIGateway.5.checks whether all methods in Amazon API Gateway REST API stages are encrypted at rest. Security Hub CSPM updated the control to evaluate the encryption of a particular method only when caching is enabled for that method.

Date of change	Control ID and title	Description of change
May 18, 2023	[Lambda.2] Lambda functions should use supported runtimes	Lambda.2 checks whether the AWS Lambda function settings for runtimes match the expected values set for the supported runtimes in each language. Security Hub CSPM now supports `java17` as a parameter.
May 18, 2023	[Lambda.2] Lambda functions should use supported runtimes	Lambda.2 checks whether the AWS Lambda function settings for runtimes match the expected values set for the supported runtimes in each language. Security Hub CSPM no longer supports `nodejs12.x` as a parameter.

Date of change	Control ID and title	Description of change
April 23, 2023	[ECS.10] ECS Fargate services should run on the latest Fargate platform version	ECS.10 checks whether Amazon ECS Fargate services are running the latest Fargate platform version. Customers can deploy Amazon ECS through ECS directly, or by using CodeDeploy. Security Hub CSPM updated this control to produce **Passed** findings when you use CodeDeploy to deploy ECS Fargate services.
April 20, 2023	[S3.6] S3 general purpose bucket policies should restrict access to other AWS accounts	S3.6 checks whether an Amazon Simple Storage Service (Amazon S3) bucket policy prevents principals from other AWS accounts from performing denied actions on resources in the S3 bucket. Security Hub CSPM updated the control to account for conditionals in a bucket policy.

Date of change	Control ID and title	Description of change
April 18, 2023	[Lambda.2] Lambda functions should use supported runtimes	Lambda.2 checks whether the AWS Lambda function settings for runtimes match the expected values set for the supported runtimes in each language. Security Hub CSPM now supports `python3.10` as a parameter.
April 18, 2023	[Lambda.2] Lambda functions should use supported runtimes	Lambda.2 checks whether the AWS Lambda function settings for runtimes match the expected values set for the supported runtimes in each language. Security Hub CSPM no longer supports `dotnetcore3.1` as a parameter.

Date of change	Control ID and title	Description of change
April 17, 2023	[RDS.11] RDS instances should have automatic backups enabled	RDS.11 checks whether Amazon RDS instances have automated backups enabled, with a backup retention period that's greater than or equal to seven days. Security Hub CSPM updated this control to exclude read replicas from evaluation, as not all engines support automated backups on read replicas. Additionally, RDS doesn't provide the option to specify a backup retention period when creating read replicas. Read replicas are created with a backup retention period of `0` by default.

Security Hub CSPM controls for AWS accounts

These Security Hub CSPM controls evaluate AWS accounts.

These controls may not be available in all AWS Regions. For more information, see Availability of controls by Region.

[Account.1] Security contact information should be provided for an AWS account

Related requirements: CIS AWS Foundations Benchmark v5.0.0/1.2, NIST.800-53.r5 CM-2, NIST.800-53.r5 CM-2(2), CRI Profile v2.2/DE.AE-06.01, CRI Profile v2.2/RS.CO-02.01, CRI Profile v2.2/RS.CO-02.03

Category: Identify > Resource Configuration

Severity: Medium

Resource type: `AWS::::Account`

AWS Config rule: `security-account-information-provided`

Schedule type: Periodic

Parameters: None

This control checks if an Amazon Web Services (AWS) account has security contact information. The control fails if security contact information is not provided for the account.

Alternate security contacts allow AWS to contact another person about issues with your account in case you're unavailable. Notifications can be from Support, or other AWS service teams about security-related topics associated with your AWS account usage.

Remediation

To add an alternate contact as a security contact to your AWS account, see Update the alternate contacts for your AWS account in the *AWS Account Management Reference Guide*.

[Account.2] AWS accounts should be part of an AWS Organizations organization

Category: Protect > Secure access management > Access control

Related requirements: NIST.800-53.r5 CA-9(1), NIST.800-53.r5 CM-2, CRI Profile v2.2/ID.AM-08.02

Severity: High

Resource type: `AWS::::Account`

AWS Config rule: `account-part-of-organizations`

Schedule type: Periodic

Parameters: None

This control checks if an AWS account is part of an organization managed through AWS Organizations. The control fails if the account is not part of an organization.

Organizations helps you centrally manage your environment as you scale your workloads on AWS. You can use multiple AWS accounts to isolate workloads that have specific security requirements, or to comply with frameworks such as HIPAA or PCI. By creating an organization, you can administer multiple accounts as a single unit and centrally manage their access to AWS services, resources, and Regions.

Remediation

To create a new organization and automatically add AWS accounts to it, see Creating an organization in the *AWS Organizations User Guide*. To add accounts to an existing organization, see Inviting an AWS account to join your organization in the *AWS Organizations User Guide*.

Security Hub CSPM controls for AWS Amplify

These Security Hub CSPM controls evaluate the AWS Amplify service and resources. The controls might not be available in all AWS Regions. For more information, see Availability of controls by Region.

[Amplify.1] Amplify apps should be tagged

Category: Identify > Inventory > Tagging

Severity: Low

Resource type: `AWS::Amplify::App`

AWS Config rule: amplify-app-tagged

Schedule type: Change triggered

Parameters:

Parameter	Description	Type	Allowed custom values	Security Hub CSPM default value
`requiredKeyTags`	A list of non-system tag keys that must be assigned to an evaluated resource. Tag keys are case sensitive.	StringList (maximum of 6 items)	1–6 tag keys that meet AWS requirements.	No default value

This control checks whether an AWS Amplify app has the tag keys specified by the `requiredKeyTags` parameter. The control fails if the app doesn't have any tag keys, or it doesn't have all the keys specified by the `requiredKeyTags` parameter. If you don't specify any values for the `requiredKeyTags` parameter, the control checks only for the existence of a tag key and fails if the app doesn't have any tag keys. The control ignores system tags, which are applied automatically and have the `aws:` prefix.

A tag is a label that you create and assign to an AWS resource. Each tag consists of a required tag key and an optional tag value. You can use tags to categorize resources by purpose, owner, environment, or other criteria. They can help you identify, organize, search for, and filter resources. They can also help you track resource owners for actions and notifications. You can also use tags to implement attribute-based access control (ABAC) as an authorization strategy. For more information about ABAC strategies, see Define permissions based on attributes with ABAC authorization in the *IAM User Guide*. For more information about tags, see the Tagging AWS Resources and Tag Editor User Guide.

Note

Do not store personally identifiable information (PII) or other confidential or sensitive information in tags. Tags are accessible from many AWS services. They aren't intended to be used for private or sensitive data.

Remediation

For information about adding tags to an AWS Amplify app, see Resource tagging support in the *AWS Amplify Hosting User Guide*.

[Amplify.2] Amplify branches should be tagged

Related requirements: CRI Profile v2.2/ID.AM-02.01, CRI Profile v2.2/ID.AM-05.01

Category: Identify > Inventory > Tagging

Severity: Low

Resource type: `AWS::Amplify::Branch`

AWS Config rule: amplify-branch-tagged

Schedule type: Change triggered

Parameters:

Parameter	Description	Type	Allowed custom values	Security Hub CSPM default value
`requiredKeyTags`	A list of non-system tag keys that must be assigned to an evaluated resource. Tag keys are case sensitive.	StringList (maximum of 6 items)	1–6 tag keys that meet AWS requirements.	No default value

This control checks whether an AWS Amplify branch has the tag keys specified by the `requiredKeyTags` parameter. The control fails if the branch doesn't have any tag keys, or it doesn't have all the keys specified by the `requiredKeyTags` parameter. If you don't specify any values for the `requiredKeyTags` parameter, the control checks only for the existence of a tag key and fails if the branch doesn't have any tag keys. The control ignores system tags, which are applied automatically and have the `aws:` prefix.

A tag is a label that you create and assign to an AWS resource. Each tag consists of a required tag key and an optional tag value. You can use tags to categorize resources by purpose, owner, environment, or other criteria. They can help you identify, organize, search for, and filter resources. They can also help you track resource owners for actions and notifications. You can also use tags to implement attribute-based access control (ABAC) as an authorization strategy. For more information about ABAC strategies, see Define permissions based on attributes with ABAC authorization in the *IAM User Guide*. For more information about tags, see the Tagging AWS Resources and Tag Editor User Guide.

> **Note**
>
> Do not store personally identifiable information (PII) or other confidential or sensitive information in tags. Tags are accessible from many AWS services. They aren't intended to be used for private or sensitive data.

Remediation

For information about adding tags to an AWS Amplify branch, see Resource tagging support in the *AWS Amplify Hosting User Guide*.

Security Hub CSPM controls for Amazon API Gateway

These AWS Security Hub CSPM controls evaluate the Amazon API Gateway service and resources. The controls might not be available in all AWS Regions. For more information, see Availability of controls by Region.

[APIGateway.1] API Gateway REST and WebSocket API execution logging should be enabled

Related requirements: NIST.800-53.r5 AC-4(26), NIST.800-53.r5 AU-10, NIST.800-53.r5 AU-12, NIST.800-53.r5 AU-2, NIST.800-53.r5 AU-3, NIST.800-53.r5 AU-6(3), NIST.800-53.r5 AU-6(4), NIST.800-53.r5 CA-7, NIST.800-53.r5 SC-7(9), NIST.800-53.r5 SI-7(8), CRI Profile v2.2/DE.AE-02.01, CRI Profile v2.2/DE.AE-03.02, CRI Profile v2.2/DE.AE-07.02, CRI Profile v2.2/DE.CM-03.01, CRI Profile v2.2/DE.CM-03.02, CRI Profile v2.2/DE.CM-03.03, CRI Profile v2.2/PR.PS-04.02, CRI Profile v2.2/PR.PS-04.03, CRI Profile v2.2/RS.MA-02.01

Category: Identify > Logging

Severity: Medium

Resource type: `AWS::ApiGateway::Stage`, `AWS::ApiGatewayV2::Stage`

AWS Config rule: api-gw-execution-logging-enabled

Schedule type: Change triggered

Parameters:

Parameter	Description	Type	Allowed custom values	Security Hub CSPM default value
`loggingLevel`	Logging level	Enum	`ERROR`, `INFO`	`No default value`

This control checks whether all stages of an Amazon API Gateway REST or WebSocket API have logging enabled. The control fails if the `loggingLevel` isn't `ERROR` or `INFO` for all stages of the API. Unless you provide custom parameter values to indicate that a specific log type should be enabled, Security Hub CSPM produces a passed finding if the logging level is either `ERROR` or `INFO`.

API Gateway REST or WebSocket API stages should have relevant logs enabled. API Gateway REST and WebSocket API execution logging provides detailed records of requests made to API Gateway REST and WebSocket API stages. The stages include API integration backend responses, Lambda authorizer responses, and the `requestId` for AWS integration endpoints.

Remediation

To enable logging for REST and WebSocket API operations, see Set up CloudWatch API logging using the API Gateway console in the *API Gateway Developer Guide*.

[APIGateway.2] API Gateway REST API stages should be configured to use SSL certificates for backend authentication

Related requirements: NIST.800-53.r5 AC-17(2), NIST.800-53.r5 AC-4, NIST.800-53.r5 IA-5(1), NIST.800-53.r5 SC-12(3), NIST.800-53.r5 SC-13, NIST.800-53.r5 SC-23, NIST.800-53.r5 SC-23(3), NIST.800-53.r5 SC-7(4), NIST.800-53.r5 SC-8, NIST.800-53.r5 SC-8(1), NIST.800-53.r5 SC-8(2), NIST.800-53.r5 SI-7(6), NIST.800-171.r2 3.13.15, CRI Profile v2.2/PR.DS-02.01, CRI Profile v2.2/PR.PS-01.06, CRI Profile v2.2/PR.PS-01.07

Category: Protect > Data Protection > Encryption of data-in-transit

Severity: Medium

Resource type: `AWS::ApiGateway::Stage`

AWS Config rule: api-gw-ssl-enabled

Schedule type: Change triggered

Parameters: None

This control checks whether Amazon API Gateway REST API stages have SSL certificates configured. Backend systems use these certificates to authenticate that incoming requests are from API Gateway.

API Gateway REST API stages should be configured with SSL certificates to allow backend systems to authenticate that requests originate from API Gateway.

Remediation

For detailed instructions on how to generate and configure API Gateway REST API SSL certificates, see Generate and configure an SSL certificate for backend authentication in the *API Gateway Developer Guide*.

[APIGateway.3] API Gateway REST API stages should have AWS X-Ray tracing enabled

Related requirements: NIST.800-53.r5 CA-7, CRI Profile v2.2/DE.AE-03.01, CRI Profile v2.2/DE.AE-03.02, CRI Profile v2.2/PR.PS-04.02

Category: Detect > Detection services

Severity: Low

Resource type: `AWS::ApiGateway::Stage`

AWS Config rule: api-gw-xray-enabled

Schedule type: Change triggered

Parameters: None

This control checks whether AWS X-Ray active tracing is enabled for your Amazon API Gateway REST API stages.

X-Ray active tracing enables a more rapid response to performance changes in the underlying infrastructure. Changes in performance could result in a lack of availability of the API. X-Ray active tracing provides real-time metrics of user requests that flow through your API Gateway REST API operations and connected services.

Remediation

For detailed instructions on how to enable X-Ray active tracing for API Gateway REST API operations, see Amazon API Gateway active tracing support for AWS X-Ray in the *AWS X-Ray Developer Guide*.

[APIGateway.4] API Gateway should be associated with a WAF Web ACL

Related requirements: NIST.800-53.r5 AC-4(21), CRI Profile v2.2/DE.CM-01.03, CRI Profile v2.2/PR.IR-01.03

Category: Protect > Protective services

Severity: Medium

Resource type: `AWS::ApiGateway::Stage`

AWS Config rule: api-gw-associated-with-waf

Schedule type: Change triggered

Parameters: None

This control checks whether an API Gateway stage uses an AWS WAF web access control list (ACL). This control fails if an AWS WAF web ACL is not attached to a REST API Gateway stage.

AWS WAF is a web application firewall that helps protect web applications and APIs from attacks. It enables you to configure an ACL, which is a set of rules that allow, block, or count web requests based on customizable web security rules and conditions that you define. Ensure that your API Gateway stage is associated with an AWS WAF web ACL to help protect it from malicious attacks.

Remediation

For information on how to use the API Gateway console to associate an AWS WAF Regional web ACL with an existing API Gateway API stage, see Using AWS WAF to protect your APIs in the *API Gateway Developer Guide*.

[APIGateway.5] API Gateway REST API cache data should be encrypted at rest

Related requirements: NIST.800-53.r5 CA-9(1), NIST.800-53.r5 CM-3(6), NIST.800-53.r5 SC-13, NIST.800-53.r5 SC-28, NIST.800-53.r5 SC-28(1), NIST.800-53.r5 SC-7(10), NIST.800-53.r5 SI-7(6), CRI Profile v2.2/PR.DS-01.01, CRI Profile v2.2/PR.PS-01.06

Category: Protect > Data protection > Encryption of data at rest

Severity: Medium

Resource type: `AWS::ApiGateway::Stage`

AWS Config rule: `api-gw-cache-encrypted` (custom Security Hub CSPM rule)

Schedule type: Change triggered

Parameters: None

This control checks whether all methods in API Gateway REST API stages that have cache enabled are encrypted. The control fails if any method in an API Gateway REST API stage is configured to cache and the cache is not encrypted. Security Hub CSPM evaluates the encryption of a particular method only when caching is enabled for that method.

Encrypting data at rest reduces the risk of data stored on disk being accessed by a user not authenticated to AWS. It adds another set of access controls to limit unauthorized users ability access the data. For example, API permissions are required to decrypt the data before it can be read.

API Gateway REST API caches should be encrypted at rest for an added layer of security.

Remediation

To configure API caching for a stage, see Enable Amazon API Gateway caching in the *API Gateway Developer Guide*. In **Cache Settings**, choose **Encrypt cache data**.

[APIGateway.8] API Gateway routes should specify an authorization type

Related requirements: NIST.800-53.r5 AC-3, NIST.800-53.r5 CM-2, NIST.800-53.r5 CM-2(2), CRI Profile v2.2/PR.IR-01.02

Category: Protect > Secure Access Management

Severity: Medium

Resource type: `AWS::ApiGatewayV2::Route`

AWS Config rule: api-gwv2-authorization-type-configured

Schedule type: Periodic

Parameters:

Parameter	Description	Type	Allowed custom values	Security Hub CSPM default value
`authorizationType`	Authorization type of the API routes	Enum	`AWS_IAM`, `CUSTOM`, `JWT`	No default value

This control checks if Amazon API Gateway routes have an authorization type. The control fails if the API Gateway route doesn't have any authorization type. Optionally, you can provide a custom parameter value if you want the control to pass only if the route uses the authorization type specified in the `authorizationType` parameter.

API Gateway supports multiple mechanisms for controlling and managing access to your API. By specifying an authorization type, you can restrict access to your API to only authorized users or processes.

Remediation

To set an authorization type for HTTP APIs, see Controlling and managing access to an HTTP API in API Gateway in the *API Gateway Developer Guide*. To set an authorization type for WebSocket APIs, see Controlling and managing access to a WebSocket API in API Gateway in the *API Gateway Developer Guide*.

[APIGateway.9] Access logging should be configured for API Gateway V2 Stages

Related requirements: NIST.800-53.r5 AC-4(26), NIST.800-53.r5 AU-10, NIST.800-53.r5 AU-12, NIST.800-53.r5 AU-2, NIST.800-53.r5 AU-3, NIST.800-53.r5 AU-6(3), NIST.800-53.r5 AU-6(4), NIST.800-53.r5 CA-7, NIST.800-53.r5 SC-7(9), NIST.800-53.r5 SI-7(8), PCI DSS v4.0.1/10.4.2, CRI Profile v2.2/DE.AE-03.01, CRI Profile v2.2/DE.CM-03.01, CRI Profile v2.2/DE.CM-03.02, CRI Profile v2.2/PR.PS-04.02, CRI Profile v2.2/PR.PS-04.03

Category: Identify > Logging

Severity: Medium

Resource type: `AWS::ApiGatewayV2::Stage`

AWS Config rule: api-gwv2-access-logs-enabled

Schedule type: Change triggered

Parameters: None

This control checks if Amazon API Gateway V2 stages have access logging configured. This control fails if access log settings aren't defined.

API Gateway access logs provide detailed information about who has accessed your API and how the caller accessed the API. These logs are useful for applications such as security and access audits and forensics investigation. Enable these access logs to analyze traffic patterns and to troubleshoot issues.

For additional best practices, see Monitoring REST APIs in the *API Gateway Developer Guide*.

Remediation

To set up access logging, see Set up CloudWatch API logging using the API Gateway console in the *API Gateway Developer Guide*.

[APIGateway.10] API Gateway V2 integrations should use HTTPS for private connections

Category: Protect > Data Protection > Encryption of data-in-transit

Severity: Medium

Resource type: `AWS::ApiGatewayV2::Integration`

AWS Config rule: apigatewayv2-integration-private-https-enabled

Schedule type: Change triggered

Parameters: None

This control checks whether an API Gateway V2 integration has HTTPS enabled for private connections. The control fails if a private connection doesn't have TLS configured.

VPC Links connect API Gateway to private resources. While VPC Links create private connectivity, they don't inherently encrypt data. Configuring TLS ensures use of HTTPS for end-to-end encryption from client through API Gateway to backend. Without TLS, sensitive API traffic flows unencrypted across private connections. HTTPS encryption protects the traffic through private connections from data interception, man-in-the-middle attacks and credential exposure.

Remediation

To enable encryption in transit for private connections in an API Gateway v2 Integration, see Update a private integration in the *Amazon API Gateway Developer Guide*. Configure TLS configuration so that the private integration uses HTTPS protocol.

[APIGateway.11] API Gateway domain names should use recommended security policies

Category: Protect > Encryption of data-in-transit

Severity: Medium

Resource type: `AWS::ApiGateway::DomainName`

AWS Config rule: apigateway-domain-name-tls-check

Schedule type: Change triggered

Parameters:

- `allowedSecurityPolicies`: `SecurityPolicy_TLS13_1_3_2025_09`, `SecurityPolicy_TLS13_1_3_FIPS_2025_09`, `SecurityPolicy_TLS13_1_2_PFS_PQ_2025_09`, `SecurityPolicy_TLS13_2025_EDGE`, `SecurityPolicy_TLS12_PFS_2025_EDGE` (not customizable)

This control checks whether an API Gateway domain name is configured to encrypt data in transit by using a recommended security policy. The control fails if the API Gateway domain name isn't configured to use a recommended security policy.

This control generates a `FAILED` finding for custom domain names that are attached to HTTP APIs. If you have a legitimate use case for HTTP APIs, you can suppress the finding.

A security policy is a predefined combination of minimum TLS version and cipher suites offered by API Gateway. When your clients establish a TLS handshake to your API or custom domain name,

the security policy enforces the TLS version and cipher suite accepted by API Gateway. Security policies protect your APIs and custom domain names from network security problems such as tampering and eavesdropping between a client and server. Using a recommended security policy helps ensure that API Gateway domain names use modern, secure TLS configurations that protect data in transit between clients and your API.

Remediation

To update the TLS security policy for an API Gateway domain name, see How to change a security policy in the *Amazon API Gateway Developer Guide*.

Security Hub CSPM controls for AWS AppConfig

These Security Hub CSPM controls evaluate the AWS AppConfig service and resources.

These controls may not be available in all AWS Regions. For more information, see Availability of controls by Region.

[AppConfig.1] AWS AppConfig applications should be tagged

Category: Identify > Inventory > Tagging

Severity: Low

Resource type: `AWS::AppConfig::Application`

AWS Config rule: `appconfig-application-tagged`

Schedule type: Change triggered

Parameters:

Parameter	Description	Type	Allowed custom values	Security Hub CSPM default value
`requiredKeyTags`	List of non-system tag keys that the evaluated resource must contain. Tag keys are case sensitive.	StringList (maximum of 6 items)	1–6 tag keys that meet AWS	No default value

Parameter	Description	Type	Allowed custom values	Security Hub CSPM default value
			requirements.	

This control checks whether an AWS AppConfig application has tags with the specific keys defined in the parameter `requiredKeyTags`. The control fails if the application doesn't have any tag keys or if it doesn't have all the keys specified in the parameter `requiredKeyTags`. If the parameter `requiredKeyTags` isn't provided, the control only checks for the existence of a tag key and fails if the application isn't tagged with any key. System tags, which are automatically applied and begin with `aws:`, are ignored.

A tag is a label that you assign to an AWS resource, and it consists of a key and an optional value. You can create tags to categorize resources by purpose, owner, environment, or other criteria. Tags can help you identify, organize, search for, and filter resources. Tagging also helps you track accountable resource owners for actions and notifications. When you use tagging, you can implement attribute-based access control (ABAC) as an authorization strategy, which defines permissions based on tags. You can attach tags to IAM entities (users or roles) and to AWS resources. You can create a single ABAC policy or a separate set of policies for your IAM principals. You can design these ABAC policies to allow operations when the principal's tag matches the resource tag. For more information, see Define permissions based on attributes with ABAC authorization in the *IAM User Guide*.

Note

Don't add personally identifiable information (PII) or other confidential or sensitive information in tags. Tags are accessible to many AWS services, including AWS Billing. For more tagging best practices, see Best practices and strategies in the *Tagging AWS Resources and Tag Editor User Guide*.

Remediation

To add tags to an AWS AppConfig application, see TagResource in the *AWS AppConfig API Reference*.

[AppConfig.2] AWS AppConfig configuration profiles should be tagged

Category: Identify > Inventory > Tagging

Severity: Low

Resource type: `AWS::AppConfig::ConfigurationProfile`

AWS Config rule: `appconfig-configuration-profile-tagged`

Schedule type: Change triggered

Parameters:

Parameter	Description	Type	Allowed custom values	Security Hub CSPM default value
`requiredKeyTags`	List of non-system tag keys that the evaluated resource must contain. Tag keys are case sensitive.	StringList (maximum of 6 items)	1–6 tag keys that meet AWS requirements.	No default value

This control checks whether an AWS AppConfig configuration profile has tags with the specific keys defined in the parameter `requiredKeyTags`. The control fails if the configuration profile doesn't have any tag keys or if it doesn't have all the keys specified in the parameter `requiredKeyTags`. If the parameter `requiredKeyTags` isn't provided, the control only checks for the existence of a tag key and fails if the configuration profile isn't tagged with any key. System tags, which are automatically applied and begin with `aws:`, are ignored.

A tag is a label that you assign to an AWS resource, and it consists of a key and an optional value. You can create tags to categorize resources by purpose, owner, environment, or other criteria. Tags can help you identify, organize, search for, and filter resources. Tagging also helps you track accountable resource owners for actions and notifications. When you use tagging, you can implement attribute-based access control (ABAC) as an authorization strategy, which defines permissions based on tags. You can attach tags to IAM entities (users or roles) and to AWS resources. You can create a single ABAC policy or a separate set of policies for your IAM

principals. You can design these ABAC policies to allow operations when the principal's tag matches the resource tag. For more information, see Define permissions based on attributes with ABAC authorization in the *IAM User Guide*.

> **Note**
>
> Don't add personally identifiable information (PII) or other confidential or sensitive information in tags. Tags are accessible to many AWS services, including AWS Billing. For more tagging best practices, see Best practices and strategies in the *Tagging AWS Resources and Tag Editor User Guide*.

Remediation

To add tags to an AWS AppConfig configuration profile, see TagResource in the *AWS AppConfig API Reference*.

[AppConfig.3] AWS AppConfig environments should be tagged

Category: Identify > Inventory > Tagging

Severity: Low

Resource type: `AWS::AppConfig::Environment`

AWS Config rule: `appconfig-environment-tagged`

Schedule type: Change triggered

Parameters:

Parameter	Description	Type	Allowed custom values	Security Hub CSPM default value
`requiredKeyTags`	List of non-system tag keys that the evaluated resource must contain. Tag keys are case sensitive.	StringList (maximum of 6 items)	1–6 tag keys that meet AWS requirements.	No default value

This control checks whether an AWS AppConfig environment has tags with the specific keys defined in the parameter `requiredKeyTags`. The control fails if the environment doesn't have any tag keys or if it doesn't have all the keys specified in the parameter `requiredKeyTags`. If the parameter `requiredKeyTags` isn't provided, the control only checks for the existence of a tag key and fails if the environment isn't tagged with any key. System tags, which are automatically applied and begin with `aws:`, are ignored.

A tag is a label that you assign to an AWS resource, and it consists of a key and an optional value. You can create tags to categorize resources by purpose, owner, environment, or other criteria. Tags can help you identify, organize, search for, and filter resources. Tagging also helps you track accountable resource owners for actions and notifications. When you use tagging, you can implement attribute-based access control (ABAC) as an authorization strategy, which defines permissions based on tags. You can attach tags to IAM entities (users or roles) and to AWS resources. You can create a single ABAC policy or a separate set of policies for your IAM principals. You can design these ABAC policies to allow operations when the principal's tag matches the resource tag. For more information, see Define permissions based on attributes with ABAC authorization in the *IAM User Guide*.

> **Note**
>
> Don't add personally identifiable information (PII) or other confidential or sensitive information in tags. Tags are accessible to many AWS services, including AWS Billing. For more tagging best practices, see Best practices and strategies in the *Tagging AWS Resources and Tag Editor User Guide*.

Remediation

To add tags to an AWS AppConfig environment, see TagResource in the *AWS AppConfig API Reference*.

[AppConfig.4] AWS AppConfig extension associations should be tagged

Category: Identify > Inventory > Tagging

Severity: Low

Resource type: `AWS::AppConfig::ExtensionAssociation`

AWS Config rule: `appconfig-extension-association-tagged`

Schedule type: Change triggered

Parameters:

Parameter	Description	Type	Allowed custom values	Security Hub CSPM default value
`requiredKeyTags`	List of non-system tag keys that the evaluated resource must contain. Tag keys are case sensitive.	StringList (maximum of 6 items)	1–6 tag keys that meet AWS requirements.	No default value

This control checks whether an AWS AppConfig extension association has tags with the specific keys defined in the parameter `requiredKeyTags`. The control fails if the extension association doesn't have any tag keys or if it doesn't have all the keys specified in the parameter `requiredKeyTags`. If the parameter `requiredKeyTags` isn't provided, the control only checks for the existence of a tag key and fails if the extension association isn't tagged with any key. System tags, which are automatically applied and begin with `aws:`, are ignored.

A tag is a label that you assign to an AWS resource, and it consists of a key and an optional value. You can create tags to categorize resources by purpose, owner, environment, or other criteria. Tags can help you identify, organize, search for, and filter resources. Tagging also helps you track accountable resource owners for actions and notifications. When you use tagging, you can implement attribute-based access control (ABAC) as an authorization strategy, which defines permissions based on tags. You can attach tags to IAM entities (users or roles) and to AWS resources. You can create a single ABAC policy or a separate set of policies for your IAM principals. You can design these ABAC policies to allow operations when the principal's tag matches the resource tag. For more information, see Define permissions based on attributes with ABAC authorization in the *IAM User Guide*.

> **Note**
>
> Don't add personally identifiable information (PII) or other confidential or sensitive information in tags. Tags are accessible to many AWS services, including AWS Billing. For

more tagging best practices, see Best practices and strategies in the *Tagging AWS Resources and Tag Editor User Guide*.

Remediation

To add tags to an AWS AppConfig extension association, see TagResource in the *AWS AppConfig API Reference*.

Security Hub CSPM controls for Amazon AppFlow

These Security Hub CSPM controls evaluate the Amazon AppFlow service and resources.

These controls may not be available in all AWS Regions. For more information, see Availability of controls by Region.

[AppFlow.1] Amazon AppFlow flows should be tagged

Related requirements: CRI Profile v2.2/ID.AM-02.01, CRI Profile v2.2/ID.AM-05.01

Category: Identify > Inventory > Tagging

Severity: Low

Resource type: `AWS::AppFlow::Flow`

AWS Config rule: `appflow-flow-tagged`

Schedule type: Change triggered

Parameters:

Parameter	Description	Type	Allowed custom values	Security Hub CSPM default value
`requiredKeyTags`	List of non-system tag keys that the evaluated resource must contain. Tag keys are case sensitive.	StringList (maximum of 6 items)	1–6 tag keys that meet AWS requirements.	No default value

This control checks whether an Amazon AppFlow flow has tags with the specific keys defined in the parameter `requiredKeyTags`. The control fails if the flow doesn't have any tag keys or if it doesn't have all the keys specified in the parameter `requiredKeyTags`. If the parameter `requiredKeyTags` isn't provided, the control only checks for the existence of a tag key and fails if the flow isn't tagged with any key. System tags, which are automatically applied and begin with `aws:`, are ignored.

A tag is a label that you assign to an AWS resource, and it consists of a key and an optional value. You can create tags to categorize resources by purpose, owner, environment, or other criteria. Tags can help you identify, organize, search for, and filter resources. Tagging also helps you track accountable resource owners for actions and notifications. When you use tagging, you can implement attribute-based access control (ABAC) as an authorization strategy, which defines permissions based on tags. You can attach tags to IAM entities (users or roles) and to AWS resources. You can create a single ABAC policy or a separate set of policies for your IAM principals. You can design these ABAC policies to allow operations when the principal's tag matches the resource tag. For more information, see Define permissions based on attributes with ABAC authorization in the *IAM User Guide*.

> **Note**
>
> Don't add personally identifiable information (PII) or other confidential or sensitive information in tags. Tags are accessible to many AWS services, including AWS Billing. For more tagging best practices, see Best practices and strategies in the *Tagging AWS Resources and Tag Editor User Guide*.

Remediation

To add tags to an Amazon AppFlow flow, see Creating flows in Amazon AppFlow in the *Amazon AppFlow User Guide*.

Security Hub CSPM controls for AWS App Runner

These AWS Security Hub CSPM controls evaluate the AWS App Runner service and resources. The controls might not be available in all AWS Regions. For more information, see Availability of controls by Region.

[AppRunner.1] App Runner services should be tagged

Related requirements: CRI Profile v2.2/ID.AM-02.01, CRI Profile v2.2/ID.AM-05.01

Category: Identify > Inventory > Tagging

Severity: Low

Resource type: `AWS::AppRunner::Service`

AWS Config rule: apprunner-service-tagged

Schedule type: Change triggered

Parameters:

Parameter	Description	Type	Allowed custom values	Security Hub CSPM default value
`requiredKeyTags`	List of non-system tag keys that the evaluated resource must contain. Tag keys are case sensitive.	StringList (maximum of 6 items)	1–6 tag keys that meet AWS requirements.	No default value

This control checks whether an AWS App Runner service has tags with the specific keys defined in the parameter `requiredKeyTags`. The control fails if the App Runner service doesn't have any tag keys or if it doesn't have all the keys specified in the parameter `requiredKeyTags`. If the parameter `requiredKeyTags` isn't provided, the control only checks for the existence of a tag key and fails if the App Runner service isn't tagged with any key. System tags, which are automatically applied and begin with `aws:`, are ignored.

A tag is a label that you assign to an AWS resource, and it consists of a key and an optional value. You can create tags to categorize resources by purpose, owner, environment, or other criteria. Tags can help you identify, organize, search for, and filter resources. Tagging also helps you track accountable resource owners for actions and notifications. When you use tagging, you can implement attribute-based access control (ABAC) as an authorization strategy, which defines permissions based on tags. You can attach tags to IAM entities (users or roles) and to AWS resources. You can create a single ABAC policy or a separate set of policies for your IAM principals. You can design these ABAC policies to allow operations when the principal's tag matches

the resource tag. For more information, see Define permissions based on attributes with ABAC authorization in the *IAM User Guide*.

> **Note**
>
> Don't add personally identifiable information (PII) or other confidential or sensitive information in tags. Tags are accessible to many AWS services, including AWS Billing. For more tagging best practices, see Best practices and strategies in the *Tagging AWS Resources and Tag Editor User Guide*.

Remediation

For information about adding tags to an AWS App Runner service, see TagResource in the *AWS App Runner API Reference*.

[AppRunner.2] App Runner VPC connectors should be tagged

Category: Identify > Inventory > Tagging

Severity: Low

Resource type: `AWS::AppRunner::VpcConnector`

AWS Config rule: apprunner-vpc-connector-tagged

Schedule type: Change triggered

Parameters:

Parameter	Description	Type	Allowed custom values	Security Hub CSPM default value
`requiredKeyTags`	List of non-system tag keys that the evaluated resource must contain. Tag keys are case sensitive.	StringList (maximum of 6 items)	1–6 tag keys that meet AWS	No default value

Parameter	Description	Type	Allowed custom values	Security Hub CSPM default value
			requirements.	

This control checks whether an AWS App Runner VPC connector has tags with the specific keys defined in the parameter `requiredKeyTags`. The control fails if the VPC connector doesn't have any tag keys or if it doesn't have all the keys specified in the parameter `requiredKeyTags`. If the parameter `requiredKeyTags` isn't provided, the control only checks for the existence of a tag key and fails if the VPC connector isn't tagged with any key. System tags, which are automatically applied and begin with `aws:`, are ignored.

A tag is a label that you assign to an AWS resource, and it consists of a key and an optional value. You can create tags to categorize resources by purpose, owner, environment, or other criteria. Tags can help you identify, organize, search for, and filter resources. Tagging also helps you track accountable resource owners for actions and notifications. When you use tagging, you can implement attribute-based access control (ABAC) as an authorization strategy, which defines permissions based on tags. You can attach tags to IAM entities (users or roles) and to AWS resources. You can create a single ABAC policy or a separate set of policies for your IAM principals. You can design these ABAC policies to allow operations when the principal's tag matches the resource tag. For more information, see Define permissions based on attributes with ABAC authorization in the *IAM User Guide*.

> **Note**
>
> Don't add personally identifiable information (PII) or other confidential or sensitive information in tags. Tags are accessible to many AWS services, including AWS Billing. For more tagging best practices, see Best practices and strategies in the *Tagging AWS Resources and Tag Editor User Guide*.

Remediation

For information about adding tags to an AWS App Runner VPC connector, see TagResource in the *AWS App Runner API Reference*.

Security Hub CSPM controls for AWS AppSync

These Security Hub CSPM controls evaluate the AWS AppSync service and resources.

These controls may not be available in all AWS Regions. For more information, see Availability of controls by Region.

[AppSync.2] AWS AppSync should have field-level logging enabled

Related requirements: PCI DSS v4.0.1/10.4.2, CRI Profile v2.2/DE.AE-02.01, CRI Profile v2.2/DE.AE-03.01, CRI Profile v2.2/DE.AE-03.02, CRI Profile v2.2/DE.AE-07.02, CRI Profile v2.2/PR.PS-04.01, CRI Profile v2.2/PR.PS-04.02, CRI Profile v2.2/PR.PS-04.03

Category: Identify > Logging

Severity: Medium

Resource type: `AWS::AppSync::GraphQLApi`

AWS Config rule: `appsync-logging-enabled`

Schedule type: Change triggered

Parameters:

Parameter	Description	Type	Allowed custom values	Security Hub CSPM default value	
`fieldLoggingLevel`	Field logging level	Enum	`ERROR`, `ALL`, `INFO`, `DEBUG`	`No default value`	

This control checks whether an AWS AppSync API has field-level logging turned on. The control fails if the field resolver log level is set to **None**. Unless you provide custom parameter values to indicate that a specific log type should be enabled, Security Hub CSPM produces a passed finding if the field resolver log level is either `ERROR` or `ALL`.

You can use logging and metrics to identify, troubleshoot, and optimize your GraphQL queries. Turning on logging for AWS AppSync GraphQL helps you get detailed information about API requests and responses, identify and respond to issues, and comply with regulatory requirements.

Remediation

To turn on logging for AWS AppSync, see Setup and configuration in the *AWS AppSync Developer Guide*.

[AppSync.4] AWS AppSync GraphQL APIs should be tagged

Category: Identify > Inventory > Tagging

Severity: Low

Resource type: `AWS::AppSync::GraphQLApi`

AWS Config rule: `tagged-appsync-graphqlapi` (custom Security Hub CSPM rule)

Schedule type: Change triggered

Parameters:

Parameter	Description	Type	Allowed custom values	Security Hub CSPM default value
`requiredTagKeys`	List of non-system tag keys that the evaluated resource must contain. Tag keys are case sensitive.	StringList (maximum of 6 items)	1–6 tag keys that meet AWS requirements.	No default value

This control checks whether an AWS AppSync GraphQL API has tags with the specific keys defined in the parameter `requiredTagKeys`. The control fails if the GraphQL API doesn't have any tag keys or if it doesn't have all the keys specified in the parameter `requiredTagKeys`. If the parameter `requiredTagKeys` isn't provided, the control only checks for the existence of a tag key and fails if the GraphQL API isn't tagged with any key. System tags, which are automatically applied and begin with `aws:`, are ignored.

A tag is a label that you assign to an AWS resource, and it consists of a key and an optional value. You can create tags to categorize resources by purpose, owner, environment, or other criteria. Tags can help you identify, organize, search for, and filter resources. Tagging also helps you track accountable resource owners for actions and notifications. When you use tagging, you can implement attribute-based access control (ABAC) as an authorization strategy, which defines permissions based on tags. You can attach tags to IAM entities (users or roles) and to AWS resources. You can create a single ABAC policy or a separate set of policies for your IAM principals. You can design these ABAC policies to allow operations when the principal's tag matches the resource tag. For more information, see What is ABAC for AWS? in the *IAM User Guide*.

> **Note**
>
> Don't add personally identifiable information (PII) or other confidential or sensitive information in tags. Tags are accessible to many AWS services, including AWS Billing. For more tagging best practices, see Tagging your AWS resources in the *AWS General Reference*.

Remediation

To add tags to an AWS AppSync GraphQL API, see TagResource in the *AWS AppSync API Reference*.

[AppSync.5] AWS AppSync GraphQL APIs should not be authenticated with API keys

Related requirements: NIST.800-53.r5 AC-2(1), NIST.800-53.r5 AC-3, NIST.800-53.r5 AC-3(15), NIST.800-53.r5 AC-3(7), NIST.800-53.r5 AC-6, CRI Profile v2.2/PR.AA-01.01, CRI Profile v2.2/PR.AA-03.01

Category: Protect > Secure access management > Passwordless authentication

Severity: High

Resource type: `AWS::AppSync::GraphQLApi`

AWS Config rule: `appsync-authorization-check`

Schedule type: Change triggered

Parameters:

- `AllowedAuthorizationTypes: AWS_LAMBDA, AWS_IAM, OPENID_CONNECT, AMAZON_COGNITO_USER_POOLS` (not customizable)

This control checks whether your application uses an API key to interact with an AWS AppSync GraphQL API. The control fails if an AWS AppSync GraphQL API is authenticated with an API key.

An API key is a hard-coded value in your application that is generated by the AWS AppSync service when you create an unauthenticated GraphQL endpoint. If this API key is compromised, your endpoint is vulnerable to unintended access. Unless you are supporting a publicly accessible application or website, we don't recommend using an API key for authentication.

Remediation

To set an authorization option for your AWS AppSync GraphQL API, see Authorization and authentication in the *AWS AppSync Developer Guide*.

Security Hub CSPM controls for Amazon Athena

These AWS Security Hub CSPM controls evaluate the Amazon Athena service and resources. The controls might not be available in all AWS Regions. For more information, see Availability of controls by Region.

[Athena.2] Athena data catalogs should be tagged

Category: Identify > Inventory > Tagging

Severity: Low

Resource type: `AWS::Athena::DataCatalog`

AWS Config rule: `tagged-athena-datacatalog` (custom Security Hub CSPM rule)

Schedule type: Change triggered

Parameters:

Parameter	Description	Type	Allowed custom values	Security Hub CSPM default value
`requiredTagKeys`	List of non-system tag keys that the evaluated resource	StringList (maximum of 6 items)	1–6 tag keys that meet AWS	`No default value`

Parameter	Description	Type	Allowed custom values	Security Hub CSPM default value
	must contain. Tag keys are case sensitive.		requirements.	

This control checks whether an Amazon Athena data catalog has tags with the specific keys defined in the parameter `requiredTagKeys`. The control fails if the data catalog doesn't have any tag keys or if it doesn't have all the keys specified in the parameter `requiredTagKeys`. If the parameter `requiredTagKeys` isn't provided, the control only checks for the existence of a tag key and fails if the data catalog isn't tagged with any key. System tags, which are automatically applied and begin with `aws:`, are ignored.

A tag is a label that you assign to an AWS resource, and it consists of a key and an optional value. You can create tags to categorize resources by purpose, owner, environment, or other criteria. Tags can help you identify, organize, search for, and filter resources. Tagging also helps you track accountable resource owners for actions and notifications. When you use tagging, you can implement attribute-based access control (ABAC) as an authorization strategy, which defines permissions based on tags. You can attach tags to IAM entities (users or roles) and to AWS resources. You can create a single ABAC policy or a separate set of policies for your IAM principals. You can design these ABAC policies to allow operations when the principal's tag matches the resource tag. For more information, see What is ABAC for AWS? in the *IAM User Guide*.

> **Note**
>
> Don't add personally identifiable information (PII) or other confidential or sensitive information in tags. Tags are accessible to many AWS services, including AWS Billing. For more tagging best practices, see Tagging your AWS resources in the *AWS General Reference*.

Remediation

To add tags to an Athena data catalog, see Tagging Athena resources in the *Amazon Athena User Guide*.

[Athena.3] Athena workgroups should be tagged

Category: Identify > Inventory > Tagging

Severity: Low

Resource type: `AWS::Athena::WorkGroup`

AWS Config rule: `tagged-athena-workgroup` (custom Security Hub CSPM rule)

Schedule type: Change triggered

Parameters:

Parameter	Description	Type	Allowed custom values	Security Hub CSPM default value
`requiredTagKeys`	List of non-system tag keys that the evaluated resource must contain. Tag keys are case sensitive.	StringList (maximum of 6 items)	1–6 tag keys that meet AWS requirements.	`No default value`

This control checks whether an Amazon Athena workgroup has tags with the specific keys defined in the parameter `requiredTagKeys`. The control fails if the workgroup doesn't have any tag keys or if it doesn't have all the keys specified in the parameter `requiredTagKeys`. If the parameter `requiredTagKeys` isn't provided, the control only checks for the existence of a tag key and fails if the workgroup isn't tagged with any key. System tags, which are automatically applied and begin with `aws:`, are ignored.

A tag is a label that you assign to an AWS resource, and it consists of a key and an optional value. You can create tags to categorize resources by purpose, owner, environment, or other criteria. Tags can help you identify, organize, search for, and filter resources. Tagging also helps you track accountable resource owners for actions and notifications. When you use tagging, you can implement attribute-based access control (ABAC) as an authorization strategy, which defines permissions based on tags. You can attach tags to IAM entities (users or roles) and to AWS resources. You can create a single ABAC policy or a separate set of policies for your IAM principals.

You can design these ABAC policies to allow operations when the principal's tag matches the resource tag. For more information, see What is ABAC for AWS? in the *IAM User Guide*.

> **Note**
>
> Don't add personally identifiable information (PII) or other confidential or sensitive information in tags. Tags are accessible to many AWS services, including AWS Billing. For more tagging best practices, see Tagging your AWS resources in the *AWS General Reference*.

Remediation

To add tags to an Athena workgroup, see Adding and deleting tags on an individual workgroup in the *Amazon Athena User Guide*.

[Athena.4] Athena workgroups should have logging enabled

Related requirements: CRI Profile v2.2/DE.AE-03.01, CRI Profile v2.2/DE.CM-03.01, CRI Profile v2.2/PR.IR-04.01, CRI Profile v2.2/PR.PS-04.02, CRI Profile v2.2/PR.PS-04.03

Category: Identify > Logging

Severity: Medium

Resource type: `AWS::Athena::WorkGroup`

AWS Config rule: athena-workgroup-logging-enabled

Schedule type: Change triggered

Parameters: None

This control checks whether an Amazon Athena workgroup has logging enabled. The control fails if the workgroup doesn't have logging enabled.

Audit logs track and monitor system activities. They provide a record of events that can help you detect security breaches, investigate incidents, and comply with regulations. Audit logs also enhance the overall accountability and transparency of your organization.

Remediation

For information about enabling logging for an Athena workgroup, see Enable CloudWatch query metrics in Athena in the *Amazon Athena User Guide*.

Security Hub CSPM controls for AWS Backup

These Security Hub CSPM controls evaluate the AWS Backup service and resources.

These controls may not be available in all AWS Regions. For more information, see Availability of controls by Region.

[Backup.1] AWS Backup recovery points should be encrypted at rest

Related requirements: NIST.800-53.r5 CP-9(8), NIST.800-53.r5 SI-12, CRI Profile v2.2/PR.DS-01.01, CRI Profile v2.2/PR.DS-11.01, CRI Profile v2.2/PR.PS-01.06

Category: Protect > Data Protection > Encryption of data-at-rest

Severity: Medium

Resource type: `AWS::Backup::RecoveryPoint`

AWS Config rule: `backup-recovery-point-encrypted`

Schedule type: Change triggered

Parameters: None

This control checks if an AWS Backup recovery point is encrypted at rest. The control fails if the recovery point isn't encrypted at rest.

An AWS Backup recovery point refers to a specific copy or snapshot of data that is created as part of a backup process. It represents a particular moment in time when the data was backed up and serves as a restore point in case the original data becomes lost, corrupted, or inaccessible. Encrypting the backup recovery points adds an extra layer of protection against unauthorized access. Encryption is a best practice to protect the confidentiality, integrity, and security of backup data.

Remediation

To encrypt an AWS Backup recovery point, see Encryption for backups in AWS Backup in the *AWS Backup Developer Guide*.

[Backup.2] AWS Backup recovery points should be tagged

Category: Identify > Inventory > Tagging

Severity: Low

Resource type: `AWS::Backup::RecoveryPoint`

AWS Configrule: `tagged-backup-recoverypoint` (custom Security Hub CSPM rule)

Schedule type: Change triggered

Parameters:

Parameter	Description	Type	Allowed custom values	Security Hub CSPM default value
`requiredTagKeys`	List of non-system tag keys that the evaluated resource must contain. Tag keys are case sensitive.	StringList (maximum of 6 items)	1–6 tag keys that meet AWS requirements.	No default value

This control checks whether an AWS Backup recovery point has tags with the specific keys defined in the parameter `requiredTagKeys`. The control fails if the recovery point doesn't have any tag keys or if it doesn't have all the keys specified in the parameter `requiredTagKeys`. If the parameter `requiredTagKeys` isn't provided, the control only checks for the existence of a tag key and fails if the recovery point isn't tagged with any key. System tags, which are automatically applied and begin with `aws:`, are ignored.

A tag is a label that you assign to an AWS resource, and it consists of a key and an optional value. You can create tags to categorize resources by purpose, owner, environment, or other criteria. Tags can help you identify, organize, search for, and filter resources. Tagging also helps you track accountable resource owners for actions and notifications. When you use tagging, you can implement attribute-based access control (ABAC) as an authorization strategy, which defines permissions based on tags. You can attach tags to IAM entities (users or roles) and to AWS resources. You can create a single ABAC policy or a separate set of policies for your IAM principals. You can design these ABAC policies to allow operations when the principal's tag matches the resource tag. For more information, see What is ABAC for AWS? in the *IAM User Guide*.

> **Note**
>
> Don't add personally identifiable information (PII) or other confidential or sensitive information in tags. Tags are accessible to many AWS services, including AWS Billing. For more tagging best practices, see Tagging your AWS resources in the *AWS General Reference*.

Remediation

To copy tags from source resources at backup creation time, see Copy tags onto backups in *AWS Backup Developer Guide*.

Tags are not copied at creation time for parent/composite recovery points. To add tags on existing recovery points including parent/composite recovery points, see Add or remove tags on existing recovery points in *AWS Backup Developer Guide*.

[Backup.3] AWS Backup vaults should be tagged

Category: Identify > Inventory > Tagging

Severity: Low

Resource type: `AWS::Backup::BackupVault`

AWS Configrule: `tagged-backup-backupvault` (custom Security Hub CSPM rule)

Schedule type: Change triggered

Parameters:

Parameter	Description	Type	Allowed custom values	Security Hub CSPM default value
`requiredTagKeys`	List of non-system tag keys that the evaluated resource must contain. Tag keys are case sensitive.	StringList (maximum of 6 items)	1–6 tag keys that meet AWS	No default value

Parameter	Description	Type	Allowed custom values	Security Hub CSPM default value
			requirements.	

This control checks whether an AWS Backup vault has tags with the specific keys defined in the parameter `requiredTagKeys`. The control fails if the recovery point doesn't have any tag keys or if it doesn't have all the keys specified in the parameter `requiredTagKeys`. If the parameter `requiredTagKeys` isn't provided, the control only checks for the existence of a tag key and fails if the recovery point isn't tagged with any key. System tags, which are automatically applied and begin with `aws:`, are ignored.

A tag is a label that you assign to an AWS resource, and it consists of a key and an optional value. You can create tags to categorize resources by purpose, owner, environment, or other criteria. Tags can help you identify, organize, search for, and filter resources. Tagging also helps you track accountable resource owners for actions and notifications. When you use tagging, you can implement attribute-based access control (ABAC) as an authorization strategy, which defines permissions based on tags. You can attach tags to IAM entities (users or roles) and to AWS resources. You can create a single ABAC policy or a separate set of policies for your IAM principals. You can design these ABAC policies to allow operations when the principal's tag matches the resource tag. For more information, see What is ABAC for AWS? in the *IAM User Guide*.

> **Note**
>
> Don't add personally identifiable information (PII) or other confidential or sensitive information in tags. Tags are accessible to many AWS services, including AWS Billing. For more tagging best practices, see Tagging your AWS resources in the *AWS General Reference*.

Remediation

To add tags to an AWS Backup vault

1. Open the AWS Backup console at https://console.aws.amazon.com/backup.
2. In the navigation pane, choose **Backup vaults**.

3. Select a backup vault from the list.
4. In the **Backup vault tags** section, choose **Manage tags**.
5. Enter the key and value for the tag. Choose **Add new tag** for additional key-value pairs.
6. When you are finished adding tags, choose **Save**.

[Backup.4] AWS Backup report plans should be tagged

Category: Identify > Inventory > Tagging

Severity: Low

Resource type: `AWS::Backup::ReportPlan`

AWS Configrule: `tagged-backup-reportplan` (custom Security Hub CSPM rule)

Schedule type: Change triggered

Parameters:

Parameter	Description	Type	Allowed custom values	Security Hub CSPM default value
`requiredTagKeys`	List of non-system tag keys that the evaluated resource must contain. Tag keys are case sensitive.	StringList (maximum of 6 items)	1–6 tag keys that meet AWS requirements.	No default value

This control checks whether an AWS Backup report plan has tags with the specific keys defined in the parameter `requiredTagKeys`. The control fails if the report plan doesn't have any tag keys or if it doesn't have all the keys specified in the parameter `requiredTagKeys`. If the parameter `requiredTagKeys` isn't provided, the control only checks for the existence of a tag key and fails if the report plan isn't tagged with any key. System tags, which are automatically applied and begin with `aws:`, are ignored.

A tag is a label that you assign to an AWS resource, and it consists of a key and an optional value. You can create tags to categorize resources by purpose, owner, environment, or other criteria. Tags can help you identify, organize, search for, and filter resources. Tagging also helps you track accountable resource owners for actions and notifications. When you use tagging, you can implement attribute-based access control (ABAC) as an authorization strategy, which defines permissions based on tags. You can attach tags to IAM entities (users or roles) and to AWS resources. You can create a single ABAC policy or a separate set of policies for your IAM principals. You can design these ABAC policies to allow operations when the principal's tag matches the resource tag. For more information, see What is ABAC for AWS? in the *IAM User Guide*.

> **Note**
>
> Don't add personally identifiable information (PII) or other confidential or sensitive information in tags. Tags are accessible to many AWS services, including AWS Billing. For more tagging best practices, see Tagging your AWS resources in the *AWS General Reference*.

Remediation

To add tags to an AWS Backup report plan

1. Open the AWS Backup console at https://console.aws.amazon.com/backup.
2. In the navigation pane, choose **Backup vaults**.
3. Select a backup vault from the list.
4. In the **Backup vault tags** section, choose **Manage tags**.
5. Choose **Add new tag**. Enter the key and value for the tag. Repeat for additional key-value pairs.
6. When you are finished adding tags, choose **Save**.

[Backup.5] AWS Backup backup plans should be tagged

Category: Identify > Inventory > Tagging

Severity: Low

Resource type: `AWS::Backup::BackupPlan`

AWS Configrule: `tagged-backup-backupplan` (custom Security Hub CSPM rule)

Schedule type: Change triggered

Parameters:

Parameter	Description	Type	Allowed custom values	Security Hub CSPM default value
`requiredTagKeys`	List of non-system tag keys that the evaluated resource must contain. Tag keys are case sensitive.	StringList (maximum of 6 items)	1–6 tag keys that meet AWS requirements.	No default value

This control checks whether an AWS Backup backup plan has tags with the specific keys defined in the parameter `requiredTagKeys`. The control fails if the backup plan doesn't have any tag keys or if it doesn't have all the keys specified in the parameter `requiredTagKeys`. If the parameter `requiredTagKeys` isn't provided, the control only checks for the existence of a tag key and fails if the backup plan isn't tagged with any key. System tags, which are automatically applied and begin with `aws:`, are ignored.

A tag is a label that you assign to an AWS resource, and it consists of a key and an optional value. You can create tags to categorize resources by purpose, owner, environment, or other criteria. Tags can help you identify, organize, search for, and filter resources. Tagging also helps you track accountable resource owners for actions and notifications. When you use tagging, you can implement attribute-based access control (ABAC) as an authorization strategy, which defines permissions based on tags. You can attach tags to IAM entities (users or roles) and to AWS resources. You can create a single ABAC policy or a separate set of policies for your IAM principals. You can design these ABAC policies to allow operations when the principal's tag matches the resource tag. For more information, see What is ABAC for AWS? in the *IAM User Guide*.

> **Note**
>
> Don't add personally identifiable information (PII) or other confidential or sensitive information in tags. Tags are accessible to many AWS services, including AWS Billing. For more tagging best practices, see Tagging your AWS resources in the *AWS General Reference*.

Remediation

To add tags to an AWS Backup backup plan

1. Open the AWS Backup console at https://console.aws.amazon.com/backup.
2. In the navigation pane, choose **Backup vaults**.
3. Select a backup vault from the list.
4. In the **Backup vault tags** section, choose **Manage tags**.
5. Choose **Add new tag**. Enter the key and value for the tag. Repeat for additional key-value pairs.
6. When you are finished adding tags, choose **Save**.

Security Hub CSPM controls for AWS Batch

These Security Hub CSPM controls evaluate the AWS Batch service and resources. The controls might not be available in all AWS Regions. For more information, see Availability of controls by Region.

[Batch.1] Batch job queues should be tagged

Category: Identify > Inventory > Tagging

Severity: Low

Resource type: `AWS::Batch::JobQueue`

AWS Config rule: batch-job-queue-tagged

Schedule type: Change triggered

Parameters:

Parameter	Description	Type	Allowed custom values	Security Hub CSPM default value
`requiredKeyTags`	List of non-system tag keys that the evaluated resource	StringList (maximum of 6 items)	1–6 tag keys that meet AWS	No default value

Parameter	Description	Type	Allowed custom values	Security Hub CSPM default value
	must contain. Tag keys are case sensitive.		requirements.	

This control checks whether an AWS Batch job queue has tags with the specific keys defined in the parameter `requiredKeyTags`. The control fails if the job queue doesn't have any tag keys or if it doesn't have all the keys specified in the parameter `requiredKeyTags`. If the parameter `requiredKeyTags` isn't provided, the control only checks for the existence of a tag key and fails if the job queue isn't tagged with any key. System tags, which are automatically applied and begin with `aws:`, are ignored.

A tag is a label that you assign to an AWS resource, and it consists of a key and an optional value. You can create tags to categorize resources by purpose, owner, environment, or other criteria. Tags can help you identify, organize, search for, and filter resources. Tagging also helps you track accountable resource owners for actions and notifications. When you use tagging, you can implement attribute-based access control (ABAC) as an authorization strategy, which defines permissions based on tags. You can attach tags to IAM entities (users or roles) and to AWS resources. You can create a single ABAC policy or a separate set of policies for your IAM principals. You can design these ABAC policies to allow operations when the principal's tag matches the resource tag. For more information, see Define permissions based on attributes with ABAC authorization in the *IAM User Guide*.

> **Note**
>
> Don't add personally identifiable information (PII) or other confidential or sensitive information in tags. Tags are accessible to many AWS services, including AWS Billing. For more tagging best practices, see Best practices and strategies in the *Tagging AWS Resources and Tag Editor User Guide*.

Remediation

To add tags to a Batch job queue, see Tag your resources in the *AWS Batch User Guide*.

[Batch.2] Batch scheduling policies should be tagged

Related requirements: CRI Profile v2.2/ID.AM-02.01, CRI Profile v2.2/ID.AM-05.01

Category: Identify > Inventory > Tagging

Severity: Low

Resource type: `AWS::Batch::SchedulingPolicy`

AWS Config rule: batch-scheduling-policy-tagged

Schedule type: Change triggered

Parameters:

Parameter	Description	Type	Allowed custom values	Security Hub CSPM default value
`requiredKeyTags`	List of non-system tag keys that the evaluated resource must contain. Tag keys are case sensitive.	StringList (maximum of 6 items)	1–6 tag keys that meet AWS requirements.	No default value

This control checks whether an AWS Batch scheduling policy has tags with the specific keys defined in the parameter `requiredKeyTags`. The control fails if the scheduling policy doesn't have any tag keys or if it doesn't have all the keys specified in the parameter `requiredKeyTags`. If the parameter `requiredKeyTags` isn't provided, the control only checks for the existence of a tag key and fails if the scheduling policy isn't tagged with any key. System tags, which are automatically applied and begin with `aws:`, are ignored.

A tag is a label that you assign to an AWS resource, and it consists of a key and an optional value. You can create tags to categorize resources by purpose, owner, environment, or other criteria. Tags can help you identify, organize, search for, and filter resources. Tagging also helps you track accountable resource owners for actions and notifications. When you use tagging, you can implement attribute-based access control (ABAC) as an authorization strategy, which

defines permissions based on tags. You can attach tags to IAM entities (users or roles) and to AWS resources. You can create a single ABAC policy or a separate set of policies for your IAM principals. You can design these ABAC policies to allow operations when the principal's tag matches the resource tag. For more information, see Define permissions based on attributes with ABAC authorization in the *IAM User Guide*.

> **Note**
>
> Don't add personally identifiable information (PII) or other confidential or sensitive information in tags. Tags are accessible to many AWS services, including AWS Billing. For more tagging best practices, see Best practices and strategies in the *Tagging AWS Resources and Tag Editor User Guide*.

Remediation

To add tags to a Batch scheduling policy, see Tag your resources in the *AWS Batch User Guide*.

[Batch.3] Batch compute environments should be tagged

Category: Identify > Inventory > Tagging

Severity: Low

Resource type: `AWS::Batch::ComputeEnvironment`

AWS Config rule: batch-compute-environment-tagged

Schedule type: Change triggered

Parameters:

Parameter	Description	Type	Allowed custom values	Security Hub CSPM default value
`requiredKeyTags`	List of non-system tag keys that the evaluated resource	StringList (maximum of 6 items)	1–6 tag keys that meet AWS	No default value

Parameter	Description	Type	Allowed custom values	Security Hub CSPM default value
	must contain. Tag keys are case sensitive.		requirements.	

This control checks whether an AWS Batch compute environment has tags with the specific keys defined in the parameter `requiredKeyTags`. The control fails if the compute environment doesn't have any tag keys or if it doesn't have all the keys specified in the parameter `requiredKeyTags`. If the parameter `requiredKeyTags` isn't provided, the control only checks for the existence of a tag key and fails if the compute environment isn't tagged with any key. System tags, which are automatically applied and begin with `aws:`, are ignored.

A tag is a label that you assign to an AWS resource, and it consists of a key and an optional value. You can create tags to categorize resources by purpose, owner, environment, or other criteria. Tags can help you identify, organize, search for, and filter resources. Tagging also helps you track accountable resource owners for actions and notifications. When you use tagging, you can implement attribute-based access control (ABAC) as an authorization strategy, which defines permissions based on tags. You can attach tags to IAM entities (users or roles) and to AWS resources. You can create a single ABAC policy or a separate set of policies for your IAM principals. You can design these ABAC policies to allow operations when the principal's tag matches the resource tag. For more information, see Define permissions based on attributes with ABAC authorization in the *IAM User Guide*.

> **Note**
>
> Don't add personally identifiable information (PII) or other confidential or sensitive information in tags. Tags are accessible to many AWS services, including AWS Billing. For more tagging best practices, see Best practices and strategies in the *Tagging AWS Resources and Tag Editor User Guide*.

Remediation

To add tags to a Batch compute environment, see Tag your resources in the *AWS Batch User Guide*.

[Batch.4] Compute resources properties in managed Batch compute environments should be tagged

Related requirements: CRI Profile v2.2/ID.AM-02.01, CRI Profile v2.2/ID.AM-05.01

Category: Identify > Inventory > Tagging

Severity: Low

Resource type: `AWS::Batch::ComputeEnvironment`

AWS Config rule: batch-managed-compute-env-compute-resources-tagged

Schedule type: Change triggered

Parameters:

Parameter	Description	Type	Allowed custom values	Security Hub CSPM default value
`requiredKeyTags`	A list of non-system tag keys that must be assigned to an evaluated resource. Tag keys are case sensitive.	StringList (maximum of 6 items)	1–6 tag keys that meet AWS requirements.	No default value

This control checks whether the compute resources property in a managed AWS Batch compute environment has the tag keys specified by the `requiredKeyTags` parameter. The control fails if the compute resources property doesn't have any tag keys, or it doesn't have all the keys specified by the `requiredKeyTags` parameter. If you don't specify any values for the `requiredKeyTags` parameter, the control checks only for the existence of a tag key and fails if a compute resources property doesn't have any tag keys. The control ignores system tags, which are applied automatically and have the `aws:` prefix. This control doesn't evaluate unmanaged compute environments, or managed environments that use AWS Fargate resources.

A tag is a label that you create and assign to an AWS resource. Each tag consists of a required tag key and an optional tag value. You can use tags to categorize resources by purpose, owner,

environment, or other criteria. They can help you identify, organize, search for, and filter resources. They can also help you track resource owners for actions and notifications. You can also use tags to implement attribute-based access control (ABAC) as an authorization strategy. For more information about ABAC strategies, see Define permissions based on attributes with ABAC authorization in the *IAM User Guide*. For more information about tags, see the Tagging AWS Resources and Tag Editor User Guide.

> **Note**
>
> Do not store personally identifiable information (PII) or other confidential or sensitive information in tags. Tags are accessible from many AWS services. They aren't intended to be used for private or sensitive data.

Remediation

For information about adding tags to compute resources in a managed AWS Batch compute environment, see Tag your resources in the *AWS Batch User Guide*.

Security Hub CSPM controls for Amazon Bedrock

These AWS Security Hub CSPM controls evaluate the Amazon Bedrock service and resources. The controls might not be available in all AWS Regions. For more information, see Availability of controls by Region.

[Bedrock.1] Amazon Bedrock data sources should be encrypted with customer managed AWS KMS keys

Related requirements: NIST.800-53.r5 AU-9, NIST.800-53.r5 CA-9(1), NIST.800-53.r5 CM-3(6), NIST.800-53.r5 SC-7(10), NIST.800-53.r5 SC-12(2), NIST.800-53.r5 SC-13, NIST.800-53.r5 SC-28, NIST.800-53.r5 SC-28(1), NIST.800-53.r5 SI-7(6)

Category: Protect > Data protection > Encryption of data at rest

Severity: Medium

Resource type: `AWS::Bedrock::DataSource`

AWS Config rule: bedrock-data-source-encryption-enabled

Schedule type: Change triggered

Parameters: None

This control checks whether an Amazon Bedrock data source is encrypted at rest with a customer managed AWS KMS key. The control fails if the data source isn't encrypted with a customer managed KMS key. The control doesn't evaluate data sources that belong to a managed knowledge base.

By default, Amazon Bedrock encrypts data source content with AWS managed keys. Using a customer managed KMS key gives you full control over the encryption key lifecycle, including rotation, access policies, and auditing through AWS CloudTrail. This helps meet compliance requirements that mandate customer-controlled encryption for sensitive data ingested into knowledge bases.

Remediation

To encrypt your Amazon Bedrock data source with a customer managed KMS key, see Modify a data source for your Amazon Bedrock knowledge base in the *Amazon Bedrock User Guide*.

Security Hub CSPM controls for Amazon Bedrock AgentCore

These AWS Security Hub CSPM controls evaluate the Amazon Bedrock AgentCore service and resources. The controls might not be available in all AWS Regions. For more information, see Availability of controls by Region.

[BedrockAgentCore.1] Bedrock AgentCore runtimes should be configured with VPC network mode

Category: Protect > Secure access management > Resource not publicly accessible

Severity: High

Resource type: `AWS::BedrockAgentCore::Runtime`

AWS Config rule: bedrockagentcore-runtime-private-network-required

Schedule type: Change triggered

Parameters: None

This control checks whether an Amazon Bedrock AgentCore runtime is configured with VPC network mode. The control fails if the runtime has its network mode set to PUBLIC.

The control doesn't produce findings for runtimes that are backed by a capacity provider. These runtimes define their network configuration on the capacity provider instead of on the runtime, so they are out of scope for this control.

Using public network mode for Amazon Bedrock AgentCore runtimes exposes the runtime directly to the internet, increasing the attack surface and risk of unauthorized access. Configuring runtimes with VPC network mode ensures that runtime traffic is confined within your private network, enabling you to apply network-level security controls such as security groups, network ACLs, and VPC flow logs.

Remediation

To remediate this finding, update the non-compliant Bedrock AgentCore runtime and configure it with VPC network mode. For instructions, see Configure Amazon Bedrock AgentCore Runtime and tools for VPC in the *Amazon Bedrock AgentCore Developer Guide*.

[BedrockAgentCore.2] Bedrock AgentCore Gateways should require authorization for inbound requests

Category: Protect > Secure access management

Severity: High

Resource type: `AWS::BedrockAgentCore::Gateway`

AWS Config rule: bedrockagentcore-gateway-authorizer-enabled

Schedule type: Change triggered

Parameters: None

This control checks whether an Amazon Bedrock AgentCore Gateway requires authorization for inbound requests. The control fails if the Bedrock AgentCore Gateway doesn't have inbound authorization set up.

Configuring authentication on Amazon Bedrock AgentCore gateways ensures that only authorized clients can send requests to your AI agents. Without an authorizer, any entity with network access to the gateway endpoint can invoke your agents, potentially leading to unauthorized data access,

resource abuse, or unexpected costs. Inbound authorization validates users who attempt to access targets through your AgentCore gateway.

Remediation

To set up inbound authorization for an Amazon Bedrock AgentCore Gateway, see Set up inbound authorization for your gateway in the *Amazon Bedrock AgentCore Developer Guide*.

[BedrockAgentCore.3] Bedrock AgentCore Memory should be encrypted with customer managed AWS KMS keys

Related requirements: NIST.800-53.r5 AU-9, NIST.800-53.r5 CA-9(1), NIST.800-53.r5 CM-3(6), NIST.800-53.r5 SC-7(10), NIST.800-53.r5 SC-12(2), NIST.800-53.r5 SC-13, NIST.800-53.r5 SC-28, NIST.800-53.r5 SC-28(1), NIST.800-53.r5 SI-7(6)

Category: Protect > Data protection > Encryption of data at rest

Severity: Medium

Resource type: `AWS::BedrockAgentCore::Memory`

AWS Config rule: bedrock-agentcore-memory-encryption-enabled

Schedule type: Change triggered

Parameters: None

This control checks whether an Amazon Bedrock AgentCore Memory is encrypted at rest with a customer managed AWS KMS key. The control fails if the Bedrock AgentCore Memory isn't encrypted with a customer managed KMS key.

Using a customer managed KMS key for encryption of Amazon Bedrock AgentCore memory provides enhanced security over the default service managed key. Customer managed KMS keys give you full control over the encryption key lifecycle and access policies. Additionally, all encryption key usage can be logged and monitored through AWS CloudTrail for auditability.

Remediation

To encrypt your Amazon Bedrock AgentCore Memory with a customer managed KMS key, see Encrypt your Amazon Bedrock AgentCore Memory in the *Amazon Bedrock AgentCore Developer Guide*.

[BedrockAgentCore.4] Bedrock AgentCore Gateway should be encrypted with customer managed AWS KMS keys

Related requirements: NIST.800-53.r5 AU-9, NIST.800-53.r5 CA-9(1), NIST.800-53.r5 CM-3(6), NIST.800-53.r5 SC-7(10), NIST.800-53.r5 SC-12(2), NIST.800-53.r5 SC-13, NIST.800-53.r5 SC-28, NIST.800-53.r5 SC-28(1), NIST.800-53.r5 SI-7(6)

Category: Protect > Data protection > Encryption of data at rest

Severity: Medium

Resource type: `AWS::BedrockAgentCore::Gateway`

AWS Config rule: bedrockagentcore-gateway-encryption-enabled

Schedule type: Change triggered

Parameters: None

This control checks whether an Amazon Bedrock AgentCore Gateway is encrypted at rest with a customer managed AWS KMS key. The control fails if the Bedrock AgentCore Gateway isn't encrypted with a customer managed KMS key. The control doesn't evaluate whether the configured customer managed KMS key is disabled or deleted.

By default, Amazon Bedrock AgentCore encrypts gateway data with AWS managed keys. Using a customer managed KMS key gives you full control over the encryption key lifecycle, including rotation, access policies, and auditing through AWS CloudTrail. This helps meet compliance requirements that mandate customer-controlled encryption for sensitive AI workloads.

Remediation

To encrypt your Bedrock AgentCore Gateway with a customer managed KMS key, see Encrypt your AgentCore gateway with a customer-managed KMS key in the *Amazon Bedrock AgentCore Developer Guide*.

[BedrockAgentCore.5] Bedrock AgentCore custom browsers should not use public network mode

Category: Protect > Secure network configuration > Resources within VPC

Severity: High

Resource type: `AWS::BedrockAgentCore::BrowserCustom`

AWS Config rule: bedrockagentcore-browsercustom-network-mode-not-public

Schedule type: Change triggered

Parameters: None

This control checks whether an Amazon Bedrock AgentCore custom browser is configured with public network mode. The control fails if the network mode is set to public.

Using PUBLIC network mode for Amazon Bedrock AgentCore custom browsers exposes browser sessions directly to the internet, increasing the attack surface and risk of unauthorized access. Configuring browsers with VPC network mode ensures that browser traffic is confined within your private network, enabling you to apply network-level security controls such as security groups, network ACLs, and VPC flow logs.

Remediation

To remediate this finding, delete the non-compliant Bedrock AgentCore custom browser and recreate it with VPC network mode. For instructions, see Configure Amazon Bedrock AgentCore Runtime and tools for VPC in the *Amazon Bedrock AgentCore Developer Guide*.

[BedrockAgentCore.6] Bedrock AgentCore custom browsers should have session recording enabled

Category: Identify > Logging

Severity: Medium

Resource type: `AWS::BedrockAgentCore::BrowserCustom`

AWS Config rule: bedrockagentcore-browsercustom-recording-enabled

Schedule type: Change triggered

Parameters: None

This control checks whether an Amazon Bedrock AgentCore custom browser has session recording enabled with an S3 destination configured. The control fails if a custom browser does not have recording enabled or does not have an S3 location configured for storing recordings.

Session recording for Bedrock AgentCore custom browsers ensures full auditability of browser interactions, enabling detection of unauthorized access, data exfiltration, or malicious activity during automated browsing sessions.

Remediation

For instructions on how to enable browser session recording, see Session Recording and Replay in the *Amazon Bedrock AgentCore Developer Guide*.

[BedrockAgentCore.7] Bedrock AgentCore custom code interpreters should use a private network configuration

Category: Protect > Secure network configuration > Resources within VPC

Severity: High

Resource type: `AWS::BedrockAgentCore::CodeInterpreterCustom`

AWS Config rule: bedrockagentcore-codeinterpreter-networkmode-check

Schedule type: Change triggered

Parameters: None

This control checks whether an Amazon Bedrock AgentCore custom code interpreter is configured with a private network mode. The control fails if the network mode is set to `PUBLIC` or `SANDBOX`.

Configuring Bedrock AgentCore custom code interpreters with a private network mode ensures that code execution environments are isolated within your VPC. Public or sandbox network modes expose the code interpreter to the internet, increasing the risk of unauthorized access and data exfiltration. Using private network mode restricts network access and helps protect sensitive data processed during code interpretation.

Remediation

To remediate this finding, delete the non-compliant Bedrock AgentCore custom code interpreter and recreate it with VPC network mode. For instructions, see Configuring VPC access for runtime and tools in the *Amazon Bedrock AgentCore Developer Guide*.

Security Hub CSPM controls for AWS Certificate Manager

These AWS Security Hub CSPM controls evaluate the AWS Certificate Manager (ACM) service and resources. The controls might not be available in all AWS Regions. For more information, see Availability of controls by Region.

[ACM.1] Imported and ACM-issued certificates should be renewed after a specified time period

Related requirements: NIST.800-53.r5 SC-28(3), NIST.800-53.r5 SC-7(16), NIST.800-171.r2 3.13.15, PCI DSS v4.0.1/4.2.1, CRI Profile v2.2/PR.DS-02.01, CRI Profile v2.2/PR.PS-01.06, CRI Profile v2.2/PR.PS-01.07

Category: Protect > Data Protection > Encryption of data-in-transit

Severity: Medium

Resource type: `AWS::ACM::Certificate`

AWS Config rule: acm-certificate-expiration-check

Schedule type: Change triggered and periodic

Parameters:

Parameter	Description	Type	Allowed custom values	Security Hub CSPM default value
`daysToExpiration`	Number of days within which the ACM certificate must be renewed	Integer	14 to 365	30

This control checks whether an AWS Certificate Manager (ACM) certificate is renewed within the specified time period. It checks both imported certificates and certificates provided by ACM. The control fails if the certificate isn't renewed within the specified time period. Unless you provide a custom parameter value for the renewal period, Security Hub CSPM uses a default value of 30 days.

ACM can automatically renew certificates that use DNS validation. For certificates that use email validation, you must respond to a domain validation email. ACM doesn't automatically renew certificates that you import. You must renew imported certificates manually.

Remediation

ACM provides managed renewal for your SSL/TLS certificates issued by Amazon. This means that ACM either renews your certificates automatically (if you use DNS validation), or it sends you email

notices when the certificate expiration approaches. These services are provided for both public and private ACM certificates.

For domains validated by email

When a certificate is 45 days from expiration, ACM sends to the domain owner an email for each domain name. To validate the domains and complete the renewal, you must respond to the email notifications.

For more information, see Renewal for domains validated by email in the *AWS Certificate Manager User Guide*.

For domains validated by DNS

ACM automatically renews certificates that use DNS validation. 60 days before the expiration, ACM verifies that the certificate can be renewed.

If it cannot validate a domain name, then ACM sends a notification that manual validation is required. It sends these notifications 45 days, 30 days, 7 days, and 1 day before the expiration.

For more information, see Renewal for domains validated by DNS in the *AWS Certificate Manager User Guide*.

[ACM.2] RSA certificates managed by ACM should use a key length of at least 2,048 bits

Related requirements: PCI DSS v4.0.1/4.2.1, CRI Profile v2.2/PR.PS-01.06

Category: Identify > Inventory > Inventory services

Severity: High

Resource type: `AWS::ACM::Certificate`

AWS Config rule: acm-certificate-rsa-check

Schedule type: Change triggered

Parameters: None

This control checks whether RSA certificates managed by AWS Certificate Manager use a key length of at least 2,048 bits. The control fails if the key length is smaller than 2,048 bits.

The strength of encryption directly correlates with key size. We recommend key lengths of at least 2,048 bits to protect your AWS resources as computing power becomes less expensive and servers become more advanced.

Remediation

The minimum key length for RSA certificates issued by ACM is already 2,048 bits. For instructions on issuing new RSA certificates with ACM, see Issuing and managing certificates in the *AWS Certificate Manager User Guide*.

While ACM allows you to import certificates with shorter key lengths, you must use keys of at least 2,048 bits to pass this control. You can't change the key length after importing a certificate. Instead, you must delete certificates with a key length smaller than 2,048 bits. For more information about importing certificates into ACM, see Prerequisites for importing certificates in the *AWS Certificate Manager User Guide*.

[ACM.3] ACM certificates should be tagged

Category: Identify > Inventory > Tagging

Severity: Low

Resource type: `AWS::ACM::Certificate`

AWS Config rule: `tagged-acm-certificate` (custom Security Hub CSPM rule)

Schedule type: Change triggered

Parameters:

Parameter	Description	Type	Allowed custom values	Security Hub CSPM default value
`requiredTagKeys`	List of non-system tag keys that the evaluated resource must contain. Tag keys are case sensitive.	StringList (maximum of 6 items)	1–6 tag keys that meet AWS	No default value

Parameter	Description	Type	Allowed custom values	Security Hub CSPM default value
			requirements.	

This control checks whether an AWS Certificate Manager (ACM) certificate has tags with the specific keys defined in the parameter `requiredTagKeys`. The control fails if the certificate doesn't have any tag keys or if it doesn't have all the keys specified in the parameter `requiredTagKeys`. If the parameter `requiredTagKeys` isn't provided, the control only checks for the existence of a tag key and fails if the certificate isn't tagged with any key. System tags, which are automatically applied and begin with `aws:`, are ignored.

A tag is a label that you assign to an AWS resource, and it consists of a key and an optional value. You can create tags to categorize resources by purpose, owner, environment, or other criteria. Tags can help you identify, organize, search for, and filter resources. Tagging also helps you track accountable resource owners for actions and notifications. When you use tagging, you can implement attribute-based access control (ABAC) as an authorization strategy, which defines permissions based on tags. You can attach tags to IAM entities (users or roles) and to AWS resources. You can create a single ABAC policy or a separate set of policies for your IAM principals. You can design these ABAC policies to allow operations when the principal's tag matches the resource tag. For more information, see What is ABAC for AWS? in the *IAM User Guide*.

Note

Don't add personally identifiable information (PII) or other confidential or sensitive information in tags. Tags are accessible to many AWS services, including AWS Billing. For more tagging best practices, see Tagging your AWS resources in the *AWS General Reference*.

Remediation

To add tags to an ACM certificate, see Tagging AWS Certificate Manager certificates in the *AWS Certificate Manager User Guide*.

Security Hub CSPM controls for CloudFormation

These Security Hub CSPM controls evaluate the AWS CloudFormation service and resources.

These controls may not be available in all AWS Regions. For more information, see Availability of controls by Region.

[CloudFormation.1] CloudFormation stacks should be integrated with Simple Notification Service (SNS)

> **Important**
>
> Security Hub CSPM retired this control in April 2024. For more information, see Change log for Security Hub CSPM controls.

Related requirements: NIST.800-53.r5 SI-4(12), NIST.800-53.r5 SI-4(5)

Category: Detect > Detection services > Application monitoring

Severity: Low

Resource type: `AWS::CloudFormation::Stack`

AWS Config rule: `cloudformation-stack-notification-check`

Schedule type: Change triggered

Parameters: None

This control checks whether an Amazon Simple Notification Service notification is integrated with an CloudFormation stack. The control fails for a CloudFormation stack if no SNS notification is associated with it.

Configuring an SNS notification with your CloudFormation stack helps immediately notify stakeholders of any events or changes occurring with the stack.

Remediation

To integrate a CloudFormation stack and an SNS topic, see Updating stacks directly in the *AWS CloudFormation User Guide*.

[CloudFormation.2] CloudFormation stacks should be tagged

Category: Identify > Inventory > Tagging

Severity: Low

Resource type: `AWS::CloudFormation::Stack`

AWS Config rule: `tagged-cloudformation-stack` (custom Security Hub CSPM rule)

Schedule type: Change triggered

Parameters:

Parameter	Description	Type	Allowed custom values	Security Hub CSPM default value
`requiredTagKeys`	List of non-system tag keys that the evaluated resource must contain. Tag keys are case sensitive.	StringList (maximum of 6 items)	1–6 tag keys that meet AWS requirements.	No default value

This control checks whether an AWS CloudFormation stack has tags with the specific keys defined in the parameter `requiredTagKeys`. The control fails if the stack doesn't have any tag keys or if it doesn't have all the keys specified in the parameter `requiredTagKeys`. If the parameter `requiredTagKeys` isn't provided, the control only checks for the existence of a tag key and fails if the stack isn't tagged with any key. System tags, which are automatically applied and begin with `aws:`, are ignored.

A tag is a label that you assign to an AWS resource, and it consists of a key and an optional value. You can create tags to categorize resources by purpose, owner, environment, or other criteria. Tags can help you identify, organize, search for, and filter resources. Tagging also helps you track accountable resource owners for actions and notifications. When you use tagging, you can implement attribute-based access control (ABAC) as an authorization strategy, which defines permissions based on tags. You can attach tags to IAM entities (users or roles) and to AWS resources. You can create a single ABAC policy or a separate set of policies for your IAM principals.

You can design these ABAC policies to allow operations when the principal's tag matches the resource tag. For more information, see What is ABAC for AWS? in the *IAM User Guide*.

> **Note**
>
> Don't add personally identifiable information (PII) or other confidential or sensitive information in tags. Tags are accessible to many AWS services, including AWS Billing. For more tagging best practices, see Tagging your AWS resources in the *AWS General Reference*.

Remediation

To add tags to a CloudFormation stack, see CreateStack in the *AWS CloudFormation API Reference*.

[CloudFormation.3] CloudFormation stacks should have termination protection enabled

Category: Protect > Data Protection > Data deletion protection

Severity: Medium

Resource type: `AWS::CloudFormation::Stack`

AWS Config rule: cloudformation-termination-protection-check

Schedule type: Change triggered

Parameters: None

This control checks whether an AWS CloudFormation stack has termination protection enabled. The control fails if termination protection is not enabled on a CloudFormation stack.

CloudFormation helps to manage related resources as a single unit called a Stack. You can prevent a stack from being accidentally deleted by enabling termination protection on the stack. If a user attempts to delete a stack with termination protection enabled, the deletion fails and the stack, including its status, remains unchanged. You can set termination protection on a stack with any status except `DELETE_IN_PROGRESS` or `DELETE_COMPLETE`.

> **Note**
>
> Enabling or disabling termination protection on a stack passes the same choice on to any nested stacks belonging to that stack as well. You can't enable or disable termination protection directly on a nested stack. You can't directly delete a nested stack belonging

with a stack that has termination protection enabled. If NESTED is displayed next to the stack name, the stack is a nested stack. You can only change termination protection on the root stack to which the nested stack belongs.

Remediation

To enable termination protection on a CloudFormation stack, see Protect CloudFormation stacks from being deleted in the *AWS CloudFormation User Guide*.

[CloudFormation.4] CloudFormation stacks should have associated service roles

Category: Detect > Secure access management

Severity: Medium

Resource type: `AWS::CloudFormation::Stack`

AWS Config rule: cloudformation-stack-service-role-check

Schedule type: Change triggered

Parameters: None

This control checks whether an AWS CloudFormation stack has a service role associated with it. The control fails for a CloudFormation stack if no service role is associated with it.

Service-managed StackSets use execution roles through AWS Organizations trusted access integration. The control also generates a FAILED finding for an AWS CloudFormation stack created by service-managed StackSets because there is no service role associated with it. Due to how service-managed StackSets authenticate, the `roleARN` field cannot be populated for these stacks.

Using service roles with CloudFormation stacks helps implement least privilege access by separating permissions between the user who creates/updates stacks and the permissions needed by CloudFormation to create/update resources. This reduces the risk of privilege escalation and helps maintain security boundaries between different operational roles.

Note

It is not possible to remove a service role attached to a stack after the stack is created. Other users that have permissions to perform operations on this stack are able to use this

role, regardless of whether those users have the `iam:PassRole` permission or not. If the role includes permissions that the user shouldn't have, you can unintentionally escalate a user's permissions. Ensure that the role grants least privilege.

Remediation

To associate a service role with a CloudFormation stack, see CloudFormation service role in the *AWS CloudFormation User Guide*.

Security Hub CSPM controls for Amazon CloudFront

These AWS Security Hub CSPM controls evaluate the Amazon CloudFront service and resources. The controls might not be available in all AWS Regions. For more information, see Availability of controls by Region.

[CloudFront.1] CloudFront distributions should have a default root object configured

Related requirements: NIST.800-53.r5 SC-7(11), NIST.800-53.r5 SC-7(16), PCI DSS v4.0.1/2.2.6, CRI Profile v2.2/DE.CM-01.03, CRI Profile v2.2/PR.DS-01.01, CRI Profile v2.2/PR.PS-01.01, CRI Profile v2.2/PR.PS-01.03

Category: Protect > Secure access management > Resources not publicly accessible

Severity: High

Resource type: `AWS::CloudFront::Distribution`

AWS Config rule: cloudfront-default-root-object-configured

Schedule type: Change triggered

Parameters: None

This control checks whether an Amazon CloudFront distribution with S3 origins is configured to return a specific object that is the default root object. The control fails if the CloudFront distribution uses S3 origins and doesn't have a default root object configured. This control doesn't apply to CloudFront distributions that use custom origins.

A user might sometimes request the distribution's root URL instead of an object in the distribution. When this happens, specifying a default root object can help you to avoid exposing the contents of your web distribution.

Remediation

To configure a default root object for a CloudFront distribution, see How to specify a default root object in the *Amazon CloudFront Developer Guide*.

[CloudFront.3] CloudFront distributions should require encryption in transit

Related requirements: NIST.800-53.r5 AC-17(2), NIST.800-53.r5 AC-4, NIST.800-53.r5 IA-5(1), NIST.800-53.r5 SC-12(3), NIST.800-53.r5 SC-13, NIST.800-53.r5 SC-23, NIST.800-53.r5 SC-23(3), NIST.800-53.r5 SC-7(4), NIST.800-53.r5 SC-8, NIST.800-53.r5 SC-8(1), NIST.800-53.r5 SC-8(2), NIST.800-53.r5 SI-7(6), PCI DSS v4.0.1/4.2.1, CRI Profile v2.2/PR.DS-02.01, CRI Profile v2.2/PR.PS-01.06

Category: Protect > Data Protection > Encryption of data-in-transit

Severity: Medium

Resource type: `AWS::CloudFront::Distribution`

AWS Config rule: cloudfront-viewer-policy-https

Schedule type: Change triggered

Parameters: None

This control checks whether an Amazon CloudFront distribution requires viewers to use HTTPS directly or whether it uses redirection. The control fails if `ViewerProtocolPolicy` is set to `allow-all` for `defaultCacheBehavior` or for `cacheBehaviors`.

HTTPS (TLS) can be used to help prevent potential attackers from using person-in-the-middle or similar attacks to eavesdrop on or manipulate network traffic. Only encrypted connections over HTTPS (TLS) should be allowed. Encrypting data in transit can affect performance. You should test your application with this feature to understand the performance profile and the impact of TLS.

Remediation

To encrypt a CloudFront distribution in transit, see Requiring HTTPS for communication between viewers and CloudFront in the *Amazon CloudFront Developer Guide*.

[CloudFront.4] CloudFront distributions should have origin failover configured

Related requirements: NIST.800-53.r5 CP-10, NIST.800-53.r5 SC-36, NIST.800-53.r5 SC-5(2), NIST.800-53.r5 SI-13(5), CRI Profile v2.2/PR.IR-03.01, CRI Profile v2.2/PR.IR-04.02

Category: Recover > Resilience > High availability

Severity: Low

Resource type: `AWS::CloudFront::Distribution`

AWS Config rule: cloudfront-origin-failover-enabled

Schedule type: Change triggered

Parameters: None

This control checks whether an Amazon CloudFront distribution is configured with an origin group that has two or more origins.

CloudFront origin failover can increase availability. Origin failover automatically redirects traffic to a secondary origin if the primary origin is unavailable or if it returns specific HTTP response status codes.

Remediation

To configure origin failover for a CloudFront distribution, see Creating an origin group in the *Amazon CloudFront Developer Guide*.

[CloudFront.5] CloudFront distributions should have logging enabled

Related requirements: NIST.800-53.r5 AC-2(4), NIST.800-53.r5 AC-4(26), NIST.800-53.r5 AC-6(9), NIST.800-53.r5 AU-10, NIST.800-53.r5 AU-12, NIST.800-53.r5 AU-2, NIST.800-53.r5 AU-3, NIST.800-53.r5 AU-6(3), NIST.800-53.r5 AU-6(4), NIST.800-53.r5 CA-7, NIST.800-53.r5 SC-7(9), NIST.800-53.r5 SI-3(8), NIST.800-53.r5 SI-4(20), NIST.800-53.r5 SI-7(8), PCI DSS v4.0.1/10.4.2, CRI Profile v2.2/DE.AE-03.01, CRI Profile v2.2/DE.CM-03.01, CRI Profile v2.2/PR.PS-04.02, CRI Profile v2.2/PR.PS-04.03

Category: Identify > Logging

Severity: Medium

Resource type: `AWS::CloudFront::Distribution`

AWS Config rule: cloudfront-accesslogs-enabled

Schedule type: Change triggered

Parameters: None

This control checks whether server access logging is enabled on CloudFront distributions. The control fails if access logging is not enabled for a distribution. This control only evaluates whether standard logging (legacy) is enabled for a distribution.

CloudFront access logs provide detailed information about every user request that CloudFront receives. Each log contains information such as the date and time the request was received, the IP address of the viewer that made the request, the source of the request, and the port number of the request from the viewer. These logs are useful for applications such as security and access audits and forensics investigation. For more information about analyzing access logs, see Query Amazon CloudFront logs in the *Amazon Athena User Guide*.

Remediation

To configure standard logging (legacy) for a CloudFront distribution, see Configure standard logging (legacy) in the *Amazon CloudFront Developer Guide*.

[CloudFront.6] CloudFront distributions should have WAF enabled

Related requirements: NIST.800-53.r5 AC-4(21), PCI DSS v4.0.1/6.4.2, CRI Profile v2.2/DE.CM-01.03, CRI Profile v2.2/GV.OC-04.03, CRI Profile v2.2/PR.IR-01.02, CRI Profile v2.2/PR.IR-01.03, CRI Profile v2.2/PR.IR-01.05, CRI Profile v2.2/PR.IR-04.02

Category: Protect > Protective services

Severity: Medium

Resource type: `AWS::CloudFront::Distribution`

AWS Config rule: cloudfront-associated-with-waf

Schedule type: Change triggered

Parameters: None

This control checks whether CloudFront distributions are associated with either AWS WAF Classic or AWS WAF web ACLs. The control fails if the distribution is not associated with a web ACL.

AWS WAF is a web application firewall that helps protect web applications and APIs from attacks. It allows you to configure a set of rules, called a web access control list (web ACL), that allow, block,

or count web requests based on customizable web security rules and conditions that you define. Ensure your CloudFront distribution is associated with an AWS WAF web ACL to help protect it from malicious attacks.

Remediation

To associate an AWS WAF web ACL with a CloudFront distribution, see Using AWS WAF to control access to your content in the *Amazon CloudFront Developer Guide*.

[CloudFront.7] CloudFront distributions should use custom SSL/TLS certificates

Related requirements: NIST.800-53.r5 AC-17(2), NIST.800-53.r5 AC-4, NIST.800-53.r5 IA-5(1), NIST.800-53.r5 SC-12(3), NIST.800-53.r5 SC-13, NIST.800-53.r5 SC-23, NIST.800-53.r5 SC-23(3), NIST.800-53.r5 SC-7(4), NIST.800-53.r5 SC-8, NIST.800-53.r5 SC-8(1), NIST.800-53.r5 SC-8(2), NIST.800-53.r5 SI-7(6), NIST.800-171.r2 3.13.15, CRI Profile v2.2/PR.DS-02.01, CRI Profile v2.2/PR.PS-01.06

Category: Protect > Data Protection > Encryption of data-in-transit

Severity: Low

Resource type: `AWS::CloudFront::Distribution`

AWS Config rule: cloudfront-custom-ssl-certificate

Schedule type: Change triggered

Parameters: None

This control checks whether CloudFront distributions are using the default SSL/TLS certificate CloudFront provides. This control passes if the CloudFront distribution uses a custom SSL/TLS certificate. This control fails if the CloudFront distribution uses the default SSL/TLS certificate.

Custom SSL/TLS allow your users to access content by using alternate domain names. You can store custom certificates in AWS Certificate Manager (recommended), or in IAM.

Remediation

To add an alternate domain name for a CloudFront distribution using a custom SSL/TLS certificate, see Adding an alternate domain name in the *Amazon CloudFront Developer Guide*.

[CloudFront.8] CloudFront distributions should use SNI to serve HTTPS requests

Related requirements: NIST.800-53.r5 CA-9(1), NIST.800-53.r5 CM-2, CRI Profile v2.2/PR.DS-02.01, CRI Profile v2.2/PR.PS-01.06

Category: Protect > Secure network configuration

Severity: Low

Resource type: `AWS::CloudFront::Distribution`

AWS Config rule: cloudfront-sni-enabled

Schedule type: Change triggered

Parameters: None

This control checks if Amazon CloudFront distributions are using a custom SSL/TLS certificate and are configured to use SNI to serve HTTPS requests. This control fails if a custom SSL/TLS certificate is associated but the SSL/TLS support method is a dedicated IP address. The control also fails if the distribution uses default CloudFront SSL/TLS certificate.

Server Name Indication (SNI) is an extension to the TLS protocol that is supported by browsers and clients released after 2010. If you configure CloudFront to serve HTTPS requests using SNI, CloudFront associates your alternate domain name with an IP address for each edge location. When a viewer submits an HTTPS request for your content, DNS routes the request to the IP address for the correct edge location. The IP address to your domain name is determined during the SSL/TLS handshake negotiation; the IP address isn't dedicated to your distribution.

Remediation

To configure a CloudFront distribution to use SNI to serve HTTPS requests, see Using SNI to Serve HTTPS Requests (works for Most Clients) in the CloudFront Developer Guide. For information about custom SSL certificates, see Requirements for using SSL/TLS certificates with CloudFront.

[CloudFront.9] CloudFront distributions should encrypt traffic to custom origins

Related requirements: NIST.800-53.r5 AC-17(2), NIST.800-53.r5 AC-4, NIST.800-53.r5 IA-5(1), NIST.800-53.r5 SC-12(3), NIST.800-53.r5 SC-13, NIST.800-53.r5 SC-23, NIST.800-53.r5 SC-23(3), NIST.800-53.r5 SC-7(4), NIST.800-53.r5 SC-8, NIST.800-53.r5 SC-8(1), NIST.800-53.r5 SC-8(2), NIST.800-53.r5 SI-7(6), PCI DSS v4.0.1/4.2.1, CRI Profile v2.2/PR.DS-02.01, CRI Profile v2.2/PR.PS-01.06

Category: Protect > Data Protection > Encryption of data-in-transit

Severity: Medium

Resource type: `AWS::CloudFront::Distribution`

AWS Config rule: cloudfront-traffic-to-origin-encrypted

Schedule type: Change triggered

Parameters: None

This control checks if Amazon CloudFront distributions are encrypting traffic to custom origins. This control fails for a CloudFront distribution whose origin protocol policy allows 'http-only'. This control also fails if the distribution's origin protocol policy is 'match-viewer' while the viewer protocol policy is 'allow-all'.

HTTPS (TLS) can be used to help prevent eavesdropping or manipulation of network traffic. Only encrypted connections over HTTPS (TLS) should be allowed.

Remediation

To update the Origin Protocol Policy to require encryption for a CloudFront connection, see Requiring HTTPS for communication between CloudFront and your custom origin in the *Amazon CloudFront Developer Guide*.

[CloudFront.10] CloudFront distributions should not use deprecated SSL protocols between edge locations and custom origins

Related requirements: NIST.800-53.r5 AC-17(2), NIST.800-53.r5 AC-4, NIST.800-53.r5 IA-5(1), NIST.800-53.r5 SC-12(3), NIST.800-53.r5 SC-13, NIST.800-53.r5 SC-23, NIST.800-53.r5 SC-7(4), NIST.800-53.r5 SC-8, NIST.800-53.r5 SC-8(1), NIST.800-53.r5 SC-8(2), NIST.800-53.r5 SI-7(6), NIST.800-171.r2 3.13.15, PCI DSS v4.0.1/4.2.1, CRI Profile v2.2/PR.PS-01.05, CRI Profile v2.2/PR.PS-01.06, CRI Profile v2.2/PR.PS-02.03

Category: Protect > Data Protection > Encryption of data-in-transit

Severity: Medium

Resource type: `AWS::CloudFront::Distribution`

AWS Config rule: cloudfront-no-deprecated-ssl-protocols

Schedule type: Change triggered

Parameters: None

This control checks if Amazon CloudFront distributions are using deprecated SSL protocols for HTTPS communication between CloudFront edge locations and your custom origins. This control fails if a CloudFront distribution has a `CustomOriginConfig` where `OriginSslProtocols` includes `SSLv3`.

In 2015, the Internet Engineering Task Force (IETF) officially announced that SSL 3.0 should be deprecated due to the protocol being insufficiently secure. It is recommended that you use TLSv1.2 or later for HTTPS communication to your custom origins.

Remediation

To update the Origin SSL Protocols for a CloudFront distribution, see Requiring HTTPS for communication between CloudFront and your custom origin in the *Amazon CloudFront Developer Guide*.

[CloudFront.12] CloudFront distributions should not point to non-existent S3 origins

Related requirements: NIST.800-53.r5 CM-2, NIST.800-53.r5 CM-2(2), PCI DSS v4.0.1/2.2.6, CRI Profile v2.2/DE.CM-09.03, CRI Profile v2.2/PR.PS-01.03

Category: Identify > Resource configuration

Severity: High

Resource type: `AWS::CloudFront::Distribution`

AWS Config rule: cloudfront-s3-origin-non-existent-bucket

Schedule type: Periodic

Parameters: None

This control checks whether Amazon CloudFront distributions are pointing to non-existent Amazon S3 origins. The control fails for a CloudFront distribution if the origin is configured to point to a non-existent bucket. This control only applies to CloudFront distributions where an S3 bucket without static website hosting is the S3 origin.

When a CloudFront distribution in your account is configured to point to a non-existent bucket, a malicious third party can create the referenced bucket and serve their own content through your

distribution. We recommend checking all origins regardless of routing behavior to ensure that your distributions are pointing to appropriate origins.

Remediation

To modify a CloudFront distribution to point to a new origin, see Updating a distribution in the *Amazon CloudFront Developer Guide*.

[CloudFront.13] CloudFront distributions should use origin access control

Related requirements: CRI Profile v2.2/PR.AA-01.02, CRI Profile v2.2/PR.AA-03.02

Category: Protect > Secure access management > Resource not publicly accessible

Severity: Medium

Resource type: `AWS::CloudFront::Distribution`

AWS Config rule: cloudfront-s3-origin-access-control-enabled

Schedule type: Change triggered

Parameters: None

This control checks whether an Amazon CloudFront distribution with an Amazon S3 origin has origin access control (OAC) configured. The control fails if OAC isn't configured for the CloudFront distribution.

When using an S3 bucket as an origin for your CloudFront distribution, you can enable OAC. This permits access to the content in the bucket only through the specified CloudFront distribution, and prohibits access directly from the bucket or another distribution. Although CloudFront supports Origin Access Identity (OAI), OAC offers additional functionality, and distributions using OAI can migrate to OAC. While OAI provides a secure way to access S3 origins, it has limitations, such as lack of support for granular policy configurations and for HTTP/HTTPS requests that use the POST method in AWS Regions that require AWS Signature Version 4 (SigV4). OAI also doesn't support encryption with AWS Key Management Service. OAC is based on an AWS best practice of using IAM service principals to authenticate with S3 origins.

Remediation

To configure OAC for a CloudFront distribution with S3 origins, see Restricting access to an Amazon S3 origin in the *Amazon CloudFront Developer Guide*.

[CloudFront.14] CloudFront distributions should be tagged

Category: Identify > Inventory > Tagging

Severity: Low

Resource type: `AWS::CloudFront::Distribution`

AWS Config rule:`tagged-cloudfront-distribution` (custom Security Hub CSPM rule)

Schedule type: Change triggered

Parameters:

Parameter	Description	Type	Allowed custom values	Security Hub CSPM default value
`requiredTagKeys`	List of non-system tag keys that the evaluated resource must contain. Tag keys are case sensitive.	StringList (maximum of 6 items)	1–6 tag keys that meet AWS requirements.	No default value

This control checks whether an Amazon CloudFront distribution has tags with the specific keys defined in the parameter `requiredTagKeys`. The control fails if the distribution doesn't have any tag keys or if it doesn't have all the keys specified in the parameter `requiredTagKeys`. If the parameter `requiredTagKeys` isn't provided, the control only checks for the existence of a tag key and fails if the distribution isn't tagged with any key. System tags, which are automatically applied and begin with `aws:`, are ignored.

A tag is a label that you assign to an AWS resource, and it consists of a key and an optional value. You can create tags to categorize resources by purpose, owner, environment, or other criteria. Tags can help you identify, organize, search for, and filter resources. Tagging also helps you track accountable resource owners for actions and notifications. When you use tagging, you can implement attribute-based access control (ABAC) as an authorization strategy, which defines permissions based on tags. You can attach tags to IAM entities (users or roles) and to AWS

resources. You can create a single ABAC policy or a separate set of policies for your IAM principals. You can design these ABAC policies to allow operations when the principal's tag matches the resource tag. For more information, see What is ABAC for AWS? in the *IAM User Guide*.

> **Note**
>
> Don't add personally identifiable information (PII) or other confidential or sensitive information in tags. Tags are accessible to many AWS services, including AWS Billing. For more tagging best practices, see Tagging your AWS resources in the *AWS General Reference*.

Remediation

To add tags to a CloudFront distribution, see Tagging Amazon CloudFront distributions in the *Amazon CloudFront Developer Guide*.

[CloudFront.15] CloudFront distributions should use the recommended TLS security policy

Related requirements: CRI Profile v2.2/PR.DS-02.01, CRI Profile v2.2/PR.IR-01.02, CRI Profile v2.2/PR.PS-01.06

Category: Protect > Data Protection > Encryption of data-in-transit

Severity: Medium

Resource type: `AWS::CloudFront::Distribution`

AWS Config rule: cloudfront-ssl-policy-check

Schedule type: Change triggered

Parameters: `securityPolicies`: `TLSv1.2_2025,TLSv1.3_2025` (not customizable)

This control checks whether an Amazon CloudFront distribution is configured to use a recommended TLS security policy. The control fails if the CloudFront distribution is not configured to use a recommended TLS security policy.

If you configure an Amazon CloudFront distribution to require viewers to use HTTPS to access content, you have to choose a security policy and specify the minimum SSL/TLS protocol version to use. This determines which protocol version CloudFront uses to communicate with viewers, and the ciphers that CloudFront uses to encrypt the communications. We recommend using the latest

security policy that CloudFront provides. This ensures that CloudFront uses the latest cipher suites to encrypt data in transit between a viewer and a CloudFront distribution.

> **Note**
>
> This control generates findings only for CloudFront distributions that are configured to use custom SSL certificates and are not configured to support legacy clients.

Remediation

For information about configuring the security policy for a CloudFront distribution, see Update a distribution in the *Amazon CloudFront Developer Guide*. When you configure the security policy for a distribution, choose the latest security policy.

[CloudFront.16] CloudFront distributions should use origin access control for Lambda function URL origins

Category: Protect > Secure access management > Access control

Severity: Medium

Resource type: `AWS::CloudFront::Distribution`

AWS Config rule: cloudfront-origin-lambda-url-oac-enabled

Schedule type: Change triggered

Parameters: None

This control checks whether an Amazon CloudFront distribution with an AWS Lambda function URL as an origin has origin access control (OAC) enabled. The control fails if the CloudFront distribution has a Lambda function URL as an origin and OAC isn't enabled.

An AWS Lambda function URL is a dedicated HTTPS endpoint for a Lambda function. If a Lambda function URL is the origin for a CloudFront distribution, the function URL must be publicly accessible. Therefore, as a security best practice, you should create an OAC and add it to the Lambda function URL in a distribution. OAC uses IAM service principals to authenticate requests between CloudFront and the function URL. It also supports the use of resource-based policies to allow invocation of a function only if a request is on behalf of a CloudFront distribution specified in the policy.

Remediation

For information about configuring OAC for an Amazon CloudFront distribution that uses a Lambda function URL as an origin, see Restrict access to an AWS Lambda function URL origin in the *Amazon CloudFront Developer Guide*.

[CloudFront.17] CloudFront distributions should use trusted key groups for signed URLs and cookies

Category: Protect > Secure access management > Access control

Severity: Medium

Resource type: `AWS::CloudFront::Distribution`

AWS Config rule: cloudfront-distribution-key-group-enabled

Schedule type: Change triggered

Parameters: None

This control checks whether an Amazon CloudFront distribution is configured to use trusted key groups for signed URL or signed cookie authentication. The control fails if the CloudFront distribution uses trusted signers, or if the distribution has no authentication configured.

To use signed URLs or signed cookies, you need a signer. A signer is either a trusted key group that you create in CloudFront, or an AWS account that contains a CloudFront key pair. We recommend that you use trusted key groups because with CloudFront key groups, you don't need to use the AWS account root user to manage the public keys for CloudFront signed URLs and signed cookies.

> **Note**
>
> This control does not evaluate multi-tenant CloudFront distributions (`connectionMode=tenant-only`).

Remediation

For information about using trusted key groups with signed URLs and cookies, see Using trusted key groups in the *Amazon CloudFront Developer Guide*.

Security Hub CSPM controls for AWS CloudTrail

These AWS Security Hub CSPM controls evaluate the AWS CloudTrail service and resources. The controls might not be available in all AWS Regions. For more information, see Availability of controls by Region.

[CloudTrail.1] CloudTrail should be enabled and configured with at least one multi-Region trail that includes read and write management events

Related requirements: CIS AWS Foundations Benchmark v5.0.0/3.1, CIS AWS Foundations Benchmark v1.2.0/2.1, CIS AWS Foundations Benchmark v1.4.0/3.1, CIS AWS Foundations Benchmark v3.0.0/3.1, NIST.800-53.r5 AC-2(4), NIST.800-53.r5 AC-4(26), NIST.800-53.r5 AC-6(9), NIST.800-53.r5 AU-10, NIST.800-53.r5 AU-12, NIST.800-53.r5 AU-2, NIST.800-53.r5 AU-3, NIST.800-53.r5 AU-6(3), NIST.800-53.r5 AU-6(4), NIST.800-53.r5 AU-14(1), NIST.800-53.r5 CA-7, NIST.800-53.r5 SC-7(9), NIST.800-53.r5 SI-3(8), NIST.800-53.r5 SI-4(20), NIST.800-53.r5 SI-7(8), NIST.800-53.r5 SA-8(22), CRI Profile v2.2/DE.AE-03.01, CRI Profile v2.2/PR.PS-04.02, CRI Profile v2.2/PR.PS-04.03

Category: Identify > Logging

Severity: High

Resource type: `AWS::::Account`

AWS Config rule: multi-region-cloudtrail-enabled

Schedule type: Periodic

Parameters:

- `readWriteType`: `ALL` (not customizable)

  `includeManagementEvents`: `true` (not customizable)

This control checks whether there is at least one multi-Region AWS CloudTrail trail that captures read and write management events. The control fails if CloudTrail is disabled or if there isn't at least one CloudTrail trail that captures read and write management events.

AWS CloudTrail records AWS API calls for your account and delivers log files to you. The recorded information includes the following information:

- Identity of the API caller
- Time of the API call
- Source IP address of the API caller
- Request parameters
- Response elements returned by the AWS service

CloudTrail provides a history of AWS API calls for an account, including API calls made from the AWS Management Console, AWS SDKs, command line tools. The history also includes API calls from higher-level AWS services such as AWS CloudFormation.

The AWS API call history produced by CloudTrail enables security analysis, resource change tracking, and compliance auditing. Multi-Region trails also provide the following benefits.

- A multi-Region trail helps to detect unexpected activity occurring in otherwise unused Regions.
- A multi-Region trail ensures that global service event logging is enabled for a trail by default. Global service event logging records events generated by AWS global services.
- For a multi-Region trail, management events for all read and write operations ensure that CloudTrail records management operations on all resources in an AWS account.

By default, CloudTrail trails that are created using the AWS Management Console are multi-Region trails.

Remediation

To create a new multi-Region trail in CloudTrail, see Creating a trail in the *AWS CloudTrail User Guide*. Use the following values:

Field	Value
Additional settings, Log file validation	Enabled
Choose log events, Management events, API activity	**Read** and **Write**. Clear check boxes for exclusions.

To update an existing trail, see Updating a trail in the *AWS CloudTrail User Guide*. In **Management events**, for **API activity**, choose **Read** and **Write**.

[CloudTrail.2] CloudTrail should have encryption at-rest enabled

Related requirements: CIS AWS Foundations Benchmark v5.0.0/3.5, CIS AWS Foundations Benchmark v1.2.0/2.7, CIS AWS Foundations Benchmark v1.4.0/3.7, CIS AWS Foundations Benchmark v3.0.0/3.5, NIST.800-53.r5 AU-9, NIST.800-53.r5 CA-9(1), NIST.800-53.r5 CM-3(6), NIST.800-53.r5 SC-13, NIST.800-53.r5 SC-28, NIST.800-53.r5 SC-28(1), NIST.800-53.r5 SC-7(10), NIST.800-53.r5 SI-7(6), NIST.800-171.r2 3.3.8, PCI DSS v3.2.1/3.4, PCI DSS v4.0.1/10.3.2, CRI Profile v2.2/PR.DS-01.01, CRI Profile v2.2/PR.PS-01.06

Category: Protect > Data Protection > Encryption of data-at-rest

Severity: Medium

Resource type: `AWS::CloudTrail::Trail`

AWS Config rule: cloud-trail-encryption-enabled

Schedule type: Periodic

Parameters: None

This control checks whether CloudTrail is configured to use the server-side encryption (SSE) AWS KMS key encryption. The control fails if the `KmsKeyId` isn't defined.

For an added layer of security for your sensitive CloudTrail log files, you should use server-side encryption with AWS KMS keys (SSE-KMS) for your CloudTrail log files for encryption at rest. Note that by default, the log files delivered by CloudTrail to your buckets are encrypted by Amazon server-side encryption with Amazon S3-managed encryption keys (SSE-S3).

Remediation

To enable SSE-KMS encryption for CloudTrail log files, see Update a trail to use a KMS key in the *AWS CloudTrail User Guide*.

[CloudTrail.3] At least one CloudTrail trail should be enabled

Related requirements: NIST.800-171.r2 3.3.1, NIST.800-171.r2 3.14.6, NIST.800-171.r2 3.14.7, PCI DSS v3.2.1/10.1, PCI DSS v3.2.1/10.2.1, PCI DSS v3.2.1/10.2.2, PCI DSS v3.2.1/10.2.3, PCI DSS v3.2.1/10.2.4, PCI DSS v3.2.1/10.2.5, PCI DSS v3.2.1/10.2.6, PCI DSS v3.2.1/10.2.7, PCI DSS v3.2.1/10.3.1, PCI DSS v3.2.1/10.3.2, PCI DSS v3.2.1/10.3.3, PCI DSS v3.2.1/10.3.4, PCI DSS v3.2.1/10.3.5, PCI DSS v3.2.1/10.3.6, PCI DSS v4.0.1/10.2.1, CRI Profile v2.2/DE.AE-02.01, CRI

Profile v2.2/DE.AE-03.01, CRI Profile v2.2/DE.AE-03.02, CRI Profile v2.2/PR.PS-01.01, CRI Profile v2.2/PR.PS-04.02, CRI Profile v2.2/PR.PS-04.03, CRI Profile v2.2/RS.AN-07.01

Category: Identify > Logging

Severity: High

Resource type: `AWS::::Account`

AWS Config rule: cloudtrail-enabled

Schedule type: Periodic

Parameters: None

This control checks whether an AWS CloudTrail trail is enabled in your AWS account. The control fails if your account doesn't have at least one CloudTrail trail enabled.

However, some AWS services do not enable logging of all APIs and events. You should implement any additional audit trails other than CloudTrail and review the documentation for each service in CloudTrail Supported Services and Integrations.

Remediation

To get started with CloudTrail and create a trail, see the Getting started with AWS CloudTrail tutorial in the *AWS CloudTrail User Guide*.

[CloudTrail.4] CloudTrail log file validation should be enabled

Related requirements: CIS AWS Foundations Benchmark v5.0.0/3.2, CIS AWS Foundations Benchmark v1.2.0/2.2, CIS AWS Foundations Benchmark v1.4.0/3.2, CIS AWS Foundations Benchmark v3.0.0/3.2, NIST.800-53.r5 AU-9, NIST.800-53.r5 SI-4, NIST.800-53.r5 SI-7(1), NIST.800-53.r5 SI-7(3), NIST.800-53.r5 SI-7(7), NIST.800-171.r2 3.3.8, PCI DSS v3.2.1/10.5.2, PCI DSS v3.2.1/10.5.5, PCI DSS v4.0.1/10.3.2, CRI Profile v2.2/PR.DS-01.01, CRI Profile v2.2/PR.PS-04.03, CRI Profile v2.2/RS.AN-07.01

Category: Data protection > Data integrity

Severity: Low

Resource type: `AWS::CloudTrail::Trail`

AWS Config rule: cloud-trail-log-file-validation-enabled

Schedule type: Periodic

Parameters: None

This control checks whether log file integrity validation is enabled on a CloudTrail trail.

CloudTrail log file validation creates a digitally signed digest file that contains a hash of each log that CloudTrail writes to Amazon S3. You can use these digest files to determine whether a log file was changed, deleted, or unchanged after CloudTrail delivered the log.

Security Hub CSPM recommends that you enable file validation on all trails. Log file validation provides additional integrity checks of CloudTrail logs.

Remediation

To enable CloudTrail log file validation, see Enabling log file integrity validation for CloudTrail in the *AWS CloudTrail User Guide*.

[CloudTrail.5] CloudTrail trails should be integrated with Amazon CloudWatch Logs

Related requirements: CIS AWS Foundations Benchmark v5.0.0/3.4, PCI DSS v3.2.1/10.5.3, CIS AWS Foundations Benchmark v1.2.0/2.4, CIS AWS Foundations Benchmark v1.4.0/3.4, NIST.800-53.r5 AC-2(4), NIST.800-53.r5 AC-4(26), NIST.800-53.r5 AC-6(9), NIST.800-53.r5 AU-10, NIST.800-53.r5 AU-12, NIST.800-53.r5 AU-2, NIST.800-53.r5 AU-3, NIST.800-53.r5 AU-6(1), NIST.800-53.r5 AU-6(3), NIST.800-53.r5 AU-6(4), NIST.800-53.r5 AU-6(5), NIST.800-53.r5 AU-7(1), NIST.800-53.r5 CA-7, NIST.800-53.r5 SC-7(9), NIST.800-53.r5 SI-20, NIST.800-53.r5 SI-3(8), NIST.800-53.r5 SI-4(20), NIST.800-53.r5 SI-4(5), NIST.800-53.r5 SI-7(8), CRI Profile v2.2/DE.AE-03.01, CRI Profile v2.2/DE.AE-03.02, CRI Profile v2.2/DE.CM-03.01, CRI Profile v2.2/DE.CM-03.02, CRI Profile v2.2/DE.CM-03.03, CRI Profile v2.2/PR.PS-04.02, CRI Profile v2.2/PR.PS-04.03, CRI Profile v2.2/RS.AN-07.01, CRI Profile v2.2/RS.MA-02.01

Category: Identify > Logging

Severity: Medium

Resource type: `AWS::CloudTrail::Trail`

AWS Config rule: cloud-trail-cloud-watch-logs-enabled

Schedule type: Periodic

Parameters: None

This control checks whether CloudTrail trails are configured to send logs to CloudWatch Logs. The control fails if the `CloudWatchLogsLogGroupArn` property of the trail is empty.

CloudTrail records AWS API calls that are made in a given account. The recorded information includes the following:

- The identity of the API caller
- The time of the API call
- The source IP address of the API caller
- The request parameters
- The response elements returned by the AWS service

CloudTrail uses Amazon S3 for log file storage and delivery. You can capture CloudTrail logs in a specified S3 bucket for long-term analysis. To perform real-time analysis, you can configure CloudTrail to send logs to CloudWatch Logs.

For a trail that is enabled in all Regions in an account, CloudTrail sends log files from all of those Regions to a CloudWatch Logs log group.

Security Hub CSPM recommends that you send CloudTrail logs to CloudWatch Logs. Note that this recommendation is intended to ensure that account activity is captured, monitored, and appropriately alarmed on. You can use CloudWatch Logs to set this up with your AWS services. This recommendation does not preclude the use of a different solution.

Sending CloudTrail logs to CloudWatch Logs facilitates real-time and historic activity logging based on user, API, resource, and IP address. You can use this approach to establish alarms and notifications for anomalous or sensitivity account activity.

Remediation

To integrate CloudTrail with CloudWatch Logs, see Sending events to CloudWatch Logs in the *AWS CloudTrail User Guide*.

[CloudTrail.6] Ensure the S3 bucket used to store CloudTrail logs is not publicly accessible

Related requirements: CIS AWS Foundations Benchmark v1.2.0/2.3, CIS AWS Foundations Benchmark v1.4.0/3.3, PCI DSS v4.0.1/1.4.4, CRI Profile v2.2/PR.AA-03.02, CRI Profile v2.2/

PR.DS-01.01, CRI Profile v2.2/PR.PS-01.01, CRI Profile v2.2/PR.PS-01.03, CRI Profile v2.2/PR.PS-04.03, CRI Profile v2.2/RS.AN-07.01

Category: Identify > Logging

Severity: Critical

Resource type: `AWS::S3::Bucket`

AWS Config rule: None (custom Security Hub CSPM rule)

Schedule type: Periodic and change triggered

Parameters: None

CloudTrail logs a record of every API call made in your account. These log files are stored in an S3 bucket. CIS recommends that the S3 bucket policy, or access control list (ACL), applied to the S3 bucket that CloudTrail logs to prevents public access to the CloudTrail logs. Allowing public access to CloudTrail log content might aid an adversary in identifying weaknesses in the affected account's use or configuration.

To run this check, Security Hub CSPM first uses custom logic to look for the S3 bucket where your CloudTrail logs are stored. It then uses the AWS Config managed rules to check that bucket is publicly accessible.

If you aggregate your logs into a single centralized S3 bucket, then Security Hub CSPM only runs the check against the account and Region where the centralized S3 bucket is located. For other accounts and Regions, the control status is **No data**.

If the bucket is publicly accessible, the check generates a failed finding.

Remediation

To block public access to your CloudTrail S3 bucket, see Configuring block public access settings for your S3 buckets in the *Amazon Simple Storage Service User Guide*. Select all four Amazon S3 Block Public Access Settings.

[CloudTrail.7] Ensure S3 bucket access logging is enabled on the CloudTrail S3 bucket

Related requirements: CIS AWS Foundations Benchmark v1.2.0/2.6, CIS AWS Foundations Benchmark v1.4.0/3.6, CIS AWS Foundations Benchmark v3.0.0/3.4, PCI DSS v4.0.1/10.2.1, CRI Profile v2.2/DE.CM-03.01, CRI Profile v2.2/PR.PS-04.02

Category: Identify > Logging

Severity: Low

Resource type: `AWS::S3::Bucket`

AWS Config rule: None (custom Security Hub CSPM rule)

Schedule type: Periodic

Parameters: None

S3 bucket access logging generates a log that contains access records for each request made to your S3 bucket. An access log record contains details about the request, such as the request type, the resources specified in the request worked, and the time and date the request was processed.

CIS recommends that you enable bucket access logging on the CloudTrail S3 bucket.

By enabling S3 bucket logging on target S3 buckets, you can capture all events that might affect objects in a target bucket. Configuring logs to be placed in a separate bucket enables access to log information, which can be useful in security and incident response workflows.

To run this check, Security Hub CSPM first uses custom logic to look for the bucket where your CloudTrail logs are stored and then uses the AWS Config managed rule to check if logging is enabled.

If CloudTrail delivers log files from multiple AWS accounts into a single destination Amazon S3 bucket, Security Hub CSPM evaluates this control only against the destination bucket in the Region where it's located. This streamlines your findings. However, you should turn on CloudTrail in all accounts that deliver logs to the destination bucket. For all accounts except the one that holds the destination bucket, the control status is **No data**.

Remediation

To enable server access logging for your CloudTrail S3 bucket, see Enabling Amazon S3 server access logging in the *Amazon Simple Storage Service User Guide*.

[CloudTrail.9] CloudTrail trails should be tagged

Category: Identify > Inventory > Tagging

Severity: Low

Resource type: `AWS::CloudTrail::Trail`

AWS Config rule: `tagged-cloudtrail-trail` (custom Security Hub CSPM rule)

Schedule type: Change triggered

Parameters:

Parameter	Description	Type	Allowed custom values	Security Hub CSPM default value
`requiredTagKeys`	List of non-system tag keys that the evaluated resource must contain. Tag keys are case sensitive.	StringList (maximum of 6 items)	1–6 tag keys that meet AWS requirements.	`No default value`

This control checks whether an AWS CloudTrail trail has tags with the specific keys defined in the parameter `requiredTagKeys`. The control fails if the trail doesn't have any tag keys or if it doesn't have all the keys specified in the parameter `requiredTagKeys`. If the parameter `requiredTagKeys` isn't provided, the control only checks for the existence of a tag key and fails if the trail isn't tagged with any key. System tags, which are automatically applied and begin with `aws:`, are ignored.

A tag is a label that you assign to an AWS resource, and it consists of a key and an optional value. You can create tags to categorize resources by purpose, owner, environment, or other criteria. Tags can help you identify, organize, search for, and filter resources. Tagging also helps you track accountable resource owners for actions and notifications. When you use tagging, you can implement attribute-based access control (ABAC) as an authorization strategy, which defines permissions based on tags. You can attach tags to IAM entities (users or roles) and to AWS resources. You can create a single ABAC policy or a separate set of policies for your IAM principals. You can design these ABAC policies to allow operations when the principal's tag matches the resource tag. For more information, see What is ABAC for AWS? in the *IAM User Guide*.

> **Note**
>
> Don't add personally identifiable information (PII) or other confidential or sensitive information in tags. Tags are accessible to many AWS services, including AWS Billing. For more tagging best practices, see Tagging your AWS resources in the *AWS General Reference*.

Remediation

To add tags to a CloudTrail trail, see AddTags in the *AWS CloudTrail API Reference*.

[CloudTrail.10] CloudTrail Lake event data stores should be encrypted with customer managed AWS KMS keys

Related requirements: NIST.800-53.r5 AU-9, NIST.800-53.r5 CA-9(1), NIST.800-53.r5 CM-3(6), NIST.800-53.r5 SC-7(10), NIST.800-53.r5 SC-12(2), NIST.800-53.r5 SC-13, NIST.800-53.r5 SC-28, NIST.800-53.r5 SC-28(1), NIST.800-53.r5 SI-7(6)

Category: Protect > Data Protection > Encryption of data-at-rest

Severity: Medium

Resource type: `AWS::CloudTrail::EventDataStore`

AWS Config rule: event-data-store-cmk-encryption-enabled

Schedule type: Periodic

Parameters:

Parameter	Description	Type	Allowed custom values	Security Hub CSPM default value
`kmsKeyArns`	A list of Amazon Resource Names (ARNs) of AWS KMS keys to include in the evaluation.	StringList (maximum of 3 items)	1–3 ARNs of existing KMS keys. For example: `arn:aws:k`	No default value

Parameter	Description	Type	Allowed custom values	Security Hub CSPM default value
	The control generates a FAILED finding if an event data store isn't encrypted with a KMS key in the list.		`ms:us-west-2:111122223333:key/1234abcd-12ab-34cd-56ef-1234567890ab` .	

This control checks whether an AWS CloudTrail Lake event data store is encrypted at rest with a customer managed AWS KMS key. The control fails if the event data store isn't encrypted with a customer managed KMS key. You can optionally specify a list of KMS keys for the control to include in the evaluation.

By default, AWS CloudTrail Lake encrypts event data stores with Amazon S3 managed keys (SSE-S3), using an AES-256 algorithm. For additional control, you can configure CloudTrail Lake to encrypt an event data store with a customer managed AWS KMS key (SSE-KMS) instead. A customer managed KMS key is an AWS KMS key that you create, own, and manage in your AWS account. You have full control over this type of KMS key. This includes defining and maintaining the key policy, managing grants, rotating cryptographic material, assigning tags, creating aliases, and enabling and disabling the key. You can use a customer managed KMS key in cryptographic operations for your CloudTrail data and audit usage with CloudTrail logs.

Remediation

For information about encrypting an AWS CloudTrail Lake event data store with an AWS KMS key that you specify, see Update an event data store in the *AWS CloudTrail User Guide*. After you associate an event data store with a KMS key, the KMS key can't be removed or changed.

Security Hub CSPM controls for Amazon CloudWatch

These AWS Security Hub CSPM controls evaluate the Amazon CloudWatch service and resources. The controls might not be available in all AWS Regions. For more information, see Availability of controls by Region.

[CloudWatch.1] A log metric filter and alarm should exist for usage of the "root" user

Related requirements: CIS AWS Foundations Benchmark v1.2.0/1.1,CIS AWS Foundations Benchmark v1.2.0/3.3, CIS AWS Foundations Benchmark v1.4.0/1.7,CIS AWS Foundations Benchmark v1.4.0/4.3, NIST.800-171.r2 3.14.6, NIST.800-171.r2 3.14.7, PCI DSS v3.2.1/7.2.1, CRI Profile v2.2/DE.AE-02.02, CRI Profile v2.2/DE.CM-03.01, CRI Profile v2.2/DE.CM-03.02, CRI Profile v2.2/DE.CM-03.03, CRI Profile v2.2/PR.AA-02.01, CRI Profile v2.2/PR.AA-05.01

Category: Detect > Detection services

Severity: Low

Resource type: `AWS::Logs::MetricFilter`, `AWS::CloudWatch::Alarm`, `AWS::CloudTrail::Trail`, `AWS::SNS::Topic`

AWS Config rule: None (custom Security Hub CSPM rule)

Schedule type: Periodic

Parameters: None

The root user has unrestricted access to all services and resources in an AWS account. We highly recommend that you avoid using the root user for daily tasks. Minimizing the use of the root user and adopting the principle of least privilege for access management reduces the risk of accidental changes and unintended disclosure of highly privileged credentials.

As a best practice, use your root user credentials only when required to perform account and service management tasks. Apply AWS Identity and Access Management (IAM) policies directly to groups and roles but not users. For a tutorial on how to set up an administrator for daily use, see Creating your first IAM admin user and group in the *IAM User Guide*

To run this check, Security Hub CSPM uses custom logic to perform the exact audit steps prescribed for control 1.7 in the CIS AWS Foundations Benchmark v1.4.0. This control fails if the exact metric filters prescribed by CIS are not used. Additional fields or terms cannot be added to the metric filters.

> **Note**
>
> When Security Hub CSPM performs the check for this control, it looks for CloudTrail trails that the current account uses. These trails might be organization trails that belong to another account. Multi-Region trails also might be based in a different Region.
> The check results in `FAILED` findings in the following cases:

- No trail is configured.
- The available trails that are in the current Region and that are owned by current account do not meet the control requirements.

The check results in a control status of `NO_DATA` in the following cases:

- A multi-Region trail is based in a different Region. Security Hub CSPM can only generate findings in the Region where the trail is based.
- A multi-Region trail belongs to a different account. Security Hub CSPM can only generate findings for the account that owns the trail.

  As a best practice, use organization trails to log events from many accounts in an organization. Organization trails are multi-Region trails by default and can only be managed by the AWS Organizations management account or the CloudTrail delegated administrator account. Using an organization trail results in a control status of `NO_DATA` for controls evaluated in organization member accounts. In member accounts, Security Hub CSPM only generates findings for member-owned resources. Findings that pertain to organization trails are generated in the resource owner's account. You can see these findings in your Security Hub CSPM delegated administrator account by using cross-Region aggregation.

For the alarm, the current account must either own the referenced Amazon SNS topic, or must get access to the Amazon SNS topic by calling `ListSubscriptionsByTopic`. Otherwise Security Hub CSPM generates `WARNING` findings for the control.

Remediation

To pass this control, follow these steps to create an Amazon SNS topic, an AWS CloudTrail trail, a metric filter, and an alarm for the metric filter.

1. Create an Amazon SNS topic. For instructions, see Getting started with Amazon SNS in the *Amazon Simple Notification Service Developer Guide*. Create a topic that receives all CIS alarms, and create at least one subscription to the topic.
2. Create a CloudTrail trail that applies to all AWS Regions. For instructions, see Creating a trail in the *AWS CloudTrail User Guide*.

Make note of the name of the CloudWatch Logs log group that you associate with the CloudTrail trail. You create the metric filter for that log group in the next step.

3. Create a metric filter. For instructions, see Create a metric filter for a log group in the *Amazon CloudWatch User Guide*. Use the following values:

Field	Value
Define pattern, Filter pattern	`{$.userIdentity.type="Root" && $.userIdentity.invokedBy NOT EXISTS && $.eventType !="AwsServiceEvent"}`
Metric namespace	**`LogMetrics`**
Metric value	**`1`**
Default value	**`0`**

4. Create an alarm based on the filter. For instructions, see Create a CloudWatch alarm based on a log group-metric filter in the *Amazon CloudWatch User Guide*. Use the following values:

Field	Value
Conditions, Threshold type	Static
Whenever *`your-metric-name`* is...	Greater/Equal
than...	**`1`**

[CloudWatch.2] Ensure a log metric filter and alarm exist for unauthorized API calls

Related requirements: CIS AWS Foundations Benchmark v1.2.0/3.1, NIST.800-171.r2 3.13.1, NIST.800-171.r2 3.14.6, NIST.800-171.r2 3.14.7, CRI Profile v2.2/DE.AE-02.02, CRI Profile v2.2/DE.AE-03.01, CRI Profile v2.2/DE.CM-03.01, CRI Profile v2.2/DE.CM-03.02, CRI Profile v2.2/RS.MA-02.01

Category: Detect > Detection services

Severity: Low

Resource type: `AWS::Logs::MetricFilter`, `AWS::CloudWatch::Alarm`, `AWS::CloudTrail::Trail`, `AWS::SNS::Topic`

AWS Config rule: None (custom Security Hub CSPM rule)

Schedule type: Periodic

Parameters: None

You can do real-time monitoring of API calls by directing CloudTrail logs to CloudWatch Logs and establishing corresponding metric filters and alarms.

CIS recommends that you create a metric filter and alarm for unauthorized API calls. Monitoring unauthorized API calls helps reveal application errors and might reduce time to detect malicious activity.

To run this check, Security Hub CSPM uses custom logic to perform the exact audit steps prescribed for control 3.1 in the CIS AWS Foundations Benchmark v1.2. This control fails if the exact metric filters prescribed by CIS are not used. Additional fields or terms cannot be added to the metric filters.

Note

When Security Hub CSPM performs the check for this control, it looks for CloudTrail trails that the current account uses. These trails might be organization trails that belong to another account. Multi-Region trails also might be based in a different Region.
The check results in `FAILED` findings in the following cases:

- No trail is configured.
- The available trails that are in the current Region and that are owned by current account do not meet the control requirements.

The check results in a control status of `NO_DATA` in the following cases:

- A multi-Region trail is based in a different Region. Security Hub CSPM can only generate findings in the Region where the trail is based.
- A multi-Region trail belongs to a different account. Security Hub CSPM can only generate findings for the account that owns the trail.

As a best practice, use organization trails to log events from many accounts in an organization. Organization trails are multi-Region trails by default and can only be managed by the AWS Organizations management account or the CloudTrail delegated administrator account. Using an organization trail results in a control status of `NO_DATA` for controls evaluated in organization member accounts. In member accounts, Security Hub CSPM only generates findings for member-owned resources. Findings that pertain to organization trails are generated in the resource owner's account. You can see these findings in your Security Hub CSPM delegated administrator account by using cross-Region aggregation.

For the alarm, the current account must either own the referenced Amazon SNS topic, or must get access to the Amazon SNS topic by calling `ListSubscriptionsByTopic`. Otherwise Security Hub CSPM generates `WARNING` findings for the control.

Remediation

To pass this control, follow these steps to create an Amazon SNS topic, an AWS CloudTrail trail, a metric filter, and an alarm for the metric filter.

1. Create an Amazon SNS topic. For instructions, see Getting started with Amazon SNS in the *Amazon Simple Notification Service Developer Guide*. Create a topic that receives all CIS alarms, and create at least one subscription to the topic.
2. Create a CloudTrail trail that applies to all AWS Regions. For instructions, see Creating a trail in the *AWS CloudTrail User Guide*.

   Make note of the name of the CloudWatch Logs log group that you associate with the CloudTrail trail. You create the metric filter for that log group in the next step.
3. Create a metric filter. For instructions, see Create a metric filter for a log group in the *Amazon CloudWatch User Guide*. Use the following values:

Field	Value
Define pattern, Filter pattern	`{($.errorCode="*UnauthorizedOperation") \|\| ($.errorCode="AccessDenied*")}`

Field	Value
Metric namespace	**`LogMetrics`**
Metric value	**1**
Default value	**0**

4. Create an alarm based on the filter. For instructions, see Create a CloudWatch alarm based on a log group-metric filter in the *Amazon CloudWatch User Guide*. Use the following values:

Field	Value
Conditions, Threshold type	Static
Whenever *`your-metric-name`* is...	Greater/Equal
than...	**1**

[CloudWatch.3] Ensure a log metric filter and alarm exist for Management Console sign-in without MFA

Related requirements: CIS AWS Foundations Benchmark v1.2.0/3.2, CRI Profile v2.2/DE.AE-02.02, CRI Profile v2.2/DE.CM-03.01, CRI Profile v2.2/DE.CM-03.02, CRI Profile v2.2/DE.CM-03.03

Category: Detect > Detection services

Severity: Low

Resource type: `AWS::Logs::MetricFilter`, `AWS::CloudWatch::Alarm`, `AWS::CloudTrail::Trail`, `AWS::SNS::Topic`

AWS Config rule: None (custom Security Hub CSPM rule)

Schedule type: Periodic

Parameters: None

You can do real-time monitoring of API calls by directing CloudTrail logs to CloudWatch Logs and establishing corresponding metric filters and alarms.

CIS recommends that you create a metric filter and alarm console logins that aren't protected by MFA. Monitoring for single-factor console logins increases visibility into accounts that aren't protected by MFA.

To run this check, Security Hub CSPM uses custom logic to perform the exact audit steps prescribed for control 3.2 in the CIS AWS Foundations Benchmark v1.2. This control fails if the exact metric filters prescribed by CIS are not used. Additional fields or terms cannot be added to the metric filters.

Note

When Security Hub CSPM performs the check for this control, it looks for CloudTrail trails that the current account uses. These trails might be organization trails that belong to another account. Multi-Region trails also might be based in a different Region.
The check results in `FAILED` findings in the following cases:

- No trail is configured.
- The available trails that are in the current Region and that are owned by current account do not meet the control requirements.

The check results in a control status of `NO_DATA` in the following cases:

- A multi-Region trail is based in a different Region. Security Hub CSPM can only generate findings in the Region where the trail is based.
- A multi-Region trail belongs to a different account. Security Hub CSPM can only generate findings for the account that owns the trail.

  As a best practice, use organization trails to log events from many accounts in an organization. Organization trails are multi-Region trails by default and can only be managed by the AWS Organizations management account or the CloudTrail delegated administrator account. Using an organization trail results in a control status of `NO_DATA` for controls evaluated in organization member accounts. In member accounts, Security Hub CSPM only generates findings for member-owned resources. Findings that pertain to organization trails are generated in the resource owner's account. You can see these findings in your Security Hub CSPM delegated administrator account by using cross-Region aggregation.

For the alarm, the current account must either own the referenced Amazon SNS topic, or must get access to the Amazon SNS topic by calling `ListSubscriptionsByTopic`. Otherwise Security Hub CSPM generates `WARNING` findings for the control.

Remediation

To pass this control, follow these steps to create an Amazon SNS topic, an AWS CloudTrail trail, a metric filter, and an alarm for the metric filter.

1. Create an Amazon SNS topic. For instructions, see Getting started with Amazon SNS in the *Amazon Simple Notification Service Developer Guide*. Create a topic that receives all CIS alarms, and create at least one subscription to the topic.
2. Create a CloudTrail trail that applies to all AWS Regions. For instructions, see Creating a trail in the *AWS CloudTrail User Guide*.

   Make note of the name of the CloudWatch Logs log group that you associate with the CloudTrail trail. You create the metric filter for that log group in the next step.
3. Create a metric filter. For instructions, see Create a metric filter for a log group in the *Amazon CloudWatch User Guide*. Use the following values:

Field	Value
Define pattern, Filter pattern	`{ ($.eventName = "ConsoleLogin") && ($.additionalEventData.MFAUsed != "Yes") && ($.userIdentity.type = "IAMUser") && ($.responseElements.ConsoleLogin = "Success") }`
Metric namespace	**`LogMetrics`**
Metric value	**`1`**
Default value	**`0`**

4. Create an alarm based on the filter. For instructions, see Create a CloudWatch alarm based on a log group-metric filter in the *Amazon CloudWatch User Guide*. Use the following values:

Field	Value
Conditions, Threshold type	Static
Whenever *your-metric-name* is...	Greater/Equal
than...	**1**

[CloudWatch.4] Ensure a log metric filter and alarm exist for IAM policy changes

Related requirements: CIS AWS Foundations Benchmark v1.2.0/3.4, CIS AWS Foundations Benchmark v1.4.0/4.4, NIST.800-171.r2 3.14.6, NIST.800-171.r2 3.14.7, CRI Profile v2.2/DE.AE-02.02, CRI Profile v2.2/DE.AE-03.01, CRI Profile v2.2/DE.CM-09.03, CRI Profile v2.2/PR.PS-01.03, CRI Profile v2.2/RS.MA-02.01

Category: Detect > Detection services

Severity: Low

Resource type: `AWS::Logs::MetricFilter`, `AWS::CloudWatch::Alarm`, `AWS::CloudTrail::Trail`, `AWS::SNS::Topic`

AWS Config rule: None (custom Security Hub CSPM rule)

Schedule type: Periodic

Parameters: None

This control checks whether you monitor API calls in real time by directing CloudTrail logs to CloudWatch Logs and establishing corresponding metric filters and alarms.

CIS recommends that you create a metric filter and alarm for changes made to IAM policies. Monitoring these changes helps ensure that authentication and authorization controls remain intact.

Note

When Security Hub CSPM performs the check for this control, it looks for CloudTrail trails that the current account uses. These trails might be organization trails that belong to another account. Multi-Region trails also might be based in a different Region.
The check results in `FAILED` findings in the following cases:

- No trail is configured.
- The available trails that are in the current Region and that are owned by current account do not meet the control requirements.

The check results in a control status of `NO_DATA` in the following cases:

- A multi-Region trail is based in a different Region. Security Hub CSPM can only generate findings in the Region where the trail is based.
- A multi-Region trail belongs to a different account. Security Hub CSPM can only generate findings for the account that owns the trail.

  As a best practice, use organization trails to log events from many accounts in an organization. Organization trails are multi-Region trails by default and can only be managed by the AWS Organizations management account or the CloudTrail delegated administrator account. Using an organization trail results in a control status of `NO_DATA` for controls evaluated in organization member accounts. In member accounts, Security Hub CSPM only generates findings for member-owned resources. Findings that pertain to organization trails are generated in the resource owner's account. You can see these findings in your Security Hub CSPM delegated administrator account by using cross-Region aggregation.

For the alarm, the current account must either own the referenced Amazon SNS topic, or must get access to the Amazon SNS topic by calling `ListSubscriptionsByTopic`. Otherwise Security Hub CSPM generates `WARNING` findings for the control.

Remediation

> **Note**
>
> Our recommended filter pattern in these remediation steps differs from the filter pattern in the CIS guidance. Our recommended filters target only events coming from IAM API calls.

To pass this control, follow these steps to create an Amazon SNS topic, an AWS CloudTrail trail, a metric filter, and an alarm for the metric filter.

1. Create an Amazon SNS topic. For instructions, see Getting started with Amazon SNS in the *Amazon Simple Notification Service Developer Guide*. Create a topic that receives all CIS alarms, and create at least one subscription to the topic.
2. Create a CloudTrail trail that applies to all AWS Regions. For instructions, see Creating a trail in the *AWS CloudTrail User Guide*.

   Make note of the name of the CloudWatch Logs log group that you associate with the CloudTrail trail. You create the metric filter for that log group in the next step.
3. Create a metric filter. For instructions, see Create a metric filter for a log group in the *Amazon CloudWatch User Guide*. Use the following values:

Field	Value
Define pattern, Filter pattern	`{($.eventSource=iam.amazonaws.com) && (($.eventName=DeleteGroupPolicy) || ($.eventName=DeleteRolePolicy) \|\| ($.eventName=DeleteUserPolicy) || ($.eventName=PutGroupPolicy) \|\| ($.eventName=PutRolePolicy) || ($.eventName=PutUserPolicy) \|\| ($.eventName=CreatePolicy) || ($.eventName=DeletePolicy) \|\| ($.eventName=CreatePolicyVersion) || ($.eventName=DeletePolicyVersion) ||`

Field	Value
	`($.eventName=AttachRolePolicy) || ($.eventName=DetachRolePolicy) || ($.eventName=AttachUserPolicy) || ($.eventName=DetachUserPolicy) || ($.eventName=AttachGroupPolicy) || ($.eventName=DetachGroupPolicy))}`
Metric namespace	**`LogMetrics`**
Metric value	**`1`**
Default value	**`0`**

4. Create an alarm based on the filter. For instructions, see Create a CloudWatch alarm based on a log group-metric filter in the *Amazon CloudWatch User Guide*. Use the following values:

Field	Value
Conditions, Threshold type	Static
Whenever *`your-metric-name`* is...	Greater/Equal
than...	**`1`**

[CloudWatch.5] Ensure a log metric filter and alarm exist for CloudTrail configuration changes

Related requirements: CIS AWS Foundations Benchmark v1.2.0/3.5, CIS AWS Foundations Benchmark v1.4.0/4.5, NIST.800-171.r2 3.3.8, NIST.800-171.r2 3.14.6, NIST.800-171.r2 3.14.7, CRI Profile v2.2/DE.AE-02.01, CRI Profile v2.2/DE.AE-03.01, CRI Profile v2.2/DE.AE-03.02, CRI Profile v2.2/PR.PS-04.02, CRI Profile v2.2/PR.PS-04.03, CRI Profile v2.2/RS.AN-07.01, CRI Profile v2.2/RS.MA-02.01

Category: Detect > Detection services

Severity: Low

Resource type: `AWS::Logs::MetricFilter`, `AWS::CloudWatch::Alarm`, `AWS::CloudTrail::Trail`, `AWS::SNS::Topic`

AWS Config rule: None (custom Security Hub CSPM rule)

Schedule type: Periodic

Parameters: None

You can do real-time monitoring of API calls by directing CloudTrail logs to CloudWatch Logs and establishing corresponding metric filters and alarms.

CIS recommends that you create a metric filter and alarm for changes to CloudTrail configuration settings. Monitoring these changes helps ensure sustained visibility to activities in the account.

To run this check, Security Hub CSPM uses custom logic to perform the exact audit steps prescribed for control 4.5 in the CIS AWS Foundations Benchmark v1.4.0. This control fails if the exact metric filters prescribed by CIS are not used. Additional fields or terms cannot be added to the metric filters.

Note

When Security Hub CSPM performs the check for this control, it looks for CloudTrail trails that the current account uses. These trails might be organization trails that belong to another account. Multi-Region trails also might be based in a different Region.
The check results in `FAILED` findings in the following cases:

- No trail is configured.
- The available trails that are in the current Region and that are owned by current account do not meet the control requirements.

The check results in a control status of `NO_DATA` in the following cases:

- A multi-Region trail is based in a different Region. Security Hub CSPM can only generate findings in the Region where the trail is based.
- A multi-Region trail belongs to a different account. Security Hub CSPM can only generate findings for the account that owns the trail.

  As a best practice, use organization trails to log events from many accounts in an organization. Organization trails are multi-Region trails by default and can only be

managed by the AWS Organizations management account or the CloudTrail delegated administrator account. Using an organization trail results in a control status of `NO_DATA` for controls evaluated in organization member accounts. In member accounts, Security Hub CSPM only generates findings for member-owned resources. Findings that pertain to organization trails are generated in the resource owner's account. You can see these findings in your Security Hub CSPM delegated administrator account by using cross-Region aggregation.

For the alarm, the current account must either own the referenced Amazon SNS topic, or must get access to the Amazon SNS topic by calling `ListSubscriptionsByTopic`. Otherwise Security Hub CSPM generates `WARNING` findings for the control.

Remediation

To pass this control, follow these steps to create an Amazon SNS topic, an AWS CloudTrail trail, a metric filter, and an alarm for the metric filter.

1. Create an Amazon SNS topic. For instructions, see Getting started with Amazon SNS in the *Amazon Simple Notification Service Developer Guide*. Create a topic that receives all CIS alarms, and create at least one subscription to the topic.
2. Create a CloudTrail trail that applies to all AWS Regions. For instructions, see Creating a trail in the *AWS CloudTrail User Guide*.

   Make note of the name of the CloudWatch Logs log group that you associate with the CloudTrail trail. You create the metric filter for that log group in the next step.
3. Create a metric filter. For instructions, see Create a metric filter for a log group in the *Amazon CloudWatch User Guide*. Use the following values:

Field	Value
Define pattern, Filter pattern	`{($.eventName=CreateTrail) \|\| ($.eventName=UpdateTrail) || ($.eventName=DeleteTrail) \|\| ($.eventName=StartLogging) || ($.eventName=StopLogging)}`

Field	Value
Metric namespace	**`LogMetrics`**
Metric value	**`1`**
Default value	**`0`**

4. Create an alarm based on the filter. For instructions, see Create a CloudWatch alarm based on a log group-metric filter in the *Amazon CloudWatch User Guide*. Use the following values:

Field	Value
Conditions, Threshold type	Static
Whenever *`your-metric-name`* is...	Greater/Equal
than...	**`1`**

[CloudWatch.6] Ensure a log metric filter and alarm exist for AWS Management Console authentication failures

Related requirements: CIS AWS Foundations Benchmark v1.2.0/3.6, CIS AWS Foundations Benchmark v1.4.0/4.6, NIST.800-171.r2 3.14.6, NIST.800-171.r2 3.14.7, CRI Profile v2.2/DE.AE-02.01, CRI Profile v2.2/DE.AE-02.02, CRI Profile v2.2/DE.AE-03.01, CRI Profile v2.2/DE.AE-03.02, CRI Profile v2.2/DE.CM-03.01, CRI Profile v2.2/PR.PS-04.02, CRI Profile v2.2/RS.MA-02.01

Category: Detect > Detection services

Severity: Low

Resource type: `AWS::Logs::MetricFilter`, `AWS::CloudWatch::Alarm`, `AWS::CloudTrail::Trail`, `AWS::SNS::Topic`

AWS Config rule: None (custom Security Hub CSPM rule)

Schedule type: Periodic

Parameters: None

You can do real-time monitoring of API calls by directing CloudTrail logs to CloudWatch Logs and establishing corresponding metric filters and alarms.

CIS recommends that you create a metric filter and alarm for failed console authentication attempts. Monitoring failed console logins might decrease lead time to detect an attempt to brute-force a credential, which might provide an indicator, such as source IP, that you can use in other event correlations.

To run this check, Security Hub CSPM uses custom logic to perform the exact audit steps prescribed for control 4.6 in the CIS AWS Foundations Benchmark v1.4.0. This control fails if the exact metric filters prescribed by CIS are not used. Additional fields or terms cannot be added to the metric filters.

Note

When Security Hub CSPM performs the check for this control, it looks for CloudTrail trails that the current account uses. These trails might be organization trails that belong to another account. Multi-Region trails also might be based in a different Region.
The check results in `FAILED` findings in the following cases:

- No trail is configured.
- The available trails that are in the current Region and that are owned by current account do not meet the control requirements.

The check results in a control status of `NO_DATA` in the following cases:

- A multi-Region trail is based in a different Region. Security Hub CSPM can only generate findings in the Region where the trail is based.
- A multi-Region trail belongs to a different account. Security Hub CSPM can only generate findings for the account that owns the trail.

  As a best practice, use organization trails to log events from many accounts in an organization. Organization trails are multi-Region trails by default and can only be managed by the AWS Organizations management account or the CloudTrail delegated administrator account. Using an organization trail results in a control status of `NO_DATA` for controls evaluated in organization member accounts. In member accounts, Security Hub CSPM only generates findings for member-owned resources. Findings that pertain to organization trails are generated in the resource owner's account. You can see these

findings in your Security Hub CSPM delegated administrator account by using cross-Region aggregation.

For the alarm, the current account must either own the referenced Amazon SNS topic, or must get access to the Amazon SNS topic by calling `ListSubscriptionsByTopic`. Otherwise Security Hub CSPM generates `WARNING` findings for the control.

Remediation

To pass this control, follow these steps to create an Amazon SNS topic, an AWS CloudTrail trail, a metric filter, and an alarm for the metric filter.

1. Create an Amazon SNS topic. For instructions, see Getting started with Amazon SNS in the *Amazon Simple Notification Service Developer Guide*. Create a topic that receives all CIS alarms, and create at least one subscription to the topic.
2. Create a CloudTrail trail that applies to all AWS Regions. For instructions, see Creating a trail in the *AWS CloudTrail User Guide*.

   Make note of the name of the CloudWatch Logs log group that you associate with the CloudTrail trail. You create the metric filter for that log group in the next step.
3. Create a metric filter. For instructions, see Create a metric filter for a log group in the *Amazon CloudWatch User Guide*. Use the following values:

Field	Value
Define pattern, Filter pattern	`{($.eventName=ConsoleLogin) && ($.errorMessage="Failed authentication")}`
Metric namespace	**`LogMetrics`**
Metric value	**`1`**
Default value	**`0`**

4. Create an alarm based on the filter. For instructions, see Create a CloudWatch alarm based on a log group-metric filter in the *Amazon CloudWatch User Guide*. Use the following values:

Field	Value
Conditions, Threshold type	Static
Whenever *your-metric-name* is...	Greater/Equal
than...	**1**

[CloudWatch.7] Ensure a log metric filter and alarm exist for disabling or scheduled deletion of customer managed keys

Related requirements: CIS AWS Foundations Benchmark v1.2.0/3.7, CIS AWS Foundations Benchmark v1.4.0/4.7, NIST.800-171.r2 3.13.10, NIST.800-171.r2 3.13.16, NIST.800-171.r2 3.14.6, NIST.800-171.r2 3.14.7, CRI Profile v2.2/DE.AE-02.01, CRI Profile v2.2/DE.AE-02.02, CRI Profile v2.2/DE.AE-03.01, CRI Profile v2.2/DE.CM-09.03, CRI Profile v2.2/RS.MA-02.01

Category: Detect > Detection services

Severity: Low

Resource type: `AWS::Logs::MetricFilter`, `AWS::CloudWatch::Alarm`, `AWS::CloudTrail::Trail`, `AWS::SNS::Topic`

AWS Config rule: None (custom Security Hub CSPM rule)

Schedule type: Periodic

Parameters: None

You can do real-time monitoring of API calls by directing CloudTrail logs to CloudWatch Logs and establishing corresponding metric filters and alarms.

CIS recommends that you create a metric filter and alarm for customer managed keys that have changed state to disabled or scheduled deletion. Data encrypted with disabled or deleted keys is no longer accessible.

To run this check, Security Hub CSPM uses custom logic to perform the exact audit steps prescribed for control 4.7 in the CIS AWS Foundations Benchmark v1.4.0. This control fails if the exact metric filters prescribed by CIS are not used. Additional fields or terms cannot be added

to the metric filters. The control also fails if `ExcludeManagementEventSources` contains `kms.amazonaws.com`.

Note

When Security Hub CSPM performs the check for this control, it looks for CloudTrail trails that the current account uses. These trails might be organization trails that belong to another account. Multi-Region trails also might be based in a different Region.
The check results in `FAILED` findings in the following cases:

- No trail is configured.
- The available trails that are in the current Region and that are owned by current account do not meet the control requirements.

The check results in a control status of `NO_DATA` in the following cases:

- A multi-Region trail is based in a different Region. Security Hub CSPM can only generate findings in the Region where the trail is based.
- A multi-Region trail belongs to a different account. Security Hub CSPM can only generate findings for the account that owns the trail.

  As a best practice, use organization trails to log events from many accounts in an organization. Organization trails are multi-Region trails by default and can only be managed by the AWS Organizations management account or the CloudTrail delegated administrator account. Using an organization trail results in a control status of `NO_DATA` for controls evaluated in organization member accounts. In member accounts, Security Hub CSPM only generates findings for member-owned resources. Findings that pertain to organization trails are generated in the resource owner's account. You can see these findings in your Security Hub CSPM delegated administrator account by using cross-Region aggregation.

For the alarm, the current account must either own the referenced Amazon SNS topic, or must get access to the Amazon SNS topic by calling `ListSubscriptionsByTopic`. Otherwise Security Hub CSPM generates `WARNING` findings for the control.

Remediation

To pass this control, follow these steps to create an Amazon SNS topic, an AWS CloudTrail trail, a metric filter, and an alarm for the metric filter.

1. Create an Amazon SNS topic. For instructions, see Getting started with Amazon SNS in the *Amazon Simple Notification Service Developer Guide*. Create a topic that receives all CIS alarms, and create at least one subscription to the topic.
2. Create a CloudTrail trail that applies to all AWS Regions. For instructions, see Creating a trail in the *AWS CloudTrail User Guide*.

   Make note of the name of the CloudWatch Logs log group that you associate with the CloudTrail trail. You create the metric filter for that log group in the next step.
3. Create a metric filter. For instructions, see Create a metric filter for a log group in the *Amazon CloudWatch User Guide*. Use the following values:

Field	Value
Define pattern, Filter pattern	`{($.eventSource=kms.amazonaws.com) && (($.eventName=DisableKey) || ($.eventName=ScheduleKeyDeletion))}`
Metric namespace	**`LogMetrics`**
Metric value	**`1`**
Default value	**`0`**

4. Create an alarm based on the filter. For instructions, see Create a CloudWatch alarm based on a log group-metric filter in the *Amazon CloudWatch User Guide*. Use the following values:

Field	Value
Conditions, Threshold type	Static
Whenever *`your-metric-name`* is...	Greater/Equal
than...	**`1`**

[CloudWatch.8] Ensure a log metric filter and alarm exist for S3 bucket policy changes

Related requirements: CIS AWS Foundations Benchmark v1.2.0/3.8, CIS AWS Foundations Benchmark v1.4.0/4.8, NIST.800-171.r2 3.14.6, NIST.800-171.r2 3.14.7, CRI Profile v2.2/DE.AE-02.02, CRI Profile v2.2/DE.AE-03.01, CRI Profile v2.2/DE.CM-03.03, CRI Profile v2.2/PR.DS-01.01, CRI Profile v2.2/PR.PS-01.01, CRI Profile v2.2/PR.PS-01.03, CRI Profile v2.2/RS.MA-02.01

Category: Detect > Detection services

Severity: Low

Resource type: `AWS::Logs::MetricFilter`, `AWS::CloudWatch::Alarm`, `AWS::CloudTrail::Trail`, `AWS::SNS::Topic`

AWS Config rule: None (custom Security Hub CSPM rule)

Schedule type: Periodic

Parameters: None

You can do real-time monitoring of API calls by directing CloudTrail logs to CloudWatch Logs and establishing corresponding metric filters and alarms.

CIS recommends that you create a metric filter and alarm for changes to S3 bucket policies. Monitoring these changes might reduce time to detect and correct permissive policies on sensitive S3 buckets.

To run this check, Security Hub CSPM uses custom logic to perform the exact audit steps prescribed for control 4.8 in the CIS AWS Foundations Benchmark v1.4.0. This control fails if the exact metric filters prescribed by CIS are not used. Additional fields or terms cannot be added to the metric filters.

> **Note**
>
> When Security Hub CSPM performs the check for this control, it looks for CloudTrail trails that the current account uses. These trails might be organization trails that belong to another account. Multi-Region trails also might be based in a different Region.
> The check results in `FAILED` findings in the following cases:
>
> - No trail is configured.

- The available trails that are in the current Region and that are owned by current account do not meet the control requirements.

The check results in a control status of `NO_DATA` in the following cases:

- A multi-Region trail is based in a different Region. Security Hub CSPM can only generate findings in the Region where the trail is based.
- A multi-Region trail belongs to a different account. Security Hub CSPM can only generate findings for the account that owns the trail.

  As a best practice, use organization trails to log events from many accounts in an organization. Organization trails are multi-Region trails by default and can only be managed by the AWS Organizations management account or the CloudTrail delegated administrator account. Using an organization trail results in a control status of `NO_DATA` for controls evaluated in organization member accounts. In member accounts, Security Hub CSPM only generates findings for member-owned resources. Findings that pertain to organization trails are generated in the resource owner's account. You can see these findings in your Security Hub CSPM delegated administrator account by using cross-Region aggregation.

For the alarm, the current account must either own the referenced Amazon SNS topic, or must get access to the Amazon SNS topic by calling `ListSubscriptionsByTopic`. Otherwise Security Hub CSPM generates `WARNING` findings for the control.

Remediation

To pass this control, follow these steps to create an Amazon SNS topic, an AWS CloudTrail trail, a metric filter, and an alarm for the metric filter.

1. Create an Amazon SNS topic. For instructions, see Getting started with Amazon SNS in the *Amazon Simple Notification Service Developer Guide*. Create a topic that receives all CIS alarms, and create at least one subscription to the topic.
2. Create a CloudTrail trail that applies to all AWS Regions. For instructions, see Creating a trail in the *AWS CloudTrail User Guide*.

Make note of the name of the CloudWatch Logs log group that you associate with the CloudTrail trail. You create the metric filter for that log group in the next step.

3. Create a metric filter. For instructions, see Create a metric filter for a log group in the *Amazon CloudWatch User Guide*. Use the following values:

Field	Value
Define pattern, Filter pattern	`{($.eventSource=s3.amazonaws.com) && (($.eventName=PutBucketAcl) || ($.eventName=PutBucketPolicy) \|\| ($.eventName=PutBucketCors) || ($.eventName=PutBucketLifecycle) \|\| ($.eventName=PutBucketReplication) || ($.eventName=DeleteBucketPolicy) \|\| ($.eventName=DeleteBucketCors) || ($.eventName=DeleteBucketLifecycle) \|\| ($.eventName=DeleteBucketReplication))}`
Metric namespace	**`LogMetrics`**
Metric value	**`1`**
Default value	**`0`**

4. Create an alarm based on the filter. For instructions, see Create a CloudWatch alarm based on a log group-metric filter in the *Amazon CloudWatch User Guide*. Use the following values:

Field	Value
Conditions, Threshold type	Static
Whenever *`your-metric-name`* is...	Greater/Equal
than...	**`1`**

[CloudWatch.9] Ensure a log metric filter and alarm exist for AWS Config configuration changes

Related requirements: CIS AWS Foundations Benchmark v1.2.0/3.9, CIS AWS Foundations Benchmark v1.4.0/4.9, NIST.800-171.r2 3.3.8, NIST.800-171.r2 3.14.6, NIST.800-171.r2 3.14.7, CRI Profile v2.2/DE.CM-09.03, CRI Profile v2.2/PR.PS-01.01, CRI Profile v2.2/PR.PS-01.03

Category: Detect > Detection services

Severity: Low

Resource type: `AWS::Logs::MetricFilter`, `AWS::CloudWatch::Alarm`, `AWS::CloudTrail::Trail`, `AWS::SNS::Topic`

AWS Config rule: None (custom Security Hub CSPM rule)

Schedule type: Periodic

Parameters: None

You can do real-time monitoring of API calls by directing CloudTrail logs to CloudWatch Logs and establishing corresponding metric filters and alarms.

CIS recommends that you create a metric filter and alarm for changes to AWS Config configuration settings. Monitoring these changes helps ensure sustained visibility of configuration items in the account.

To run this check, Security Hub CSPM uses custom logic to perform the exact audit steps prescribed for control 4.9 in the CIS AWS Foundations Benchmark v1.4.0. This control fails if the exact metric filters prescribed by CIS are not used. Additional fields or terms cannot be added to the metric filters.

> **Note**
>
> When Security Hub CSPM performs the check for this control, it looks for CloudTrail trails that the current account uses. These trails might be organization trails that belong to another account. Multi-Region trails also might be based in a different Region.
> The check results in `FAILED` findings in the following cases:
>

Category: Detect > Detection services

Severity: Low

Resource type: `AWS::Logs::MetricFilter`, `AWS::CloudWatch::Alarm`, `AWS::CloudTrail::Trail`, `AWS::SNS::Topic`

AWS Config rule: None (custom Security Hub CSPM rule)

Schedule type: Periodic

Parameters: None

You can do real-time monitoring of API calls by directing CloudTrail logs to CloudWatch Logs and establishing corresponding metric filters and alarms. Security groups are a stateful packet filter that controls ingress and egress traffic in a VPC.

CIS recommends that you create a metric filter and alarm for changes to security groups. Monitoring these changes helps ensure that resources and services aren't unintentionally exposed.

To run this check, Security Hub CSPM uses custom logic to perform the exact audit steps prescribed for control 4.10 in the CIS AWS Foundations Benchmark v1.4.0. This control fails if the exact metric filters prescribed by CIS are not used. Additional fields or terms cannot be added to the metric filters.

Note

When Security Hub CSPM performs the check for this control, it looks for CloudTrail trails that the current account uses. These trails might be organization trails that belong to another account. Multi-Region trails also might be based in a different Region.
The check results in `FAILED` findings in the following cases:

- No trail is configured.
- The available trails that are in the current Region and that are owned by current account do not meet the control requirements.

The check results in a control status of `NO_DATA` in the following cases:

- A multi-Region trail is based in a different Region. Security Hub CSPM can only generate findings in the Region where the trail is based.
- A multi-Region trail belongs to a different account. Security Hub CSPM can only generate findings for the account that owns the trail.

  As a best practice, use organization trails to log events from many accounts in an organization. Organization trails are multi-Region trails by default and can only be managed by the AWS Organizations management account or the CloudTrail delegated administrator account. Using an organization trail results in a control status of `NO_DATA` for controls evaluated in organization member accounts. In member accounts, Security Hub CSPM only generates findings for member-owned resources. Findings that pertain to organization trails are generated in the resource owner's account. You can see these findings in your Security Hub CSPM delegated administrator account by using cross-Region aggregation.

For the alarm, the current account must either own the referenced Amazon SNS topic, or must get access to the Amazon SNS topic by calling `ListSubscriptionsByTopic`. Otherwise Security Hub CSPM generates `WARNING` findings for the control.

Remediation

To pass this control, follow these steps to create an Amazon SNS topic, an AWS CloudTrail trail, a metric filter, and an alarm for the metric filter.

1. Create an Amazon SNS topic. For instructions, see Getting started with Amazon SNS in the *Amazon Simple Notification Service Developer Guide*. Create a topic that receives all CIS alarms, and create at least one subscription to the topic.
2. Create a CloudTrail trail that applies to all AWS Regions. For instructions, see Creating a trail in the *AWS CloudTrail User Guide*.

   Make note of the name of the CloudWatch Logs log group that you associate with the CloudTrail trail. You create the metric filter for that log group in the next step.
3. Create a metric filter. For instructions, see Create a metric filter for a log group in the *Amazon CloudWatch User Guide*. Use the following values:

Field	Value
Define pattern, Filter pattern	`{($.eventName=AuthorizeSecurityGroupIngress) \|\| ($.eventName=AuthorizeSecurityGroupEgress) || ($.eventName=RevokeSecurityGroupIngress) \|\| ($.eventName=RevokeSecurityGroupEgress) || ($.eventName=CreateSecurityGroup) \|\| ($.eventName=DeleteSecurityGroup)}`
Metric namespace	**`LogMetrics`**
Metric value	**`1`**
Default value	**`0`**

4. Create an alarm based on the filter. For instructions, see Create a CloudWatch alarm based on a log group-metric filter in the *Amazon CloudWatch User Guide*. Use the following values:

Field	Value
Conditions, Threshold type	Static
Whenever *`your-metric-name`* is...	Greater/Equal
than...	**`1`**

[CloudWatch.11] Ensure a log metric filter and alarm exist for changes to Network Access Control Lists (NACL)

Related requirements: CIS AWS Foundations Benchmark v1.2.0/3.11, CIS AWS Foundations Benchmark v1.4.0/4.11, NIST.800-171.r2 3.14.6, NIST.800-171.r2 3.14.7, CRI Profile v2.2/DE.CM-01.03, CRI Profile v2.2/DE.CM-09.03, CRI Profile v2.2/PR.IR-01.02

Category: Detect > Detection services

Severity: Low

Resource type: `AWS::Logs::MetricFilter`, `AWS::CloudWatch::Alarm`, `AWS::CloudTrail::Trail`, `AWS::SNS::Topic`

AWS Config rule: None (custom Security Hub CSPM rule)

Schedule type: Periodic

Parameters: None

You can do real-time monitoring of API calls by directing CloudTrail logs to CloudWatch Logs and establishing corresponding metric filters and alarms. NACLs are used as a stateless packet filter to control ingress and egress traffic for subnets in a VPC.

CIS recommends that you create a metric filter and alarm for changes to NACLs. Monitoring these changes helps ensure that AWS resources and services aren't unintentionally exposed.

To run this check, Security Hub CSPM uses custom logic to perform the exact audit steps prescribed for control 4.11 in the CIS AWS Foundations Benchmark v1.4.0. This control fails if the exact metric filters prescribed by CIS are not used. Additional fields or terms cannot be added to the metric filters.

Note

When Security Hub CSPM performs the check for this control, it looks for CloudTrail trails that the current account uses. These trails might be organization trails that belong to another account. Multi-Region trails also might be based in a different Region.
The check results in `FAILED` findings in the following cases:

- No trail is configured.
- The available trails that are in the current Region and that are owned by current account do not meet the control requirements.

The check results in a control status of `NO_DATA` in the following cases:

- A multi-Region trail is based in a different Region. Security Hub CSPM can only generate findings in the Region where the trail is based.

- A multi-Region trail belongs to a different account. Security Hub CSPM can only generate findings for the account that owns the trail.

  As a best practice, use organization trails to log events from many accounts in an organization. Organization trails are multi-Region trails by default and can only be managed by the AWS Organizations management account or the CloudTrail delegated administrator account. Using an organization trail results in a control status of `NO_DATA` for controls evaluated in organization member accounts. In member accounts, Security Hub CSPM only generates findings for member-owned resources. Findings that pertain to organization trails are generated in the resource owner's account. You can see these findings in your Security Hub CSPM delegated administrator account by using cross-Region aggregation.

For the alarm, the current account must either own the referenced Amazon SNS topic, or must get access to the Amazon SNS topic by calling `ListSubscriptionsByTopic`. Otherwise Security Hub CSPM generates `WARNING` findings for the control.

Remediation

To pass this control, follow these steps to create an Amazon SNS topic, an AWS CloudTrail trail, a metric filter, and an alarm for the metric filter.

1. Create an Amazon SNS topic. For instructions, see Getting started with Amazon SNS in the *Amazon Simple Notification Service Developer Guide*. Create a topic that receives all CIS alarms, and create at least one subscription to the topic.
2. Create a CloudTrail trail that applies to all AWS Regions. For instructions, see Creating a trail in the *AWS CloudTrail User Guide*.

   Make note of the name of the CloudWatch Logs log group that you associate with the CloudTrail trail. You create the metric filter for that log group in the next step.
3. Create a metric filter. For instructions, see Create a metric filter for a log group in the *Amazon CloudWatch User Guide*. Use the following values:

Field	Value
Define pattern, Filter pattern	`{($.eventName=CreateNetworkAcl) \|\| ($.eventName=CreateNetworkAclEntry) || ($.eventName=DeleteNetworkAcl) \|\| ($.eventName=DeleteNetworkAclEntry) || ($.eventName=ReplaceNetworkAclEntry) \|\| ($.eventName=ReplaceNetworkAclAssociation)}`
Metric namespace	**`LogMetrics`**
Metric value	**`1`**
Default value	**`0`**

4. Create an alarm based on the filter. For instructions, see Create a CloudWatch alarm based on a log group-metric filter in the *Amazon CloudWatch User Guide*. Use the following values:

Field	Value
Conditions, Threshold type	Static
Whenever *`your-metric-name`* is...	Greater/Equal
than...	**`1`**

[CloudWatch.12] Ensure a log metric filter and alarm exist for changes to network gateways

Related requirements: CIS AWS Foundations Benchmark v1.2.0/3.12, CIS AWS Foundations Benchmark v1.4.0/4.12, NIST.800-171.r2 3.3.1, NIST.800-171.r2 3.13.1, CRI Profile v2.2/DE.AE-02.02, CRI Profile v2.2/DE.AE-03.01, CRI Profile v2.2/DE.CM-03.03, CRI Profile v2.2/RS.AN-07.01, CRI Profile v2.2/RS.MA-02.01

Category: Detect > Detection services

Severity: Low

Resource type: `AWS::Logs::MetricFilter`, `AWS::CloudWatch::Alarm`, `AWS::CloudTrail::Trail`, `AWS::SNS::Topic`

AWS Config rule: None (custom Security Hub CSPM rule)

Schedule type: Periodic

Parameters: None

You can do real-time monitoring of API calls by directing CloudTrail logs to CloudWatch Logs and establishing corresponding metric filters and alarms. Network gateways are required to send and receive traffic to a destination outside a VPC.

CIS recommends that you create a metric filter and alarm for changes to network gateways. Monitoring these changes helps ensure that all ingress and egress traffic traverses the VPC border via a controlled path.

To run this check, Security Hub CSPM uses custom logic to perform the exact audit steps prescribed for control 4.12 in the CIS AWS Foundations Benchmark v1.2. This control fails if the exact metric filters prescribed by CIS are not used. Additional fields or terms cannot be added to the metric filters.

Note

When Security Hub CSPM performs the check for this control, it looks for CloudTrail trails that the current account uses. These trails might be organization trails that belong to another account. Multi-Region trails also might be based in a different Region.
The check results in `FAILED` findings in the following cases:

- No trail is configured.
- The available trails that are in the current Region and that are owned by current account do not meet the control requirements.

The check results in a control status of `NO_DATA` in the following cases:

- A multi-Region trail is based in a different Region. Security Hub CSPM can only generate findings in the Region where the trail is based.

- A multi-Region trail belongs to a different account. Security Hub CSPM can only generate findings for the account that owns the trail.

  As a best practice, use organization trails to log events from many accounts in an organization. Organization trails are multi-Region trails by default and can only be managed by the AWS Organizations management account or the CloudTrail delegated administrator account. Using an organization trail results in a control status of `NO_DATA` for controls evaluated in organization member accounts. In member accounts, Security Hub CSPM only generates findings for member-owned resources. Findings that pertain to organization trails are generated in the resource owner's account. You can see these findings in your Security Hub CSPM delegated administrator account by using cross-Region aggregation.

For the alarm, the current account must either own the referenced Amazon SNS topic, or must get access to the Amazon SNS topic by calling `ListSubscriptionsByTopic`. Otherwise Security Hub CSPM generates `WARNING` findings for the control.

Remediation

To pass this control, follow these steps to create an Amazon SNS topic, an AWS CloudTrail trail, a metric filter, and an alarm for the metric filter.

1. Create an Amazon SNS topic. For instructions, see Getting started with Amazon SNS in the *Amazon Simple Notification Service Developer Guide*. Create a topic that receives all CIS alarms, and create at least one subscription to the topic.
2. Create a CloudTrail trail that applies to all AWS Regions. For instructions, see Creating a trail in the *AWS CloudTrail User Guide*.

   Make note of the name of the CloudWatch Logs log group that you associate with the CloudTrail trail. You create the metric filter for that log group in the next step.
3. Create a metric filter. For instructions, see Create a metric filter for a log group in the *Amazon CloudWatch User Guide*. Use the following values:

Field	Value
Define pattern, Filter pattern	`{($.eventName=CreateCustomerGateway) \|\| ($.eventName=DeleteCustomerGateway) || ($.eventName=AttachInternetGateway) \|\| ($.eventName=CreateInternetGateway) || ($.eventName=DeleteInternetGateway) \|\| ($.eventName=DetachInternetGateway)}`
Metric namespace	**`LogMetrics`**
Metric value	**`1`**
Default value	**`0`**

4. Create an alarm based on the filter. For instructions, see Create a CloudWatch alarm based on a log group-metric filter in the *Amazon CloudWatch User Guide*. Use the following values:

Field	Value
Conditions, Threshold type	Static
Whenever *`your-metric-name`* is...	Greater/Equal
than...	**`1`**

[CloudWatch.13] Ensure a log metric filter and alarm exist for route table changes

Related requirements: CIS AWS Foundations Benchmark v1.2.0/3.13, CIS AWS Foundations Benchmark v1.4.0/4.13, NIST.800-171.r2 3.3.1, NIST.800-171.r2 3.13.1, NIST.800-171.r2 3.14.6, NIST.800-171.r2 3.14.7, CRI Profile v2.2/DE.AE-02.01, CRI Profile v2.2/DE.AE-02.02, CRI Profile v2.2/DE.AE-03.01, CRI Profile v2.2/DE.AE-03.02, CRI Profile v2.2/PR.PS-01.03, CRI Profile v2.2/RS.MA-02.01

Category: Detect > Detection services

Severity: Low

Resource type: `AWS::Logs::MetricFilter`, `AWS::CloudWatch::Alarm`, `AWS::CloudTrail::Trail`, `AWS::SNS::Topic`

AWS Config rule: None (custom Security Hub CSPM rule)

Schedule type: Periodic

Parameters: None

This control checks whether you monitor API calls in real time by directing CloudTrail logs to CloudWatch Logs and establishing corresponding metric filters and alarms. Routing tables route network traffic between subnets and to network gateways.

CIS recommends that you create a metric filter and alarm for changes to route tables. Monitoring these changes helps ensure that all VPC traffic flows through an expected path.

Note

When Security Hub CSPM performs the check for this control, it looks for CloudTrail trails that the current account uses. These trails might be organization trails that belong to another account. Multi-Region trails also might be based in a different Region.
The check results in `FAILED` findings in the following cases:

- No trail is configured.
- The available trails that are in the current Region and that are owned by current account do not meet the control requirements.

The check results in a control status of `NO_DATA` in the following cases:

- A multi-Region trail is based in a different Region. Security Hub CSPM can only generate findings in the Region where the trail is based.
- A multi-Region trail belongs to a different account. Security Hub CSPM can only generate findings for the account that owns the trail.

  As a best practice, use organization trails to log events from many accounts in an organization. Organization trails are multi-Region trails by default and can only be managed by the AWS Organizations management account or the CloudTrail delegated

administrator account. Using an organization trail results in a control status of `NO_DATA` for controls evaluated in organization member accounts. In member accounts, Security Hub CSPM only generates findings for member-owned resources. Findings that pertain to organization trails are generated in the resource owner's account. You can see these findings in your Security Hub CSPM delegated administrator account by using cross-Region aggregation.

For the alarm, the current account must either own the referenced Amazon SNS topic, or must get access to the Amazon SNS topic by calling `ListSubscriptionsByTopic`. Otherwise Security Hub CSPM generates `WARNING` findings for the control.

Remediation

Note

Our recommended filter pattern in these remediation steps differs from the filter pattern in the CIS guidance. Our recommended filters target only events coming from Amazon Elastic Compute Cloud (EC2) API calls.

To pass this control, follow these steps to create an Amazon SNS topic, an AWS CloudTrail trail, a metric filter, and an alarm for the metric filter.

1. Create an Amazon SNS topic. For instructions, see Getting started with Amazon SNS in the *Amazon Simple Notification Service Developer Guide*. Create a topic that receives all CIS alarms, and create at least one subscription to the topic.
2. Create a CloudTrail trail that applies to all AWS Regions. For instructions, see Creating a trail in the *AWS CloudTrail User Guide*.

   Make note of the name of the CloudWatch Logs log group that you associate with the CloudTrail trail. You create the metric filter for that log group in the next step.
3. Create a metric filter. For instructions, see Create a metric filter for a log group in the *Amazon CloudWatch User Guide*. Use the following values:

Field	Value
Define pattern, Filter pattern	`{($.eventSource=ec2.amazonaws.com) && (($.eventName=CreateRoute) || ($.eventName=CreateRouteTable) \|\| ($.eventName=ReplaceRoute) || ($.eventName=ReplaceRouteTableAssociation) \|\| ($.eventName=DeleteRouteTable) || ($.eventName=DeleteRoute) \|\| ($.eventName=DisassociateRouteTable))}`
Metric namespace	**`LogMetrics`**
Metric value	**`1`**
Default value	**`0`**

4. Create an alarm based on the filter. For instructions, see Create a CloudWatch alarm based on a log group-metric filter in the *Amazon CloudWatch User Guide*. Use the following values:

Field	Value
Conditions, Threshold type	Static
Whenever *`your-metric-name`* is...	Greater/Equal
than...	**`1`**

[CloudWatch.14] Ensure a log metric filter and alarm exist for VPC changes

Related requirements: CIS AWS Foundations Benchmark v1.2.0/3.14, CIS AWS Foundations Benchmark v1.4.0/4.14, NIST.800-171.r2 3.3.1, NIST.800-171.r2 3.13.1, NIST.800-171.r2 3.14.6, NIST.800-171.r2 3.14.7, CRI Profile v2.2/DE.CM-09.03, CRI Profile v2.2/PR.PS-01.01, CRI Profile v2.2/PR.PS-01.03

Category: Detect > Detection services

Severity: Low

Resource type: `AWS::Logs::MetricFilter`, `AWS::CloudWatch::Alarm`, `AWS::CloudTrail::Trail`, `AWS::SNS::Topic`

AWS Config rule: None (custom Security Hub CSPM rule)

Schedule type: Periodic

Parameters: None

You can do real-time monitoring of API calls by directing CloudTrail logs to CloudWatch Logs and establishing corresponding metric filters and alarms. You can have more than one VPC in an account, and you can create a peer connection between two VPCs, enabling network traffic to route between VPCs.

CIS recommends that you create a metric filter and alarm for changes to VPCs. Monitoring these changes helps ensure that authentication and authorization controls remain intact.

To run this check, Security Hub CSPM uses custom logic to perform the exact audit steps prescribed for control 4.14 in the CIS AWS Foundations Benchmark v1.4.0. This control fails if the exact metric filters prescribed by CIS are not used. Additional fields or terms cannot be added to the metric filters.

Note

When Security Hub CSPM performs the check for this control, it looks for CloudTrail trails that the current account uses. These trails might be organization trails that belong to another account. Multi-Region trails also might be based in a different Region.
The check results in `FAILED` findings in the following cases:

- No trail is configured.
- The available trails that are in the current Region and that are owned by current account do not meet the control requirements.

The check results in a control status of `NO_DATA` in the following cases:

- A multi-Region trail is based in a different Region. Security Hub CSPM can only generate findings in the Region where the trail is based.

- A multi-Region trail belongs to a different account. Security Hub CSPM can only generate findings for the account that owns the trail.

  As a best practice, use organization trails to log events from many accounts in an organization. Organization trails are multi-Region trails by default and can only be managed by the AWS Organizations management account or the CloudTrail delegated administrator account. Using an organization trail results in a control status of `NO_DATA` for controls evaluated in organization member accounts. In member accounts, Security Hub CSPM only generates findings for member-owned resources. Findings that pertain to organization trails are generated in the resource owner's account. You can see these findings in your Security Hub CSPM delegated administrator account by using cross-Region aggregation.

For the alarm, the current account must either own the referenced Amazon SNS topic, or must get access to the Amazon SNS topic by calling `ListSubscriptionsByTopic`. Otherwise Security Hub CSPM generates `WARNING` findings for the control.

Remediation

To pass this control, follow these steps to create an Amazon SNS topic, an AWS CloudTrail trail, a metric filter, and an alarm for the metric filter.

1. Create an Amazon SNS topic. For instructions, see Getting started with Amazon SNS in the *Amazon Simple Notification Service Developer Guide*. Create a topic that receives all CIS alarms, and create at least one subscription to the topic.
2. Create a CloudTrail trail that applies to all AWS Regions. For instructions, see Creating a trail in the *AWS CloudTrail User Guide*.

   Make note of the name of the CloudWatch Logs log group that you associate with the CloudTrail trail. You create the metric filter for that log group in the next step.
3. Create a metric filter. For instructions, see Create a metric filter for a log group in the *Amazon CloudWatch User Guide*. Use the following values:

Field	Value
Define pattern, Filter pattern	`{($.eventName=CreateVpc) \|\| ($.eventName=DeleteVpc) || ($.eventName=ModifyVpcAttribute) \|\| ($.eventName=AcceptVpcPeeringConnection) || ($.eventName=CreateVpcPeeringConnection) \|\| ($.eventName=DeleteVpcPeeringConnection) || ($.eventName=RejectVpcPeeringConnection) \|\| ($.eventName=AttachClassicLinkVpc) || ($.eventName=DetachClassicLinkVpc) \|\| ($.eventName=DisableVpcClassicLink) || ($.eventName=EnableVpcClassicLink)}`
Metric namespace	**`LogMetrics`**
Metric value	**`1`**
Default value	**`0`**

4. Create an alarm based on the filter. For instructions, see Create a CloudWatch alarm based on a log group-metric filter in the *Amazon CloudWatch User Guide*. Use the following values:

Field	Value
Conditions, Threshold type	Static
Whenever *`your-metric-name`* is...	Greater/Equal
than...	**`1`**

[CloudWatch.15] CloudWatch alarms should have specified actions configured

Related requirements: NIST.800-53.r5 AU-6(1), NIST.800-53.r5 AU-6(5), NIST.800-53.r5 CA-7, NIST.800-53.r5 IR-4(1), NIST.800-53.r5 IR-4(5), NIST.800-53.r5 SI-2, NIST.800-53.r5 SI-20, NIST.800-53.r5 SI-4(12), NIST.800-53.r5 SI-4(5), NIST.800-171.r2 3.3.4, NIST.800-171.r2 3.14.6, CRI Profile v2.2/DE.AE-02.02, CRI Profile v2.2/DE.AE-03.01, CRI Profile v2.2/RS.MA-02.01

Category: Detect > Detection services

Severity: High

Resource type: `AWS::CloudWatch::Alarm`

AWS Config rule: `cloudwatch-alarm-action-check`

Schedule type: Change triggered

Parameters:

Parameter	Description	Type	Allowed custom values	Security Hub CSPM default value
`alarmActionRequired`	The control produces a `PASSED` finding if the parameter is set to `true` and the alarm has an action when the alarm state changes to `ALARM`.	Boolean	Not customizable	`true`
`insufficientDataActionRequired`	The control produces a `PASSED` finding if the parameter is set to `true` and the alarm has an action when the alarm state changes to `INSUFFICIENT_DATA` .	Boolean	`true` or `false`	`false`
`okActionRequired`	The control produces a `PASSED` finding if the	Boolean	`true` or `false`	`false`

Parameter	Description	Type	Allowed custom values	Security Hub CSPM default value
	parameter is set to `true` and the alarm has an action when the alarm state changes to `OK`.			

This control checks whether an Amazon CloudWatch alarm has at least one action configured for the `ALARM` state. The control fails if the alarm doesn't have an action configured for the `ALARM` state. Optionally, you can include custom parameter values to also require alarm actions for the `INSUFFICIENT_DATA` or `OK` states.

> **Note**
>
> Security Hub CSPM evaluates this control based on CloudWatch metric alarms. Metric alarms may be part of composite alarms that have the specified actions configured. The control generates `FAILED` findings in the following cases:
>
> - The specified actions aren't configured for a metric alarm.
> - The metric alarm is part of a composite alarm that has the specified actions configured.

This control focuses on whether a CloudWatch alarm has an alarm action configured, whereas CloudWatch.17 focuses on the activation status of a CloudWatch alarm action.

We recommend CloudWatch alarm actions to automatically alert you when a monitored metric is outside the defined threshold. Monitoring alarms help you identify unusual activities and quickly respond to security and operational issues when an alarm goes into a specific state. The most common type of alarm action is to notify one or more users by sending a message to an Amazon Simple Notification Service (Amazon SNS) topic.

Remediation

For information about actions supported by CloudWatch alarms, see Alarm actions in the *Amazon CloudWatch User Guide*.

[CloudWatch.16] CloudWatch log groups should be retained for a specified time period

Category: Identify > Logging

Related requirements: NIST.800-53.r5 AU-10, NIST.800-53.r5 AU-11, NIST.800-53.r5 AU-6(3), NIST.800-53.r5 AU-6(4), NIST.800-53.r5 CA-7, NIST.800-53.r5 SI-12, CRI Profile v2.2/ID.AM-08.03, CRI Profile v2.2/ID.AM-08.05, CRI Profile v2.2/PR.PS-04.01, CRI Profile v2.2/PR.PS-04.03

Severity: Medium

Resource type: `AWS::Logs::LogGroup`

AWS Config rule: `cw-loggroup-retention-period-check`

Schedule type: Periodic

Parameters:

Parameter	Description	Type	Allowed custom values	Security Hub CSPM default value	
`minRetentionTime`	Minimum retention period in days for CloudWatch log groups	Enum	`365`, `400`, `545`, `731`, `1827`, `3653`	`365`	

This control checks whether an Amazon CloudWatch log group has a retention period of at least the specified number of days. The control fails if the retention period is less than the specified number. Unless you provide a custom parameter value for the retention period, Security Hub CSPM uses a default value of 365 days.

CloudWatch Logs centralize logs from all of your systems, applications, and AWS services in a single, highly scalable service. You can use CloudWatch Logs to monitor, store, and access your log files from Amazon Elastic Compute Cloud (EC2) instances, AWS CloudTrail, Amazon Route 53, and other sources. Retaining your logs for at least 1 year can help you comply with log retention standards.

Remediation

To configure log retention settings, see Change log data retention in CloudWatch Logs in the *Amazon CloudWatch User Guide*.

[CloudWatch.17] CloudWatch alarm actions should be activated

Category: Detect > Detection services

Related requirements: NIST.800-53.r5 AU-6(1), NIST.800-53.r5 AU-6(5), NIST.800-53.r5 CA-7, NIST.800-53.r5 SI-2, NIST.800-53.r5 SI-4(12), CRI Profile v2.2/DE.AE-02.01, CRI Profile v2.2/DE.AE-02.02, CRI Profile v2.2/DE.AE-03.01

Severity: High

Resource type: `AWS::CloudWatch::Alarm`

AWS Config rule: `cloudwatch-alarm-action-enabled-check`

Schedule type: Change triggered

Parameters: None

This control checks whether CloudWatch alarm actions are activated (`ActionEnabled` should be set to true). The control fails if the alarm action for a CloudWatch alarm is deactivated.

> **Note**
>
> Security Hub CSPM evaluates this control based on CloudWatch metric alarms. Metric alarms may be part of composite alarms that have the alarm actions activated. The control generates `FAILED` findings in the following cases:
>
> - The specified actions aren't configured for a metric alarm.
> - The metric alarm is part of a composite alarm that has alarm actions activated.

This control focuses on the activation status of a CloudWatch alarm action, whereas CloudWatch.15 focuses on whether any `ALARM` action is configured in a CloudWatch alarm.

Alarm actions automatically alert you when a monitored metric is outside the defined threshold. If the alarm action is deactivated, no actions are run when the alarm changes state, and you won't be

alerted to changes in monitored metrics. We recommend activating CloudWatch alarm actions to help you quickly respond to security and operational issues.

Remediation

To activate a CloudWatch alarm action (console)

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. In the navigation pane, under **Alarms**, choose **All alarms**.
3. Select the alarm that you want to activate actions for.
4. For **Actions**, choose **Alarm actions–new**, and then choose **Enable**.

For more information about activating CloudWatch alarm actions, see Alarm actions in the *Amazon CloudWatch User Guide*.

Security Hub CSPM controls for CodeArtifact

These Security Hub CSPM controls evaluate the AWS CodeArtifact service and resources.

These controls may not be available in all AWS Regions. For more information, see Availability of controls by Region.

[CodeArtifact.1]CodeArtifact repositories should be tagged

Category: Identify > Inventory > Tagging

Severity: Low

Resource type: `AWS::CodeArtifact::Repository`

AWS Config rule: `tagged-codeartifact-repository` (custom Security Hub CSPM rule)

Schedule type: Change triggered

Parameters:

Parameter	Description	Type	Allowed custom values	Security Hub CSPM default value
`requiredTagKeys`	List of non-system tag keys that the evaluated resource must contain. Tag keys are case sensitive.	StringList (maximum of 6 items)	1–6 tag keys that meet AWS requirements.	No default value

This control checks whether an AWS CodeArtifact repository has tags with the specific keys defined in the parameter `requiredTagKeys`. The control fails if the repository doesn't have any tag keys or if it doesn't have all the keys specified in the parameter `requiredTagKeys`. If the parameter `requiredTagKeys` isn't provided, the control only checks for the existence of a tag key and fails if the repository isn't tagged with any key. System tags, which are automatically applied and begin with `aws:`, are ignored.

A tag is a label that you assign to an AWS resource, and it consists of a key and an optional value. You can create tags to categorize resources by purpose, owner, environment, or other criteria. Tags can help you identify, organize, search for, and filter resources. Tagging also helps you track accountable resource owners for actions and notifications. When you use tagging, you can implement attribute-based access control (ABAC) as an authorization strategy, which defines permissions based on tags. You can attach tags to IAM entities (users or roles) and to AWS resources. You can create a single ABAC policy or a separate set of policies for your IAM principals. You can design these ABAC policies to allow operations when the principal's tag matches the resource tag. For more information, see What is ABAC for AWS? in the *IAM User Guide*.

Note

Don't add personally identifiable information (PII) or other confidential or sensitive information in tags. Tags are accessible to many AWS services, including AWS Billing. For more tagging best practices, see Tagging your AWS resources in the *AWS General Reference*.

Remediation

To add tags to a CodeArtifact repository, see Tag a repository in CodeArtifact in the *AWS CodeArtifact User Guide*.

Security Hub CSPM controls for CodeBuild

These Security Hub CSPM controls evaluate the AWS CodeBuild service and resources.

These controls may not be available in all AWS Regions. For more information, see Availability of controls by Region.

[CodeBuild.1] CodeBuild Bitbucket source repository URLs should not contain sensitive credentials

Related requirements: NIST.800-53.r5 SA-3, PCI DSS v3.2.1/8.2.1, PCI DSS v4.0.1/8.3.2, CRI Profile v2.2/PR.AA-04.01, CRI Profile v2.2/PR.DS-02.01

Category: Protect > Secure development

Severity: Critical

Resource type: `AWS::CodeBuild::Project`

AWS Config rule: `codebuild-project-source-repo-url-check`

Schedule type: Change triggered

Parameters: None

This control checks whether an AWS CodeBuild project Bitbucket source repository URL contains personal access tokens or a user name and password. The control fails if the Bitbucket source repository URL contains personal access tokens or a user name and password.

> **Note**
>
> This control evaluates both the primary source and secondary sources of a CodeBuild build project. For more information about project sources, see Multiple input sources and output artifacts sample in the *AWS CodeBuild User Guide*.

Sign-in credentials shouldn't be stored or transmitted in clear text or appear in the source repository URL. Instead of personal access tokens or sign-in credentials, you should access your

source provider in CodeBuild, and change your source repository URL to contain only the path to the Bitbucket repository location. Using personal access tokens or sign-in credentials could result in unintended data exposure or unauthorized access.

Remediation

You can update your CodeBuild project to use OAuth.

To remove basic authentication / (GitHub) Personal Access Token from CodeBuild project source

1. Open the CodeBuild console at https://console.aws.amazon.com/codebuild/.
2. Choose the build project that contains personal access tokens or a user name and password.
3. From **Edit**, choose **Source**.
4. Choose **Disconnect from GitHub / Bitbucket**.
5. Choose **Connect using OAuth**, then choose **Connect to GitHub / Bitbucket**.
6. When prompted, choose **authorize as appropriate**.
7. Reconfigure your repository URL and additional configuration settings, as needed.
8. Choose **Update source**.

For more information, refer to CodeBuild use case-based samples in the *AWS CodeBuild User Guide*.

[CodeBuild.2] CodeBuild project environment variables should not contain clear text credentials

Related requirements: NIST.800-53.r5 IA-5(7), NIST.800-53.r5 SA-3, PCI DSS v3.2.1/8.2.1, PCI DSS v4.0.1/8.3.2, CRI Profile v2.2/PR.AA-01.01, CRI Profile v2.2/PR.DS-01.01, CRI Profile v2.2/PR.PS-06.04

Category: Protect > Secure development

Severity: Critical

Resource type: `AWS::CodeBuild::Project`

AWS Config rule: `codebuild-project-envvar-awscred-check`

Schedule type: Change triggered

Parameters: None

This control checks whether the project contains the environment variables `AWS_ACCESS_KEY_ID` and `AWS_SECRET_ACCESS_KEY`.

Authentication credentials `AWS_ACCESS_KEY_ID` and `AWS_SECRET_ACCESS_KEY` should never be stored in clear text, as this could lead to unintended data exposure and unauthorized access.

Remediation

To remove environment variables from a CodeBuild project, see Change a build project's settings in AWS CodeBuild in the *AWS CodeBuild User Guide*. Ensure nothing is selected for **Environment variables**.

You can store environment variables with sensitive values in the AWS Systems Manager Parameter Store or AWS Secrets Manager and then retrieve them from your build spec. For instructions, see the box labeled **Important** in the Environment section in the *AWS CodeBuild User Guide*.

[CodeBuild.3] CodeBuild S3 logs should be encrypted

Related requirements: NIST.800-53.r5 CA-9(1), NIST.800-53.r5 CM-3(6), NIST.800-53.r5 SC-13, NIST.800-53.r5 SC-28, NIST.800-53.r5 SC-28(1), NIST.800-53.r5 SI-7(6), PCI DSS v4.0.1/10.3.2, CRI Profile v2.2/PR.DS-01.01, CRI Profile v2.2/PR.PS-01.06, CRI Profile v2.2/PR.PS-04.03

Category: Protect > Data Protection > Encryption of data-at-rest

Severity: Low

Resource type: `AWS::CodeBuild::Project`

AWS Config rule: `codebuild-project-s3-logs-encrypted`

Schedule type: Change triggered

Parameters: None

This control checks if Amazon S3 logs for an AWS CodeBuild project are encrypted. The control fails if encryption is deactivated for S3 logs for a CodeBuild project.

Encryption of data at rest is a recommended best practice to add a layer of access management around your data. Encrypting the logs at rest reduces the risk that a user not authenticated by AWS will access the data stored on disk. It adds another set of access controls to limit the ability of unauthorized users to access the data.

Remediation

To change the encryption settings for CodeBuild project S3 logs, see Change a build project's settings in AWS CodeBuild in the *AWS CodeBuild User Guide*.

[CodeBuild.4] CodeBuild project environments should have a logging AWS Configuration

Related requirements: NIST.800-53.r5 AC-2(12), NIST.800-53.r5 AC-2(4), NIST.800-53.r5 AC-4(26), NIST.800-53.r5 AC-6(9), NIST.800-53.r5 AU-10, NIST.800-53.r5 AU-12, NIST.800-53.r5 AU-2, NIST.800-53.r5 AU-3, NIST.800-53.r5 AU-6(3), NIST.800-53.r5 AU-6(4), NIST.800-53.r5 AU-9(7), NIST.800-53.r5 CA-7, NIST.800-53.r5 SC-7(9), NIST.800-53.r5 SI-3(8), NIST.800-53.r5 SI-4, NIST.800-53.r5 SI-4(20), NIST.800-53.r5 SI-7(8), CRI Profile v2.2/DE.AE-03.01, CRI Profile v2.2/PR.IR-04.01, CRI Profile v2.2/PR.PS-04.02

Category: Identify > Logging

Severity: Medium

Resource type: `AWS::CodeBuild::Project`

AWS Config rule: `codebuild-project-logging-enabled`

Schedule type: Change triggered

Parameters: None

This control checks whether a CodeBuild project environment has at least one log option, either to S3 or CloudWatch logs enabled. This control fails if a CodeBuild project environment does not have at least one log option enabled.

From a security perspective, logging is an important feature to enable for future forensics efforts in the case of any security incidents. Correlating anomalies in CodeBuild projects with threat detections can increase confidence in the accuracy of those threat detections.

Remediation

For more information on how to configure CodeBuild project log settings, see Create a build project (console) in the CodeBuild User Guide.

[CodeBuild.7] CodeBuild report group exports should be encrypted at rest

Related requirements: CRI Profile v2.2/PR.DS-01.01, CRI Profile v2.2/PR.PS-01.06

Category: Protect > Data Protection > Encryption of data-at-rest

Severity: Medium

Resource type: `AWS::CodeBuild::ReportGroup`

AWS Config rule: `codebuild-report-group-encrypted-at-rest`

Schedule type: Change triggered

Parameters: None

This control checks whether the test results of an AWS CodeBuild report group that are exported to an Amazon Simple Storage Service (Amazon S3) bucket are encrypted at rest. The control fails if the report group export isn't encrypted at rest.

Data at rest refers to data that's stored in persistent, non-volatile storage for any duration. Encrypting data at rest helps you protect its confidentiality, which reduces the risk that an unauthorized user can access it.

Remediation

To encrypt the report group export to S3, see Update a report group in the *AWS CodeBuild User Guide*.

Security Hub CSPM controls for Amazon CodeGuru Profiler

These Security Hub CSPM controls evaluate the Amazon CodeGuru Profiler service and resources.

These controls may not be available in all AWS Regions. For more information, see Availability of controls by Region.

[CodeGuruProfiler.1] CodeGuru Profiler profiling groups should be tagged

Related requirements: CRI Profile v2.2/ID.AM-02.01, CRI Profile v2.2/ID.AM-05.01

Category: Identify > Inventory > Tagging

Severity: Low

Resource type: `AWS::CodeGuruProfiler::ProfilingGroup`

AWS Config rule: `codeguruprofiler-profiling-group-tagged`

Schedule type: Change triggered

Parameters:

Parameter	Description	Type	Allowed custom values	Security Hub CSPM default value
`requiredKeyTags`	List of non-system tag keys that the evaluated resource must contain. Tag keys are case sensitive.	StringList (maximum of 6 items)	1–6 tag keys that meet AWS requirements.	No default value

This control checks whether an Amazon CodeGuru Profiler profiling group has tags with the specific keys defined in the parameter `requiredKeyTags`. The control fails if the profiling group doesn't have any tag keys or if it doesn't have all the keys specified in the parameter `requiredKeyTags`. If the parameter `requiredKeyTags` isn't provided, the control only checks for the existence of a tag key and fails if the profiling group isn't tagged with any key. System tags, which are automatically applied and begin with `aws:`, are ignored.

A tag is a label that you assign to an AWS resource, and it consists of a key and an optional value. You can create tags to categorize resources by purpose, owner, environment, or other criteria. Tags can help you identify, organize, search for, and filter resources. Tagging also helps you track accountable resource owners for actions and notifications. When you use tagging, you can implement attribute-based access control (ABAC) as an authorization strategy, which defines permissions based on tags. You can attach tags to IAM entities (users or roles) and to AWS resources. You can create a single ABAC policy or a separate set of policies for your IAM principals. You can design these ABAC policies to allow operations when the principal's tag matches the resource tag. For more information, see Define permissions based on attributes with ABAC authorization in the *IAM User Guide*.

> **Note**
>
> Don't add personally identifiable information (PII) or other confidential or sensitive information in tags. Tags are accessible to many AWS services, including AWS Billing. For

more tagging best practices, see Best practices and strategies in the *Tagging AWS Resources and Tag Editor User Guide*.

Remediation

To add tags to a CodeGuru Profiler profiling group, see Tagging profiling groups in the *Amazon CodeGuru Profiler User Guide*.

Security Hub CSPM controls for Amazon CodeGuru Reviewer

These Security Hub CSPM controls evaluate the Amazon CodeGuru Reviewer service and resources.

These controls may not be available in all AWS Regions. For more information, see Availability of controls by Region.

[CodeGuruReviewer.1] CodeGuru Reviewer repository associations should be tagged

Related requirements: CRI Profile v2.2/ID.AM-02.01, CRI Profile v2.2/ID.AM-05.01

Category: Identify > Inventory > Tagging

Severity: Low

Resource type: `AWS::CodeGuruReviewer::RepositoryAssociation`

AWS Config rule: `codegurureviewer-repository-association-tagged`

Schedule type: Change triggered

Parameters:

Parameter	Description	Type	Allowed custom values	Security Hub CSPM default value
`requiredKeyTags`	List of non-system tag keys that the evaluated resource must contain. Tag keys are case sensitive.	StringList (maximum of 6 items)	1–6 tag keys that meet AWS	No default value

Parameter	Description	Type	Allowed custom values	Security Hub CSPM default value
			requirements.	

This control checks whether an Amazon CodeGuru Reviewer repository association has tags with the specific keys defined in the parameter `requiredKeyTags`. The control fails if the repository association doesn't have any tag keys or if it doesn't have all the keys specified in the parameter `requiredKeyTags`. If the parameter `requiredKeyTags` isn't provided, the control only checks for the existence of a tag key and fails if the repository association isn't tagged with any key. System tags, which are automatically applied and begin with `aws:`, are ignored.

A tag is a label that you assign to an AWS resource, and it consists of a key and an optional value. You can create tags to categorize resources by purpose, owner, environment, or other criteria. Tags can help you identify, organize, search for, and filter resources. Tagging also helps you track accountable resource owners for actions and notifications. When you use tagging, you can implement attribute-based access control (ABAC) as an authorization strategy, which defines permissions based on tags. You can attach tags to IAM entities (users or roles) and to AWS resources. You can create a single ABAC policy or a separate set of policies for your IAM principals. You can design these ABAC policies to allow operations when the principal's tag matches the resource tag. For more information, see Define permissions based on attributes with ABAC authorization in the *IAM User Guide*.

Note

Don't add personally identifiable information (PII) or other confidential or sensitive information in tags. Tags are accessible to many AWS services, including AWS Billing. For more tagging best practices, see Best practices and strategies in the *Tagging AWS Resources and Tag Editor User Guide*.

Remediation

To add tags to a CodeGuru Reviewer repository association, see Tagging a repository association in the *Amazon CodeGuru Reviewer User Guide*.

Security Hub CSPM controls for Amazon Cognito

These AWS Security Hub CSPM controls evaluate the Amazon Cognito service and resources. The controls might not be available in all AWS Regions. For more information, see Availability of controls by Region.

[Cognito.1] Cognito user pools should have threat protection activated with full function enforcement mode for standard authentication

Category: Protect > Secure access management

Severity: Medium

Resource type: `AWS::Cognito::UserPool`

AWS Config rule: cognito-user-pool-advanced-security-enabled

Schedule type: Change triggered

Parameters:

Parameter	Description	Type	Allowed custom values	Security Hub CSPM default value
`SecurityMode`	The threat protection enforcement mode that the control checks for.	String	`AUDIT`, `ENFORCED`	`ENFORCED`

This control checks whether an Amazon Cognito user pool has threat protection activated with the enforcement mode set to full function for standard authentication. The control fails if the user pool has threat protection deactivated or if the enforcement mode isn't set to full function for standard authentication. Unless you provide custom parameter values, Security Hub CSPM uses the default value of `ENFORCED` for enforcement mode set to full function for standard authentication.

After you create an Amazon Cognito user pool, you can activate threat protection and customize the actions that are taken in response to different risks. Or, you can use audit mode to gather metrics on detected risks without applying any security mitigations. In audit mode, threat

protection publishes metrics to Amazon CloudWatch. You can see metrics after Amazon Cognito generates its first event.

Remediation

For information about activating threat protection for an Amazon Cognito user pool, see Advanced security with threat protection in the *Amazon Cognito Developer Guide*.

[Cognito.2] Cognito identity pools should not allow unauthenticated identities

Related requirements: CRI Profile v2.2/PR.AA-01.02, CRI Profile v2.2/PR.AA-02.01, CRI Profile v2.2/PR.AA-03.01, CRI Profile v2.2/PR.AA-03.02, CRI Profile v2.2/PR.AA-04.01

Category: Protect > Secure access management > Passwordless authentication

Severity: Medium

Resource type: `AWS::Cognito::IdentityPool`

AWS Config rule: cognito-identity-pool-unauth-access-check

Schedule type: Change triggered

Parameters: None

This control checks whether an Amazon Cognito identity pool is configured to allow unauthenticated identities. The control fails if guest access is activated (the `AllowUnauthenticatedIdentities` parameter is set to `true`) for the identity pool.

If an Amazon Cognito identity pool allows unauthenticated identities, the identity pool provides temporary AWS credentials to users who haven't authenticated through an identity provider (guests). This creates security risks because it allows anonymous access to AWS resources. If you deactivate guest access, you can help ensure that only properly authenticated users can access your AWS resources, which reduces the risk of unauthorized access and potential security breaches. As a best practice, an identity pool should require authentication through supported identity providers. If unauthenticated access is necessary, it's important to carefully restrict permissions for unauthenticated identities, and regularly review and monitor their usage.

Remediation

For information about deactivating guest access for an Amazon Cognito identity pool, see Activate or deactivate guest access in the *Amazon Cognito Developer Guide*.

[Cognito.3] Password policies for Cognito user pools should have strong configurations

Related requirements: CRI Profile v2.2/PR.AA-01.01, CRI Profile v2.2/PR.PS-01.01

Category: Protect > Secure access management

Severity: Medium

Resource type: `AWS::Cognito::UserPool`

AWS Config rule: cognito-user-pool-password-policy-check

Schedule type: Change triggered

Parameters:

Parameter	Description	Type	Allowed custom values	Security Hub CSPM default value
`minLength`	The minimum number of characters that a password must contain.	Integer	8 to 99	8
`requireLowercase`	Require at least one lowercase character in a password.	Boolean	`True`, `False`	`True`
`requireUppercase`	Require at least one uppercase character in a password.	Boolean	`True`, `False`	`True`
`requireNumbers`	Require at least one number in a password.	Boolean	`True`, `False`	`True`
`requireSymbols`	Require at least one symbol in a password.	Boolean	`True`, `False`	`True`

Parameter	Description	Type	Allowed custom values	Security Hub CSPM default value
`temporaryPasswordValidity`	The maximum number of days that a password can exist before it expires.	Integer	1 to 365	7

This control checks whether the password policy for an Amazon Cognito user pool requires the use of strong passwords, based on recommended settings for password policies. The control fails if the password policy for the user pool doesn't require strong passwords. You can optionally specify custom values for the policy settings that the control checks.

Strong passwords are a security best practice for Amazon Cognito user pools. Weak passwords can expose users' credentials to systems that guess passwords and try to access data. This is especially the case for applications that are open to the internet. Password policies are a central element of the security of user directories. By using a password policy, you can configure a user pool to require password complexity and other settings that comply with your security standards and requirements.

Remediation

For information about creating or updating the password policy for an Amazon Cognito user pool, see Adding user pool password requirements in the *Amazon Cognito Developer Guide*.

[Cognito.4] Cognito user pools should have threat protection activated with full function enforcement mode for custom authentication

Category: Protect > Secure access management

Severity: Medium

Resource type: `AWS::Cognito::UserPool`

AWS Config rule: cognito-userpool-cust-auth-threat-full-check

Schedule type: Change triggered

Parameters: None

This control checks whether an Amazon Cognito user pool has threat protection activated with the enforcement mode set to full function for custom authentication. The control fails if the user pool has threat protection disabled or if the enforcement mode isn't set to full function for custom authentication.

Threat protection, formerly called advanced security features, is a set of monitoring tools for unwanted activity in your user pool, and configuration tools to automatically shut down potentially malicious activity. After you create an Amazon Cognito user pool, you can activate threat protection with full function enforcement mode for custom authentication and customize the actions that are taken in response to different risks. Full-function mode includes a set of automatic reactions to detect unwanted activity and compromised passwords.

Remediation

For information about activating threat protection for an Amazon Cognito user pool, see Advanced security with threat protection in the *Amazon Cognito Developer Guide*.

[Cognito.5] MFA should be enabled for Cognito user pools

Category: Protect > Secure access management > Multi-factor authentication

Severity: Medium

Resource type: `AWS::Cognito::UserPool`

AWS Config rule: cognito-user-pool-mfa-enabled

Schedule type: Change triggered

Parameters: None

This control checks whether an Amazon Cognito user pool configured with a password-only sign-in policy has multi-factor authentication (MFA) enabled. The control fails if the user pool configured with a password-only sign-in policy does not have MFA enabled.

Multi-factor authentication (MFA) adds a something you have authentication factor to the something you know factor (typically username and password). For federated users, Amazon Cognito delegates authentication to the identity provider (IdP) and doesn't offer additional authentication factors. However, if you have local users with password authentication, configuring MFA for the user pool increases their security.

> **Note**
>
> This control is not applicable for federated users and users signing in with passwordless factors.

Remediation

For information about how to configure MFA for an Amazon Cognito user pool, see Adding MFA to a user pool in the *Amazon Cognito Developer Guide*.

[Cognito.6] Cognito user pools should have deletion protection enabled

Category: Protect > Data Protection > Data deletion protection

Severity: Medium

Resource type: `AWS::Cognito::UserPool`

AWS Config rule: cognito-user-pool-deletion-protection-enabled

Schedule type: Change triggered

Parameters: None

This control checks whether an Amazon Cognito user pool has deletion protection enabled. The control fails if deletion protection is disabled for the user pool.

Deletion protection helps ensure that your user pool is not accidentally deleted. When you configure a user pool with deletion protection, the pool cannot be deleted by any user. Deletion protection prevents you from requesting the deletion of a user pool unless you first modify the pool and deactivate deletion protection.

Remediation

To configure deletion protection for an Amazon Cognito user pool, see User pool deletion protection in the *Amazon Cognito Developer Guide*.

Security Hub CSPM controls for AWS Config

These Security Hub CSPM controls evaluate the AWS Config service and resources.

These controls may not be available in all AWS Regions. For more information, see Availability of controls by Region.

[Config.1] AWS Config should be enabled and use the service-linked role for resource recording

> **Note**
>
> When Security Hub CSPM and Security Hub are enabled the Config.1 rule will always have a status of PASSED. This is because Security Hub CSPM has direct access to configuration items via a service-linked configuration recorder. The parameter for this control is not applicable as the internal service-linked configuration recorder is automatically created with the AWS Config service-linked role. For more information, see Using the service-linked configuration recorder.
>
> Multicloud controls (such as Azure controls) and their associated resource recording are not factored into Config.1 evaluations. Multicloud standards always use an internal service-linked configuration recorder that the CSPM multicloud connector sets up automatically, regardless of Security Hub enablement status. Because multicloud recording is fully managed by the connector, it does not affect Config.1 compliance status. Config.1 evaluates only AWS resource recording configuration.

Related requirements: CIS AWS Foundations Benchmark v5.0.0/3.3, CIS AWS Foundations Benchmark v1.2.0/2.5, CIS AWS Foundations Benchmark v1.4.0/3.5, CIS AWS Foundations Benchmark v3.0.0/3.3, NIST.800-53.r5 CM-3, NIST.800-53.r5 CM-6(1), NIST.800-53.r5 CM-8, NIST.800-53.r5 CM-8(2), PCI DSS v3.2.1/10.5.2, PCI DSS v3.2.1/11.5, CRI Profile v2.2/DE.CM-09.03, CRI Profile v2.2/PR.PS-01.01, CRI Profile v2.2/PR.PS-01.03

Category: Identify > Inventory

Severity: Critical

Resource type: `AWS::::Account`

AWS Config rule: None (custom Security Hub CSPM rule)

Schedule type: Periodic

Parameters:

Parameter	Description	Type	Allowed custom values	Security Hub CSPM default value
`includeConfigServiceLinkedRoleCheck`	The control doesn't evaluate whether AWS Config uses the service-linked role if the parameter is set to `false`.	Boolean	`true` or `false`	`true`

This control checks whether AWS Config is enabled in your account in the current AWS Region, records all resources that correspond to controls that are enabled in the current Region, and uses the service-linked AWS Config role. The name of the service-linked role is **AWSServiceRoleForConfig**. If you don't use the service-linked role and don't set the `includeConfigServiceLinkedRoleCheck` parameter to `false`, the control fails because other roles might not have the necessary permissions for AWS Config to accurately record your resources.

The AWS Config service performs configuration management of supported AWS resources in your account and delivers log files to you. The recorded information includes the configuration item (AWS resource), relationships between configuration items, and any configuration changes within resources. Global resources are resources that are available in any Region.

The control is evaluated as follows:

- If the current Region is set as your aggregation Region, the control produces PASSED findings only if AWS Identity and Access Management (IAM) global resources are recorded (if you have enabled controls that require them).
- If the current Region is set as a linked Region, the control doesn't evaluate whether IAM global resources are recorded.
- If the current Region isn't in your aggregator, or if cross-Region aggregation isn't set up in your account, the control produces PASSED findings only if IAM global resources are recorded (if you have enabled controls that require them).

Control results aren't impacted by whether you choose daily or continuous recording of changes in resource state in AWS Config. However, the results of this control can change when new controls are released if you have configured automatic enablement of new controls or have a central

configuration policy that automatically enables new controls. In these cases, if you don't record all resources, you must configure recording for resources that are associated with new controls in order to receive a PASSED finding.

Security Hub CSPM security checks work as intended only if you enable AWS Config in all Regions and configure resource recording for controls that require it.

Note

Config.1 requires that AWS Config is enabled in all Regions in which you use Security Hub CSPM.
Since Security Hub CSPM is a Regional service, the check performed for this control evaluates only the current Region for the account.
To allow security checks against IAM global resources in a Region, you must record IAM global resources in that Region. Regions that don't have IAM global resources recorded will receive a default PASSED finding for controls that check IAM global resources. Since IAM global resources are identical across AWS Regions, we recommend that you record IAM global resources in only the home Region (if cross-Region aggregation is enabled in your account). IAM resources will be recorded only in the Region in which global resource recording is turned on.
The IAM globally recorded resource types that AWS Config supports are IAM users, groups, roles, and customer managed policies. You can consider disabling Security Hub CSPM controls that check these resource types in Regions where global resource recording is turned off. For more information, see Suggested controls to disable in Security Hub CSPM.

Remediation

In the home Region and Regions that aren't part of an aggregator, record all resources that are required for controls that are enabled in the current Region, including IAM global resources if you have enabled controls that require IAM global resources.

In linked Regions, you can use any AWS Config recording mode, as long as you are recording all resources that correspond to controls that are enabled in the current Region. In linked Regions, if you have enabled controls that require recording of IAM global resources, you won't receive a FAILED finding (your recording of other resources is sufficient).

The `StatusReasons` field in the `Compliance` object of your finding can help you determine why you have a failed finding for this control. For more information, see Compliance details for control findings.

For a list of which resources must be recorded for each control, see Required AWS Config resources for control findings. For general information about enabling AWS Config and configuring resource recording, see Enabling and configuring AWS Config for Security Hub CSPM.

Security Hub CSPM controls for Amazon Connect

These Security Hub CSPM controls evaluate the Amazon Connect service and resources.

These controls may not be available in all AWS Regions. For more information, see Availability of controls by Region.

[Connect.1] Amazon Connect Customer Profiles object types should be tagged

Category: Identify > Inventory > Tagging

Severity: Low

Resource type: `AWS::CustomerProfiles::ObjectType`

AWS Config rule: `customerprofiles-object-type-tagged`

Schedule type: Change triggered

Parameters:

Parameter	Description	Type	Allowed custom values	Security Hub CSPM default value
`requiredKeyTags`	List of non-system tag keys that the evaluated resource must contain. Tag keys are case sensitive.	StringList (maximum of 6 items)	1–6 tag keys that meet AWS requirements.	No default value

This control checks whether an Amazon Connect Customer Profiles object type has tags with the specific keys defined in the parameter `requiredKeyTags`. The control fails if the object type doesn't have any tag keys or if it doesn't have all the keys specified in the parameter `requiredKeyTags`. If the parameter `requiredKeyTags` isn't provided, the control only checks for the existence of a tag key and fails if the object type isn't tagged with any key. System tags, which are automatically applied and begin with `aws:`, are ignored.

A tag is a label that you assign to an AWS resource, and it consists of a key and an optional value. You can create tags to categorize resources by purpose, owner, environment, or other criteria. Tags can help you identify, organize, search for, and filter resources. Tagging also helps you track accountable resource owners for actions and notifications. When you use tagging, you can implement attribute-based access control (ABAC) as an authorization strategy, which defines permissions based on tags. You can attach tags to IAM entities (users or roles) and to AWS resources. You can create a single ABAC policy or a separate set of policies for your IAM principals. You can design these ABAC policies to allow operations when the principal's tag matches the resource tag. For more information, see Define permissions based on attributes with ABAC authorization in the *IAM User Guide*.

> **Note**
>
> Don't add personally identifiable information (PII) or other confidential or sensitive information in tags. Tags are accessible to many AWS services, including AWS Billing. For more tagging best practices, see Best practices and strategies in the *Tagging AWS Resources and Tag Editor User Guide*.

Remediation

To add tags to a Customer Profiles object type, see Add tags to resources in Amazon Connect Customer in the *Connect Customer Administrator Guide*.

[Connect.2] Connect Customer instances should have CloudWatch logging enabled

Related requirements: CRI Profile v2.2/DE.AE-02.01, CRI Profile v2.2/DE.AE-03.01, CRI Profile v2.2/DE.AE-03.02, CRI Profile v2.2/DE.AE-07.02, CRI Profile v2.2/DE.CM-03.01, CRI Profile v2.2/DE.CM-03.02, CRI Profile v2.2/DE.CM-03.03, CRI Profile v2.2/PR.PS-04.02, CRI Profile v2.2/PR.PS-04.03, CRI Profile v2.2/RS.AN-07.01, CRI Profile v2.2/RS.MA-02.01

Category: Identify > Logging

Severity: Medium

Resource type: `AWS::Connect::Instance`

AWS Config rule: connect-instance-logging-enabled

Schedule type: Change triggered

Parameters: None

This control checks whether an Connect Customer instance is configured to generate and store flow logs in an Amazon CloudWatch log group. The control fails if the Connect Customer instance isn't configured to generate and store flow logs in a CloudWatch log group.

Amazon Connect Customer flow logs provide real-time details about events in Amazon Connect Customer flows. A *flow* defines the customer experience with an Amazon Connect Customer contact center from start to finish. By default, when you create a new Amazon Connect Customer instance, an Amazon CloudWatch log group is created automatically to store flow logs for the instance. Flow logs can help you analyze flows, find errors, and monitor operational metrics. You can also set up alerts for specific events that can occur in a flow.

Remediation

For information about enabling flow logs for an Amazon Connect Customer instance, see Enable Amazon Connect Customer flow logs in an Amazon CloudWatch log group in the *Connect Customer Administrator Guide*.

Security Hub CSPM controls for Amazon Data Firehose

These Security Hub CSPM controls evaluate the Amazon Data Firehose service and resources.

These controls may not be available in all AWS Regions. For more information, see Availability of controls by Region.

[DataFirehose.1] Firehose delivery streams should be encrypted at rest

Related requirements: NIST.800-53.r5 AC-3, NIST.800-53.r5 AU-3, NIST.800-53.r5 SC-12, NIST.800-53.r5 SC-13, NIST.800-53.r5 SC-28, CRI Profile v2.2/PR.DS-01.01, CRI Profile v2.2/PR.PS-01.06

Category: Protect > Data Protection > Encryption of data-at-rest

Severity: Medium

Resource type: `AWS::KinesisFirehose::DeliveryStream`

AWS Config rule: `kinesis-firehose-delivery-stream-encrypted`

Schedule type: Periodic

Parameters: None

This control checks whether an Amazon Data Firehose delivery stream is encrypted at rest with server-side encryption. This control fails if a Firehose delivery stream isn't encrypted at rest with server-side encryption.

Server-side encryption is a feature in Amazon Data Firehose delivery streams that automatically encrypts data before it's at rest by using a key created in AWS Key Management Service (AWS KMS). Data is encrypted before it's written to the Data Firehose stream storage layer, and decrypted after it’s retrieved from storage. This allows you to comply with regulatory requirements and enhance the security of your data.

Remediation

To enable server-side encryption on Firehose delivery streams,, see Data Protection in Amazon Data Firehose in the *Amazon Data Firehose Developer Guide*.

Security Hub CSPM controls for AWS Database Migration Service

These AWS Security Hub CSPM controls evaluate the AWS Database Migration Service (AWS DMS) and AWS DMS resources. The controls might not be available in all AWS Regions. For more information, see Availability of controls by Region.

[DMS.1] Database Migration Service replication instances should not be public

Related requirements: NIST.800-53.r5 AC-21, NIST.800-53.r5 AC-3, NIST.800-53.r5 AC-3(7), NIST.800-53.r5 AC-4, NIST.800-53.r5 AC-4(21), NIST.800-53.r5 AC-6, NIST.800-53.r5 SC-7, NIST.800-53.r5 SC-7(11), NIST.800-53.r5 SC-7(16), NIST.800-53.r5 SC-7(20), NIST.800-53.r5 SC-7(21), NIST.800-53.r5 SC-7(3), NIST.800-53.r5 SC-7(4), NIST.800-53.r5 SC-7(9), PCI DSS v3.2.1/1.2.1,PCI DSS v3.2.1/1.3.1,PCI DSS v3.2.1/1.3.4,PCI DSS v3.2.1/1.3.2,PCI DSS v3.2.1/1.3.6, PCI DSS v4.0.1/1.4.4, CRI Profile v2.2/PR.AA-03.02, CRI Profile v2.2/PR.AA-05.01, CRI Profile v2.2/PR.DS-01.01, CRI Profile v2.2/PR.IR-01.01, CRI Profile v2.2/PR.PS-01.01

Category: Protect > Secure network configuration

Severity: Critical

Resource type: `AWS::DMS::ReplicationInstance`

AWS Config rule: dms-replication-not-public

Schedule type: Periodic

Parameters: None

This control checks whether AWS DMS replication instances are public. To do this, it examines the value of the `PubliclyAccessible` field.

A private replication instance has a private IP address that you cannot access outside of the replication network. A replication instance should have a private IP address when the source and target databases are in the same network. The network must also be connected to the replication instance's VPC using a VPN, Direct Connect, or VPC peering. To learn more about public and private replication instances, see Public and private replication instances in the *AWS Database Migration Service User Guide*.

You should also ensure that access to your AWS DMS instance configuration is limited to only authorized users. To do this, restrict users' IAM permissions to modify AWS DMS settings and resources.

Remediation

You can't change the public access setting for a DMS replication instance after creating it. To change the public access setting, delete your current instance, and then recreate it. Don't select the **Publicly accessible** option.

[DMS.2] DMS certificates should be tagged

Category: Identify > Inventory > Tagging

Severity: Low

Resource type: `AWS::DMS::Certificate`

AWS Config rule: `tagged-dms-certificate` (custom Security Hub CSPM rule)

Schedule type: Change triggered

Parameters:

Parameter	Description	Type	Allowed custom values	Security Hub CSPM default value
`requiredTagKeys`	List of non-system tag keys that the evaluated resource must contain. Tag keys are case sensitive.	StringList (maximum of 6 items)	1–6 tag keys that meet AWS requirements.	`No default value`

This control checks whether an AWS DMS certificate has tags with the specific keys defined in the parameter `requiredTagKeys`. The control fails if the certificate doesn't have any tag keys or if it doesn't have all the keys specified in the parameter `requiredTagKeys`. If the parameter `requiredTagKeys` isn't provided, the control only checks for the existence of a tag key and fails if the certificate isn't tagged with any key. System tags, which are automatically applied and begin with `aws:`, are ignored.

A tag is a label that you assign to an AWS resource, and it consists of a key and an optional value. You can create tags to categorize resources by purpose, owner, environment, or other criteria. Tags can help you identify, organize, search for, and filter resources. Tagging also helps you track accountable resource owners for actions and notifications. When you use tagging, you can implement attribute-based access control (ABAC) as an authorization strategy, which defines permissions based on tags. You can attach tags to IAM entities (users or roles) and to AWS resources. You can create a single ABAC policy or a separate set of policies for your IAM principals. You can design these ABAC policies to allow operations when the principal's tag matches the resource tag. For more information, see What is ABAC for AWS? in the *IAM User Guide*.

> **Note**
>
> Don't add personally identifiable information (PII) or other confidential or sensitive information in tags. Tags are accessible to many AWS services, including AWS Billing. For more tagging best practices, see Tagging your AWS resources in the *AWS General Reference*.

Remediation

To add tags to a DMS certificate, see Tagging resources in AWS Database Migration Service in the *AWS Database Migration Service User Guide*.

[DMS.3] DMS event subscriptions should be tagged

Category: Identify > Inventory > Tagging

Severity: Low

Resource type: `AWS::DMS::EventSubscription`

AWS Config rule: `tagged-dms-eventsubscription` (custom Security Hub CSPM rule)

Schedule type: Change triggered

Parameters:

Parameter	Description	Type	Allowed custom values	Security Hub CSPM default value
`requiredTagKeys`	List of non-system tag keys that the evaluated resource must contain. Tag keys are case sensitive.	StringList (maximum of 6 items)	1–6 tag keys that meet AWS requirements.	`No default value`

This control checks whether an AWS DMS event subscription has tags with the specific keys defined in the parameter `requiredTagKeys`. The control fails if the event subscription doesn't have any tag keys or if it doesn't have all the keys specified in the parameter `requiredTagKeys`. If the parameter `requiredTagKeys` isn't provided, the control only checks for the existence of a tag key and fails if the event subscription isn't tagged with any key. System tags, which are automatically applied and begin with `aws:`, are ignored.

A tag is a label that you assign to an AWS resource, and it consists of a key and an optional value. You can create tags to categorize resources by purpose, owner, environment, or other criteria. Tags can help you identify, organize, search for, and filter resources. Tagging also helps

you track accountable resource owners for actions and notifications. When you use tagging, you can implement attribute-based access control (ABAC) as an authorization strategy, which defines permissions based on tags. You can attach tags to IAM entities (users or roles) and to AWS resources. You can create a single ABAC policy or a separate set of policies for your IAM principals. You can design these ABAC policies to allow operations when the principal's tag matches the resource tag. For more information, see What is ABAC for AWS? in the *IAM User Guide*.

> **Note**
>
> Don't add personally identifiable information (PII) or other confidential or sensitive information in tags. Tags are accessible to many AWS services, including AWS Billing. For more tagging best practices, see Tagging your AWS resources in the *AWS General Reference*.

Remediation

To add tags to a DMS event subscription, see Tagging resources in AWS Database Migration Service in the *AWS Database Migration Service User Guide*.

[DMS.4] DMS replication instances should be tagged

Category: Identify > Inventory > Tagging

Severity: Low

Resource type: `AWS::DMS::ReplicationInstance`

AWS Config rule: `tagged-dms-replicationinstance` (custom Security Hub CSPM rule)

Schedule type: Change triggered

Parameters:

Parameter	Description	Type	Allowed custom values	Security Hub CSPM default value
`requiredTagKeys`	List of non-system tag keys that the evaluated resource	StringList (maximum of 6 items)	1–6 tag keys that meet AWS	`No default value`

Parameter	Description	Type	Allowed custom values	Security Hub CSPM default value
	must contain. Tag keys are case sensitive.		requirements.	

This control checks whether an AWS DMS replication instance has tags with the specific keys defined in the parameter `requiredTagKeys`. The control fails if the replication instance doesn't have any tag keys or if it doesn't have all the keys specified in the parameter `requiredTagKeys`. If the parameter `requiredTagKeys` isn't provided, the control only checks for the existence of a tag key and fails if the replication instance isn't tagged with any key. System tags, which are automatically applied and begin with `aws:`, are ignored.

A tag is a label that you assign to an AWS resource, and it consists of a key and an optional value. You can create tags to categorize resources by purpose, owner, environment, or other criteria. Tags can help you identify, organize, search for, and filter resources. Tagging also helps you track accountable resource owners for actions and notifications. When you use tagging, you can implement attribute-based access control (ABAC) as an authorization strategy, which defines permissions based on tags. You can attach tags to IAM entities (users or roles) and to AWS resources. You can create a single ABAC policy or a separate set of policies for your IAM principals. You can design these ABAC policies to allow operations when the principal's tag matches the resource tag. For more information, see What is ABAC for AWS? in the *IAM User Guide*.

Note

Don't add personally identifiable information (PII) or other confidential or sensitive information in tags. Tags are accessible to many AWS services, including AWS Billing. For more tagging best practices, see Tagging your AWS resources in the *AWS General Reference*.

Remediation

To add tags to a DMS replication instance, see Tagging resources in AWS Database Migration Service in the *AWS Database Migration Service User Guide*.

[DMS.5] DMS replication subnet groups should be tagged

Category: Identify > Inventory > Tagging

Severity: Low

Resource type: `AWS::DMS::ReplicationSubnetGroup`

AWS Config rule: `tagged-dms-replicationsubnetgroup` (custom Security Hub CSPM rule)

Schedule type: Change triggered

Parameters:

Parameter	Description	Type	Allowed custom values	Security Hub CSPM default value
`requiredTagKeys`	List of non-system tag keys that the evaluated resource must contain. Tag keys are case sensitive.	StringList (maximum of 6 items)	1–6 tag keys that meet AWS requirements.	`No default value`

This control checks whether an AWS DMS replication subnet group has tags with the specific keys defined in the parameter `requiredTagKeys`. The control fails if the replication subnet group doesn't have any tag keys or if it doesn't have all the keys specified in the parameter `requiredTagKeys`. If the parameter `requiredTagKeys` isn't provided, the control only checks for the existence of a tag key and fails if the replication subnet group isn't tagged with any key. System tags, which are automatically applied and begin with `aws:`, are ignored.

A tag is a label that you assign to an AWS resource, and it consists of a key and an optional value. You can create tags to categorize resources by purpose, owner, environment, or other criteria. Tags can help you identify, organize, search for, and filter resources. Tagging also helps you track accountable resource owners for actions and notifications. When you use tagging, you can implement attribute-based access control (ABAC) as an authorization strategy, which defines permissions based on tags. You can attach tags to IAM entities (users or roles) and to AWS

resources. You can create a single ABAC policy or a separate set of policies for your IAM principals. You can design these ABAC policies to allow operations when the principal's tag matches the resource tag. For more information, see What is ABAC for AWS? in the *IAM User Guide*.

> **Note**
>
> Don't add personally identifiable information (PII) or other confidential or sensitive information in tags. Tags are accessible to many AWS services, including AWS Billing. For more tagging best practices, see Tagging your AWS resources in the *AWS General Reference*.

Remediation

To add tags to a DMS replication subnet group, see Tagging resources in AWS Database Migration Service in the *AWS Database Migration Service User Guide*.

[DMS.6] DMS replication instances should have automatic minor version upgrade enabled

Related requirements: NIST.800-53.r5 SI-2, NIST.800-53.r5 SI-2(2), NIST.800-53.r5 SI-2(4), NIST.800-53.r5 SI-2(5), PCI DSS v4.0.1/6.3.3, CRI Profile v2.2/ID.RA-01.03, CRI Profile v2.2/PR.PS-02.01

Category: Identify > Vulnerability, patch, and version management

Severity: Medium

Resource type: `AWS::DMS::ReplicationInstance`

AWS Config rule: dms-auto-minor-version-upgrade-check

Schedule type: Change triggered

Parameters: None

This control checks if automatic minor version upgrade is enabled for an AWS DMS replication instance. The control fails if automatic minor version upgrade isn't enabled for a DMS replication instance.

DMS provides automatic minor version upgrade to each supported replication engine so that you can keep your replication instance up-to-date. Minor versions can introduce new software

features, bug fixes, security patches, and performance improvements. By enabling automatic minor version upgrade on DMS replication instances, minor upgrades are applied automatically during the maintenance window or immediately if the **Apply changes immediately option is chosen**.

Remediation

To enable automatic minor version upgrade on DMS replication instances, see Modifying a replication instance in the *AWS Database Migration Service User Guide*.

[DMS.7] DMS replication tasks for the target database should have logging enabled

Related requirements: NIST.800-53.r5 AC-2(4), NIST.800-53.r5 AC-4(26), NIST.800-53.r5 AC-6(9), NIST.800-53.r5 AU-10, NIST.800-53.r5 AU-12, NIST.800-53.r5 AU-2, NIST.800-53.r5 AU-3, NIST.800-53.r5 AU-6(3), NIST.800-53.r5 AU-6(4), NIST.800-53.r5 CA-7, NIST.800-53.r5 SC-7(9), NIST.800-53.r5 SI-3(8), NIST.800-53.r5 SI-4(20), NIST.800-53.r5 SI-7(8), PCI DSS v4.0.1/10.4.2, CRI Profile v2.2/PR.PS-04.02, CRI Profile v2.2/PR.PS-04.03

Category: Identify > Logging

Severity: Medium

Resource type: `AWS::DMS::ReplicationTask`

AWS Config rule: dms-replication-task-targetdb-logging

Schedule type: Change triggered

Parameters: None

This control checks whether logging is enabled with the minimum severity level of `LOGGER_SEVERITY_DEFAULT` for DMS replication tasks `TARGET_APPLY` and `TARGET_LOAD`. The control fails if logging isn't enabled for these tasks or if the minimum severity level is less than `LOGGER_SEVERITY_DEFAULT`.

DMS uses Amazon CloudWatch to log information during the migration process. Using logging task settings, you can specify which component activities are logged and how much information is logged. You should specify logging for the following tasks:

- `TARGET_APPLY` – Data and data definition language (DDL) statements are applied to the target database.
- `TARGET_LOAD` – Data is loaded into the target database.

Logging plays a critical role in DMS replication tasks by enabling monitoring, troubleshooting, auditing, performance analysis, error detection, and recovery, as well as historical analysis and reporting. It helps ensure the successful replication of data between databases while maintaining data integrity and compliance with regulatory requirements. Logging levels other than `DEFAULT` are rarely needed for these components during troubleshooting. We recommend keeping the logging level as `DEFAULT` for these components unless specifically requested to change it by Support. A minimal logging level of `DEFAULT` ensures that informational messages, warnings, and error messages are written to the logs. This control checks if the logging level is at least one of the following for the preceding replication tasks: `LOGGER_SEVERITY_DEFAULT`, `LOGGER_SEVERITY_DEBUG`, or `LOGGER_SEVERITY_DETAILED_DEBUG`.

Remediation

To enable logging for target database DMS replication tasks, see Viewing and managing AWS DMS task logs in the *AWS Database Migration Service User Guide*.

[DMS.8] DMS replication tasks for the source database should have logging enabled

Related requirements: NIST.800-53.r5 AC-2(4), NIST.800-53.r5 AC-4(26), NIST.800-53.r5 AC-6(9), NIST.800-53.r5 AU-10, NIST.800-53.r5 AU-12, NIST.800-53.r5 AU-2, NIST.800-53.r5 AU-3, NIST.800-53.r5 AU-6(3), NIST.800-53.r5 AU-6(4), NIST.800-53.r5 CA-7, NIST.800-53.r5 SC-7(9), NIST.800-53.r5 SI-3(8), NIST.800-53.r5 SI-4(20), NIST.800-53.r5 SI-7(8), PCI DSS v4.0.1/10.4.2, CRI Profile v2.2/DE.AE-03.01, CRI Profile v2.2/PR.PS-04.02, CRI Profile v2.2/PR.PS-04.03

Category: Identify > Logging

Severity: Medium

Resource type: `AWS::DMS::ReplicationTask`

AWS Config rule: dms-replication-task-sourcedb-logging

Schedule type: Change triggered

Parameters: None

This control checks whether logging is enabled with the minimum severity level of `LOGGER_SEVERITY_DEFAULT` for DMS replication tasks `SOURCE_CAPTURE` and `SOURCE_UNLOAD`. The control fails if logging isn't enabled for these tasks or if the minimum severity level is less than `LOGGER_SEVERITY_DEFAULT`.

DMS uses Amazon CloudWatch to log information during the migration process. Using logging task settings, you can specify which component activities are logged and how much information is logged. You should specify logging for the following tasks:

- SOURCE_CAPTURE – Ongoing replication or change data capture (CDC) data is captured from the source database or service, and passed to the SORTER service component.
- SOURCE_UNLOAD – Data is unloaded from the source database or service during full load.

Logging plays a critical role in DMS replication tasks by enabling monitoring, troubleshooting, auditing, performance analysis, error detection, and recovery, as well as historical analysis and reporting. It helps ensure the successful replication of data between databases while maintaining data integrity and compliance with regulatory requirements. Logging levels other than DEFAULT are rarely needed for these components during troubleshooting. We recommend keeping the logging level as DEFAULT for these components unless specifically requested to change it by Support. A minimal logging level of DEFAULT ensures that informational messages, warnings, and error messages are written to the logs. This control checks if the logging level is at least one of the following for the preceding replication tasks: LOGGER_SEVERITY_DEFAULT, LOGGER_SEVERITY_DEBUG, or LOGGER_SEVERITY_DETAILED_DEBUG.

Remediation

To enable logging for source database DMS replication tasks, see Viewing and managing AWS DMS task logs in the *AWS Database Migration Service User Guide*.

[DMS.9] DMS endpoints should use SSL

Related requirements: NIST.800-53.r5 AC-4, NIST.800-53.r5 SC-13, NIST.800-53.r5 SC-23, NIST.800-53.r5 SC-23(3), NIST.800-53.r5 SC-7(4), NIST.800-53.r5 SC-8, NIST.800-53.r5 SC-8(1), NIST.800-53.r5 SC-8(2), PCI DSS v4.0.1/4.2.1, CRI Profile v2.2/PR.DS-02.01, CRI Profile v2.2/PR.PS-01.06

Category: Protect > Data Protection > Encryption of data-in-transit

Severity: Medium

Resource type: AWS::DMS::Endpoint

AWS Config rule: dms-endpoint-ssl-configured

Schedule type: Change triggered

Parameters: None

This control checks whether an AWS DMS endpoint uses an SSL connection. The control fails if the endpoint doesn't use SSL.

SSL/TLS connections provide a layer of security by encrypting connections between DMS replication instances and your database. Using certificates provides an extra layer of security by validating that the connection is being made to the expected database. It does so by checking the server certificate that is automatically installed on all database instances that you provision. By enabling SSL connection on your DMS endpoints, you protect the confidentiality of the data during the migration.

Remediation

To add an SSL connection to a new or existing DMS endpoint, see Using SSL with AWS Database Migration Service in the *AWS Database Migration Service User Guide*.

[DMS.10] DMS endpoints for Neptune databases should have IAM authorization enabled

Related requirements: NIST.800-53.r5 AC-2, NIST.800-53.r5 AC-3, NIST.800-53.r5 AC-6, NIST.800-53.r5 AC-17, NIST.800-53.r5 IA-2, NIST.800-53.r5 IA-5, PCI DSS v4.0.1/7.3.1, CRI Profile v2.2/PR.AA-02.01, CRI Profile v2.2/PR.AA-03.01, CRI Profile v2.2/PR.AA-03.02, CRI Profile v2.2/PR.AA-05.01, CRI Profile v2.2/PR.DS-01.01, CRI Profile v2.2/PR.PS-01.02

Category: Protect > Secure access management > Passwordless authentication

Severity: Medium

Resource type: `AWS::DMS::Endpoint`

AWS Config rule: dms-neptune-iam-authorization-enabled

Schedule type: Change triggered

Parameters: None

This control checks whether an AWS DMS endpoint for an Amazon Neptune database is configured with IAM authorization. The control fails if the DMS endpoint doesn't have IAM authorization enabled.

AWS Identity and Access Management (IAM) provides fine-grained access control across AWS. With IAM, you can specify who can access which services and resources, and under which conditions. With IAM policies, you manage permissions to your workforce and systems to ensure least-privilege

permissions. By enabling IAM authorization on AWS DMS endpoints for Neptune databases, you can grant authorization privileges to IAM users by using a service role specified by the `ServiceAccessRoleARN` parameter.

Remediation

To enable IAM authorization on DMS endpoints for Neptune databases, see Using Amazon Neptune as a target for AWS Database Migration Service in the *AWS Database Migration Service User Guide*.

[DMS.11] DMS endpoints for MongoDB should have an authentication mechanism enabled

Related requirements: NIST.800-53.r5 AC-3, NIST.800-53.r5 AC-6, NIST.800-53.r5 IA-2, NIST.800-53.r5 IA-5, PCI DSS v4.0.1/7.3.1, CRI Profile v2.2/PR.AA-02.01, CRI Profile v2.2/PR.AA-03.01, CRI Profile v2.2/PR.AA-04.01, CRI Profile v2.2/PR.DS-01.01

Category: Protect > Secure access management > Passwordless authentication

Severity: Medium

Resource type: `AWS::DMS::Endpoint`

AWS Config rule: dms-mongo-db-authentication-enabled

Schedule type: Change triggered

Parameters: None

This control checks whether an AWS DMS endpoint for MongoDB is configured with an authentication mechanism. The control fails if an authentication type isn't set for the endpoint.

AWS Database Migration Service supports two authentications methods for MongoDB —**MONGODB-CR** for MongoDB version 2.x, and **SCRAM-SHA-1** for MongoDB version 3.x or later. These authentication methods are used to authenticate and encrypt MongoDB passwords if users want to use the passwords to access the databases. Authentication on AWS DMS endpoints ensures that only authorized users can access and modify the data being migrated between databases. Without proper authentication, unauthorized users may be able to gain access to sensitive data during the migration process. This can result in data breaches, data loss, or other security incidents.

Remediation

To enable an authentication mechanism on DMS endpoints for MongoDB, see Using MongoDB as a source for AWS DMS in the *AWS Database Migration Service User Guide*.

[DMS.12] DMS endpoints for Redis OSS should have TLS enabled

Related requirements: NIST.800-53.r5 SC-8, NIST.800-53.r5 SC-13, PCI DSS v4.0.1/4.2.1, CRI Profile v2.2/PR.DS-02.01, CRI Profile v2.2/PR.PS-01.06

Category: Protect > Data Protection > Encryption of data-in-transit

Severity: Medium

Resource type: `AWS::DMS::Endpoint`

AWS Config rule: dms-redis-tls-enabled

Schedule type: Change triggered

Parameters: None

This control checks whether an AWS DMS endpoint for Redis OSS is configured with a TLS connection. The control fails if the endpoint doesn't have TLS enabled.

TLS provides end-to-end security when data is sent between applications or databases over the internet. When you configure SSL encryption for your DMS endpoint, it enables encrypted communication between the source and target databases during the migration process. This helps prevent eavesdropping and interception of sensitive data by malicious actors. Without SSL encryption, sensitive data may be accessed, resulting in data breaches, data loss, or other security incidents.

Remediation

To enable a TLS connection on DMS endpoints for Redis, see Using Redis as a target for AWS Database Migration Service in the *AWS Database Migration Service User Guide*.

[DMS.13] DMS replication instances should be configured to use multiple Availability Zones

Category: Recover > Resilience > High availability

Severity: Medium

Resource type: `AWS::DMS::ReplicationInstance`

AWS Config rule: dms-replication-instance-multi-az-enabled

Schedule type: Change triggered

Parameters: None

This control checks whether an AWS Database Migration Service (AWS DMS) replication instance is configured to use multiple Availability Zones (Multi-AZ deployment). The control fails if the AWS DMS replication instance isn't configured to use a Multi-AZ deployment.

In a Multi-AZ deployment, AWS DMS automatically provisions and maintains a standby replica of a replication instance in a different Availability Zone (AZ). The primary replication instance is then synchronously replicated to the standby replica. If the primary replication instance fails or becomes unresponsive, the standby resumes any running tasks with minimal interruption. For more information, see Working with a replication instance in the *AWS Database Migration Service User Guide*.

Remediation

After you create an AWS DMS replication instance, you can change the Multi-AZ deployment setting for it. For information about changing this and other settings for an existing replication instance, see Modifying a replication instance in the *AWS Database Migration Service User Guide*.

Security Hub CSPM controls for AWS DataSync

These Security Hub CSPM controls evaluate the AWS DataSync service and resources. The controls might not be available in all AWS Regions. For more information, see Availability of controls by Region.

[DataSync.1] DataSync tasks should have logging enabled

Related requirements: CRI Profile v2.2/DE.AE-02.01, CRI Profile v2.2/DE.AE-03.01, CRI Profile v2.2/DE.AE-03.02, CRI Profile v2.2/DE.AE-07.02, CRI Profile v2.2/PR.PS-04.02, CRI Profile v2.2/PR.PS-04.03

Category: Identify > Logging

Severity: Medium

Resource type: `AWS::DataSync::Task`

AWS Config rule: datasync-task-logging-enabled

Schedule type: Change triggered

Parameters: None

This control checks whether an AWS DataSync task has logging enabled. The control fails if the task doesn't have logging enabled.

Audit logs track and monitor system activities. They provide a record of events that can help you detect security breaches, investigate incidents, and comply with regulations. Audit logs also enhance the overall accountability and transparency of your organization.

Remediation

For information about configuring logging for AWS DataSync tasks, see Monitoring data transfers with Amazon CloudWatch Logs in the *AWS DataSync User Guide*.

[DataSync.2] DataSync tasks should be tagged

Related requirements: CRI Profile v2.2/ID.AM-02.01, CRI Profile v2.2/ID.AM-05.01

Category: Identify > Inventory > Tagging

Severity: Low

Resource type: `AWS::DataSync::Task`

AWS Config rule: datasync-task-tagged

Schedule type: Change triggered

Parameters:

Parameter	Description	Type	Allowed custom values	Security Hub CSPM default value
`requiredKeyTags`	A list of non-system tag keys that must be assigned to an evaluated resource. Tag keys are case sensitive.	StringList (maximum of 6 items)	1–6 tag keys that meet AWS requirements.	No default value

This control checks whether an AWS DataSync task has the tag keys specified by the `requiredKeyTags` parameter. The control fails if the task doesn't have any tag keys, or it doesn't

have all the keys specified by the `requiredKeyTags` parameter. If you don't specify any values for the `requiredKeyTags` parameter, the control checks only for the existence of a tag key and fails if the task doesn't have any tag keys. The control ignores system tags, which are applied automatically and have the `aws:` prefix.

A tag is a label that you create and assign to an AWS resource. Each tag consists of a required tag key and an optional tag value. You can use tags to categorize resources by purpose, owner, environment, or other criteria. They can help you identify, organize, search for, and filter resources. They can also help you track resource owners for actions and notifications. You can also use tags to implement attribute-based access control (ABAC) as an authorization strategy. For more information about ABAC strategies, see Define permissions based on attributes with ABAC authorization in the *IAM User Guide*. For more information about tags, see the Tagging AWS Resources and Tag Editor User Guide.

> **Note**
>
> Do not store personally identifiable information (PII) or other confidential or sensitive information in tags. Tags are accessible from many AWS services. They aren't intended to be used for private or sensitive data.

Remediation

For information about adding tags to an AWS DataSync task, see Tagging your AWS DataSync tasks in the *AWS DataSync User Guide*.

Security Hub CSPM controls for Amazon Detective

This AWS Security Hub CSPM control evaluates the Amazon Detective service and resources. The control might not be available in all AWS Regions. For more information, see Availability of controls by Region.

[Detective.1] Detective behavior graphs should be tagged

Category: Identify > Inventory > Tagging

Severity: Low

Resource type: `AWS::Detective::Graph`

AWS Config rule: `tagged-detective-graph` (custom Security Hub CSPM rule)

Schedule type: Change triggered

Parameters:

Parameter	Description	Type	Allowed custom values	Security Hub CSPM default value
`requiredTagKeys`	List of non-system tag keys that the evaluated resource must contain. Tag keys are case sensitive.	StringList (maximum of 6 items)	1–6 tag keys that meet AWS requirements.	`No default value`

This control checks whether an Amazon Detective behavior graph has tags with the specific keys defined in the parameter `requiredTagKeys`. The control fails if the behavior graph doesn't have any tag keys or if it doesn't have all the keys specified in the parameter `requiredTagKeys`. If the parameter `requiredTagKeys` isn't provided, the control only checks for the existence of a tag key and fails if the behavior graph isn't tagged with any key. System tags, which are automatically applied and begin with `aws:`, are ignored.

A tag is a label that you assign to an AWS resource, and it consists of a key and an optional value. You can create tags to categorize resources by purpose, owner, environment, or other criteria. Tags can help you identify, organize, search for, and filter resources. Tagging also helps you track accountable resource owners for actions and notifications. When you use tagging, you can implement attribute-based access control (ABAC) as an authorization strategy, which defines permissions based on tags. You can attach tags to IAM entities (users or roles) and to AWS resources. You can create a single ABAC policy or a separate set of policies for your IAM principals. You can design these ABAC policies to allow operations when the principal's tag matches the resource tag. For more information, see What is ABAC for AWS? in the *IAM User Guide*.

> **Note**
>
> Don't add personally identifiable information (PII) or other confidential or sensitive information in tags. Tags are accessible to many AWS services, including AWS Billing. For more tagging best practices, see Tagging your AWS resources in the *AWS General Reference*.

Remediation

To add tags to a Detective behavior graph, see Adding tags to a behavior graph in the *Amazon Detective Administration Guide*.

Security Hub CSPM controls for Amazon DocumentDB

These AWS Security Hub CSPM controls evaluate the Amazon DocumentDB (with MongoDB compatibility) service and resources. The controls might not be available in all AWS Regions. For more information, see Availability of controls by Region.

[DocumentDB.1] Amazon DocumentDB clusters should be encrypted at rest

Related requirements: NIST.800-53.r5 CA-9(1), NIST.800-53.r5 CM-3(6), NIST.800-53.r5 SC-13, NIST.800-53.r5 SC-28, NIST.800-53.r5 SC-28(1), NIST.800-53.r5 SC-7(10), NIST.800-53.r5 SI-7(6), CRI Profile v2.2/PR.DS-01.01, CRI Profile v2.2/PR.PS-01.06

Category: Protect > Data Protection > Encryption of data-at-rest

Severity: Medium

Resource type: `AWS::RDS::DBCluster`

AWS Config rule: docdb-cluster-encrypted

Schedule type: Change triggered

Parameters: None

This control checks whether an Amazon DocumentDB cluster is encrypted at rest. The control fails if an Amazon DocumentDB cluster isn't encrypted at rest.

Data at rest refers to any data that's stored in persistent, non-volatile storage for any duration. Encryption helps you protect the confidentiality of such data, reducing the risk that an unauthorized user gets access to it. Data in Amazon DocumentDB clusters should be encrypted at rest for an added layer of security. Amazon DocumentDB uses the 256-bit Advanced Encryption Standard (AES-256) to encrypt your data using encryption keys stored in AWS Key Management Service (AWS KMS).

Remediation

You can enable encryption at rest when you create an Amazon DocumentDB cluster. You can't change encryption settings after creating a cluster. For more information, see Enabling encryption at rest for an Amazon DocumentDB cluster in the *Amazon DocumentDB Developer Guide*.

[DocumentDB.2] Amazon DocumentDB clusters should have an adequate backup retention period

Related requirements: NIST.800-53.r5 SI-12, PCI DSS v4.0.1/3.2.1, CRI Profile v2.2/PR.DS-11.01

Category: Recover > Resilience > Backups enabled

Severity: Medium

Resource type: `AWS::RDS::DBCluster`

AWS Config rule: docdb-cluster-backup-retention-check

Schedule type: Change triggered

Parameters:

Parameter	Description	Type	Allowed custom values	Security Hub CSPM default value	
`minimumBackupRetentionPeriod`	Minimum backup retention period in days	Integer	7 to 35	7	

This control checks whether an Amazon DocumentDB cluster has a backup retention period greater than or equal to the specified time frame. The control fails if the backup retention period is less than the specified time frame. Unless you provide a custom parameter value for the backup retention period, Security Hub CSPM uses a default value of 7 days.

Backups help you recover more quickly from a security incident and strengthen the resilience of your systems. By automating backups for your Amazon DocumentDB clusters, you'll be able

to restore your systems to a point in time and minimize downtime and data loss. In Amazon DocumentDB, clusters have a default backup retention period of 1 day. This must be increased to a value between 7 and 35 days to pass this control.

Remediation

To change the backup retention period for your Amazon DocumentDB clusters, see Modifying an Amazon DocumentDB cluster in the *Amazon DocumentDB Developer Guide*. For **Backup**, choose the backup retention period.

[DocumentDB.3] Amazon DocumentDB manual cluster snapshots should not be public

Related requirements: NIST.800-53.r5 AC-21, NIST.800-53.r5 AC-3, NIST.800-53.r5 AC-3(7), NIST.800-53.r5 AC-4, NIST.800-53.r5 AC-4(21), NIST.800-53.r5 AC-6, NIST.800-53.r5 SC-7, NIST.800-53.r5 SC-7(11), NIST.800-53.r5 SC-7(16), NIST.800-53.r5 SC-7(20), NIST.800-53.r5 SC-7(21), NIST.800-53.r5 SC-7(3), NIST.800-53.r5 SC-7(4), NIST.800-53.r5 SC-7(9), PCI DSS v4.0.1/1.4.4, CRI Profile v2.2/PR.AA-05.01, CRI Profile v2.2/PR.DS-01.01

Category: Protect > Secure network configuration

Severity: Critical

Resource type: `AWS::RDS::DBClusterSnapshot`

AWS Config rule: docdb-cluster-snapshot-public-prohibited

Schedule type: Change triggered

Parameters: None

This control checks whether an Amazon DocumentDB manual cluster snapshot is public. The control fails if the manual cluster snapshot is public.

An Amazon DocumentDB manual cluster snapshot should not be public unless intended. If you share an unencrypted manual snapshot as public, the snapshot is available to all AWS accounts. Public snapshots may result in unintended data exposure.

> **Note**
>
> This control evaluates manual cluster snapshots. You can't share an Amazon DocumentDB automated cluster snapshot. However, you can create a manual snapshot by copying the automated snapshot, and then share the copy.

Remediation

To remove public access for Amazon DocumentDB manual cluster snapshots, see Sharing a snapshot in the *Amazon DocumentDB Developer Guide*. Programmatically, you can use the Amazon DocumentDB operation `modify-db-snapshot-attribute`. Set `attribute-name` as `restore` and `values-to-remove` as `all`.

[DocumentDB.4] Amazon DocumentDB clusters should publish audit logs to CloudWatch Logs

Related requirements: NIST.800-53.r5 AC-2(4), NIST.800-53.r5 AC-4(26), NIST.800-53.r5 AC-6(9), NIST.800-53.r5 AU-10, NIST.800-53.r5 AU-12, NIST.800-53.r5 AU-2, NIST.800-53.r5 AU-3, NIST.800-53.r5 AU-6(3), NIST.800-53.r5 AU-6(4), NIST.800-53.r5 CA-7, NIST.800-53.r5 SC-7(9), NIST.800-53.r5 SI-3(8), NIST.800-53.r5 SI-4(20), NIST.800-53.r5 SI-7(8), PCI DSS v4.0.1/10.3.3, CRI Profile v2.2/DE.AE-03.02, CRI Profile v2.2/PR.PS-04.01, CRI Profile v2.2/PR.PS-04.02, CRI Profile v2.2/PR.PS-04.03

Category: Identify > Logging

Severity: Medium

Resource type: `AWS::RDS::DBCluster`

AWS Config rule: docdb-cluster-audit-logging-enabled

Schedule type: Change triggered

Parameters: None

This control checks whether an Amazon DocumentDB cluster publishes audit logs to Amazon CloudWatch Logs. The control fails if the cluster doesn't publish audit logs to CloudWatch Logs.

Amazon DocumentDB (with MongoDB compatibility) allows you to audit events that were performed in your cluster. Examples of logged events include successful and failed authentication attempts, dropping a collection in a database, or creating an index. By default, auditing is disabled in Amazon DocumentDB and requires that you take action to enable it.

Remediation

To publish Amazon DocumentDB audit logs to CloudWatch Logs, see Enabling auditing in the *Amazon DocumentDB Developer Guide*.

[DocumentDB.5] Amazon DocumentDB clusters should have deletion protection enabled

Related requirements: NIST.800-53.r5 CA-9(1), NIST.800-53.r5 CM-2, NIST.800-53.r5 CM-2(2), NIST.800-53.r5 CM-3, NIST.800-53.r5 SC-5(2), CRI Profile v2.2/PR.DS-01.01, CRI Profile v2.2/PR.IR-03.01, CRI Profile v2.2/PR.PS-01.01, CRI Profile v2.2/PR.PS-01.03

Category: Protect > Data protection > Data deletion protection

Severity: Medium

Resource type: `AWS::RDS::DBCluster`

AWS Config rule: docdb-cluster-deletion-protection-enabled

Schedule type: Change triggered

Parameters: None

This control checks whether an Amazon DocumentDB cluster has deletion protection enabled. The control fails if the cluster doesn't have deletion protection enabled.

Enabling cluster deletion protection offers an additional layer of protection against accidental database deletion or deletion by an unauthorized user. An Amazon DocumentDB cluster can't be deleted while deletion protection is enabled. You must first disable deletion protection before a delete request can succeed. Deletion protection is enabled by default when you create a cluster in the Amazon DocumentDB console.

Remediation

To enable deletion protection for an existing Amazon DocumentDB cluster, see Modifying an Amazon DocumentDB cluster in the *Amazon DocumentDB Developer Guide*. In the **Modify Cluster** section, choose **Enable** for **Deletion protection**.

[DocumentDB.6] Amazon DocumentDB clusters should be encrypted in transit

Related requirements: CRI Profile v2.2/PR.DS-02.01, CRI Profile v2.2/PR.PS-01.06

Category: Protect > Data Protection > Encryption of data-in-transit

Severity: Medium

Resource type: `AWS::RDS::DBCluster`

AWS Config rule: docdb-cluster-encrypted-in-transit

Schedule type: Periodic

Parameters: `excludeTlsParameters`: `disabled`, `enabled` (not customizable)

This controls checks whether an Amazon DocumentDB cluster requires TLS for connections to the cluster. The control fails if the cluster parameter group associated with the cluster is not in sync, or the TLS cluster parameter is set to `disabled` or `enabled`.

You can use TLS to encrypt the connection between an application and an Amazon DocumentDB cluster. Use of TLS can help protect data from being intercepted while the data is in transit between an application and an Amazon DocumentDB cluster. Encryption in transit for an Amazon DocumentDB cluster is managed using the TLS parameter in the cluster parameter group that's associated with the cluster. When encryption in transit is enabled, secure connections using TLS are required to connect to the cluster. We recommend using the following TLS parameters: `tls1.2+`, `tls1.3+`, and `fips-140-3`.

Remediation

For information about changing the TLS settings for an Amazon DocumentDB cluster, see Encrypting data in transit in the *Amazon DocumentDB Developer Guide*.

Security Hub CSPM controls for DynamoDB

These AWS Security Hub CSPM controls evaluate the Amazon DynamoDB service and resources. The controls might not be available in all AWS Regions. For more information, see Availability of controls by Region.

[DynamoDB.1] DynamoDB tables should automatically scale capacity with demand

Related requirements: NIST.800-53.r5 CP-10, NIST.800-53.r5 CP-2(2), NIST.800-53.r5 CP-6(2), NIST.800-53.r5 SC-36, NIST.800-53.r5 SC-5(2), NIST.800-53.r5 SI-13(5), CRI Profile v2.2/PR.IR-03.01, CRI Profile v2.2/PR.IR-04.02

Category: Recover > Resilience > High availability

Severity: Medium

Resource type: `AWS::DynamoDB::Table`

AWS Config rule: `dynamodb-autoscaling-enabled`

Schedule type: Periodic

Parameters:

Parameter	Description	Type	Valid custom values	Security Hub CSPM default value
`minProvisionedReadCapacity`	Minimum number of provisioned read capacity units for DynamoDB auto scaling	Integer	`1` to `40000`	No default value
`targetReadUtilization`	Target utilization percentage for read capacity	Integer	`20` to `90`	No default value
`minProvisionedWriteCapacity`	Minimum number of provisioned write capacity units for DynamoDB auto scaling	Integer	`1` to `40000`	No default value
`targetWriteUtilization`	Target utilization percentage for write capacity	Integer	`20` to `90`	No default value

This control checks whether an Amazon DynamoDB table can scale its read and write capacity as needed. The control fails if the table doesn't use on-demand capacity mode or provisioned mode with auto scaling configured. By default, this control only requires that one of these modes be configured, without regard to specific levels of read or write capacity. Optionally, you can provide custom parameter values to require specific levels of read and write capacity or target utilization.

Scaling capacity with demand avoids throttling exceptions, which helps to maintain availability of your applications. DynamoDB tables that use on-demand capacity mode are limited only by the DynamoDB throughput default table quotas. To raise these quotas, you can file a support ticket with Support. DynamoDB tables that use provisioned mode with auto scaling adjust the provisioned throughput capacity dynamically in response to traffic patterns. For more information

about DynamoDB request throttling, see Request throttling and burst capacity in the *Amazon DynamoDB Developer Guide*.

Remediation

To enable DynamoDB automatic scaling on existing tables in capacity mode, see Enabling DynamoDB auto scaling on existing tables in the *Amazon DynamoDB Developer Guide*.

[DynamoDB.2] DynamoDB tables should have point-in-time recovery enabled

Related requirements: NIST.800-53.r5 CP-10, NIST.800-53.r5 CP-6(2), NIST.800-53.r5 CP-9, NIST.800-53.r5 SC-5(2), NIST.800-53.r5 SI-12, NIST.800-53.r5 SI-13(5), CRI Profile v2.2/PR.DS-11.01

Category: Recover > Resilience > Backups enabled

Severity: Medium

Resource type: `AWS::DynamoDB::Table`

AWS Config rule: `dynamodb-pitr-enabled`

Schedule type: Change triggered

Parameters: None

This control checks whether point-in-time recovery (PITR) is enabled for an Amazon DynamoDB table.

Backups help you to recover more quickly from a security incident. They also strengthen the resilience of your systems. DynamoDB point-in-time recovery automates backups for DynamoDB tables. It reduces the time to recover from accidental delete or write operations. DynamoDB tables that have PITR enabled can be restored to any point in time in the last 35 days.

Remediation

To restore a DynamoDB table to a point in time, see Restoring a DynamoDB table to a point in time in the *Amazon DynamoDB Developer Guide*.

[DynamoDB.3] DynamoDB Accelerator (DAX) clusters should be encrypted at rest

Related requirements: NIST.800-53.r5 CA-9(1), NIST.800-53.r5 CM-3(6), NIST.800-53.r5 SC-13, NIST.800-53.r5 SC-28, NIST.800-53.r5 SC-28(1), NIST.800-53.r5 SC-7(10), NIST.800-53.r5 SI-7(6), CRI Profile v2.2/PR.DS-01.01, CRI Profile v2.2/PR.PS-01.06

Category: Protect > Data Protection > Encryption of data-at-rest

Severity: Medium

Resource type: `AWS::DAX::Cluster`

AWS Config rule: `dax-encryption-enabled`

Schedule type: Periodic

Parameters: None

This control checks whether an Amazon DynamoDB Accelerator (DAX) cluster is encrypted at rest. The control fails if the DAX cluster isn't encrypted at rest.

Encrypting data at rest reduces the risk of data stored on disk being accessed by a user not authenticated to AWS. The encryption adds another set of access controls to limit the ability of unauthorized users to access to the data. For example, API permissions are required to decrypt the data before it can be read.

Remediation

You cannot enable or disable encryption at rest after a cluster is created. You must recreate the cluster in order to enable encryption at rest. For detailed instructions on how to create a DAX cluster with encryption at rest enabled, see Enabling encryption at rest using the AWS Management Console in the *Amazon DynamoDB Developer Guide*.

[DynamoDB.4] DynamoDB tables should be present in a backup plan

Related requirements: NIST.800-53.r5 CP-10, NIST.800-53.r5 CP-6, NIST.800-53.r5 CP-6(1), NIST.800-53.r5 CP-6(2), NIST.800-53.r5 CP-9, NIST.800-53.r5 SC-5(2), NIST.800-53.r5 SI-12, NIST.800-53.r5 SI-13(5), CRI Profile v2.2/PR.DS-11.01

Category: Recover > Resilience > Backups enabled

Severity: Medium

Resource type: `AWS::DynamoDB::Table`

AWS Config rule: `dynamodb-resources-protected-by-backup-plan`

Schedule type: Periodic

Parameters:

Parameter	Description	Type	Allowed custom values	Security Hub CSPM default value
`backupVaultLockCheck`	The control produces a `PASSED` finding if the parameter is set to `true` and the resource uses AWS Backup Vault Lock.	Boolean	`true` or `false`	No default value

This control evaluates whether an Amazon DynamoDB table in `ACTIVE` state is covered by a backup plan. The control fails if the DynamoDB table isn't covered by a backup plan. If you set the `backupVaultLockCheck` parameter equal to `true`, the control passes only if the DynamoDB table is backed up in an AWS Backup locked vault.

AWS Backup is a fully managed backup service that helps you centralize and automate the backing up of data across AWS services. With AWS Backup, you can create backup plans that define your backup requirements, such as how frequently to back up your data and how long to retain those backups. Including DynamoDB tables in your backup plans helps you protect your data from unintended loss or deletion.

Remediation

To add a DynamoDB table to an AWS Backup backup plan, see Assigning resources to a backup plan in the *AWS Backup Developer Guide*.

[DynamoDB.5] DynamoDB tables should be tagged

Category: Identify > Inventory > Tagging

Severity: Low

Resource type: `AWS::DynamoDB::Table`

AWS Config rule: `tagged-dynamodb-table` (custom Security Hub CSPM rule)

Schedule type: Change triggered

Parameters:

Parameter	Description	Type	Allowed custom values	Security Hub CSPM default value
`requiredTagKeys`	List of non-system tag keys that the evaluated resource must contain. Tag keys are case sensitive.	StringList (maximum of 6 items)	1–6 tag keys that meet AWS requirements.	`No default value`

This control checks whether an Amazon DynamoDB table has tags with the specific keys defined in the parameter `requiredTagKeys`. The control fails if the table doesn't have any tag keys or if it doesn't have all the keys specified in the parameter `requiredTagKeys`. If the parameter `requiredTagKeys` isn't provided, the control only checks for the existence of a tag key and fails if the table isn't tagged with any key. System tags, which are automatically applied and begin with `aws:`, are ignored.

A tag is a label that you assign to an AWS resource, and it consists of a key and an optional value. You can create tags to categorize resources by purpose, owner, environment, or other criteria. Tags can help you identify, organize, search for, and filter resources. Tagging also helps you track accountable resource owners for actions and notifications. When you use tagging, you can implement attribute-based access control (ABAC) as an authorization strategy, which defines permissions based on tags. You can attach tags to IAM entities (users or roles) and to AWS resources. You can create a single ABAC policy or a separate set of policies for your IAM principals. You can design these ABAC policies to allow operations when the principal's tag matches the resource tag. For more information, see What is ABAC for AWS? in the *IAM User Guide*.

> **Note**
>
> Don't add personally identifiable information (PII) or other confidential or sensitive information in tags. Tags are accessible to many AWS services, including AWS Billing. For more tagging best practices, see Tagging your AWS resources in the *AWS General Reference*.

Remediation

To add tags to a DynamoDB table, see Tagging resources in DynamoDB in the *Amazon DynamoDB Developer Guide*.

[DynamoDB.6] DynamoDB tables should have deletion protection enabled

Related requirements: NIST.800-53.r5 CA-9(1), NIST.800-53.r5 CM-2, NIST.800-53.r5 CM-2(2), NIST.800-53.r5 CM-3, NIST.800-53.r5 SC-5(2), CRI Profile v2.2/GV.RM-01.03, CRI Profile v2.2/PR.DS-01.01

Category: Protect > Data protection > Data deletion protection

Severity: Medium

Resource type: `AWS::DynamoDB::Table`

AWS Config rule: `dynamodb-table-deletion-protection-enabled`

Schedule type: Change triggered

Parameters: None

This control checks whether an Amazon DynamoDB table has deletion protection enabled. The control fails if a DynamoDB table doesn't have deletion protection enabled.

You can protect a DynamoDB table from accidental deletion with the deletion protection property. Enabling this property for tables helps ensure that tables don't get accidentally deleted during regular table management operations by your administrators. This helps prevent disruption to your normal business operations.

Remediation

To enable deletion protection for a DynamoDB table, see Using deletion protection in the *Amazon DynamoDB Developer Guide*.

[DynamoDB.7] DynamoDB Accelerator clusters should be encrypted in transit

Related requirements: NIST.800-53.r5 AC-17, NIST.800-53.r5 SC-8, NIST.800-53.r5 SC-13, NIST.800-53.r5 SC-23, PCI DSS v4.0.1/4.2.1, CRI Profile v2.2/PR.DS-02.01, CRI Profile v2.2/PR.PS-01.06

Category: Protect > Data Protection > Encryption of data-in-transit

Severity: Medium

Resource type: `AWS::DAX::Cluster`

AWS Config rule: `dax-tls-endpoint-encryption`

Schedule type: Periodic

Parameters: None

This control checks whether an Amazon DynamoDB Accelerator (DAX) cluster is encrypted in transit, with the endpoint encryption type set to TLS. The control fails if the DAX cluster isn't encrypted in transit.

HTTPS (TLS) can be used to help prevent potential attackers from using person-in-the-middle or similar attacks to eavesdrop on or manipulate network traffic. You should only allow encrypted connections over TLS to access DAX clusters. However, encrypting data in transit can affect performance. You should test your application with encryption turned on to understand the performance profile and the impact of TLS.

Remediation

You can't change the TLS encryption setting after creating a DAX cluster. To encrypt an existing DAX cluster, create a new cluster with encryption in transit enabled, shift your application's traffic to it, and then delete the old cluster. For more information, see Using deletion protection in the *Amazon DynamoDB Developer Guide*.

Security Hub CSPM controls for Amazon EC2

These AWS Security Hub CSPM controls evaluate the Amazon Elastic Compute Cloud (Amazon EC2) service and resources. The controls might not be available in all AWS Regions. For more information, see Availability of controls by Region.

[EC2.1] Amazon EBS snapshots should not be configured to be publicly restorable

Related requirements: PCI DSS v3.2.1/1.2.1,PCI DSS v3.2.1/1.3.1,PCI DSS v3.2.1/1.3.4,PCI DSS v3.2.1/7.2.1, NIST.800-53.r5 AC-21, NIST.800-53.r5 AC-3, NIST.800-53.r5 AC-3(7), NIST.800-53.r5 AC-4, NIST.800-53.r5 AC-4(21), NIST.800-53.r5 AC-6, NIST.800-53.r5 SC-7, NIST.800-53.r5 SC-7(11), NIST.800-53.r5 SC-7(16), NIST.800-53.r5 SC-7(20), NIST.800-53.r5

SC-7(21), NIST.800-53.r5 SC-7(3), NIST.800-53.r5 SC-7(4), NIST.800-53.r5 SC-7(9), CRI Profile v2.2/DE.CM-01.03, CRI Profile v2.2/PR.AA-01.02, CRI Profile v2.2/PR.AA-03.02, CRI Profile v2.2/PR.DS-01.01, CRI Profile v2.2/PR.PS-01.01, CRI Profile v2.2/PR.PS-01.03

Category: Protect > Secure network configuration

Severity: Critical

Resource type: `AWS::::Account`

AWS Config rule: `ebs-snapshot-public-restorable-check`

Schedule type: Periodic

Parameters: None

This control checks whether Amazon Elastic Block Store snapshots are configured to be publicly restorable. The control fails if Amazon EBS snapshots are configured to be restorable by all.

EBS snapshots are used to back up the data on your EBS volumes to Amazon S3 at a specific point in time. You can use the snapshots to restore previous states of EBS volumes. It is rarely acceptable to share a snapshot with the public. Typically the decision to share a snapshot publicly was made in error or without a complete understanding of the implications. This check helps ensure that all such sharing was fully planned and intentional.

Remediation

To make a public EBS snapshot private, see Share a snapshot in the *Amazon EC2 User Guide*. For **Actions, Modify permissions**, choose **Private**.

[EC2.2] VPC default security groups should not allow inbound or outbound traffic

Related requirements: CIS AWS Foundations Benchmark v5.0.0/5.5, PCI DSS v3.2.1/1.2.1,PCI DSS v3.2.1/1.3.4,PCI DSS v3.2.1/2.1, CIS AWS Foundations Benchmark v1.2.0/4.3, CIS AWS Foundations Benchmark v1.4.0/5.3, CIS AWS Foundations Benchmark v3.0.0/5.4, NIST.800-53.r5 AC-4, NIST.800-53.r5 AC-4(21), NIST.800-53.r5 SC-7, NIST.800-53.r5 SC-7(11), NIST.800-53.r5 SC-7(16), NIST.800-53.r5 SC-7(21), NIST.800-53.r5 SC-7(4), NIST.800-53.r5 SC-7(5), CRI Profile v2.2/PR.IR-01.01, CRI Profile v2.2/PR.IR-01.02, CRI Profile v2.2/PR.PS-01.01

Category: Protect > Secure network configuration

Severity: High

Resource type: `AWS::EC2::SecurityGroup`

AWS Config rule: `vpc-default-security-group-closed`

Schedule type: Change triggered

Parameters: None

This control checks whether the default security group of a VPC allows inbound or outbound traffic. The control fails if the security group allows inbound or outbound traffic.

The rules for the default security group allow all outbound and inbound traffic from network interfaces (and their associated instances) that are assigned to the same security group. We recommend that you don't use the default security group. Because the default security group cannot be deleted, you should change the default security group rules setting to restrict inbound and outbound traffic. This prevents unintended traffic if the default security group is accidentally configured for resources such as EC2 instances.

Remediation

To remediate this issue, start by creating new least-privilege security groups. For instructions, see Create a security group in the *Amazon VPC User Guide*. Then, assign the new security groups to your EC2 instances. For instructions, see Change an instance's security group in the *Amazon EC2 User Guide*.

After you assign the new security groups to your resources, remove all inbound and outbound rules from the default security groups. For instructions, see Configure security group rules in the *Amazon VPC User Guide*.

[EC2.3] Attached Amazon EBS volumes should be encrypted at-rest

Related requirements: NIST.800-53.r5 CA-9(1), NIST.800-53.r5 CM-3(6), NIST.800-53.r5 SC-13, NIST.800-53.r5 SC-28, NIST.800-53.r5 SC-28(1), NIST.800-53.r5 SC-7(10), NIST.800-53.r5 SI-7(6), CRI Profile v2.2/PR.DS-01.01, CRI Profile v2.2/PR.PS-01.06

Category: Protect > Data Protection > Encryption of data-at-rest

Severity: Medium

Resource type: `AWS::EC2::Volume`

AWS Config rule: `encrypted-volumes`

Schedule type: Change triggered

Parameters: None

This control checks whether the EBS volumes that are in an attached state are encrypted. To pass this check, EBS volumes must be in use and encrypted. If the EBS volume is not attached, then it is not subject to this check.

For an added layer of security of your sensitive data in EBS volumes, you should enable EBS encryption at rest. Amazon EBS encryption offers a straightforward encryption solution for your EBS resources that doesn't require you to build, maintain, and secure your own key management infrastructure. It uses KMS keys when creating encrypted volumes and snapshots.

To learn more about Amazon EBS encryption, see Amazon EBS encryption in the *Amazon EC2 User Guide*.

Remediation

There's no direct way to encrypt an existing unencrypted volume or snapshot. You can only encrypt a new volume or snapshot when you create it.

If you enabled encryption by default, Amazon EBS encrypts the resulting new volume or snapshot using your default key for Amazon EBS encryption. Even if you have not enabled encryption by default, you can enable encryption when you create an individual volume or snapshot. In both cases, you can override the default key for Amazon EBS encryption and choose a symmetric customer managed key.

For more information, see Creating an Amazon EBS volume and Copying an Amazon EBS snapshot in the *Amazon EC2 User Guide*.

[EC2.4] Stopped EC2 instances should be removed after a specified time period

Related requirements: NIST.800-53.r5 CA-9(1), NIST.800-53.r5 CM-2, NIST.800-53.r5 CM-2(2), CRI Profile v2.2/ID.AM-08.01, CRI Profile v2.2/PR.PS-02.03

Category: Identify > Inventory

Severity: Medium

Resource type: `AWS::EC2::Instance`

AWS Config rule: `ec2-stopped-instance-days-check` (custom Security Hub CSPM rule)

Schedule type: Periodic

Parameters:

Parameter	Description	Type	Allowed custom values	Security Hub CSPM default value
`AllowedDays`	Number of days the EC2 instance is allowed to be in a stopped state before generating a failed finding.	Integer	1 to 365	`30`

This control checks whether an Amazon EC2 instance has been stopped for longer than the allowed number of days. The control fails if an EC2 instance is stopped for longer than the maximum allowed time period. Unless you provide a custom parameter value for the maximum allowed time period, Security Hub CSPM uses a default value of 30 days.

When an EC2 instance has not run for a significant period of time, it creates a security risk because the instance is not being actively maintained (analyzed, patched, updated). If it is later launched, the lack of proper maintenance could result in unexpected issues in your AWS environment. To safely maintain an EC2 instance over time in an inactive state, start it periodically for maintenance and then stop it after maintenance. Ideally, this should be an automated process.

Note

This control evaluates the number of days that an EC2 instance has been stopped using the timestamp from `StateTransitionReason` for the instance. When the `StateTransitionReason` does not include a timestamp (such as when an instance is stopped due to an internal error), the control uses the instance's launch time instead. In this case, if the launch time is older than the maximum allowed time period, the control generates a FAILED finding.

Remediation

To terminate an inactive EC2 instance, see Terminate an instance in the *Amazon EC2 User Guide*.

[EC2.6] VPC flow logging should be enabled in all VPCs

Related requirements: CIS AWS Foundations Benchmark v5.0.0/3.7, CIS AWS Foundations Benchmark v1.2.0/2.9, CIS AWS Foundations Benchmark v1.4.0/3.9, CIS AWS Foundations Benchmark v3.0.0/3.7, NIST.800-53.r5 AC-4(26), NIST.800-53.r5 AU-12, NIST.800-53.r5 AU-2, NIST.800-53.r5 AU-3, NIST.800-53.r5 AU-6(3), NIST.800-53.r5 AU-6(4), NIST.800-53.r5 CA-7, NIST.800-53.r5 SI-7(8), NIST.800-171.r2 3.1.20, NIST.800-171.r2 3.3.1, NIST.800-171.r2 3.13.1, PCI DSS v3.2.1/10.3.3, PCI DSS v3.2.1/10.3.4, PCI DSS v3.2.1/10.3.5, PCI DSS v3.2.1/10.3.6, CRI Profile v2.2/DE.AE-03.01, CRI Profile v2.2/PR.PS-01.01, CRI Profile v2.2/PR.PS-04.02

Category: Identify > Logging

Severity: Medium

Resource type: `AWS::EC2::VPC`

AWS Config rule: `vpc-flow-logs-enabled`

Schedule type: Periodic

Parameters:

- `trafficType`: `REJECT` (not customizable)

This control checks whether Amazon VPC Flow Logs are found and enabled for VPCs. The traffic type is set to `Reject`. The control fails if VPC Flow Logs aren't enabled for VPCs in your account.

> **Note**
>
> This control doesn't check whether Amazon VPC Flow Logs are enabled through Amazon Security Lake for the AWS account.

With the VPC Flow Logs feature, you can capture information about the IP address traffic going to and from network interfaces in your VPC. After you create a flow log, you can view and retrieve its data in CloudWatch Logs. To reduce cost, you can also send your flow logs to Amazon S3.

Security Hub CSPM recommends that you enable flow logging for packet rejects for VPCs. Flow logs provide visibility into network traffic that traverses the VPC and can detect anomalous traffic or provide insight during security workflows.

By default, the record includes values for the different components of the IP address flow, including the source, destination, and protocol. For more information and descriptions of the log fields, see VPC Flow Logs in the *Amazon VPC User Guide*.

Remediation

To create a VPC Flow Log, see Create a Flow Log in the *Amazon VPC User Guide*. After you open the Amazon VPC console, choose **Your VPCs**. For **Filter**, choose **Reject** or **All**.

[EC2.7] EBS default encryption should be enabled

Related requirements: CIS AWS Foundations Benchmark v5.0.0/5.1.1, CIS AWS Foundations Benchmark v1.4.0/2.2.1, CIS AWS Foundations Benchmark v3.0.0/2.2.1, NIST.800-53.r5 CA-9(1), NIST.800-53.r5 CM-3(6), NIST.800-53.r5 SC-13, NIST.800-53.r5 SC-28, NIST.800-53.r5 SC-28(1), NIST.800-53.r5 SC-7(10), NIST.800-53.r5 SI-7(6), CRI Profile v2.2/PR.DS-01.01, CRI Profile v2.2/PR.PS-01.06

Category: Protect > Data Protection > Encryption of data-at-rest

Severity: Medium

Resource type: `AWS::::Account`

AWS Config rule: `ec2-ebs-encryption-by-default`

Schedule type: Periodic

Parameters: None

This control checks whether account-level encryption is enabled by default for Amazon Elastic Block Store (Amazon EBS) volumes. The control fails if the account level encryption isn't enabled for EBS volumes.

When encryption is enabled for your account, Amazon EBS volumes and snapshot copies are encrypted at rest. This adds an additional layer of protection for your data. For more information, see Encryption by default in the *Amazon EC2 User Guide*.

Remediation

To configure default encryption for Amazon EBS volumes, see Encryption by default in the *Amazon EC2 User Guide*.

[EC2.8] EC2 instances should use Instance Metadata Service Version 2 (IMDSv2)

Related requirements: CIS AWS Foundations Benchmark v5.0.0/5.7, CIS AWS Foundations Benchmark v3.0.0/5.6, NIST.800-53.r5 AC-3, NIST.800-53.r5 AC-3(15), NIST.800-53.r5 AC-3(7), NIST.800-53.r5 AC-6, PCI DSS v4.0.1/2.2.6, CRI Profile v2.2/PR.AA-04.01, CRI Profile v2.2/PR.PS-01.01

Category: Protect > Network Security

Severity: High

Resource type: `AWS::EC2::Instance`

AWS Config rule: `ec2-imdsv2-check`

Schedule type: Change triggered

Parameters: None

This control checks whether your EC2 instance metadata version is configured with Instance Metadata Service Version 2 (IMDSv2). The control passes if `HttpTokens` is set to required for IMDSv2. The control fails if `HttpTokens` is set to `optional`.

You use instance metadata to configure or manage the running instance. The IMDS provides access to temporary, frequently rotated credentials. These credentials remove the need to hard code or distribute sensitive credentials to instances manually or programmatically. The IMDS is attached locally to every EC2 instance. It runs on a special "link local" IP address of 169.254.169.254. This IP address is only accessible by software that runs on the instance.

Version 2 of the IMDS adds new protections for the following types of vulnerabilities. These vulnerabilities could be used to try to access the IMDS.

- Open website application firewalls
- Open reverse proxies
- Server-side request forgery (SSRF) vulnerabilities
- Open Layer 3 firewalls and network address translation (NAT)

Security Hub CSPM recommends that you configure your EC2 instances with IMDSv2.

Remediation

To configure EC2 instances with IMDSv2, see Recommended path to requiring IMDSv2 in the *Amazon EC2 User Guide*.

[EC2.9] Amazon EC2 instances should not have a public IPv4 address

Related requirements: NIST.800-53.r5 AC-21, NIST.800-53.r5 AC-3, NIST.800-53.r5 AC-3(7), NIST.800-53.r5 AC-4, NIST.800-53.r5 AC-4(21), NIST.800-53.r5 AC-6, NIST.800-53.r5 SC-7, NIST.800-53.r5 SC-7(11), NIST.800-53.r5 SC-7(16), NIST.800-53.r5 SC-7(20), NIST.800-53.r5 SC-7(21), NIST.800-53.r5 SC-7(3), NIST.800-53.r5 SC-7(4), NIST.800-53.r5 SC-7(9), CRI Profile v2.2/PR.IR-01.01, CRI Profile v2.2/PR.PS-01.02, CRI Profile v2.2/PR.PS-01.03

Category: Protect > Secure network configuration > Resources not publicly accessible

Severity: High

Resource type: `AWS::EC2::Instance`

AWS Config rule: `ec2-instance-no-public-ip`

Schedule type: Change triggered

Parameters: None

This control checks whether EC2 instances have a public IP address. The control fails if the `publicIp` field is present in the EC2 instance configuration item. This control applies to IPv4 addresses only.

A public IPv4 address is an IP address that is reachable from the internet. If you launch your instance with a public IP address, then your EC2 instance is reachable from the internet. A private IPv4 address is an IP address that is not reachable from the internet. You can use private IPv4 addresses for communication between EC2 instances in the same VPC or in your connected private network.

IPv6 addresses are globally unique, and therefore are reachable from the internet. However, by default all subnets have the IPv6 addressing attribute set to false. For more information about IPv6, see IP addressing in your VPC in the *Amazon VPC User Guide*.

If you have a legitimate use case to maintain EC2 instances with public IP addresses, then you can suppress the findings from this control. For more information about front-end architecture options, see the AWS Architecture Blog or the This Is My Architecture series AWS video series.

Remediation

Use a non-default VPC so that your instance isn't assigned a public IP address by default.

When you launch an EC2 instance into a default VPC, it is assigned a public IP address. When you launch an EC2 instance into a non-default VPC, the subnet configuration determines whether it receives a public IP address. The subnet has an attribute to determine if new EC2 instances in the subnet receive a public IP address from the public IPv4 address pool.

You can disassociate an automatically-assigned public IP address from your EC2 instance. For more information, see Public IPv4 addresses and external DNS hostnames in the *Amazon EC2 User Guide*.

[EC2.10] Amazon EC2 should be configured to use VPC endpoints that are created for the Amazon EC2 service

Related requirements: NIST.800-53.r5 AC-21, NIST.800-53.r5 AC-3, NIST.800-53.r5 AC-3(7), NIST.800-53.r5 AC-4, NIST.800-53.r5 AC-4(21), NIST.800-53.r5 AC-6, NIST.800-53.r5 SC-7, NIST.800-53.r5 SC-7(11), NIST.800-53.r5 SC-7(16), NIST.800-53.r5 SC-7(20), NIST.800-53.r5 SC-7(21), NIST.800-53.r5 SC-7(3), NIST.800-53.r5 SC-7(4), NIST.800-171.r2 3.1.3, NIST.800-171.r2 3.13.1, CRI Profile v2.2/PR.AA-03.02, CRI Profile v2.2/PR.IR-01.01, CRI Profile v2.2/PR.PS-01.01, CRI Profile v2.2/PR.PS-01.02

Category: Protect > Secure network configuration > API private access

Severity: Medium

Resource type: `AWS::EC2::VPC`

AWS Config rule: vpc-endpoint-enabled

Schedule type: Periodic

Parameters:

- `serviceNames`: `ec2` (not customizable)

This control checks whether a service endpoint for Amazon EC2 is created for each VPC. The control fails if a VPC does not have a VPC endpoint created for the Amazon EC2 service.

This control evaluates resources in single account. It cannot describe resources that are outside of the account. Because AWS Config and Security Hub CSPM do not conduct cross-account

checks, you will see `FAILED` findings for VPCs that are shared across accounts. Security Hub CSPM recommends that you suppress these `FAILED` findings.

To improve the security posture of your VPC, you can configure Amazon EC2 to use an interface VPC endpoint. Interface endpoints are powered by AWS PrivateLink, a technology that enables you to access Amazon EC2 API operations privately. It restricts all network traffic between your VPC and Amazon EC2 to the Amazon network. Because endpoints are supported within the same Region only, you cannot create an endpoint between a VPC and a service in a different Region. This prevents unintended Amazon EC2 API calls to other Regions.

To learn more about creating VPC endpoints for Amazon EC2, see Amazon EC2 and interface VPC endpoints in the *Amazon EC2 User Guide*.

Remediation

To create an interface endpoint to Amazon EC2 from the Amazon VPC console, see Create a VPC endpoint in the *AWS PrivateLink Guide*. For **Service name**, choose **com.amazonaws.*region*.ec2**.

You can also create and attach an endpoint policy to your VPC endpoint to control access to the Amazon EC2 API. For instructions on creating a VPC endpoint policy, see Create an endpoint policy in the *Amazon EC2 User Guide*.

[EC2.12] Unused Amazon EC2 EIPs should be removed

Related requirements: PCI DSS v3.2.1/2.4, NIST.800-53.r5 CM-8(1), CRI Profile v2.2/ID.AM-08.01, CRI Profile v2.2/ID.AM-08.02

Category: Protect > Secure network configuration

Severity: Low

Resource type: `AWS::EC2::EIP`

AWS Config rule: `eip-attached`

Schedule type: Change triggered

Parameters: None

This control checks whether Elastic IP (EIP) addresses that are allocated to a VPC are attached to EC2 instances or in-use elastic network interfaces (ENIs).

A failed finding indicates you may have unused EC2 EIPs.

This will help you maintain an accurate asset inventory of EIPs in your cardholder data environment (CDE).

Remediation

To release an unused EIP, see Release an Elastic IP address in the *Amazon EC2 User Guide*.

[EC2.13] Security groups should not allow ingress from 0.0.0.0/0 or ::/0 to port 22

Related requirements: CIS AWS Foundations Benchmark v1.2.0/4.1, NIST.800-53.r5 AC-4, NIST.800-53.r5 AC-4(21), NIST.800-53.r5 CM-7, NIST.800-53.r5 SC-7, NIST.800-53.r5 SC-7(11), NIST.800-53.r5 SC-7(16), NIST.800-53.r5 SC-7(21), NIST.800-53.r5 SC-7(4), NIST.800-53.r5 SC-7(5), NIST.800-171.r2 3.1.3, NIST.800-171.r2 3.13.1, PCI DSS v3.2.1/1.2.1, PCI DSS v3.2.1/1.3.1, PCI DSS v3.2.1/2.2.2, PCI DSS v4.0.1/1.3.1, CRI Profile v2.2/PR.AA-03.02, CRI Profile v2.2/PR.IR-01.01, CRI Profile v2.2/PR.IR-01.02, CRI Profile v2.2/PR.IR-01.05, CRI Profile v2.2/PR.PS-01.01, CRI Profile v2.2/PR.PS-01.03

Category: Protect > Secure network configuration

Severity: High

Resource type: `AWS::EC2::SecurityGroup`

AWS Config rule: `restricted-ssh`

Schedule type: Change triggered and periodic

Parameters: None

This control checks whether an Amazon EC2 security group allows ingress from 0.0.0.0/0 or ::/0 to port 22. The control fails if the security group allows ingress from 0.0.0.0/0 or ::/0 to port 22.

Security groups provide stateful filtering of ingress and egress network traffic to AWS resources. We recommend that no security group allow unrestricted ingress access to port 22. Removing unfettered connectivity to remote console services, such as SSH, reduces a server's exposure to risk.

Remediation

To prohibit ingress to port 22, remove the rule that allows such access for each security group associated with a VPC. For instructions, see Update security group rules in the *Amazon EC2 User Guide*. After selecting a security group in the Amazon EC2 console, choose **Actions, Edit inbound rules**. Remove the rule that allows access to port 22.

[EC2.14] Security groups should not allow ingress from 0.0.0.0/0 or ::/0 to port 3389

Related requirements: CIS AWS Foundations Benchmark v1.2.0/4.2, PCI DSS v4.0.1/1.3.1, CRI Profile v2.2/PR.IR-01.01, CRI Profile v2.2/PR.IR-01.02, CRI Profile v2.2/PR.PS-01.02

Category: Protect > Secure network configuration

Severity: High

Resource type: `AWS::EC2::SecurityGroup`

AWS Config rule: `restricted-common-ports` (created rule is `restricted-rdp`)

Schedule type: Change triggered and periodic

Parameters: None

This control checks whether an Amazon EC2 security group allows ingress from 0.0.0.0/0 or ::/0 to port 3389. The control fails if the security group allows ingress from 0.0.0.0/0 or ::/0 to port 3389.

Security groups provide stateful filtering of ingress and egress network traffic to AWS resources. We recommend that no security group allow unrestricted ingress access to port 3389. Removing unfettered connectivity to remote console services, such as RDP, reduces a server's exposure to risk.

Remediation

To prohibit ingress to port 3389, remove the rule that allows such access for each security group associated with a VPC. For instructions, see Update security group rules in the *Amazon VPC User Guide*. After selecting a security group in the Amazon VPC Console, choose **Actions, Edit inbound rules**. Remove the rule that allows access to port 3389.

[EC2.15] Amazon EC2 subnets should not automatically assign public IP addresses

Related requirements: NIST.800-53.r5 AC-21, NIST.800-53.r5 AC-3, NIST.800-53.r5 AC-3(7), NIST.800-53.r5 AC-4, NIST.800-53.r5 AC-4(21), NIST.800-53.r5 AC-6, NIST.800-53.r5 SC-7, NIST.800-53.r5 SC-7(11), NIST.800-53.r5 SC-7(16), NIST.800-53.r5 SC-7(20), NIST.800-53.r5 SC-7(21), NIST.800-53.r5 SC-7(3), NIST.800-53.r5 SC-7(4), NIST.800-53.r5 SC-7(9), PCI DSS v4.0.1/1.4.4, CRI Profile v2.2/PR.AA-03.02, CRI Profile v2.2/PR.PS-01.01

Category: Protect > Network Security

Severity: Medium

Resource type: `AWS::EC2::Subnet`

AWS Config rule: `subnet-auto-assign-public-ip-disabled`

Schedule type: Change triggered

Parameters: None

This control checks whether an Amazon Virtual Private Cloud (Amazon VPC) subnet is configured to automatically assign public IP addresses. The control fails if the subnet is configured to automatically assign public IPv4 or IPv6 addresses.

Subnets have attributes that determine whether network interfaces automatically receive public IPv4 and IPv6 addresses. For IPv4, this attribute is set to `TRUE` for default subnets and `FALSE` for nondefault subnets (with an exception for nondefault subnets created through the EC2 launch instance wizard, where it's set to `TRUE`). For IPv6, this attribute is set to `FALSE` for all subnets by default. When these attributes are enabled, instances launched in the subnet automatically receive the corresponding IP addresses (IPv4 or IPv6) on their primary network interface.

Remediation

To configure a subnet to not assign public IP addresses, see Modify the IP addressing attributes of your subnet in the *Amazon VPC User Guide*.

[EC2.16] Unused Network Access Control Lists should be removed

Related requirements: NIST.800-53.r5 CM-8(1), NIST.800-171.r2 3.4.7, PCI DSS v4.0.1/1.2.7, CRI Profile v2.2/PR.IR-01.02, CRI Profile v2.2/PR.PS-01.02

Category: Protect > Network Security

Severity: Low

Resource type: `AWS::EC2::NetworkAcl`

AWS Config rule: `vpc-network-acl-unused-check`

Schedule type: Change triggered

Parameters: None

This control checks whether there are any unused network access control lists (network ACLs) in your virtual private cloud (VPC). The control fails if the network ACL isn't associated with a subnet. The control doesn't generate findings for an unused default network ACL.

The control checks the item configuration of the resource `AWS::EC2::NetworkAcl` and determines the relationships of the network ACL.

If the only relationship is the VPC of the network ACL, the control fails.

If other relationships are listed, then the control passes.

Remediation

For instructions on deleting an unused network ACL, see Deleting a network ACL in the *Amazon VPC User Guide*. You can't delete the default network ACL or an ACL that is associated with subnets.

[EC2.17] Amazon EC2 instances should not use multiple ENIs

Related requirements: NIST.800-53.r5 AC-4(21), CRI Profile v2.2/PR.PS-01.02

Category: Protect > Network Security

Severity: Low

Resource type: `AWS::EC2::Instance`

AWS Config rule: `ec2-instance-multiple-eni-check`

Schedule type: Change triggered

Parameters: None

This control checks whether an EC2 instance uses multiple Elastic Network Interfaces (ENIs) or Elastic Fabric Adapters (EFAs). This control passes if a single network adapter is used. The control includes an optional parameter list to identify the allowed ENIs. This control also fails if an EC2 instance that belongs to an Amazon EKS cluster uses more than one ENI. If your EC2 instances need to have multiple ENIs as part of an Amazon EKS cluster, you can suppress those control findings.

Multiple ENIs can cause dual-homed instances, meaning instances that have multiple subnets. This can add network security complexity and introduce unintended network paths and access.

Remediation

To detach a network interface from an EC2 instance, see Detach a network interface from an instance in the *Amazon EC2 User Guide*.

[EC2.18] Security groups should only allow unrestricted incoming traffic for authorized ports

Related requirements: NIST.800-53.r5 AC-4, NIST.800-53.r5 AC-4(21), NIST.800-53.r5 SC-7, NIST.800-53.r5 SC-7(11), NIST.800-53.r5 SC-7(16), NIST.800-53.r5 SC-7(21), NIST.800-53.r5 SC-7(4), NIST.800-53.r5 SC-7(5), NIST.800-171.r2 3.1.3, NIST.800-171.r2 3.1.20, NIST.800-171.r2 3.13.1, CRI Profile v2.2/PR.IR-01.01, CRI Profile v2.2/PR.IR-01.02, CRI Profile v2.2/PR.PS-01.02

Category: Protect > Secure network configuration > Security group configuration

Severity: High

Resource type: `AWS::EC2::SecurityGroup`

AWS Config rule: `vpc-sg-open-only-to-authorized-ports`

Schedule type: Change triggered

Parameters:

Parameter	Description	Type	Allowed custom values	Security Hub CSPM default value
`authorizedTcpPorts`	List of authorized TCP ports	IntegerList (minimum of 1 item and maximum of 32 items)	1 to 65535	`[80,443]`
`authorizedUdpPorts`	List of authorized UDP ports	IntegerList (minimum of 1 item and maximum of 32 items)	1 to 65535	No default value

This control checks whether an Amazon EC2 security group permits unrestricted incoming traffic from unauthorized ports. The control status is determined as follows:

- If you use the default value for `authorizedTcpPorts`, the control fails if the security group permits unrestricted incoming traffic from any port other than ports 80 and 443.
- If you provide custom values for `authorizedTcpPorts` or `authorizedUdpPorts`, the control fails if the security group permits unrestricted incoming traffic from any unlisted port.

Security groups provide stateful filtering of ingress and egress network traffic to AWS. Security group rules should follow the principal of least privileged access. Unrestricted access (IP address with a /0 suffix) increases the opportunity for malicious activity such as hacking, denial-of-service attacks, and loss of data. Unless a port is specifically allowed, the port should deny unrestricted access.

Remediation

To modify a security group, see Work with security groups in the *Amazon VPC User Guide*.

[EC2.19] Security groups should not allow unrestricted access to ports with high risk

Related requirements: NIST.800-53.r5 AC-4, NIST.800-53.r5 AC-4(21), NIST.800-53.r5 CA-9(1), NIST.800-53.r5 CM-2, NIST.800-53.r5 CM-2(2), NIST.800-53.r5 CM-7, NIST.800-53.r5 SC-7, NIST.800-53.r5 SC-7(11), NIST.800-53.r5 SC-7(16), NIST.800-53.r5 SC-7(21), NIST.800-53.r5 SC-7(4), NIST.800-53.r5 SC-7(5), NIST.800-171.r2 3.1.3, NIST.800-171.r2 3.1.20, NIST.800-171.r2 3.13.1, CRI Profile v2.2/PR.IR-01.01, CRI Profile v2.2/PR.IR-01.02, CRI Profile v2.2/PR.PS-01.02

Category: Protect > Restricted network access

Severity: Critical

Resource type: `AWS::EC2::SecurityGroup`

AWS Config rule: `restricted-common-ports` (created rule is `vpc-sg-restricted-common-ports`)

Schedule type: Change triggered and periodic

Parameters: `"blockedPorts": "20,21,22,23,25,110,135,143,445,1433,1434,3000,3306,3389,4333,5000,5432,5500,560` (not customizable)

This control checks whether unrestricted incoming traffic for an Amazon EC2 security group is accessible to the specified ports that are considered to be high risk. This control fails if any of the rules in a security group allow ingress traffic from '0.0.0.0/0' or '::/0' to those ports.

Security groups provide stateful filtering of ingress and egress network traffic to AWS resources. Unrestricted access (0.0.0.0/0) increases opportunities for malicious activity, such as hacking, denial-of-service attacks, and loss of data. No security group should allow unrestricted ingress access to the following ports:

- 20, 21 (FTP)
- 22 (SSH)
- 23 (Telnet)
- 25 (SMTP)
- 110 (POP3)
- 135 (RPC)
- 143 (IMAP)
- 445 (CIFS)
- 1433, 1434 (MSSQL)
- 3000 (Go, Node.js, and Ruby web development frameworks)
- 3306 (mySQL)
- 3389 (RDP)
- 4333 (ahsp)
- 5000 (Python web development frameworks)
- 5432 (postgresql)
- 5500 (fcp-addr-srvr1)
- 5601 (OpenSearch Dashboards)
- 8080 (proxy)
- 8088 (legacy HTTP port)
- 8888 (alternative HTTP port)
- 9200 or 9300 (OpenSearch)

Remediation

To delete rules from a security group, see Delete rules from a security group in the *Amazon EC2 User Guide*.

[EC2.20] Both VPN tunnels for an AWS Site-to-Site VPN connection should be up

Related requirements: NIST.800-53.r5 CP-10, NIST.800-53.r5 CP-6(2), NIST.800-53.r5 SC-36, NIST.800-53.r5 SC-5(2), NIST.800-53.r5 SI-13(5), NIST.800-171.r2 3.1.13, NIST.800-171.r2 3.1.20, CRI Profile v2.2/GV.RM-09.02, CRI Profile v2.2/PR.IR-01.03, CRI Profile v2.2/PR.IR-03.01, CRI Profile v2.2/PR.IR-04.02

Category: Recover > Resilience > High availability

Severity: Medium

Resource type:`AWS::EC2::VPNConnection`

AWS Config rule: `vpc-vpn-2-tunnels-up`

Schedule type: Change triggered

Parameters: None

A VPN tunnel is an encrypted link where data can pass from the customer network to or from AWS within an AWS Site-to-Site VPN connection. Each VPN connection includes two VPN tunnels which you can simultaneously use for high availability. Ensuring that both VPN tunnels are up for a VPN connection is important for confirming a secure and highly available connection between an AWS VPC and your remote network.

This control checks that both VPN tunnels provided by AWS Site-to-Site VPN are in UP status. The control fails if one or both tunnels are in DOWN status.

Remediation

To modify VPN tunnel options, see Modifying Site-to-Site VPN tunnel options in the AWS Site-to-Site VPN User Guide.

[EC2.21] Network ACLs should not allow ingress from 0.0.0.0/0 to port 22 or port 3389

Related requirements: CIS AWS Foundations Benchmark v5.0.0/5.2, CIS AWS Foundations Benchmark v1.4.0/5.1, CIS AWS Foundations Benchmark v3.0.0/5.1, NIST.800-53.r5 AC-4(21), NIST.800-53.r5 CA-9(1), NIST.800-53.r5 CM-2, NIST.800-53.r5 CM-2(2), NIST.800-53.r5 CM-7, NIST.800-53.r5 SC-7, NIST.800-53.r5 SC-7(21), NIST.800-53.r5 SC-7(5), NIST.800-171.r2 3.1.3, NIST.800-171.r2 3.1.20, NIST.800-171.r2 3.13.1, PCI DSS v4.0.1/1.3.1, CRI Profile v2.2/DE.CM-01.03, CRI Profile v2.2/PR.IR-01.01, CRI Profile v2.2/PR.IR-01.03, CRI Profile v2.2/PR.IR-01.05

Category: Protect > Secure Network Configuration

Severity: Medium

Resource type:`AWS::EC2::NetworkAcl`

AWS Config rule: `nacl-no-unrestricted-ssh-rdp`

Schedule type: Change triggered

Parameters: None

This control checks whether a network access control list (network ACL) allows unrestricted access to the default TCP ports for SSH/RDP ingress traffic. The control fails if the network ACL inbound entry allows a source CIDR block of '0.0.0.0/0' or '::/0' for TCP ports 22 or 3389. The control doesn't generate findings for a default network ACL.

Access to remote server administration ports, such as port 22 (SSH) and port 3389 (RDP), should not be publicly accessible, as this may allow unintended access to resources within your VPC.

Remediation

To edit network ACL traffic rules, see Work with network ACLs in the *Amazon VPC User Guide*.

[EC2.22] Unused Amazon EC2 security groups should be removed

Related requirements: CRI Profile v2.2/PR.IR-01.01, CRI Profile v2.2/PR.IR-01.02

Category: Identify > Inventory

Severity: Medium

Resource type: `AWS::EC2::NetworkInterface`, `AWS::EC2::SecurityGroup`

AWS Config rule: `ec2-security-group-attached-to-eni-periodic`

Schedule type: Periodic

Parameters: None

This control checks whether security groups are attached to Amazon Elastic Compute Cloud (Amazon EC2) instances or to an elastic network interface. The control fails if the security group is not associated with an Amazon EC2 instance or an elastic network interface.

> **Important**
>
> On September 20, 2023, Security Hub CSPM removed this control from the AWS Foundational Security Best Practices and NIST SP 800-53 Revision 5 standards. This control continues to be part of the AWS Control Tower service-managed standard. This control produces a passed finding if security groups are attached to EC2 instances or an elastic network interface. However, for certain use cases, unattached security groups don't pose a security risk. You can use other EC2 controls—such as EC2.2, EC2.13, EC2.14, EC2.18, and EC2.19—to monitor your security groups.

Remediation

To create, assign and delete security groups, see Security groups for your EC2 instances in the *Amazon EC2 User Guide*.

[EC2.23] Amazon EC2 Transit Gateways should not automatically accept VPC attachment requests

Related requirements: NIST.800-53.r5 AC-4(21), NIST.800-53.r5 CA-9(1), NIST.800-53.r5 CM-2, CRI Profile v2.2/PR.AA-01.02, CRI Profile v2.2/PR.AA-02.01, CRI Profile v2.2/PR.AA-03.02, CRI Profile v2.2/PR.AA-05.01

Category: Protect > Secure network configuration

Severity: High

Resource type:`AWS::EC2::TransitGateway`

AWS Config rule: `ec2-transit-gateway-auto-vpc-attach-disabled`

Schedule type: Change triggered

Parameters: None

This control checks if EC2 transit gateways are automatically accepting shared VPC attachments. This control fails for a transit gateway that automatically accepts shared VPC attachment requests.

Turning on `AutoAcceptSharedAttachments` configures a transit gateway to automatically accept any cross-account VPC attachment requests without verifying the request or the

account the attachment is originating from. To follow the best practices of authorization and authentication, we recommended turning off this feature to ensure that only authorized VPC attachment requests are accepted.

Remediation

To modify a transit gateway, see Modify a transit gateway in the Amazon VPC Developer Guide.

[EC2.24] Amazon EC2 paravirtual instance types should not be used

Related requirements: NIST.800-53.r5 CM-2, NIST.800-53.r5 CM-2(2), CRI Profile v2.2/PR.PS-01.01, CRI Profile v2.2/PR.PS-02.03

Category: Identify > Vulnerability, patch, and version management

Severity: Medium

Resource type:`AWS::EC2::Instance`

AWS Config rule: `ec2-paravirtual-instance-check`

Schedule type: Change triggered

Parameters: None

This control checks whether the virtualization type of an EC2 instance is paravirtual. The control fails if the `virtualizationType` of the EC2 instance is set to `paravirtual`.

Linux Amazon Machine Images (AMIs) use one of two types of virtualization: paravirtual (PV) or hardware virtual machine (HVM). The main differences between PV and HVM AMIs are the way in which they boot and whether they can take advantage of special hardware extensions (CPU, network, and storage) for better performance.

Historically, PV guests had better performance than HVM guests in many cases, but because of enhancements in HVM virtualization and the availability of PV drivers for HVM AMIs, this is no longer true. For more information, see Linux AMI virtualization types in the Amazon EC2 User Guide.

Remediation

To update an EC2 instance to a new instance type, see Change the instance type in the *Amazon EC2 User Guide*.

[EC2.25] Amazon EC2 launch templates should not assign public IPs to network interfaces

Related requirements: NIST.800-53.r5 AC-21, NIST.800-53.r5 AC-3, NIST.800-53.r5 AC-3(7), NIST.800-53.r5 AC-4, NIST.800-53.r5 AC-4(21), NIST.800-53.r5 AC-6, NIST.800-53.r5 SC-7, NIST.800-53.r5 SC-7(11), NIST.800-53.r5 SC-7(16), NIST.800-53.r5 SC-7(20), NIST.800-53.r5 SC-7(21), NIST.800-53.r5 SC-7(3), NIST.800-53.r5 SC-7(4), NIST.800-53.r5 SC-7(9), PCI DSS v4.0.1/1.4.4, CRI Profile v2.2/PR.IR-01.02, CRI Profile v2.2/PR.PS-01.01

Category: Protect > Secure network configuration > Resources not publicly accessible

Severity: High

Resource type:`AWS::EC2::LaunchTemplate`

AWS Config rule: `ec2-launch-template-public-ip-disabled`

Schedule type: Change triggered

Parameters: None

This control checks if Amazon EC2 launch templates are configured to assign public IP addresses to network interfaces upon launch. The control fails if an EC2 launch template is configured to assign a public IP address to network interfaces.

A public IP address is one that is reachable from the internet. If you configure your network interfaces with a public IP address, then the resources associated with those network interfaces may be reachable from the internet. EC2 resources shouldn't be publicly accessible because this may permit unintended access to your workloads.

Remediation

To update an EC2 launch template, see Change the default network interface settings in the *Amazon EC2 Auto Scaling User Guide*.

[EC2.28] EBS volumes should be covered by a backup plan

Category: Recover > Resilience > Backups enabled

Related requirements: NIST.800-53.r5 CP-10, NIST.800-53.r5 CP-6, NIST.800-53.r5 CP-6(1), NIST.800-53.r5 CP-6(2), NIST.800-53.r5 CP-9, NIST.800-53.r5 SC-5(2), NIST.800-53.r5 SI-12, NIST.800-53.r5 SI-13(5), CRI Profile v2.2/GV.RM-09.02, CRI Profile v2.2/PR.DS-01.02, CRI Profile v2.2/PR.DS-11.01, CRI Profile v2.2/PR.IR-03.01

Severity: Low

Resource type: `AWS::EC2::Volume`

AWS Config rule: `ebs-resources-protected-by-backup-plan`

Schedule type: Periodic

Parameters:

Parameter	Description	Type	Allowed custom values	Security Hub CSPM default value
`backupVaultLockCheck`	The control produces a PASSED finding if the parameter is set to `true` and the resource uses AWS Backup Vault Lock.	Boolean	`true` or `false`	No default value

This control evaluates if an Amazon EBS volume in `in-use` state is covered by a backup plan. The control fails if an EBS volume isn't covered by a backup plan. If you set the `backupVaultLockCheck` parameter equal to `true`, the control passes only if the EBS volume is backed up in an AWS Backup locked vault.

Backups help you recover more quickly from a security incident. They also strengthen the resilience of your systems. Including Amazon EBS volumes in a backup plan helps you protect your data from unintended loss or deletion.

Remediation

To add an Amazon EBS volume to an AWS Backup backup plan, see Assigning resources to a backup plan in the *AWS Backup Developer Guide*.

[EC2.33] EC2 transit gateway attachments should be tagged

Category: Identify > Inventory > Tagging

Severity: Low

Resource type: `AWS::EC2::TransitGatewayAttachment`

AWS Config rule: `tagged-ec2-transitgatewayattachment` (custom Security Hub CSPM rule)

Schedule type: Change triggered

Parameters:

Parameter	Description	Type	Allowed custom values	Security Hub CSPM default value
`requiredTagKeys`	List of non-system tag keys that the evaluated resource must contain. Tag keys are case sensitive.	StringList (maximum of 6 items)	1–6 tag keys that meet AWS requirements.	No default value

This control checks whether an Amazon EC2 transit gateway attachment has tags with the specific keys defined in the parameter `requiredTagKeys`. The control fails if the transit gateway attachment doesn't have any tag keys or if it doesn't have all the keys specified in the parameter `requiredTagKeys`. If the parameter `requiredTagKeys` isn't provided, the control only checks for the existence of a tag key and fails if the transit gateway attachment isn't tagged with any key. System tags, which are automatically applied and begin with `aws:`, are ignored.

A tag is a label that you assign to an AWS resource, and it consists of a key and an optional value. You can create tags to categorize resources by purpose, owner, environment, or other criteria. Tags can help you identify, organize, search for, and filter resources. Tagging also helps you track accountable resource owners for actions and notifications. When you use tagging, you can implement attribute-based access control (ABAC) as an authorization strategy, which defines permissions based on tags. You can attach tags to IAM entities (users or roles) and to AWS resources. You can create a single ABAC policy or a separate set of policies for your IAM principals. You can design these ABAC policies to allow operations when the principal's tag matches the resource tag. For more information, see What is ABAC for AWS? in the *IAM User Guide*.

> **Note**
>
> Don't add personally identifiable information (PII) or other confidential or sensitive information in tags. Tags are accessible to many AWS services, including AWS Billing. For more tagging best practices, see Tagging your AWS resources in the *AWS General Reference*.

Remediation

To add tags to an EC2 transit gateway attachment, see Tag your Amazon EC2 resources in the *Amazon EC2 User Guide*.

[EC2.34] EC2 transit gateway route tables should be tagged

Category: Identify > Inventory > Tagging

Severity: Low

Resource type: `AWS::EC2::TransitGatewayRouteTable`

AWS Config rule: `tagged-ec2-transitgatewayroutetable` (custom Security Hub CSPM rule)

Schedule type: Change triggered

Parameters:

Parameter	Description	Type	Allowed custom values	Security Hub CSPM default value
`requiredTagKeys`	List of non-system tag keys that the evaluated resource must contain. Tag keys are case sensitive.	StringList (maximum of 6 items)	1–6 tag keys that meet AWS requirements.	No default value

This control checks whether an Amazon EC2 transit gateway route table has tags with the specific keys defined in the parameter `requiredTagKeys`. The control fails if the transit gateway route

table doesn't have any tag keys or if it doesn't have all the keys specified in the parameter `requiredTagKeys`. If the parameter `requiredTagKeys` isn't provided, the control only checks for the existence of a tag key and fails if the transit gateway route table isn't tagged with any key. System tags, which are automatically applied and begin with `aws:`, are ignored.

A tag is a label that you assign to an AWS resource, and it consists of a key and an optional value. You can create tags to categorize resources by purpose, owner, environment, or other criteria. Tags can help you identify, organize, search for, and filter resources. Tagging also helps you track accountable resource owners for actions and notifications. When you use tagging, you can implement attribute-based access control (ABAC) as an authorization strategy, which defines permissions based on tags. You can attach tags to IAM entities (users or roles) and to AWS resources. You can create a single ABAC policy or a separate set of policies for your IAM principals. You can design these ABAC policies to allow operations when the principal's tag matches the resource tag. For more information, see What is ABAC for AWS? in the *IAM User Guide*.

> **Note**
>
> Don't add personally identifiable information (PII) or other confidential or sensitive information in tags. Tags are accessible to many AWS services, including AWS Billing. For more tagging best practices, see Tagging your AWS resources in the *AWS General Reference*.

Remediation

To add tags to an EC2 transit gateway route table, see Tag your Amazon EC2 resources in the *Amazon EC2 User Guide*.

[EC2.35] EC2 network interfaces should be tagged

Category: Identify > Inventory > Tagging

Severity: Low

Resource type: `AWS::EC2::NetworkInterface`

AWS Config rule: `tagged-ec2-networkinterface` (custom Security Hub CSPM rule)

Schedule type: Change triggered

Parameters:

Parameter	Description	Type	Allowed custom values	Security Hub CSPM default value
`requiredTagKeys`	List of non-system tag keys that the evaluated resource must contain. Tag keys are case sensitive.	StringList (maximum of 6 items)	1–6 tag keys that meet AWS requirements.	No default value

This control checks whether an Amazon EC2 network interface has tags with the specific keys defined in the parameter `requiredTagKeys`. The control fails if the network interface doesn't have any tag keys or if it doesn't have all the keys specified in the parameter `requiredTagKeys`. If the parameter `requiredTagKeys` isn't provided, the control only checks for the existence of a tag key and fails if the network interface isn't tagged with any key. System tags, which are automatically applied and begin with `aws:`, are ignored.

A tag is a label that you assign to an AWS resource, and it consists of a key and an optional value. You can create tags to categorize resources by purpose, owner, environment, or other criteria. Tags can help you identify, organize, search for, and filter resources. Tagging also helps you track accountable resource owners for actions and notifications. When you use tagging, you can implement attribute-based access control (ABAC) as an authorization strategy, which defines permissions based on tags. You can attach tags to IAM entities (users or roles) and to AWS resources. You can create a single ABAC policy or a separate set of policies for your IAM principals. You can design these ABAC policies to allow operations when the principal's tag matches the resource tag. For more information, see What is ABAC for AWS? in the *IAM User Guide*.

Note

Don't add personally identifiable information (PII) or other confidential or sensitive information in tags. Tags are accessible to many AWS services, including AWS Billing. For more tagging best practices, see Tagging your AWS resources in the *AWS General Reference*.

Remediation

To add tags to an EC2 network interface, see Tag your Amazon EC2 resources in the *Amazon EC2 User Guide*.

[EC2.36] EC2 customer gateways should be tagged

Category: Identify > Inventory > Tagging

Severity: Low

Resource type: `AWS::EC2::CustomerGateway`

AWS Config rule: `tagged-ec2-customergateway` (custom Security Hub CSPM rule)

Schedule type: Change triggered

Parameters:

Parameter	Description	Type	Allowed custom values	Security Hub CSPM default value
`requiredTagKeys`	List of non-system tag keys that the evaluated resource must contain. Tag keys are case sensitive.	StringList (maximum of 6 items)	1–6 tag keys that meet AWS requirements.	No default value

This control checks whether an Amazon EC2 customer gateway has tags with the specific keys defined in the parameter `requiredTagKeys`. The control fails if the customer gateway doesn't have any tag keys or if it doesn't have all the keys specified in the parameter `requiredTagKeys`. If the parameter `requiredTagKeys` isn't provided, the control only checks for the existence of a tag key and fails if the customer gateway isn't tagged with any key. System tags, which are automatically applied and begin with `aws:`, are ignored.

A tag is a label that you assign to an AWS resource, and it consists of a key and an optional value. You can create tags to categorize resources by purpose, owner, environment, or other criteria. Tags can help you identify, organize, search for, and filter resources. Tagging also helps

you track accountable resource owners for actions and notifications. When you use tagging, you can implement attribute-based access control (ABAC) as an authorization strategy, which defines permissions based on tags. You can attach tags to IAM entities (users or roles) and to AWS resources. You can create a single ABAC policy or a separate set of policies for your IAM principals. You can design these ABAC policies to allow operations when the principal's tag matches the resource tag. For more information, see What is ABAC for AWS? in the *IAM User Guide*.

> **Note**
>
> Don't add personally identifiable information (PII) or other confidential or sensitive information in tags. Tags are accessible to many AWS services, including AWS Billing. For more tagging best practices, see Tagging your AWS resources in the *AWS General Reference*.

Remediation

To add tags to an EC2 customer gateway, see Tag your Amazon EC2 resources in the *Amazon EC2 User Guide*.

[EC2.37] EC2 Elastic IP addresses should be tagged

Category: Identify > Inventory > Tagging

Severity: Low

Resource type: `AWS::EC2::EIP`

AWS Config rule: `tagged-ec2-eip` (custom Security Hub CSPM rule)

Schedule type: Change triggered

Parameters:

Parameter	Description	Type	Allowed custom values	Security Hub CSPM default value
`requiredTagKeys`	List of non-system tag keys that the evaluated resource	StringList (maximum of 6 items)	1–6 tag keys that meet AWS	No default value

Parameter	Description	Type	Allowed custom values	Security Hub CSPM default value
	must contain. Tag keys are case sensitive.		requirements.	

This control checks whether an Amazon EC2 Elastic IP address has tags with the specific keys defined in the parameter `requiredTagKeys`. The control fails if the Elastic IP address doesn't have any tag keys or if it doesn't have all the keys specified in the parameter `requiredTagKeys`. If the parameter `requiredTagKeys` isn't provided, the control only checks for the existence of a tag key and fails if the Elastic IP address isn't tagged with any key. System tags, which are automatically applied and begin with `aws:`, are ignored.

A tag is a label that you assign to an AWS resource, and it consists of a key and an optional value. You can create tags to categorize resources by purpose, owner, environment, or other criteria. Tags can help you identify, organize, search for, and filter resources. Tagging also helps you track accountable resource owners for actions and notifications. When you use tagging, you can implement attribute-based access control (ABAC) as an authorization strategy, which defines permissions based on tags. You can attach tags to IAM entities (users or roles) and to AWS resources. You can create a single ABAC policy or a separate set of policies for your IAM principals. You can design these ABAC policies to allow operations when the principal's tag matches the resource tag. For more information, see What is ABAC for AWS? in the *IAM User Guide*.

Note

Don't add personally identifiable information (PII) or other confidential or sensitive information in tags. Tags are accessible to many AWS services, including AWS Billing. For more tagging best practices, see Tagging your AWS resources in the *AWS General Reference*.

Remediation

To add tags to an EC2 Elastic IP address, see Tag your Amazon EC2 resources in the *Amazon EC2 User Guide*.

[EC2.38] EC2 instances should be tagged

Category: Identify > Inventory > Tagging

Severity: Low

Resource type: `AWS::EC2::Instance`

AWS Config rule: `tagged-ec2-instance` (custom Security Hub CSPM rule)

Schedule type: Change triggered

Parameters:

Parameter	Description	Type	Allowed custom values	Security Hub CSPM default value
`requiredTagKeys`	List of non-system tag keys that the evaluated resource must contain. Tag keys are case sensitive.	StringList (maximum of 6 items)	1–6 tag keys that meet AWS requirements.	No default value

This control checks whether an Amazon EC2 instance has tags with the specific keys defined in the parameter `requiredTagKeys`. The control fails if the instance doesn't have any tag keys or if it doesn't have all the keys specified in the parameter `requiredTagKeys`. If the parameter `requiredTagKeys` isn't provided, the control only checks for the existence of a tag key and fails if the instance isn't tagged with any key. System tags, which are automatically applied and begin with `aws:`, are ignored.

A tag is a label that you assign to an AWS resource, and it consists of a key and an optional value. You can create tags to categorize resources by purpose, owner, environment, or other criteria. Tags can help you identify, organize, search for, and filter resources. Tagging also helps you track accountable resource owners for actions and notifications. When you use tagging, you can implement attribute-based access control (ABAC) as an authorization strategy, which defines permissions based on tags. You can attach tags to IAM entities (users or roles) and to AWS

resources. You can create a single ABAC policy or a separate set of policies for your IAM principals. You can design these ABAC policies to allow operations when the principal's tag matches the resource tag. For more information, see What is ABAC for AWS? in the *IAM User Guide*.

> **Note**
>
> Don't add personally identifiable information (PII) or other confidential or sensitive information in tags. Tags are accessible to many AWS services, including AWS Billing. For more tagging best practices, see Tagging your AWS resources in the *AWS General Reference*.

Remediation

To add tags to an EC2 instance, see Tag your Amazon EC2 resources in the *Amazon EC2 User Guide*.

[EC2.39] EC2 internet gateways should be tagged

Category: Identify > Inventory > Tagging

Severity: Low

Resource type: `AWS::EC2::InternetGateway`

AWS Config rule: `tagged-ec2-internetgateway` (custom Security Hub CSPM rule)

Schedule type: Change triggered

Parameters:

Parameter	Description	Type	Allowed custom values	Security Hub CSPM default value
`requiredTagKeys`	List of non-system tag keys that the evaluated resource must contain. Tag keys are case sensitive.	StringList (maximum of 6 items)	1–6 tag keys that meet AWS requirements.	No default value

This control checks whether an Amazon EC2 internet gateway has tags with the specific keys defined in the parameter `requiredTagKeys`. The control fails if the internet gateway doesn't have any tag keys or if it doesn't have all the keys specified in the parameter `requiredTagKeys`. If the parameter `requiredTagKeys` isn't provided, the control only checks for the existence of a tag key and fails if the internet gateway isn't tagged with any key. System tags, which are automatically applied and begin with `aws:`, are ignored.

A tag is a label that you assign to an AWS resource, and it consists of a key and an optional value. You can create tags to categorize resources by purpose, owner, environment, or other criteria. Tags can help you identify, organize, search for, and filter resources. Tagging also helps you track accountable resource owners for actions and notifications. When you use tagging, you can implement attribute-based access control (ABAC) as an authorization strategy, which defines permissions based on tags. You can attach tags to IAM entities (users or roles) and to AWS resources. You can create a single ABAC policy or a separate set of policies for your IAM principals. You can design these ABAC policies to allow operations when the principal's tag matches the resource tag. For more information, see What is ABAC for AWS? in the *IAM User Guide*.

> **Note**
>
> Don't add personally identifiable information (PII) or other confidential or sensitive information in tags. Tags are accessible to many AWS services, including AWS Billing. For more tagging best practices, see Tagging your AWS resources in the *AWS General Reference*.

Remediation

To add tags to an EC2 internet gateway, see Tag your Amazon EC2 resources in the *Amazon EC2 User Guide*.

[EC2.40] EC2 NAT gateways should be tagged

Category: Identify > Inventory > Tagging

Severity: Low

Resource type: `AWS::EC2::NatGateway`

AWS Config rule: `tagged-ec2-natgateway` (custom Security Hub CSPM rule)

Schedule type: Change triggered

Parameters:

Parameter	Description	Type	Allowed custom values	Security Hub CSPM default value
`requiredTagKeys`	List of non-system tag keys that the evaluated resource must contain. Tag keys are case sensitive.	StringList (maximum of 6 items)	1–6 tag keys that meet AWS requirements.	No default value

This control checks whether an Amazon EC2 network address translation (NAT) gateway has tags with the specific keys defined in the parameter `requiredTagKeys`. The control fails if the NAT gateway doesn't have any tag keys or if it doesn't have all the keys specified in the parameter `requiredTagKeys`. If the parameter `requiredTagKeys` isn't provided, the control only checks for the existence of a tag key and fails if the NAT gateway isn't tagged with any key. System tags, which are automatically applied and begin with `aws:`, are ignored.

A tag is a label that you assign to an AWS resource, and it consists of a key and an optional value. You can create tags to categorize resources by purpose, owner, environment, or other criteria. Tags can help you identify, organize, search for, and filter resources. Tagging also helps you track accountable resource owners for actions and notifications. When you use tagging, you can implement attribute-based access control (ABAC) as an authorization strategy, which defines permissions based on tags. You can attach tags to IAM entities (users or roles) and to AWS resources. You can create a single ABAC policy or a separate set of policies for your IAM principals. You can design these ABAC policies to allow operations when the principal's tag matches the resource tag. For more information, see What is ABAC for AWS? in the *IAM User Guide*.

> **Note**
>
> Don't add personally identifiable information (PII) or other confidential or sensitive information in tags. Tags are accessible to many AWS services, including AWS Billing. For more tagging best practices, see Tagging your AWS resources in the *AWS General Reference*.

Remediation

To add tags to an EC2 NAT gateway, see Tag your Amazon EC2 resources in the *Amazon EC2 User Guide*.

[EC2.41] EC2 network ACLs should be tagged

Category: Identify > Inventory > Tagging

Severity: Low

Resource type: `AWS::EC2::NetworkAcl`

AWS Config rule: `tagged-ec2-networkacl` (custom Security Hub CSPM rule)

Schedule type: Change triggered

Parameters:

Parameter	Description	Type	Allowed custom values	Security Hub CSPM default value
`requiredTagKeys`	List of non-system tag keys that the evaluated resource must contain. Tag keys are case sensitive.	StringList (maximum of 6 items)	1–6 tag keys that meet AWS requirements.	No default value

This control checks whether an Amazon EC2 network access control list (network ACL) has tags with the specific keys defined in the parameter `requiredTagKeys`. The control fails if the network ACL doesn't have any tag keys or if it doesn't have all the keys specified in the parameter `requiredTagKeys`. If the parameter `requiredTagKeys` isn't provided, the control only checks for the existence of a tag key and fails if the network ACL isn't tagged with any key. System tags, which are automatically applied and begin with `aws:`, are ignored.

A tag is a label that you assign to an AWS resource, and it consists of a key and an optional value. You can create tags to categorize resources by purpose, owner, environment, or other criteria. Tags can help you identify, organize, search for, and filter resources. Tagging also helps

you track accountable resource owners for actions and notifications. When you use tagging, you can implement attribute-based access control (ABAC) as an authorization strategy, which defines permissions based on tags. You can attach tags to IAM entities (users or roles) and to AWS resources. You can create a single ABAC policy or a separate set of policies for your IAM principals. You can design these ABAC policies to allow operations when the principal's tag matches the resource tag. For more information, see What is ABAC for AWS? in the *IAM User Guide*.

> **Note**
>
> Don't add personally identifiable information (PII) or other confidential or sensitive information in tags. Tags are accessible to many AWS services, including AWS Billing. For more tagging best practices, see Tagging your AWS resources in the *AWS General Reference*.

Remediation

To add tags to an EC2 network ACL, see Tag your Amazon EC2 resources in the *Amazon EC2 User Guide*.

[EC2.42] EC2 route tables should be tagged

Category: Identify > Inventory > Tagging

Severity: Low

Resource type: `AWS::EC2::RouteTable`

AWS Config rule: `tagged-ec2-routetable` (custom Security Hub CSPM rule)

Schedule type: Change triggered

Parameters:

Parameter	Description	Type	Allowed custom values	Security Hub CSPM default value
`requiredTagKeys`	List of non-system tag keys that the evaluated resource	StringList (maximum of 6 items)	1–6 tag keys that meet AWS	No default value

Parameter	Description	Type	Allowed custom values	Security Hub CSPM default value
	must contain. Tag keys are case sensitive.		requirements.	

This control checks whether an Amazon EC2 route table has tags with the specific keys defined in the parameter `requiredTagKeys`. The control fails if the route table doesn't have any tag keys or if it doesn't have all the keys specified in the parameter `requiredTagKeys`. If the parameter `requiredTagKeys` isn't provided, the control only checks for the existence of a tag key and fails if the route table isn't tagged with any key. System tags, which are automatically applied and begin with `aws:`, are ignored.

A tag is a label that you assign to an AWS resource, and it consists of a key and an optional value. You can create tags to categorize resources by purpose, owner, environment, or other criteria. Tags can help you identify, organize, search for, and filter resources. Tagging also helps you track accountable resource owners for actions and notifications. When you use tagging, you can implement attribute-based access control (ABAC) as an authorization strategy, which defines permissions based on tags. You can attach tags to IAM entities (users or roles) and to AWS resources. You can create a single ABAC policy or a separate set of policies for your IAM principals. You can design these ABAC policies to allow operations when the principal's tag matches the resource tag. For more information, see What is ABAC for AWS? in the *IAM User Guide*.

Note

Don't add personally identifiable information (PII) or other confidential or sensitive information in tags. Tags are accessible to many AWS services, including AWS Billing. For more tagging best practices, see Tagging your AWS resources in the *AWS General Reference*.

Remediation

To add tags to an EC2 route table, see Tag your Amazon EC2 resources in the *Amazon EC2 User Guide*.

[EC2.43] EC2 security groups should be tagged

Category: Identify > Inventory > Tagging

Severity: Low

Resource type: `AWS::EC2::SecurityGroup`

AWS Config rule: `tagged-ec2-securitygroup` (custom Security Hub CSPM rule)

Schedule type: Change triggered

Parameters:

Parameter	Description	Type	Allowed custom values	Security Hub CSPM default value
`requiredTagKeys`	List of non-system tag keys that the evaluated resource must contain. Tag keys are case sensitive.	StringList (maximum of 6 items)	1–6 tag keys that meet AWS requirements.	No default value

This control checks whether an Amazon EC2 security group has tags with the specific keys defined in the parameter `requiredTagKeys`. The control fails if the security group doesn't have any tag keys or if it doesn't have all the keys specified in the parameter `requiredTagKeys`. If the parameter `requiredTagKeys` isn't provided, the control only checks for the existence of a tag key and fails if the security group isn't tagged with any key. System tags, which are automatically applied and begin with `aws:`, are ignored.

A tag is a label that you assign to an AWS resource, and it consists of a key and an optional value. You can create tags to categorize resources by purpose, owner, environment, or other criteria. Tags can help you identify, organize, search for, and filter resources. Tagging also helps you track accountable resource owners for actions and notifications. When you use tagging, you can implement attribute-based access control (ABAC) as an authorization strategy, which defines permissions based on tags. You can attach tags to IAM entities (users or roles) and to AWS

resources. You can create a single ABAC policy or a separate set of policies for your IAM principals. You can design these ABAC policies to allow operations when the principal's tag matches the resource tag. For more information, see What is ABAC for AWS? in the *IAM User Guide*.

> **Note**
>
> Don't add personally identifiable information (PII) or other confidential or sensitive information in tags. Tags are accessible to many AWS services, including AWS Billing. For more tagging best practices, see Tagging your AWS resources in the *AWS General Reference*.

Remediation

To add tags to an EC2 security group, see Tag your Amazon EC2 resources in the *Amazon EC2 User Guide*.

[EC2.44] EC2 subnets should be tagged

Category: Identify > Inventory > Tagging

Severity: Low

Resource type: `AWS::EC2::Subnet`

AWS Config rule: `tagged-ec2-subnet` (custom Security Hub CSPM rule)

Schedule type: Change triggered

Parameters:

Parameter	Description	Type	Allowed custom values	Security Hub CSPM default value
`requiredTagKeys`	List of non-system tag keys that the evaluated resource must contain. Tag keys are case sensitive.	StringList (maximum of 6 items)	1–6 tag keys that meet AWS requirements.	No default value

This control checks whether an Amazon EC2 subnet has tags with the specific keys defined in the parameter `requiredTagKeys`. The control fails if the subnet doesn't have any tag keys or if it doesn't have all the keys specified in the parameter `requiredTagKeys`. If the parameter `requiredTagKeys` isn't provided, the control only checks for the existence of a tag key and fails if the subnet isn't tagged with any key. System tags, which are automatically applied and begin with `aws:`, are ignored.

A tag is a label that you assign to an AWS resource, and it consists of a key and an optional value. You can create tags to categorize resources by purpose, owner, environment, or other criteria. Tags can help you identify, organize, search for, and filter resources. Tagging also helps you track accountable resource owners for actions and notifications. When you use tagging, you can implement attribute-based access control (ABAC) as an authorization strategy, which defines permissions based on tags. You can attach tags to IAM entities (users or roles) and to AWS resources. You can create a single ABAC policy or a separate set of policies for your IAM principals. You can design these ABAC policies to allow operations when the principal's tag matches the resource tag. For more information, see What is ABAC for AWS? in the *IAM User Guide*.

> **Note**
>
> Don't add personally identifiable information (PII) or other confidential or sensitive information in tags. Tags are accessible to many AWS services, including AWS Billing. For more tagging best practices, see Tagging your AWS resources in the *AWS General Reference*.

Remediation

To add tags to an EC2 subnet, see Tag your Amazon EC2 resources in the *Amazon EC2 User Guide*.

[EC2.45] EC2 volumes should be tagged

Category: Identify > Inventory > Tagging

Severity: Low

Resource type: `AWS::EC2::Volume`

AWS Config rule: `tagged-ec2-volume` (custom Security Hub CSPM rule)

Schedule type: Change triggered

Parameters:

Parameter	Description	Type	Allowed custom values	Security Hub CSPM default value
`requiredTagKeys`	List of non-system tag keys that the evaluated resource must contain. Tag keys are case sensitive.	StringList (maximum of 6 items)	1–6 tag keys that meet AWS requirements.	No default value

This control checks whether an Amazon EC2 volume has tags with the specific keys defined in the parameter `requiredTagKeys`. The control fails if the volume doesn't have any tag keys or if it doesn't have all the keys specified in the parameter `requiredTagKeys`. If the parameter `requiredTagKeys` isn't provided, the control only checks for the existence of a tag key and fails if the volume isn't tagged with any key. System tags, which are automatically applied and begin with `aws:`, are ignored.

A tag is a label that you assign to an AWS resource, and it consists of a key and an optional value. You can create tags to categorize resources by purpose, owner, environment, or other criteria. Tags can help you identify, organize, search for, and filter resources. Tagging also helps you track accountable resource owners for actions and notifications. When you use tagging, you can implement attribute-based access control (ABAC) as an authorization strategy, which defines permissions based on tags. You can attach tags to IAM entities (users or roles) and to AWS resources. You can create a single ABAC policy or a separate set of policies for your IAM principals. You can design these ABAC policies to allow operations when the principal's tag matches the resource tag. For more information, see What is ABAC for AWS? in the *IAM User Guide*.

> **Note**
>
> Don't add personally identifiable information (PII) or other confidential or sensitive information in tags. Tags are accessible to many AWS services, including AWS Billing. For more tagging best practices, see Tagging your AWS resources in the *AWS General Reference*.

Remediation

To add tags to an EC2 volume, see Tag your Amazon EC2 resources in the *Amazon EC2 User Guide*.

[EC2.46] Amazon VPCs should be tagged

Category: Identify > Inventory > Tagging

Severity: Low

Resource type: `AWS::EC2::VPC`

AWS Config rule: `tagged-ec2-vpc` (custom Security Hub CSPM rule)

Schedule type: Change triggered

Parameters:

Parameter	Description	Type	Allowed custom values	Security Hub CSPM default value
`requiredTagKeys`	List of non-system tag keys that the evaluated resource must contain. Tag keys are case sensitive.	StringList (maximum of 6 items)	1–6 tag keys that meet AWS requirements.	No default value

This control checks whether an Amazon Virtual Private Cloud (Amazon VPC) has tags with the specific keys defined in the parameter `requiredTagKeys`. The control fails if the Amazon VPC doesn't have any tag keys or if it doesn't have all the keys specified in the parameter `requiredTagKeys`. If the parameter `requiredTagKeys` isn't provided, the control only checks for the existence of a tag key and fails if the Amazon VPC isn't tagged with any key. System tags, which are automatically applied and begin with `aws:`, are ignored.

A tag is a label that you assign to an AWS resource, and it consists of a key and an optional value. You can create tags to categorize resources by purpose, owner, environment, or other criteria. Tags can help you identify, organize, search for, and filter resources. Tagging also helps you track accountable resource owners for actions and notifications. When you use tagging,

you can implement attribute-based access control (ABAC) as an authorization strategy, which defines permissions based on tags. You can attach tags to IAM entities (users or roles) and to AWS resources. You can create a single ABAC policy or a separate set of policies for your IAM principals. You can design these ABAC policies to allow operations when the principal's tag matches the resource tag. For more information, see What is ABAC for AWS? in the *IAM User Guide*.

> **Note**
>
> Don't add personally identifiable information (PII) or other confidential or sensitive information in tags. Tags are accessible to many AWS services, including AWS Billing. For more tagging best practices, see Tagging your AWS resources in the *AWS General Reference*.

Remediation

To add tags to a VPC, see Tag your Amazon EC2 resources in the *Amazon EC2 User Guide*.

[EC2.47] Amazon VPC endpoint services should be tagged

Category: Identify > Inventory > Tagging

Severity: Low

Resource type: `AWS::EC2::VPCEndpointService`

AWS Config rule: `tagged-ec2-vpcendpointservice` (custom Security Hub CSPM rule)

Schedule type: Change triggered

Parameters:

Parameter	Description	Type	Allowed custom values	Security Hub CSPM default value
`requiredTagKeys`	List of non-system tag keys that the evaluated resource must contain. Tag keys are case sensitive.	StringList (maximum of 6 items)	1–6 tag keys that meet AWS requirements.	No default value

This control checks whether an Amazon VPC endpoint service has tags with the specific keys defined in the parameter `requiredTagKeys`. The control fails if the endpoint service doesn't have any tag keys or if it doesn't have all the keys specified in the parameter `requiredTagKeys`. If the parameter `requiredTagKeys` isn't provided, the control only checks for the existence of a tag key and fails if the endpoint service isn't tagged with any key. System tags, which are automatically applied and begin with `aws:`, are ignored.

A tag is a label that you assign to an AWS resource, and it consists of a key and an optional value. You can create tags to categorize resources by purpose, owner, environment, or other criteria. Tags can help you identify, organize, search for, and filter resources. Tagging also helps you track accountable resource owners for actions and notifications. When you use tagging, you can implement attribute-based access control (ABAC) as an authorization strategy, which defines permissions based on tags. You can attach tags to IAM entities (users or roles) and to AWS resources. You can create a single ABAC policy or a separate set of policies for your IAM principals. You can design these ABAC policies to allow operations when the principal's tag matches the resource tag. For more information, see What is ABAC for AWS? in the *IAM User Guide*.

> **Note**
>
> Don't add personally identifiable information (PII) or other confidential or sensitive information in tags. Tags are accessible to many AWS services, including AWS Billing. For more tagging best practices, see Tagging your AWS resources in the *AWS General Reference*.

Remediation

To add tags to an Amazon VPC endpoint service, see Manage Tags in the Configure an endpoint service section of the *AWS PrivateLink Guide*.

[EC2.48] Amazon VPC flow logs should be tagged

Category: Identify > Inventory > Tagging

Severity: Low

Resource type: `AWS::EC2::FlowLog`

AWS Config rule: `tagged-ec2-flowlog` (custom Security Hub CSPM rule)

Schedule type: Change triggered

Parameters:

Parameter	Description	Type	Allowed custom values	Security Hub CSPM default value
`requiredTagKeys`	List of non-system tag keys that the evaluated resource must contain. Tag keys are case sensitive.	StringList (maximum of 6 items)	1–6 tag keys that meet AWS requirements.	No default value

This control checks whether an Amazon VPC flow log has tags with the specific keys defined in the parameter `requiredTagKeys`. The control fails if the flow log doesn't have any tag keys or if it doesn't have all the keys specified in the parameter `requiredTagKeys`. If the parameter `requiredTagKeys` isn't provided, the control only checks for the existence of a tag key and fails if the flow log isn't tagged with any key. System tags, which are automatically applied and begin with `aws:`, are ignored.

A tag is a label that you assign to an AWS resource, and it consists of a key and an optional value. You can create tags to categorize resources by purpose, owner, environment, or other criteria. Tags can help you identify, organize, search for, and filter resources. Tagging also helps you track accountable resource owners for actions and notifications. When you use tagging, you can implement attribute-based access control (ABAC) as an authorization strategy, which defines permissions based on tags. You can attach tags to IAM entities (users or roles) and to AWS resources. You can create a single ABAC policy or a separate set of policies for your IAM principals. You can design these ABAC policies to allow operations when the principal's tag matches the resource tag. For more information, see What is ABAC for AWS? in the *IAM User Guide*.

> **Note**
>
> Don't add personally identifiable information (PII) or other confidential or sensitive information in tags. Tags are accessible to many AWS services, including AWS Billing. For more tagging best practices, see Tagging your AWS resources in the *AWS General Reference*.

Remediation

To add tags to an Amazon VPC flow log, see Tag a flow log in the *Amazon VPC User Guide*.

[EC2.49] Amazon VPC peering connections should be tagged

Category: Identify > Inventory > Tagging

Severity: Low

Resource type: `AWS::EC2::VPCPeeringConnection`

AWS Config rule: `tagged-ec2-vpcpeeringconnection` (custom Security Hub CSPM rule)

Schedule type: Change triggered

Parameters:

Parameter	Description	Type	Allowed custom values	Security Hub CSPM default value
`requiredTagKeys`	List of non-system tag keys that the evaluated resource must contain. Tag keys are case sensitive.	StringList (maximum of 6 items)	1–6 tag keys that meet AWS requirements.	No default value

This control checks whether an Amazon VPC peering connection has tags with the specific keys defined in the parameter `requiredTagKeys`. The control fails if the peering connection doesn't have any tag keys or if it doesn't have all the keys specified in the parameter `requiredTagKeys`. If the parameter `requiredTagKeys` isn't provided, the control only checks for the existence of a tag key and fails if the peering connection isn't tagged with any key. System tags, which are automatically applied and begin with `aws:`, are ignored.

A tag is a label that you assign to an AWS resource, and it consists of a key and an optional value. You can create tags to categorize resources by purpose, owner, environment, or other criteria. Tags can help you identify, organize, search for, and filter resources. Tagging also helps you track accountable resource owners for actions and notifications. When you use tagging,

you can implement attribute-based access control (ABAC) as an authorization strategy, which defines permissions based on tags. You can attach tags to IAM entities (users or roles) and to AWS resources. You can create a single ABAC policy or a separate set of policies for your IAM principals. You can design these ABAC policies to allow operations when the principal's tag matches the resource tag. For more information, see What is ABAC for AWS? in the *IAM User Guide*.

> **Note**
>
> Don't add personally identifiable information (PII) or other confidential or sensitive information in tags. Tags are accessible to many AWS services, including AWS Billing. For more tagging best practices, see Tagging your AWS resources in the *AWS General Reference*.

Remediation

To add tags to an Amazon VPC peering connection, see Tag your Amazon EC2 resources in the *Amazon EC2 User Guide*.

[EC2.50] EC2 VPN gateways should be tagged

Category: Identify > Inventory > Tagging

Severity: Low

Resource type: `AWS::EC2::VPNGateway`

AWS Config rule: `tagged-ec2-vpngateway` (custom Security Hub CSPM rule)

Schedule type: Change triggered

Parameters:

Parameter	Description	Type	Allowed custom values	Security Hub CSPM default value
`requiredTagKeys`	List of non-system tag keys that the evaluated resource	StringList (maximum of 6 items)	1–6 tag keys that meet AWS	No default value

Parameter	Description	Type	Allowed custom values	Security Hub CSPM default value
	must contain. Tag keys are case sensitive.		requirements.	

This control checks whether an Amazon EC2 VPN gateway has tags with the specific keys defined in the parameter `requiredTagKeys`. The control fails if the VPN gateway doesn't have any tag keys or if it doesn't have all the keys specified in the parameter `requiredTagKeys`. If the parameter `requiredTagKeys` isn't provided, the control only checks for the existence of a tag key and fails if the VPN gateway isn't tagged with any key. System tags, which are automatically applied and begin with `aws:`, are ignored.

A tag is a label that you assign to an AWS resource, and it consists of a key and an optional value. You can create tags to categorize resources by purpose, owner, environment, or other criteria. Tags can help you identify, organize, search for, and filter resources. Tagging also helps you track accountable resource owners for actions and notifications. When you use tagging, you can implement attribute-based access control (ABAC) as an authorization strategy, which defines permissions based on tags. You can attach tags to IAM entities (users or roles) and to AWS resources. You can create a single ABAC policy or a separate set of policies for your IAM principals. You can design these ABAC policies to allow operations when the principal's tag matches the resource tag. For more information, see What is ABAC for AWS? in the *IAM User Guide*.

Note

Don't add personally identifiable information (PII) or other confidential or sensitive information in tags. Tags are accessible to many AWS services, including AWS Billing. For more tagging best practices, see Tagging your AWS resources in the *AWS General Reference*.

Remediation

To add tags to an EC2 VPN gateway, see Tag your Amazon EC2 resources in the *Amazon EC2 User Guide*.

[EC2.51] EC2 Client VPN endpoints should have client connection logging enabled

Related requirements: NIST.800-53.r5 AC-2(12), NIST.800-53.r5 AC-2(4), NIST.800-53.r5 AC-4(26), NIST.800-53.r5 AC-6(9), NIST.800-53.r5 AU-10, NIST.800-53.r5 AU-12, NIST.800-53.r5 AU-2, NIST.800-53.r5 AU-3, NIST.800-53.r5 AU-6(3), NIST.800-53.r5 AU-6(4), NIST.800-53.r5 AU-9(7), NIST.800-53.r5 CA-7, NIST.800-53.r5 SC-7(9), NIST.800-53.r5 SI-3(8), NIST.800-53.r5 SI-4, NIST.800-53.r5 SI-4(20), NIST.800-53.r5 SI-7(8), NIST.800-171.r2 3.1.12, NIST.800-171.r2 3.1.20, PCI DSS v4.0.1/10.2.1, CRI Profile v2.2/DE.AE-03.01, CRI Profile v2.2/PR.PS-04.02, CRI Profile v2.2/PR.PS-04.03

Category: Identify > Logging

Severity: Low

Resource type: `AWS::EC2::ClientVpnEndpoint`

AWS Config rule: `ec2-client-vpn-connection-log-enabled`

Schedule type: Change triggered

Parameters: None

This control checks whether an AWS Client VPN endpoint has client connection logging enabled. The control fails if the endpoint doesn't have client connection logging enabled.

Client VPN endpoints allow remote clients to securely connect to resources in a Virtual Private Cloud (VPC) in AWS. Connection logs allow you to track user activity on the VPN endpoint and provides visibility. When you enable connection logging, you can specify the name of a log stream in the log group. If you don't specify a log stream, the Client VPN service creates one for you.

Remediation

To enable connection logging, see Enable connection logging for an existing Client VPN endpoint in the *AWS Client VPN Administrator Guide*.

[EC2.52] EC2 transit gateways should be tagged

Category: Identify > Inventory > Tagging

Severity: Low

Resource type: `AWS::EC2::TransitGateway`

AWS Config rule: `tagged-ec2-transitgateway` (custom Security Hub CSPM rule)

Schedule type: Change triggered

Parameters:

Parameter	Description	Type	Allowed custom values	Security Hub CSPM default value
`requiredTagKeys`	List of non-system tag keys that the evaluated resource must contain. Tag keys are case sensitive.	StringList (maximum of 6 items)	1–6 tag keys that meet AWS requirements.	`No default value`

This control checks whether an Amazon EC2 transit gateway has tags with the specific keys defined in the parameter `requiredTagKeys`. The control fails if the transit gateway doesn't have any tag keys or if it doesn't have all the keys specified in the parameter `requiredTagKeys`. If the parameter `requiredTagKeys` isn't provided, the control only checks for the existence of a tag key and fails if the transit gateway isn't tagged with any key. System tags, which are automatically applied and begin with `aws:`, are ignored.

A tag is a label that you assign to an AWS resource, and it consists of a key and an optional value. You can create tags to categorize resources by purpose, owner, environment, or other criteria. Tags can help you identify, organize, search for, and filter resources. Tagging also helps you track accountable resource owners for actions and notifications. When you use tagging, you can implement attribute-based access control (ABAC) as an authorization strategy, which defines permissions based on tags. You can attach tags to IAM entities (users or roles) and to AWS resources. You can create a single ABAC policy or a separate set of policies for your IAM principals. You can design these ABAC policies to allow operations when the principal's tag matches the resource tag. For more information, see What is ABAC for AWS? in the *IAM User Guide*.

> **Note**
>
> Don't add personally identifiable information (PII) or other confidential or sensitive information in tags. Tags are accessible to many AWS services, including AWS Billing. For more tagging best practices, see Tagging your AWS resources in the *AWS General Reference*.

Remediation

To add tags to an EC2 transit gateway, see Tag your Amazon EC2 resources in the *Amazon EC2 User Guide*.

[EC2.53] EC2 security groups should not allow ingress from 0.0.0.0/0 to remote server administration ports

Related requirements: CIS AWS Foundations Benchmark v5.0.0/5.3, CIS AWS Foundations Benchmark v3.0.0/5.2, PCI DSS v4.0.1/1.3.1, CRI Profile v2.2/DE.CM-01.03, CRI Profile v2.2/PR.AA-03.02, CRI Profile v2.2/PR.IR-01.01, CRI Profile v2.2/PR.IR-01.03, CRI Profile v2.2/PR.IR-01.05, CRI Profile v2.2/PR.PS-01.01, CRI Profile v2.2/PR.PS-01.02

Category: Protect > Secure network configuration > Security group configuration

Severity: High

Resource type: `AWS::EC2::SecurityGroup`

AWS Config rule: `vpc-sg-port-restriction-check`

Schedule type: Periodic

Parameters:

Parameter	Description	Type	Allowed custom values	Security Hub CSPM default value
`ipType`	The IP version	String	Not customizable	`IPv4`
`restrictPorts`	List of ports that should reject ingress traffic	IntegerList	Not customizable	`22,3389`

This control checks whether an Amazon EC2 security group allows ingress from 0.0.0.0/0 to remote server administration ports (ports 22 and 3389). The control fails if the security group allows ingress from 0.0.0.0/0 to port 22 or 3389.

Security groups provide stateful filtering of ingress and egress network traffic to AWS resources. We recommend that no security group allow unrestricted ingress access to remote server administration ports, such as SSH to port 22 and RDP to port 3389, using either the TDP (6), UDP (17), or ALL (-1) protocols. Permitting public access to these ports increases resource attack surface and the risk of resource compromise.

Remediation

To update an EC2 security group rule to prohibit ingress traffic to the specified ports, see Update security group rules in the *Amazon EC2 User Guide*. After selecting a security group in the Amazon EC2 console, choose **Actions, Edit inbound rules**. Remove the rule that allows access to port 22 or port 3389.

[EC2.54] EC2 security groups should not allow ingress from ::/0 to remote server administration ports

Related requirements: CIS AWS Foundations Benchmark v5.0.0/5.4, CIS AWS Foundations Benchmark v3.0.0/5.3, PCI DSS v4.0.1/1.3.1, CRI Profile v2.2/DE.CM-01.03, CRI Profile v2.2/PR.AA-03.02, CRI Profile v2.2/PR.IR-01.01, CRI Profile v2.2/PR.IR-01.03, CRI Profile v2.2/PR.IR-01.05, CRI Profile v2.2/PR.PS-01.01, CRI Profile v2.2/PR.PS-01.02

Category: Protect > Secure network configuration > Security group configuration

Severity: High

Resource type: `AWS::EC2::SecurityGroup`

AWS Config rule: `vpc-sg-port-restriction-check`

Schedule type: Periodic

Parameters:

Parameter	Description	Type	Allowed custom values	Security Hub CSPM default value
`ipType`	The IP version	String	Not customizable	`IPv6`

Parameter	Description	Type	Allowed custom values	Security Hub CSPM default value
`restrictPorts`	List of ports that should reject ingress traffic	IntegerList	Not customizable	`22,3389`

This control checks whether an Amazon EC2 security group allows ingress from ::/0 to remote server administration ports (ports 22 and 3389). The control fails if the security group allows ingress from ::/0 to port 22 or 3389.

Security groups provide stateful filtering of ingress and egress network traffic to AWS resources. We recommend that no security group allow unrestricted ingress access to remote server administration ports, such as SSH to port 22 and RDP to port 3389, using either the TDP (6), UDP (17), or ALL (-1) protocols. Permitting public access to these ports increases resource attack surface and the risk of resource compromise.

Remediation

To update an EC2 security group rule to prohibit ingress traffic to the specified ports, see Update security group rules in the *Amazon EC2 User Guide*. After selecting a security group in the Amazon EC2 console, choose **Actions, Edit inbound rules**. Remove the rule that allows access to port 22 or port 3389.

[EC2.55] VPCs should be configured with an interface endpoint for ECR API

Related requirements: NIST.800-53.r5 AC-21, NIST.800-53.r5 AC-3, NIST.800-53.r5 AC-3(7), NIST.800-53.r5 AC-4, NIST.800-53.r5 AC-4(21), NIST.800-53.r5 AC-6, NIST.800-53.r5 SC-7, NIST.800-53.r5 SC-7(11), NIST.800-53.r5 SC-7(16), NIST.800-53.r5 SC-7(20), NIST.800-53.r5 SC-7(21), NIST.800-53.r5 SC-7(3), NIST.800-53.r5 SC-7(4)

Category: Protect > Secure access management > Access control

Severity: Medium

Resource type: `AWS::EC2::VPC`, `AWS::EC2::VPCEndpoint`

AWS Config rule: vpc-endpoint-enabled

Schedule type: Periodic

Parameters:

Parameter	Required	Description	Type	Allowed custom values	Security Hub CSPM default value
`serviceNames`	Required	The name of the service that the control evaluates	String	Not customizable	`ecr.api`
`vpcIds`	Optional	Comma-separated list of Amazon VPC IDs for VPC endpoints. If provided, the control fails if the services specified in the `serviceName` parameter don't have one of these VPC endpoints.	StringList	Customize with one or more VPC IDs	No default value

This control checks whether a virtual private cloud (VPC) that you manage has an interface VPC endpoint for Amazon ECR API. The control fails if the VPC doesn't have an interface VPC endpoint for ECR API. This control evaluates resources in a single account.

AWS PrivateLink enables customers to access services hosted on AWS in a highly available and scalable manner, while keeping all the network traffic within the AWS network. Service users can privately access services powered by PrivateLink from their VPC or their on-premises, without using public IPs, and without requiring traffic to traverse across the internet.

Remediation

To configure a VPC endpoint, see Access an AWS service using an interface VPC endpoint in the *AWS PrivateLink Guide*.

[EC2.56] VPCs should be configured with an interface endpoint for Docker Registry

Related requirements: NIST.800-53.r5 AC-21, NIST.800-53.r5 AC-3, NIST.800-53.r5 AC-3(7), NIST.800-53.r5 AC-4, NIST.800-53.r5 AC-4(21), NIST.800-53.r5 AC-6, NIST.800-53.r5 SC-7, NIST.800-53.r5 SC-7(11), NIST.800-53.r5 SC-7(16), NIST.800-53.r5 SC-7(20), NIST.800-53.r5 SC-7(21), NIST.800-53.r5 SC-7(3), NIST.800-53.r5 SC-7(4)

Category: Protect > Secure access management > Access control

Severity: Medium

Resource type: `AWS::EC2::VPC`, `AWS::EC2::VPCEndpoint`

AWS Config rule: vpc-endpoint-enabled

Schedule type: Periodic

Parameters:

Parameter	Required	Description	Type	Allowed custom values	Security Hub CSPM default value
`serviceNames`	Required	The name of the service	String	Not customizable	`ecr.dkr`

Parameter	Required	Description	Type	Allowed custom values	Security Hub CSPM default value
		that the control evaluates			
`vpcIds`	Optional	Comma-separated list of Amazon VPC IDs for VPC endpoints. If provided, the control fails if the services specified in the `serviceName` parameter don't have one of these VPC endpoints.	StringList	Customize with one or more VPC IDs	No default value

This control checks whether a virtual private cloud (VPC) that you manage has an interface VPC endpoint for Docker Registry. The control fails if the VPC doesn't have an interface VPC endpoint for Docker Registry. This control evaluates resources in a single account.

AWS PrivateLink enables customers to access services hosted on AWS in a highly available and scalable manner, while keeping all the network traffic within the AWS network. Service users can

privately access services powered by PrivateLink from their VPC or their on-premises, without using public IPs, and without requiring traffic to traverse across the internet.

Remediation

To configure a VPC endpoint, see Access an AWS service using an interface VPC endpoint in the *AWS PrivateLink Guide*.

[EC2.57] VPCs should be configured with an interface endpoint for Systems Manager

Related requirements: NIST.800-53.r5 AC-21, NIST.800-53.r5 AC-3, NIST.800-53.r5 AC-3(7), NIST.800-53.r5 AC-4, NIST.800-53.r5 AC-4(21), NIST.800-53.r5 AC-6, NIST.800-53.r5 SC-7, NIST.800-53.r5 SC-7(11), NIST.800-53.r5 SC-7(16), NIST.800-53.r5 SC-7(20), NIST.800-53.r5 SC-7(21), NIST.800-53.r5 SC-7(3), NIST.800-53.r5 SC-7(4)

Category: Protect > Secure access management > Access control

Severity: Medium

Resource type: `AWS::EC2::VPC`, `AWS::EC2::VPCEndpoint`

AWS Config rule: vpc-endpoint-enabled

Schedule type: Periodic

Parameters:

Parameter	Required	Description	Type	Allowed custom values	Security Hub CSPM default value
`serviceNames`	Required	The name of the service that the control evaluates	String	Not customizable	`ssm`
`vpcIds`	Optional	Comma-separated list of	StringList	Customize with one	No default value

Parameter	Required	Description	Type	Allowed custom values	Security Hub CSPM default value
		Amazon VPC IDs for VPC endpoints. If provided, the control fails if the services specified in the `serviceName` parameter don't have one of these VPC endpoints.		or more VPC IDs	

This control checks whether a virtual private cloud (VPC) that you manage has an interface VPC endpoint for AWS Systems Manager. The control fails if the VPC doesn't have an interface VPC endpoint for Systems Manager. This control evaluates resources in a single account.

AWS PrivateLink enables customers to access services hosted on AWS in a highly available and scalable manner, while keeping all the network traffic within the AWS network. Service users can privately access services powered by PrivateLink from their VPC or their on-premises, without using public IPs, and without requiring traffic to traverse across the internet.

Remediation

To configure a VPC endpoint, see Access an AWS service using an interface VPC endpoint in the *AWS PrivateLink Guide*.

[EC2.58] VPCs should be configured with an interface endpoint for Systems Manager Incident Manager Contacts

Related requirements: NIST.800-53.r5 AC-21, NIST.800-53.r5 AC-3, NIST.800-53.r5 AC-3(7), NIST.800-53.r5 AC-4, NIST.800-53.r5 AC-4(21), NIST.800-53.r5 AC-6, NIST.800-53.r5 SC-7, NIST.800-53.r5 SC-7(11), NIST.800-53.r5 SC-7(16), NIST.800-53.r5 SC-7(20), NIST.800-53.r5 SC-7(21), NIST.800-53.r5 SC-7(3), NIST.800-53.r5 SC-7(4)

Category: Protect > Secure access management > Access control

Severity: Medium

Resource type: `AWS::EC2::VPC`, `AWS::EC2::VPCEndpoint`

AWS Config rule: vpc-endpoint-enabled

Schedule type: Periodic

Parameters:

Parameter	Required	Description	Type	Allowed custom values	Security Hub CSPM default value
`serviceNames`	Required	The name of the service that the control evaluates	String	Not customizable	`ssm-contacts`
`vpcIds`	Optional	Comma-separated list of Amazon VPC IDs for VPC endpoints	StringList	Customize with one or more VPC IDs	No default value

Parameter	Required	Description	Type	Allowed custom values	Security Hub CSPM default value
		. If provided, the control fails if the services specified in the `serviceName` parameter don't have one of these VPC endpoints.			

This control checks whether a virtual private cloud (VPC) that you manage has an interface VPC endpoint for AWS Systems Manager Incident Manager Contacts. The control fails if the VPC doesn't have an interface VPC endpoint for Systems Manager Incident Manager Contacts. This control evaluates resources in a single account.

AWS PrivateLink enables customers to access services hosted on AWS in a highly available and scalable manner, while keeping all the network traffic within the AWS network. Service users can privately access services powered by PrivateLink from their VPC or their on-premises, without using public IPs, and without requiring traffic to traverse across the internet.

Remediation

To configure a VPC endpoint, see Access an AWS service using an interface VPC endpoint in the *AWS PrivateLink Guide*.

[EC2.60] VPCs should be configured with an interface endpoint for Systems Manager Incident Manager

Related requirements: NIST.800-53.r5 AC-21, NIST.800-53.r5 AC-3, NIST.800-53.r5 AC-3(7), NIST.800-53.r5 AC-4, NIST.800-53.r5 AC-4(21), NIST.800-53.r5 AC-6, NIST.800-53.r5 SC-7, NIST.800-53.r5 SC-7(11), NIST.800-53.r5 SC-7(16), NIST.800-53.r5 SC-7(20), NIST.800-53.r5 SC-7(21), NIST.800-53.r5 SC-7(3), NIST.800-53.r5 SC-7(4)

Category: Protect > Secure access management > Access control

Severity: Medium

Resource type: `AWS::EC2::VPC`, `AWS::EC2::VPCEndpoint`

AWS Config rule: vpc-endpoint-enabled

Schedule type: Periodic

Parameters:

Parameter	Required	Description	Type	Allowed custom values	Security Hub CSPM default value
`serviceNames`	Required	The name of the service that the control evaluates	String	Not customizable	`ssm-incidents`
`vpcIds`	Optional	Comma-separated list of Amazon VPC IDs for VPC endpoints. If	StringList	Customize with one or more VPC IDs	No default value

Parameter	Required	Description	Type	Allowed custom values	Security Hub CSPM default value
		provided, the control fails if the services specified in the `serviceName` parameter don't have one of these VPC endpoints.			

This control checks whether a virtual private cloud (VPC) that you manage has an interface VPC endpoint for AWS Systems Manager Incident Manager. The control fails if the VPC doesn't have an interface VPC endpoint for Systems Manager Incident Manager. This control evaluates resources in a single account.

AWS PrivateLink enables customers to access services hosted on AWS in a highly available and scalable manner, while keeping all the network traffic within the AWS network. Service users can privately access services powered by PrivateLink from their VPC or their on-premises, without using public IPs, and without requiring traffic to traverse across the internet.

Remediation

To configure a VPC endpoint, see Access an AWS service using an interface VPC endpoint in the *AWS PrivateLink Guide*.

[EC2.170] EC2 launch templates should use Instance Metadata Service Version 2 (IMDSv2)

Related requirements: PCI DSS v4.0.1/2.2.6, CRI Profile v2.2/PR.AA-04.01, CRI Profile v2.2/PR.PS-01.01

Category: Protect > Network Security

Severity: Low

Resource type: `AWS::EC2::LaunchTemplate`

AWS Config rule: ec2-launch-template-imdsv2-check

Schedule type: Change triggered

Parameters: None

This control checks whether an Amazon EC2 launch template is configured with Instance Metadata Service Version 2 (IMDSv2). The control fails if `HttpTokens` is set to `optional`.

Running resources on supported software versions ensures optimal performance, security, and access to the latest features. Regular updates safeguard against vulnerabilities, which help ensure a stable and efficient user experience.

Remediation

To require IMDSv2 on an EC2 launch template, see Configure the Instance Metadata Service options in the *Amazon EC2 User Guide*.

[EC2.171] EC2 VPN connections should have logging enabled

Related requirements: CIS AWS Foundations Benchmark v3.0.0/5.3, PCI DSS v4.0.1/10.4.2, CRI Profile v2.2/DE.AE-03.01, CRI Profile v2.2/DE.AE-03.02, CRI Profile v2.2/PR.PS-04.02, CRI Profile v2.2/PR.PS-04.03

Category: Identify > Logging

Severity: Medium

Resource type: `AWS::EC2::VPNConnection`

AWS Config rule: ec2-vpn-connection-logging-enabled

Schedule type: Change triggered

Parameters: None

This control checks whether an AWS Site-to-Site VPN connection has Amazon CloudWatch Logs enabled for both tunnels. The control fails if a Site-to-Site VPN connection doesn't have CloudWatch Logs enabled for both tunnels.

AWS Site-to-Site VPN logs provide you with deeper visibility into your Site-to-Site VPN deployments. With this feature, you have access to Site-to-Site VPN connection logs that provide details on IP Security (IPsec) tunnel establishment, Internet Key Exchange (IKE) negotiations, and dead peer detection (DPD) protocol messages. Site-to-Site VPN logs can be published to CloudWatch Logs. This feature provides customers with a single consistent way to access and analyze detailed logs for all of their Site-to-Site VPN connections.

Remediation

To enable tunnel logging on an EC2 VPN connection, see AWS Site-to-Site VPN logs in the *AWS Site-to-Site VPN User Guide*.

[EC2.172] EC2 VPC Block Public Access settings should block internet gateway traffic

Category: Protect > Secure network configuration > Resources not publicly accessible

Severity: Medium

Resource type: `AWS::EC2::VPCBlockPublicAccessOptions`

AWS Config rule: `ec2-vpc-bpa-internet-gateway-blocked` (custom Security Hub CSPM rule)

Schedule type: Change triggered

Parameters:

Parameter	Description	Type	Allowed custom values	Security Hub CSPM default value
`vpcBpaInternetGatewayBlockMode`	String value of the VPC BPA options mode.	Enum	`block-bidirectional` , `block-ingress`	No default value

This control checks whether Amazon EC2 VPC Block Public Access (BPA) settings are configured to block internet gateway traffic for all Amazon VPCs in the AWS account. The control fails if VPC BPA settings aren't configured to block internet gateway traffic. For the control to pass, the VPC BPA `InternetGatewayBlockMode` must be set to `block-bidirectional` or `block-ingress`. If the parameter `vpcBpaInternetGatewayBlockMode` is provided, the control passes only if the VPC BPA value for `InternetGatewayBlockMode` matches the parameter.

Configuring the VPC BPA settings for your account in an AWS Region lets you block resources in VPCs and subnets that you own in that Region from reaching or being reached from the internet through internet gateways and egress-only internet gateways. If you need specific VPCs and subnets to be able to reach or be reachable from the internet, you can exclude them by configuring VPC BPA exclusions. For instructions on creating and deleting exclusions, see Create and delete exclusions in the *Amazon VPC User Guide*.

Remediation

To enable bi-directional BPA at the account level, see Enable BPA bidirectional mode for your account in the *Amazon VPC User Guide*. To enable ingress-only BPA, see Change VPC BPA mode to ingress-only. To enable VPC BPA at the Organization level, see Enable VPC BPA at the Organization level.

[EC2.173] EC2 Spot Fleet requests with launch parameters should enable encryption for attached EBS volumes

Related requirements: CRI Profile v2.2/PR.DS-01.01, CRI Profile v2.2/PR.PS-01.06

Category: Protect > Data Protection > Encryption of data-at-rest

Severity: Medium

Resource type: `AWS::EC2::SpotFleet`

AWS Config rule: ec2-spot-fleet-request-ct-encryption-at-rest

Schedule type: Change triggered

Parameters: None

This control checks whether an Amazon EC2 Spot Fleet request that specifies launch parameters is configured to enable encryption for all Amazon Elastic Block Store (Amazon EBS) volumes attached to EC2 instances. The control fails if the Spot Fleet request specifies launch parameters and doesn't enable encryption for one or more EBS volumes specified in the request.

For an additional layer of security, you should enable encryption for Amazon EBS volumes. Encryption operations then occur on the servers that host Amazon EC2 instances, which helps ensure the security of both data at rest and data in transit between an instance and its attached EBS storage. Amazon EBS encryption is a straightforward encryption solution for EBS resources associated with your EC2 instances. With EBS encryption, you aren't required to build, maintain, and secure your own key management infrastructure. EBS encryption uses AWS KMS keys when creating encrypted volumes.

Notes

This control doesn't generate findings for Amazon EC2 Spot Fleet requests that use launch templates. It also doesn't generate findings for Spot Fleet requests that don't explicitly specify a value for the `encrypted` parameter.

Remediation

There's no direct way to encrypt an existing, unencrypted Amazon EBS volume. You can encrypt a new volume only when you create it.

However, if you enable encryption by default, Amazon EBS encrypts new volumes by using your default key for EBS encryption. If you don't enable encryption by default, you can enable encryption when you create an individual volume. In both cases, you can override the default key for EBS encryption and choose a customer managed AWS KMS key. For more information about EBS encryption, see Amazon EBS encryption in the *Amazon EBS User Guide*.

For information about creating an Amazon EC2 Spot Fleet request, see Create a Spot Fleet in the *Amazon Elastic Compute Cloud User Guide*.

[EC2.174] EC2 DHCP option sets should be tagged

Related requirements: CRI Profile v2.2/ID.AM-02.01, CRI Profile v2.2/ID.AM-05.01

Category: Identify > Inventory > Tagging

Severity: Low

Resource type: `AWS::EC2::DHCPOptions`

AWS Config rule: ec2-dhcp-options-tagged

Schedule type: Change triggered

Parameters:

Parameter	Description	Type	Allowed custom values	Security Hub CSPM default value
`requiredKeyTags`	A list of non-system tag keys that must be assigned to an evaluated resource. Tag keys are case sensitive.	StringList (maximum of 6 items)	1–6 tag keys that meet AWS requirements.	No default value

This control checks whether an Amazon EC2 DHCP option set has the tag keys specified by the `requiredKeyTags` parameter. The control fails if the option set doesn't have any tag keys, or it doesn't have all the keys specified by the `requiredKeyTags` parameter. If you don't specify any values for the `requiredKeyTags` parameter, the control checks only for the existence of a tag key and fails if the option set doesn't have any tag keys. The control ignores system tags, which are applied automatically and have the `aws:` prefix.

A tag is a label that you create and assign to an AWS resource. Each tag consists of a required tag key and an optional tag value. You can use tags to categorize resources by purpose, owner, environment, or other criteria. They can help you identify, organize, search for, and filter resources. They can also help you track resource owners for actions and notifications. You can also use tags to implement attribute-based access control (ABAC) as an authorization strategy. For more information about ABAC strategies, see Define permissions based on attributes with ABAC authorization in the *IAM User Guide*. For more information about tags, see the Tagging AWS Resources and Tag Editor User Guide.

> **Note**
>
> Do not store personally identifiable information (PII) or other confidential or sensitive information in tags. Tags are accessible from many AWS services. They aren't intended to be used for private or sensitive data.

Remediation

For information about adding tags to an Amazon EC2 DHCP option set, see Tag your Amazon EC2 resources in the *Amazon EC2 User Guide*.

[EC2.175] EC2 launch templates should be tagged

Category: Identify > Inventory > Tagging

Severity: Low

Resource type: `AWS::EC2::LaunchTemplate`

AWS Config rule: ec2-launch-template-tagged

Schedule type: Change triggered

Parameters:

Parameter	Description	Type	Allowed custom values	Security Hub CSPM default value
`requiredKeyTags`	A list of non-system tag keys that must be assigned to an evaluated resource. Tag keys are case sensitive.	StringList (maximum of 6 items)	1–6 tag keys that meet AWS requirements.	No default value

This control checks whether an Amazon EC2 launch template has the tag keys specified by the `requiredKeyTags` parameter. The control fails if the launch template doesn't have any tag keys, or it doesn't have all the keys specified by the `requiredKeyTags` parameter. If you don't specify any values for the `requiredKeyTags` parameter, the control checks only for the existence of a tag key and fails if the launch template doesn't have any tag keys. The control ignores system tags, which are applied automatically and have the `aws:` prefix.

A tag is a label that you create and assign to an AWS resource. Each tag consists of a required tag key and an optional tag value. You can use tags to categorize resources by purpose, owner,

environment, or other criteria. They can help you identify, organize, search for, and filter resources. They can also help you track resource owners for actions and notifications. You can also use tags to implement attribute-based access control (ABAC) as an authorization strategy. For more information about ABAC strategies, see Define permissions based on attributes with ABAC authorization in the *IAM User Guide*. For more information about tags, see the Tagging AWS Resources and Tag Editor User Guide.

> **Note**
>
> Do not store personally identifiable information (PII) or other confidential or sensitive information in tags. Tags are accessible from many AWS services. They aren't intended to be used for private or sensitive data.

Remediation

For information about adding tags to an Amazon EC2 launch template, see Tag your Amazon EC2 resources in the *Amazon EC2 User Guide*.

[EC2.176] EC2 prefix lists should be tagged

Related requirements: CRI Profile v2.2/ID.AM-02.01, CRI Profile v2.2/ID.AM-05.01

Category: Identify > Inventory > Tagging

Severity: Low

Resource type: `AWS::EC2::PrefixList`

AWS Config rule: ec2-prefix-list-tagged

Schedule type: Change triggered

Parameters:

Parameter	Description	Type	Allowed custom values	Security Hub CSPM default value
`requiredKeyTags`	A list of non-system tag keys that must be assigned to an evaluated resource. Tag keys are case sensitive.	StringList (maximum of 6 items)	1–6 tag keys that meet AWS requirements.	No default value

This control checks whether an Amazon EC2 prefix list has the tag keys specified by the `requiredKeyTags` parameter. The control fails if the prefix list doesn't have any tag keys, or it doesn't have all the keys specified by the `requiredKeyTags` parameter. If you don't specify any values for the `requiredKeyTags` parameter, the control checks only for the existence of a tag key and fails if the prefix list doesn't have any tag keys. The control ignores system tags, which are applied automatically and have the `aws:` prefix.

A tag is a label that you create and assign to an AWS resource. Each tag consists of a required tag key and an optional tag value. You can use tags to categorize resources by purpose, owner, environment, or other criteria. They can help you identify, organize, search for, and filter resources. They can also help you track resource owners for actions and notifications. You can also use tags to implement attribute-based access control (ABAC) as an authorization strategy. For more information about ABAC strategies, see Define permissions based on attributes with ABAC authorization in the *IAM User Guide*. For more information about tags, see the Tagging AWS Resources and Tag Editor User Guide.

Note

Do not store personally identifiable information (PII) or other confidential or sensitive information in tags. Tags are accessible from many AWS services. They aren't intended to be used for private or sensitive data.

Remediation

For information about adding tags to an Amazon EC2 prefix list, see Tag your Amazon EC2 resources in the *Amazon EC2 User Guide*.

[EC2.177] EC2 traffic mirror sessions should be tagged

Related requirements: CRI Profile v2.2/ID.AM-02.01, CRI Profile v2.2/ID.AM-05.01

Category: Identify > Inventory > Tagging

Severity: Low

Resource type: `AWS::EC2::TrafficMirrorSession`

AWS Config rule: ec2-traffic-mirror-session-tagged

Schedule type: Change triggered

Parameters:

Parameter	Description	Type	Allowed custom values	Security Hub CSPM default value
`requiredKeyTags`	A list of non-system tag keys that must be assigned to an evaluated resource. Tag keys are case sensitive.	StringList (maximum of 6 items)	1–6 tag keys that meet AWS requirements.	No default value

This control checks whether an Amazon EC2 traffic mirror session has the tag keys specified by the `requiredKeyTags` parameter. The control fails if the session doesn't have any tag keys, or it doesn't have all the keys specified by the `requiredKeyTags` parameter. If you don't specify any values for the `requiredKeyTags` parameter, the control checks only for the existence of a tag key and fails if the session doesn't have any tag keys. The control ignores system tags, which are applied automatically and have the `aws:` prefix.

A tag is a label that you create and assign to an AWS resource. Each tag consists of a required tag key and an optional tag value. You can use tags to categorize resources by purpose, owner, environment, or other criteria. They can help you identify, organize, search for, and filter resources. They can also help you track resource owners for actions and notifications. You can also use tags to implement attribute-based access control (ABAC) as an authorization strategy. For more information about ABAC strategies, see Define permissions based on attributes with ABAC authorization in the *IAM User Guide*. For more information about tags, see the Tagging AWS Resources and Tag Editor User Guide.

> **Note**
>
> Do not store personally identifiable information (PII) or other confidential or sensitive information in tags. Tags are accessible from many AWS services. They aren't intended to be used for private or sensitive data.

Remediation

For information about adding tags to an Amazon EC2 traffic mirror session, see Tag your Amazon EC2 resources in the *Amazon EC2 User Guide*.

[EC2.178] EC2 traffic mirror filters should be tagged

Related requirements: CRI Profile v2.2/ID.AM-02.01, CRI Profile v2.2/ID.AM-05.01

Category: Identify > Inventory > Tagging

Severity: Low

Resource type: `AWS::EC2::TrafficMirrorFilter`

AWS Config rule: ec2-traffic-mirror-filter-tagged

Schedule type: Change triggered

Parameters:

Parameter	Description	Type	Allowed custom values	Security Hub CSPM default value
`requiredKeyTags`	A list of non-system tag keys that must be assigned to an evaluated resource. Tag keys are case sensitive.	StringList (maximum of 6 items)	1–6 tag keys that meet AWS requirements.	No default value

This control checks whether an Amazon EC2 traffic mirror filter has the tag keys specified by the `requiredKeyTags` parameter. The control fails if the filter doesn't have any tag keys, or it doesn't have all the keys specified by the `requiredKeyTags` parameter. If you don't specify any values for the `requiredKeyTags` parameter, the control checks only for the existence of a tag key and fails if the filter doesn't have any tag keys. The control ignores system tags, which are applied automatically and have the `aws:` prefix.

A tag is a label that you create and assign to an AWS resource. Each tag consists of a required tag key and an optional tag value. You can use tags to categorize resources by purpose, owner, environment, or other criteria. They can help you identify, organize, search for, and filter resources. They can also help you track resource owners for actions and notifications. You can also use tags to implement attribute-based access control (ABAC) as an authorization strategy. For more information about ABAC strategies, see Define permissions based on attributes with ABAC authorization in the *IAM User Guide*. For more information about tags, see the Tagging AWS Resources and Tag Editor User Guide.

Note

Do not store personally identifiable information (PII) or other confidential or sensitive information in tags. Tags are accessible from many AWS services. They aren't intended to be used for private or sensitive data.

Remediation

For information about adding tags to an Amazon EC2 traffic mirror filter, see Tag your Amazon EC2 resources in the *Amazon EC2 User Guide*.

[EC2.179] EC2 traffic mirror targets should be tagged

Category: Identify > Inventory > Tagging

Severity: Low

Resource type: `AWS::EC2::TrafficMirrorTarget`

AWS Config rule: ec2-traffic-mirror-target-tagged

Schedule type: Change triggered

Parameters:

Parameter	Description	Type	Allowed custom values	Security Hub CSPM default value
`requiredKeyTags`	A list of non-system tag keys that must be assigned to an evaluated resource. Tag keys are case sensitive.	StringList (maximum of 6 items)	1–6 tag keys that meet AWS requirements.	No default value

This control checks whether an Amazon EC2 traffic mirror target has the tag keys specified by the `requiredKeyTags` parameter. The control fails if the target doesn't have any tag keys, or it doesn't have all the keys specified by the `requiredKeyTags` parameter. If you don't specify any values for the `requiredKeyTags` parameter, the control checks only for the existence of a tag key and fails if the target doesn't have any tag keys. The control ignores system tags, which are applied automatically and have the `aws:` prefix.

A tag is a label that you create and assign to an AWS resource. Each tag consists of a required tag key and an optional tag value. You can use tags to categorize resources by purpose, owner,

environment, or other criteria. They can help you identify, organize, search for, and filter resources. They can also help you track resource owners for actions and notifications. You can also use tags to implement attribute-based access control (ABAC) as an authorization strategy. For more information about ABAC strategies, see Define permissions based on attributes with ABAC authorization in the *IAM User Guide*. For more information about tags, see the Tagging AWS Resources and Tag Editor User Guide.

> **Note**
>
> Do not store personally identifiable information (PII) or other confidential or sensitive information in tags. Tags are accessible from many AWS services. They aren't intended to be used for private or sensitive data.

Remediation

For information about adding tags to an Amazon EC2 traffic mirror target, see Tag your Amazon EC2 resources in the *Amazon EC2 User Guide*.

[EC2.180] EC2 network interfaces should have source/destination checking enabled

Related requirements: CRI Profile v2.2/DE.CM-01.03, CRI Profile v2.2/PR.IR-01.01, CRI Profile v2.2/PR.PS-01.01

Category: Protect > Network Security

Severity: Medium

Resource type: `AWS::EC2::NetworkInterface`

AWS Config rule: ec2-enis-source-destination-check-enabled

Schedule type: Change triggered

Parameters: None

This control checks whether source/destination checking is enabled for an Amazon EC2 elastic network interface (ENI) that's managed by users. The control fails if source/destination checking is disabled for the user-managed ENI. This control checks only the following types of ENIs: `aws_codestar_connections_managed`, `branch`, `efa`, `interface`, `lambda`, and `quicksight`.

Source/destination checking for Amazon EC2 instances and attached ENIs should be enabled and configured consistently across your EC2 instances. Each ENI has its own setting for source/destination checks. If source/destination checking is enabled, Amazon EC2 enforces source/destination address validation, which ensures that an instance is either the source or the destination of any traffic that it receives. This provides an additional layer of network security by preventing resources from handling unintended traffic and preventing IP address spoofing.

> **Note**
>
> If you're using an EC2 instance as a NAT instance and you disabled source/destination checking for its ENI, you can use a NAT gateway instead.

Remediation

For information about enabling source/destination checks for an Amazon EC2 ENI, see Modify network interface attributes in the *Amazon EC2 User Guide*.

[EC2.181] EC2 launch templates should enable encryption for attached EBS volumes

Related requirements: CRI Profile v2.2/PR.DS-01.01, CRI Profile v2.2/PR.PS-01.06

Category: Protect > Data Protection > Encryption of data-at-rest

Severity: Medium

Resource type: `AWS::EC2::LaunchTemplate`

AWS Config rule: ec2-launch-templates-ebs-volume-encrypted

Schedule type: Change triggered

Parameters: None

This control checks whether an Amazon EC2 launch template enables encryption for all attached EBS volumes. The control fails if the encryption parameter is set to `False` for any EBS volumes specified by the EC2 launch template.

Amazon EBS encryption is a straightforward encryption solution for EBS resources that are associated with Amazon EC2 instances. With EBS encryption, you aren't required to build, maintain,

and secure your own key management infrastructure. EBS encryption uses AWS KMS keys when creating encrypted volumes and snapshots. Encryption operations occur on the servers that host EC2 instances, which helps ensure the security of data at rest and data in transit between an EC2 instance and its attached EBS storage. For more information, see Amazon EBS encryption in the *Amazon EBS User Guide*.

You can enable EBS encryption during manual launches of individual EC2 instances. However, there are several benefits to using EC2 launch templates and configuring encryption settings in those templates. You can enforce encryption as a standard and ensure the use of consistent encryption settings. You can also reduce the risk of error and security gaps that might occur with manual launches of instances.

> **Note**
>
> When this control checks an EC2 launch template, it only evaluates EBS encryption settings that are explicitly specified by the template. The evaluation doesn't include encryption settings that are inherited from account-level EBS encryption settings, AMI block device mappings, or source snapshot encryption statuses.

Remediation

After you create an Amazon EC2 launch template, you can't modify it. However, you can create a new version of a launch template and change the encryption settings in that new version of the template. You can also specify the new version as the default version of the launch template. Then, if you launch an EC2 instance from a launch template and don't specify a template version, EC2 uses the settings of the default version when it launches the instance. For more information, see Modify a launch template in the *Amazon EC2 User Guide*.

[EC2.182] Block public access settings should be enabled for Amazon EBS snapshots

Category: Protect > Secure network configuration > Resources not publicly accessible

Severity: High

Resource type: `AWS::EC2::SnapshotBlockPublicAccess`

AWS Config rule: ebs-snapshot-block-public-access

Schedule type: Change triggered

Parameters: None

This control checks whether account level block public access is enabled to prevent sharing of Amazon EBS snapshots to all. The control fails if block public access is not enabled to block sharing of Amazon EBS snapshots to all.

To prevent public sharing of your Amazon EBS snapshots, you can enable block public access for snapshots. Once block public access for snapshots is enabled in a Region, any attempt to publicly share snapshots in that Region is automatically blocked. This helps improve the security of the snapshots and protect the snapshot data from unauthorized or unintended access.

Remediation

To enable block public access for snapshots, see Configure block public access for Amazon EBS snapshots in the *Amazon EBS User Guide*. For **Block public access**, choose **Block all public access**.

[EC2.183] EC2 VPN connections should use IKEv2 protocol

Category: Protect > Data Protection > Encryption of data-in-transit

Severity: Medium

Resource type: `AWS::EC2::VPNConnection`

AWS Config rule: ec2-vpn-connection-ike-version-check

Schedule type: Change triggered

Parameters: None

This control checks whether an AWS Site-to-Site VPN connection is configured to use IKEv2 protocol. The control fails if a Site-to-Site VPN connection allows IKEv1 protocol or does not explicitly restrict to IKEv2 on all VPN tunnels.

IKEv2 provides stronger cryptographic algorithms and improved security features compared to the legacy IKEv1 protocol, including built-in protection against denial-of-service attacks and enhanced authentication mechanisms. IKEv1 has known vulnerabilities and weaknesses in its key exchange process that can be exploited by attackers to compromise VPN tunnel security. By enforcing IKEv2-only connections, you reduce your attack surface and ensure VPN communications use modern, industry-standard encryption protocols that better protect data in transit.

Remediation

To update the IKE version for a VPN tunnel on an EC2 VPN connection, see Modify AWS Site-to-Site VPN tunnel options in the *AWS Site-to-Site VPN User Guide*.

Security Hub CSPM controls for Auto Scaling

These Security Hub CSPM controls evaluate the Amazon EC2 Auto Scaling service and resources.

These controls may not be available in all AWS Regions. For more information, see Availability of controls by Region.

[AutoScaling.1] Auto Scaling groups associated with a load balancer should use ELB health checks

Related requirements: PCI DSS v3.2.1/2.2, NIST.800-53.r5 CA-7, NIST.800-53.r5 CP-2(2), NIST.800-53.r5 SI-2, CRI Profile v2.2/GV.RM-09.02, CRI Profile v2.2/PR.IR-03.01, CRI Profile v2.2/PR.IR-04.02

Category: Identify > Inventory

Severity: Low

Resource type: `AWS::AutoScaling::AutoScalingGroup`

AWS Config rule: `autoscaling-group-elb-healthcheck-required`

Schedule type: Change triggered

Parameters: None

This control checks whether an Amazon EC2 Auto Scaling group that is associated with a load balancer uses Elastic Load Balancing (ELB) health checks. The control fails if the Auto Scaling group doesn't use ELB health checks.

ELB health checks help ensure that an Auto Scaling group can determine an instance's health based on additional tests provided by the load balancer. Using Elastic Load Balancing health checks also helps support the availability of applications that use EC2 Auto Scaling groups.

Remediation

To add Elastic Load Balancing health checks, see Add Elastic Load Balancing health checks in the *Amazon EC2 Auto Scaling User Guide*.

[AutoScaling.2] Amazon EC2 Auto Scaling group should cover multiple Availability Zones

Related requirements: NIST.800-53.r5 CP-10, NIST.800-53.r5 CP-2(2), NIST.800-53.r5 CP-6(2), NIST.800-53.r5 SC-36, NIST.800-53.r5 SC-5(2), NIST.800-53.r5 SI-13(5), CRI Profile v2.2/PR.IR-03.01, CRI Profile v2.2/PR.IR-04.02

Category: Recover > Resilience > High availability

Severity: Medium

Resource type: `AWS::AutoScaling::AutoScalingGroup`

AWS Config rule: `autoscaling-multiple-az`

Schedule type: Change triggered

Parameters:

Parameter	Description	Type	Allowed custom values	Security Hub CSPM default value	
`minAvailabilityZones`	Minimum number of Availability Zones	Enum	`2, 3, 4, 5, 6`	`2`	

This control checks whether an Amazon EC2 Auto Scaling group spans at least the specified number of Availability Zones (AZs). The control fails if an Auto Scaling group doesn't span at least the specified number of AZs. Unless you provide a custom parameter value for the minimum number of AZs, Security Hub CSPM uses a default value of two AZs.

An Auto Scaling group that doesn't span multiple AZs can't launch instances in another AZ to compensate if the configured single AZ becomes unavailable. However, an Auto Scaling group with a single Availability Zone may be preferred in some use cases, such as batch jobs or when inter-AZ transfer costs need to be kept to a minimum. In such cases, you can disable this control or suppress its findings.

Remediation

To add AZs to an existing Auto Scaling group, see Add and remove Availability Zones in the *Amazon EC2 Auto Scaling User Guide*.

[AutoScaling.3] Auto Scaling group launch configurations should configure EC2 instances to require Instance Metadata Service Version 2 (IMDSv2)

Related requirements: NIST.800-53.r5 AC-3, NIST.800-53.r5 AC-3(15), NIST.800-53.r5 AC-3(7), NIST.800-53.r5 AC-6, NIST.800-53.r5 CA-9(1), NIST.800-53.r5 CM-2, PCI DSS v4.0.1/2.2.6, CRI Profile v2.2/PR.AA-04.01, CRI Profile v2.2/PR.PS-01.01

Category: Protect > Secure network configuration

Severity: High

Resource type: `AWS::AutoScaling::LaunchConfiguration`

AWS Config rule: `autoscaling-launchconfig-requires-imdsv2`

Schedule type: Change triggered

Parameters: None

This control checks whether IMDSv2 is enabled on all instances launched by Amazon EC2 Auto Scaling groups. The control fails if the Instance Metadata Service (IMDS) version isn't included in the launch configuration or is configured as `token optional`, which is a setting that allows either IMDSv1 or IMDSv2.

IMDS provides data about your instance that you can use to configure or manage the running instance.

Version 2 of the IMDS adds new protections that weren't available in IMDSv1 to further safeguard your EC2 instances.

Remediation

An Auto Scaling group is associated with one launch configuration at a time. You cannot modify a launch configuration after you create it. To change the launch configuration for an Auto Scaling group, use an existing launch configuration as the basis for a new launch configuration with

IMDSv2 enabled. For more information, see Configure instance metadata options for new instances in the *Amazon EC2 User Guide*.

[AutoScaling.4] Auto Scaling group launch configuration should not have a metadata response hop limit greater than 1

> **Important**
>
> Security Hub CSPM retired this control in April 2024. For more information, see Change log for Security Hub CSPM controls.

Related requirements: NIST.800-53.r5 CA-9(1), NIST.800-53.r5 CM-2, NIST.800-53.r5 CM-2(2)

Category: Protect > Secure network configuration

Severity: High

Resource type: `AWS::AutoScaling::LaunchConfiguration`

AWS Config rule: `autoscaling-launch-config-hop-limit`

Schedule type: Change triggered

Parameters: None

This control checks the number of network hops that a metadata token can travel. The control fails if the metadata response hop limit is greater than 1.

The Instance Metadata Service (IMDS) provides metadata information about an Amazon EC2 instance and is useful for application configuration. Restricting the HTTP PUT response for the metadata service to only the EC2 instance protects the IMDS from unauthorized use.

The Time To Live (TTL) field in the IP packet is reduced by one on every hop. This reduction can be used to ensure that the packet does not travel outside EC2. IMDSv2 protects EC2 instances that may have been misconfigured as open routers, layer 3 firewalls, VPNs, tunnels, or NAT devices, which prevents unauthorized users from retrieving metadata. With IMDSv2, the PUT response that contains the secret token cannot travel outside the instance because the default metadata response hop limit is set to 1. However, if this value is greater than 1, the token can leave the EC2 instance.

Remediation

To modify the metadata response hop limit for an existing launch configuration, see Modify instance metadata options for existing instances in the *Amazon EC2 User Guide*.

[Autoscaling.5] Amazon EC2 instances launched using Auto Scaling group launch configurations should not have Public IP addresses

Related requirements: NIST.800-53.r5 AC-21, NIST.800-53.r5 AC-3, NIST.800-53.r5 AC-3(7), NIST.800-53.r5 AC-4, NIST.800-53.r5 AC-4(21), NIST.800-53.r5 AC-6, NIST.800-53.r5 SC-7, NIST.800-53.r5 SC-7(11), NIST.800-53.r5 SC-7(16), NIST.800-53.r5 SC-7(20), NIST.800-53.r5 SC-7(21), NIST.800-53.r5 SC-7(3), NIST.800-53.r5 SC-7(4), NIST.800-53.r5 SC-7(9), PCI DSS v4.0.1/1.4.4, CRI Profile v2.2/PR.IR-01.01, CRI Profile v2.2/PR.IR-01.02, CRI Profile v2.2/PR.PS-01.02

Category: Protect > Secure network configuration > Resources not publicly accessible

Severity: High

Resource type: `AWS::AutoScaling::LaunchConfiguration`

AWS Config rule: `autoscaling-launch-config-public-ip-disabled`

Schedule type: Change triggered

Parameters: None

This control checks whether an Auto Scaling group's associated launch configuration assigns a public IP address to the group's instances. The control fails if the associated launch configuration assigns a public IP address.

Amazon EC2 instances in an Auto Scaling group launch configuration should not have an associated public IP address, except for in limited edge cases. Amazon EC2 instances should only be accessible from behind a load balancer instead of being directly exposed to the internet.

Remediation

An Auto Scaling group is associated with one launch configuration at a time. You cannot modify a launch configuration after you create it. To change the launch configuration for an Auto Scaling group, use an existing launch configuration as the basis for a new launch configuration. Then, update the Auto Scaling group to use the new launch configuration. For step-by-step instructions, see Change the launch configuration for an Auto Scaling group in the *Amazon EC2 Auto Scaling*

User Guide. When creating the new launch configuration, under **Additional configuration**, for **Advanced details, IP address type**, choose **Do not assign a public IP address to any instances**.

After you change the launch configuration, Auto Scaling launches new instances with the new configuration options. Existing instances aren't affected. To update an existing instance, we recommend that you refresh your instance, or allow automatic scaling to gradually replace older instances with newer instances based on your termination policies. For more information about updating Auto Scaling instances, see Update Auto Scaling instances in the *Amazon EC2 Auto Scaling User Guide*.

[AutoScaling.6] Auto Scaling groups should use multiple instance types in multiple Availability Zones

Related requirements: NIST.800-53.r5 CP-10, NIST.800-53.r5 CP-2(2), NIST.800-53.r5 CP-6(2), NIST.800-53.r5 SC-36, NIST.800-53.r5 SC-5(2), NIST.800-53.r5 SI-13(5), CRI Profile v2.2/GV.OC-04.03, CRI Profile v2.2/GV.RM-09.02, CRI Profile v2.2/PR.IR-03.01, CRI Profile v2.2/PR.IR-04.02

Category: Recover > Resilience > High availability

Severity: Medium

Resource type: `AWS::AutoScaling::AutoScalingGroup`

AWS Config rule: `autoscaling-multiple-instance-types`

Schedule type: Change triggered

Parameters: None

This control checks whether an Amazon EC2 Auto Scaling group uses multiple instance types. The control fails if the Auto Scaling group has only one instance type defined.

You can enhance availability by deploying your application across multiple instance types running in multiple Availability Zones. Security Hub CSPM recommends using multiple instance types so that the Auto Scaling group can launch another instance type if there is insufficient instance capacity in your chosen Availability Zones.

Remediation

To create an Auto Scaling group with multiple instance types, see Auto Scaling groups with multiple instance types and purchase options in the *Amazon EC2 Auto Scaling User Guide*.

[AutoScaling.9] Amazon EC2 Auto Scaling groups should use Amazon EC2 launch templates

Related requirements: NIST.800-53.r5 CA-9(1), NIST.800-53.r5 CM-2, NIST.800-53.r5 CM-2(2), CRI Profile v2.2/PR.PS-01.01, CRI Profile v2.2/PR.PS-01.03

Category: Identify > Resource Configuration

Severity: Medium

Resource type: `AWS::AutoScaling::AutoScalingGroup`

AWS Config rule: `autoscaling-launch-template`

Schedule type: Change triggered

Parameters: None

This control checks whether an Amazon EC2 Auto Scaling group is created from an EC2 launch template. This control fails if an Amazon EC2 Auto Scaling group is not created with a launch template or if a launch template is not specified in a mixed instances policy.

An EC2 Auto Scaling group can be created from either an EC2 launch template or a launch configuration. However, using a launch template to create an Auto Scaling group ensures that you have access to the latest features and improvements.

Remediation

To create an Auto Scaling group with an EC2 launch template, see Create an Auto Scaling group using a launch template in the *Amazon EC2 Auto Scaling User Guide*. For information about how to replace a launch configuration with a launch template, see Replace a launch configuration with a launch template in the *Amazon EC2 User Guide*.

[AutoScaling.10] EC2 Auto Scaling groups should be tagged

Category: Identify > Inventory > Tagging

Severity: Low

Resource type: `AWS::AutoScaling::AutoScalingGroup`

AWS Config rule: `tagged-autoscaling-autoscalinggroup` (custom Security Hub CSPM rule)

Schedule type: Change triggered

Parameters:

Parameter	Description	Type	Allowed custom values	Security Hub CSPM default value
`requiredTagKeys`	List of non-system tag keys that the evaluated resource must contain. Tag keys are case sensitive.	StringList (maximum of 6 items)	1–6 tag keys that meet AWS requirements.	No default value

This control checks whether an Amazon EC2 Auto Scaling group has tags with the specific keys defined in the parameter `requiredTagKeys`. The control fails if the Auto Scaling group doesn't have any tag keys or if it doesn't have all the keys specified in the parameter `requiredTagKeys`. If the parameter `requiredTagKeys` isn't provided, the control only checks for the existence of a tag key and fails if the Auto Scaling group isn't tagged with any key. System tags, which are automatically applied and begin with `aws:`, are ignored.

A tag is a label that you assign to an AWS resource, and it consists of a key and an optional value. You can create tags to categorize resources by purpose, owner, environment, or other criteria. Tags can help you identify, organize, search for, and filter resources. Tagging also helps you track accountable resource owners for actions and notifications. When you use tagging, you can implement attribute-based access control (ABAC) as an authorization strategy, which defines permissions based on tags. You can attach tags to IAM entities (users or roles) and to AWS resources. You can create a single ABAC policy or a separate set of policies for your IAM principals. You can design these ABAC policies to allow operations when the principal's tag matches the resource tag. For more information, see What is ABAC for AWS? in the *IAM User Guide*.

> **Note**
>
> Don't add personally identifiable information (PII) or other confidential or sensitive information in tags. Tags are accessible to many AWS services, including AWS Billing. For more tagging best practices, see Tagging your AWS resources in the *AWS General Reference*.

Remediation

To add tags to an Auto Scaling group, see Tag Auto Scaling groups and instances in the *Amazon EC2 Auto Scaling User Guide*.

Security Hub CSPM controls for Amazon ECR

These Security Hub CSPM controls evaluate the Amazon Elastic Container Registry (Amazon ECR) service and resources.

These controls may not be available in all AWS Regions. For more information, see Availability of controls by Region.

[ECR.1] ECR private repositories should have image scanning configured

Related requirements: NIST.800-53.r5 RA-5, PCI DSS v4.0.1/6.2.3, PCI DSS v4.0.1/6.2.4, CRI Profile v2.2/ID.RA-01.03, CRI Profile v2.2/PR.PS-02.01, CRI Profile v2.2/PR.PS-02.02

Category: Identify > Vulnerability, patch, and version management

Severity: High

Resource type: `AWS::ECR::Repository`

AWS Config rule: ecr-private-image-scanning-enabled

Schedule type: Periodic

Parameters: None

This control checks whether a private Amazon ECR repository has image scanning configured. The control fails if the private ECR repository isn't configured for scan on push or continuous scanning.

ECR image scanning helps in identifying software vulnerabilities in your container images. Configuring image scanning on ECR repositories adds a layer of verification for the integrity and safety of the images being stored.

Remediation

To configure image scanning for an ECR repository, see Image scanning in the *Amazon Elastic Container Registry User Guide*.

[ECR.2] ECR private repositories should have tag immutability configured

Related requirements: NIST.800-53.r5 CA-9(1), NIST.800-53.r5 CM-2, NIST.800-53.r5 CM-8(1), CRI Profile v2.2/DE.CM-09.03, CRI Profile v2.2/ID.AM-02.01, CRI Profile v2.2/PR.PS-01.01

Category: Identify > Inventory > Tagging

Severity: Medium

Resource type: `AWS::ECR::Repository`

AWS Config rule: ecr-private-tag-immutability-enabled

Schedule type: Change triggered

Parameters: None

This control checks whether a private ECR repository has tag immutability enabled. This control fails if a private ECR repository has tag immutability disabled. This rule passes if tag immutability is enabled and has the value `IMMUTABLE`.

Amazon ECR Tag Immutability enables customers to rely on the descriptive tags of an image as a reliable mechanism to track and uniquely identify images. An immutable tag is static, which means each tag refers to a unique image. This improves reliability and scalability as the use of a static tag will always result in the same image being deployed. When configured, tag immutability prevents the tags from being overridden, which reduces the attack surface.

Remediation

To create a repository with immutable tags configured or to update the image tag mutability settings for an existing repository, see Image tag mutability in the *Amazon Elastic Container Registry User Guide*.

[ECR.3] ECR repositories should have at least one lifecycle policy configured

Related requirements: NIST.800-53.r5 CA-9(1), NIST.800-53.r5 CM-2, NIST.800-53.r5 CM-2(2), CRI Profile v2.2/ID.AM-08.01, CRI Profile v2.2/PR.IR-04.02, CRI Profile v2.2/PR.PS-01.01, CRI Profile v2.2/PR.PS-01.03

Category: Identify > Resource configuration

Severity: Medium

Resource type: `AWS::ECR::Repository`

AWS Config rule: ecr-private-lifecycle-policy-configured

Schedule type: Change triggered

Parameters: None

This control checks whether an Amazon ECR repository has at least one lifecycle policy configured. This control fails if an ECR repository does not have any lifecycle policies configured.

Amazon ECR lifecycle policies enable you to specify the lifecycle management of images in a repository. By configuring lifecycle policies, you can automate the cleanup of unused images and the expiration of images based on age or count. Automating these tasks can help you avoid unintentionally using outdated images in your repository.

Remediation

To configure a lifecycle policy, see Creating a lifecycle policy preview in the *Amazon Elastic Container Registry User Guide*.

[ECR.4] ECR public repositories should be tagged

Category: Identify > Inventory > Tagging

Severity: Low

Resource type: `AWS::ECR::PublicRepository`

AWS Config rule: `tagged-ecr-publicrepository` (custom Security Hub CSPM rule)

Schedule type: Change triggered

Parameters:

Parameter	Description	Type	Allowed custom values	Security Hub CSPM default value
`requiredTagKeys`	List of non-system tag keys that the evaluated resource	StringList (maximum of 6 items)	1–6 tag keys that meet AWS	No default value

Parameter	Description	Type	Allowed custom values	Security Hub CSPM default value
	must contain. Tag keys are case sensitive.		requirements.	

This control checks whether an Amazon ECR public repository has tags with the specific keys defined in the parameter `requiredTagKeys`. The control fails if the public repository doesn't have any tag keys or if it doesn't have all the keys specified in the parameter `requiredTagKeys`. If the parameter `requiredTagKeys` isn't provided, the control only checks for the existence of a tag key and fails if the public repository isn't tagged with any key. System tags, which are automatically applied and begin with `aws:`, are ignored.

A tag is a label that you assign to an AWS resource, and it consists of a key and an optional value. You can create tags to categorize resources by purpose, owner, environment, or other criteria. Tags can help you identify, organize, search for, and filter resources. Tagging also helps you track accountable resource owners for actions and notifications. When you use tagging, you can implement attribute-based access control (ABAC) as an authorization strategy, which defines permissions based on tags. You can attach tags to IAM entities (users or roles) and to AWS resources. You can create a single ABAC policy or a separate set of policies for your IAM principals. You can design these ABAC policies to allow operations when the principal's tag matches the resource tag. For more information, see What is ABAC for AWS? in the *IAM User Guide*.

Note

Don't add personally identifiable information (PII) or other confidential or sensitive information in tags. Tags are accessible to many AWS services, including AWS Billing. For more tagging best practices, see Tagging your AWS resources in the *AWS General Reference*.

Remediation

To add tags to an ECR public repository, see Tagging an Amazon ECR public repository in the *Amazon Elastic Container Registry User Guide*.

[ECR.5] ECR repositories should be encrypted with customer managed AWS KMS keys

Related requirements: NIST.800-53.r5 SC-12(2), NIST.800-53.r5 CM-3(6), NIST.800-53.r5 SC-13, NIST.800-53.r5 SC-28, NIST.800-53.r5 SC-28(1), NIST.800-53.r5 SC-7(10), NIST.800-53.r5 CA-9(1), NIST.800-53.r5 SI-7(6), NIST.800-53.r5 AU-9

Category: Protect > Data Protection > Encryption of data-at-rest

Severity: Medium

Resource type: `AWS::ECR::Repository`

AWS Config rule: ecr-repository-cmk-encryption-enabled

Schedule type: Change triggered

Parameters:

Parameter	Description	Type	Allowed custom values	Security Hub CSPM default value
`kmsKeyArns`	A list of Amazon Resource Names (ARNs) of AWS KMS keys to include in the evaluation. The control generates a `FAILED` finding if an ECR repository isn't encrypted with a KMS key in the list.	StringList (maximum of 10 items)	1–10 ARNs of existing KMS keys. For example: `arn:aws:kms:us-west-2:111122223333:key/1234abcd-12ab-34cd-56ef-1234567890ab`	No default value

This control checks whether an Amazon ECR repository is encrypted at rest with a customer managed AWS KMS key. The control fails if the ECR repository isn't encrypted with a customer

managed KMS key. You can optionally specify a list of KMS keys for the control to include in the evaluation.

By default, Amazon ECR encrypts repository data with Amazon S3 managed keys (SSE-S3), using an AES-256 algorithm. For additional control, you can configure Amazon ECR to encrypt the data with an AWS KMS key (SSE-KMS or DSSE-KMS) instead. The KMS key can be: an AWS managed key that Amazon ECR creates and manages for you and has the alias `aws/ecr`, or a customer managed key that you create and manage in your AWS account. With a customer managed KMS key, you have full control of the key. This includes defining and maintaining the key policy, managing grants, rotating cryptographic material, assigning tags, creating aliases, and enabling and disabling the key.

> **Note**
>
> AWS KMS supports cross-account access to KMS keys. If an ECR repository is encrypted with a KMS key that's owned by another account, this control doesn't perform cross-account checks when it evaluates the repository. The control doesn't assess whether Amazon ECR can access and use the key when performing cryptographic operations for the repository.

Remediation

You can't change the encryption settings for an existing ECR repository. However, you can specify different encryption settings for ECR repositories that you subsequently create. Amazon ECR supports the use of different encryption settings for individual repositories.

For more information about encryption options for ECR repositories, see Encryption at rest in the *Amazon ECR User Guide*. For more information about customer managed AWS KMS keys, see AWS KMS keys in the *AWS Key Management Service Developer Guide*.

Security Hub CSPM controls for Amazon ECS

These Security Hub CSPM controls evaluate the Amazon Elastic Container Service (Amazon ECS) service and resources. The controls might not be available in all AWS Regions. For more information, see Availability of controls by Region.

[ECS.2] ECS services should not have public IP addresses assigned to them automatically

Related requirements: NIST.800-53.r5 AC-21, NIST.800-53.r5 AC-3, NIST.800-53.r5 AC-3(7), NIST.800-53.r5 AC-4, NIST.800-53.r5 AC-4(21), NIST.800-53.r5 AC-6, NIST.800-53.r5 SC-7,

NIST.800-53.r5 SC-7(11), NIST.800-53.r5 SC-7(16), NIST.800-53.r5 SC-7(20), NIST.800-53.r5 SC-7(21), NIST.800-53.r5 SC-7(3), NIST.800-53.r5 SC-7(4), NIST.800-53.r5 SC-7(9), PCI DSS v4.0.1/1.4.4, CRI Profile v2.2/PR.IR-01.01, CRI Profile v2.2/PR.PS-01.02

Category: Protect > Secure network configuration > Resources not publicly accessible

Severity: High

Resource type: `AWS::ECS::Service`

AWS Config rule: `ecs-service-assign-public-ip-disabled` (custom Security Hub CSPM rule)

Schedule type: Change triggered

Parameters: None

This control checks whether Amazon ECS services are configured to automatically assign public IP addresses. This control fails if `AssignPublicIP` is `ENABLED`. This control passes if `AssignPublicIP` is `DISABLED`.

A public IP address is an IP address that is reachable from the internet. If you launch your Amazon ECS instances with a public IP address, then your Amazon ECS instances are reachable from the internet. Amazon ECS services should not be publicly accessible, as this may allow unintended access to your container application servers.

Remediation

First, you must create a task definition for your cluster that uses the `awsvpc` network mode and specifies **FARGATE** for `requiresCompatibilities`. Then, for **Compute configuration**, choose **Launch type** and **FARGATE**. Finally, for the **Networking** field, turn off **Public IP** to disable automatic public IP assignment for your service.

[ECS.3] ECS task definitions should not share the host's process namespace

Related requirements: NIST.800-53.r5 CA-9(1), NIST.800-53.r5 CM-2, CRI Profile v2.2/DE.CM-09.03, CRI Profile v2.2/PR.PS-01.01, CRI Profile v2.2/PR.PS-01.02, CRI Profile v2.2/PR.PS-01.03, CRI Profile v2.2/PR.PS-01.09

Category: Identify > Resource configuration

Severity: High

Resource type: `AWS::ECS::TaskDefinition`

AWS Config rule: ecs-task-definition-pid-mode-check

Schedule type: Change triggered

Parameters: None

This control checks if Amazon ECS task definitions are configured to share a host's process namespace with its containers. The control fails if the task definition shares the host's process namespace with the containers running on it. This control only evaluates the latest active revision of an Amazon ECS task definition.

A process ID (PID) namespace provides separation between processes. It prevents system processes from being visible, and allows PIDs to be reused, including PID 1. If the host's PID namespace is shared with containers, it would allow containers to see all of the processes on the host system. This reduces the benefit of process level isolation between the host and the containers. These circumstances could lead to unauthorized access to processes on the host itself, including the ability to manipulate and terminate them. Customers shouldn't share the host's process namespace with containers running on it.

Remediation

To configure the `pidMode` on a task definition, see Task definition parameters in the Amazon Elastic Container Service Developer Guide.

[ECS.4] ECS containers should run as non-privileged

Related requirements: NIST.800-53.r5 AC-2(1), NIST.800-53.r5 AC-3, NIST.800-53.r5 AC-3(15), NIST.800-53.r5 AC-3(7), NIST.800-53.r5 AC-5, NIST.800-53.r5 AC-6, CRI Profile v2.2/PR.AA-05.01

Category: Protect > Secure access management > Root user access restrictions

Severity: High

Resource type: `AWS::ECS::TaskDefinition`

AWS Config rule: ecs-containers-nonprivileged

Schedule type: Change triggered

Parameters: None

This control checks if the `privileged` parameter in the container definition of Amazon ECS Task Definitions is set to `true`. The control fails if this parameter is equal to `true`. This control only evaluates the latest active revision of an Amazon ECS task definition.

We recommend that you remove elevated privileges from your ECS task definitions. When the privilege parameter is `true`, the container is given elevated privileges on the host container instance (similar to the root user).

Remediation

To configure the `privileged` parameter on a task definition, see Advanced container definition parameters in the Amazon Elastic Container Service Developer Guide.

[ECS.5] ECS task definitions should configure containers to be limited to read-only access to root filesystems

Related requirements: NIST.800-53.r5 AC-2(1), NIST.800-53.r5 AC-3, NIST.800-53.r5 AC-3(15), NIST.800-53.r5 AC-3(7), NIST.800-53.r5 AC-5, NIST.800-53.r5 AC-6, CRI Profile v2.2/PR.DS-01.01, CRI Profile v2.2/PR.PS-01.01, CRI Profile v2.2/PR.PS-01.02, CRI Profile v2.2/PR.PS-01.03

Category: Protect > Secure access management

Severity: High

Resource type: `AWS::ECS::TaskDefinition`

AWS Config rule: ecs-containers-readonly-access

Schedule type: Change triggered

Parameters: None

This control checks whether ECS task definitions configure containers to be limited to read-only access to mounted root file systems. The control fails if the `readonlyRootFilesystem` parameter in the container definitions of ECS task definition is set to `false`, or the parameter doesn't exist in the container definition within the task definition. This control evaluates only the latest active revision of an Amazon ECS task definition.

If the `readonlyRootFilesystem` parameter is set to `true` in an Amazon ECS task definition, the ECS container is given read-only access to its root file system. This reduces security attack vectors because the container instance's root file system can't be tampered with or written to without

explicit volume mounts that have read-write permissions for file system folders and directories. Enabling this option also adheres to the principle of least privilege.

> **Note**
>
> The `readonlyRootFilesystem` parameter is not supported for Windows containers. Task definitions with `runtimePlatform` configured to specify a `WINDOWS_SERVER` OS family are marked as `NOT_APPLICABLE` and will not generate findings for this control.

Remediation

To give an Amazon ECS container read-only access to its root file system, add the `readonlyRootFilesystem` parameter to the task definition for the container, and set the value for the parameter to `true`. For information about task definition parameters and how to add them to a task definition, see Amazon ECS task definitions and Updating a task definition in the *Amazon Elastic Container Service Developer Guide*.

[ECS.8] Secrets should not be passed as container environment variables

Related requirements: NIST.800-53.r5 CA-9(1), NIST.800-53.r5 CM-2, PCI DSS v4.0.1/8.6.2, CRI Profile v2.2/PR.AA-01.01, CRI Profile v2.2/PR.DS-01.01, CRI Profile v2.2/PR.PS-01.07

Category: Protect > Secure development > Credentials not hard-coded

Severity: High

Resource type: `AWS::ECS::TaskDefinition`

AWS Config rule: ecs-no-environment-secrets

Schedule type: Change triggered

Parameters: `secretKeys`: `AWS_ACCESS_KEY_ID,AWS_SECRET_ACCESS_KEY,ECS_ENGINE_AUTH_DATA` (not customizable)

This control checks if the key value of any variables in the `environment` parameter of container definitions includes `AWS_ACCESS_KEY_ID`, `AWS_SECRET_ACCESS_KEY`, or `ECS_ENGINE_AUTH_DATA`. This control fails if a single environment variable in any container definition equals `AWS_ACCESS_KEY_ID`, `AWS_SECRET_ACCESS_KEY`, or

ECS_ENGINE_AUTH_DATA. This control does not cover environmental variables passed in from other locations such as Amazon S3. This control only evaluates the latest active revision of an Amazon ECS task definition.

AWS Systems Manager Parameter Store can help you improve the security posture of your organization. We recommend using the Parameter Store to store secrets and credentials instead of directly passing them into your container instances or hard coding them into your code.

Remediation

To create parameters using SSM, see Creating Systems Manager parameters in the *AWS Systems Manager User Guide*. For more information about creating a task definition that specifies a secret, see Specifying sensitive data using Secrets Manager in the *Amazon Elastic Container Service Developer Guide*.

[ECS.9] ECS task definitions should have a logging configuration

Related requirements: NIST.800-53.r5 AC-4(26), NIST.800-53.r5 AU-10, NIST.800-53.r5 AU-12, NIST.800-53.r5 AU-2, NIST.800-53.r5 AU-3, NIST.800-53.r5 AU-6(3), NIST.800-53.r5 AU-6(4), NIST.800-53.r5 CA-7, NIST.800-53.r5 SC-7(9), NIST.800-53.r5 SI-7(8), CRI Profile v2.2/PR.PS-04.02, CRI Profile v2.2/PR.PS-04.03

Category: Identify > Logging

Severity: High

Resource type: `AWS::ECS::TaskDefinition`

AWS Config rule: ecs-task-definition-log-configuration

Schedule type: Change triggered

Parameters: None

This control checks if the latest active Amazon ECS task definition has a logging configuration specified. The control fails if the task definition doesn't have the `logConfiguration` property defined or if the value for `logDriver` is null in at least one container definition.

Logging helps you maintain the reliability, availability, and performance of Amazon ECS. Collecting data from task definitions provides visibility, which can help you debug processes and find the root cause of errors. If you are using a logging solution that does not have to be defined in the ECS task

definition (such as a third party logging solution), you can disable this control after ensuring that your logs are properly captured and delivered.

Remediation

To define a log configuration for your Amazon ECS task definitions, see Specifying a log configuration in your task definition in the *Amazon Elastic Container Service Developer Guide*.

[ECS.10] ECS Fargate services should run on the latest Fargate platform version

Related requirements: NIST.800-53.r5 SI-2, NIST.800-53.r5 SI-2(2), NIST.800-53.r5 SI-2(4), NIST.800-53.r5 SI-2(5), PCI DSS v4.0.1/6.3.3, CRI Profile v2.2/PR.PS-02.03

Category: Identify > Vulnerability, patch, and version management

Severity: Medium

Resource type: `AWS::ECS::Service`

AWS Config rule: ecs-fargate-latest-platform-version

Schedule type: Change triggered

Parameters:

- `latestLinuxVersion: 1.4.0` (not customizable)
- `latestWindowsVersion: 1.0.0` (not customizable)

This control checks if Amazon ECS Fargate services are running the latest Fargate platform version. This control fails if the platform version is not the latest.

AWS Fargate platform versions refer to a specific runtime environment for Fargate task infrastructure, which is a combination of kernel and container runtime versions. New platform versions are released as the runtime environment evolves. For example, a new version may be released for kernel or operating system updates, new features, bug fixes, or security updates. Security updates and patches are deployed automatically for your Fargate tasks. If a security issue is found that affects a platform version, AWS patches the platform version.

Remediation

To update an existing service, including its platform version, see Updating a service in the *Amazon Elastic Container Service Developer Guide*.

[ECS.12] ECS clusters should use Container Insights

Related requirements: NIST.800-53.r5 AU-6(3), NIST.800-53.r5 AU-6(4), NIST.800-53.r5 CA-7, NIST.800-53.r5 SI-2, CRI Profile v2.2/PR.IR-04.01

Category: Identify > Logging

Severity: Medium

Resource type: `AWS::ECS::Cluster`

AWS Config rule: ecs-container-insights-enabled

Schedule type: Change triggered

Parameters: None

This control checks if ECS clusters use Container Insights. This control fails if Container Insights are not set up for a cluster.

Monitoring is an important part of maintaining the reliability, availability, and performance of Amazon ECS clusters. Use CloudWatch Container Insights to collect, aggregate, and summarize metrics and logs from your containerized applications and microservices. CloudWatch automatically collects metrics for many resources, such as CPU, memory, disk, and network. Container Insights also provides diagnostic information, such as container restart failures, to help you isolate issues and resolve them quickly. You can also set CloudWatch alarms on metrics that Container Insights collects.

Remediation

To use Container Insights, see Updating a service in the *Amazon CloudWatch User Guide*.

[ECS.13] ECS services should be tagged

Category: Identify > Inventory > Tagging

Severity: Low

Resource type: `AWS::ECS::Service`

AWS Config rule: `tagged-ecs-service` (custom Security Hub CSPM rule)

Schedule type: Change triggered

Parameters:

Parameter	Description	Type	Allowed custom values	Security Hub CSPM default value
`requiredTagKeys`	List of non-system tag keys that the evaluated resource must contain. Tag keys are case sensitive.	StringList (maximum of 6 items)	1–6 tag keys that meet AWS requirements.	No default value

This control checks whether an Amazon ECS service has tags with the specific keys defined in the parameter `requiredTagKeys`. The control fails if the service doesn't have any tag keys or if it doesn't have all the keys specified in the parameter `requiredTagKeys`. If the parameter `requiredTagKeys` isn't provided, the control only checks for the existence of a tag key and fails if the service isn't tagged with any key. System tags, which are automatically applied and begin with `aws:`, are ignored.

A tag is a label that you assign to an AWS resource, and it consists of a key and an optional value. You can create tags to categorize resources by purpose, owner, environment, or other criteria. Tags can help you identify, organize, search for, and filter resources. Tagging also helps you track accountable resource owners for actions and notifications. When you use tagging, you can implement attribute-based access control (ABAC) as an authorization strategy, which defines permissions based on tags. You can attach tags to IAM entities (users or roles) and to AWS resources. You can create a single ABAC policy or a separate set of policies for your IAM principals. You can design these ABAC policies to allow operations when the principal's tag matches the resource tag. For more information, see What is ABAC for AWS? in the *IAM User Guide*.

> **Note**
>
> Don't add personally identifiable information (PII) or other confidential or sensitive information in tags. Tags are accessible to many AWS services, including AWS Billing. For more tagging best practices, see Tagging your AWS resources in the *AWS General Reference*.

Remediation

To add tags to an ECS service, see Tagging your Amazon ECS resources in the *Amazon Elastic Container Service Developer Guide*.

[ECS.14] ECS clusters should be tagged

Category: Identify > Inventory > Tagging

Severity: Low

Resource type: `AWS::ECS::Cluster`

AWS Config rule: `tagged-ecs-cluster` (custom Security Hub CSPM rule)

Schedule type: Change triggered

Parameters:

Parameter	Description	Type	Allowed custom values	Security Hub CSPM default value
`requiredTagKeys`	List of non-system tag keys that the evaluated resource must contain. Tag keys are case sensitive.	StringList (maximum of 6 items)	1–6 tag keys that meet AWS requirements.	No default value

This control checks whether an Amazon ECS cluster has tags with the specific keys defined in the parameter `requiredTagKeys`. The control fails if the cluster doesn't have any tag keys or if it doesn't have all the keys specified in the parameter `requiredTagKeys`. If the parameter `requiredTagKeys` isn't provided, the control only checks for the existence of a tag key and fails if the cluster isn't tagged with any key. System tags, which are automatically applied and begin with `aws:`, are ignored.

A tag is a label that you assign to an AWS resource, and it consists of a key and an optional value. You can create tags to categorize resources by purpose, owner, environment, or other criteria. Tags can help you identify, organize, search for, and filter resources. Tagging also helps

you track accountable resource owners for actions and notifications. When you use tagging, you can implement attribute-based access control (ABAC) as an authorization strategy, which defines permissions based on tags. You can attach tags to IAM entities (users or roles) and to AWS resources. You can create a single ABAC policy or a separate set of policies for your IAM principals. You can design these ABAC policies to allow operations when the principal's tag matches the resource tag. For more information, see What is ABAC for AWS? in the *IAM User Guide*.

> **Note**
>
> Don't add personally identifiable information (PII) or other confidential or sensitive information in tags. Tags are accessible to many AWS services, including AWS Billing. For more tagging best practices, see Tagging your AWS resources in the *AWS General Reference*.

Remediation

To add tags to an ECS cluster, see Tagging your Amazon ECS resources in the *Amazon Elastic Container Service Developer Guide*.

[ECS.15] ECS task definitions should be tagged

Category: Identify > Inventory > Tagging

Severity: Low

Resource type: `AWS::ECS::TaskDefinition`

AWS Config rule: `tagged-ecs-taskdefinition` (custom Security Hub CSPM rule)

Schedule type: Change triggered

Parameters:

Parameter	Description	Type	Allowed custom values	Security Hub CSPM default value
`requiredTagKeys`	List of non-system tag keys that the evaluated resource	StringList (maximum of 6 items)	1–6 tag keys that meet AWS	No default value

Parameter	Description	Type	Allowed custom values	Security Hub CSPM default value
	must contain. Tag keys are case sensitive.		requirements.	

This control checks whether an Amazon ECS task definition has tags with the specific keys defined in the parameter `requiredTagKeys`. The control fails if the task definition doesn't have any tag keys or if it doesn't have all the keys specified in the parameter `requiredTagKeys`. If the parameter `requiredTagKeys` isn't provided, the control only checks for the existence of a tag key and fails if the task definition isn't tagged with any key. System tags, which are automatically applied and begin with `aws:`, are ignored.

A tag is a label that you assign to an AWS resource, and it consists of a key and an optional value. You can create tags to categorize resources by purpose, owner, environment, or other criteria. Tags can help you identify, organize, search for, and filter resources. Tagging also helps you track accountable resource owners for actions and notifications. When you use tagging, you can implement attribute-based access control (ABAC) as an authorization strategy, which defines permissions based on tags. You can attach tags to IAM entities (users or roles) and to AWS resources. You can create a single ABAC policy or a separate set of policies for your IAM principals. You can design these ABAC policies to allow operations when the principal's tag matches the resource tag. For more information, see What is ABAC for AWS? in the *IAM User Guide*.

Note

Don't add personally identifiable information (PII) or other confidential or sensitive information in tags. Tags are accessible to many AWS services, including AWS Billing. For more tagging best practices, see Tagging your AWS resources in the *AWS General Reference*.

Remediation

To add tags to an ECS task definition, see Tagging your Amazon ECS resources in the *Amazon Elastic Container Service Developer Guide*.

[ECS.16] ECS task sets should not automatically assign public IP addresses

Related requirements: PCI DSS v4.0.1/1.4.4, CRI Profile v2.2/PR.AA-03.02, CRI Profile v2.2/PR.IR-01.01, CRI Profile v2.2/PR.PS-01.01

Category: Protect > Secure network configuration > Resources not publicly accessible

Severity: High

Resource type: `AWS::ECS::TaskSet`

AWS Config rule: `ecs-taskset-assign-public-ip-disabled` (custom Security Hub CSPM rule)

Schedule type: Change triggered

Parameters: None

This control checks whether an Amazon ECS task set is configured to automatically assign public IP addresses. The control fails if `AssignPublicIP` is set to `ENABLED`.

A public IP address is reachable from the internet. If you configure your task set with a public IP address, the resources associated with the task set can be reached from the internet. ECS task sets shouldn't be publicly accessible, as this may allow unintended access to your container application servers.

Remediation

To update an ECS task set so that it doesn't use a public IP address, see Updating an Amazon ECS task definition using the console in the *Amazon Elastic Container Service Developer Guide*.

[ECS.17] ECS task definitions should not use host network mode

Related requirements: NIST.800-53.r5 AC-2(1), NIST.800-53.r5 AC-3, NIST.800-53.r5 AC-3(7), NIST.800-53.r5 AC-3(15), NIST.800-53.r5 AC-5, NIST.800-53.r5 AC-6, CRI Profile v2.2/PR.IR-01.01, CRI Profile v2.2/PR.PS-01.01, CRI Profile v2.2/PR.PS-01.03

Category: Protect > Secure network configuration

Severity: Medium

Resource type: `AWS::ECS::TaskDefinition`

AWS Config rule: ecs-task-definition-network-mode-not-host

Schedule type: Change triggered

Parameters: None

This control checks whether the latest active revision of an Amazon ECS task definition uses `host` network mode. The control fails if the latest active revision of the ECS task definition uses `host` network mode.

When using `host` network mode, the networking of an Amazon ECS container is tied directly to the underlying host that's running the container. Consequently, this mode allows containers to connect to private loopback network services on the host and to impersonate the host. Other significant drawbacks are that there's no way to remap a container port when using `host` network mode, and you can't run more than a single instantiation of a task on each host.

Remediation

For information about networking modes and options for Amazon ECS tasks that are hosted on Amazon EC2 instances, see Amazon ECS task networking options for the EC2 launch type in the *Amazon Elastic Container Service Developer Guide*. For information about creating a new revision of a task definition and specifying a different network mode, see Updating an Amazon ECS task definition in that guide.

If the Amazon ECS task definition was created by AWS Batch, see Networking modes for AWS Batch jobs to learn about networking modes and typical usage for AWS Batch job types and to choose a secure option.

[ECS.18] ECS Task Definitions should use in-transit encryption for EFS volumes

Category: Protect > Encryption of data-in-transit

Severity: Medium

Resource type: `AWS::ECS::TaskDefinition`

AWS Config rule: ecs-task-definition-efs-encryption-enabled

Schedule type: Change triggered

Parameters: None

This control checks whether the latest active revision of an Amazon ECS task definition uses in-transit encryption for EFS volumes. The control fails if the latest active revision of the ECS task definition has in-transit encryption disabled for EFS volumes.

Amazon EFS volumes provide simple, scalable, and persistent shared file storage for use with your Amazon ECS tasks. Amazon EFS supports encryption of data in transit with Transport Layer Security (TLS). When encryption of data in transit is declared as a mount option for your EFS file system, Amazon EFS establishes a secure TLS connection with your EFS file system upon mounting your file system.

Remediation

For information about enabling in-transit encryption for Amazon ECS Task Definition with EFS volumes, see Step 5: Create a task definition in the *Amazon Elastic Container Service Developer Guide*.

[ECS.19] ECS capacity providers should have managed termination protection enabled

Category: Protect > Data Protection

Severity: Medium

Resource type: `AWS::ECS::CapacityProvider`

AWS Config rule: ecs-capacity-provider-termination-check

Schedule type: Change triggered

Parameters: None

This control checks whether an Amazon ECS capacity provider has managed termination protection enabled. The control fails if managed termination protection is not enabled on an ECS capacity provider.

Amazon ECS capacity providers manage the scaling of infrastructure for tasks in your clusters. When you use EC2 instances for your capacity, you use Auto Scaling group to manage the EC2 instances. Managed termination protection allows cluster auto scaling to control which instances are terminated. When you used managed termination protection, Amazon ECS only terminates EC2 instances that don't have any running Amazon ECS tasks.

> **Note**
>
> When using managed termination protection, managed scaling must also be used otherwise managed termination protection doesn't work.

Remediation

To enable managed termination protection for an Amazon ECS capacity provider, see Updating managed termination protection for Amazon ECS capacity providers in the *Amazon Elastic Container Service Developer Guide*.

[ECS.20] ECS Task Definitions should configure non-root users in Linux container definitions

Category: Protect > Secure access management > Root user access restrictions

Severity: Medium

Resource type: `AWS::ECS::TaskDefinition`

AWS Config rule: ecs-task-definition-linux-user-non-root

Schedule type: Change triggered

Parameters: None

This control checks whether the latest active revision of an Amazon ECS task definition configures Linux containers to run as non-root users. The control fails if a default root user is configured or user configuration is absent for any container.

When Linux containers run with root privileges, they pose several significant security risks. Root users have unrestricted access within the container. This elevated access increases the risk of container escape attacks, where an attacker could potentially break out of container isolation and access the underlying host system. If a container running as root is compromised, attackers may exploit this to access or modify host system resources, affecting other containers or the host itself. Furthermore, root access could enable privilege escalation attacks, allowing attackers to gain additional permissions beyond the container's intended scope. The user parameter in ECS task definitions can specify users in several formats, including username, user ID, username with group, or UID with group ID. It's important to be aware of these various formats when configuring task definitions to ensure no root access is inadvertently granted. Following the principle of least

privilege, containers should run with the minimum required permissions using non-root users. This approach significantly reduces the potential attack surface and mitigates the impact of potential security breaches.

> **Note**
>
> This control only evaluates the container definitions in a task definition if the `operatingSystemFamily` is configured as `LINUX` or `operatingSystemFamily` is not configured in the task definition. The control will generate a `FAILED` finding for an evaluated task definition if any container definition in the task definition has `user` not configured or `user` configured as default root user. The default root users for `LINUX` containers are `"root"` and `"0"`.

Remediation

For information about creating a new revision of an Amazon ECS Task Definition and updating the `user` parameter in the container definition, see Updating an Amazon ECS task defintion in the *Amazon Elastic Container Service Developer Guide*.

[ECS.21] ECS Task Definitions should configure non-administrator users in Windows container definitions

Category: Protect > Secure access management > Root user access restrictions

Severity: Medium

Resource type: `AWS::ECS::TaskDefinition`

AWS Config rule: ecs-task-definition-windows-user-non-admin

Schedule type: Change triggered

Parameters: None

This control checks whether the latest active revision of an Amazon ECS task definition configures Windows containers to run as users that are not default administrators. The control fails if a default administrator is configured as user or user configuration is absent for any container.

When Windows containers run with administrator privileges, they pose several significant security risks. Administrators have unrestricted access within the container. This elevated access increases

the risk of container escape attacks, where an attacker could potentially break out of container isolation and access the underlying host system.

> **Note**
>
> This control only evaluates the container definitions in a task definition if the `operatingSystemFamily` is configured as `WINDOWS_SERVER` or `operatingSystemFamily` is not configured in the task definition. The control will generate a `FAILED` finding for an evaluated task definition if any container definition in the task definition has `user` not configured or `user` configured as default administrator for `WINDOWS_SERVER` containers which is `"containeradministrator"`.

Remediation

For information about creating a new revision of an Amazon ECS Task Definition and updating the `user` parameter in the container definition, see Updating an Amazon ECS task defintion in the *Amazon Elastic Container Service Developer Guide*.

Security Hub CSPM controls for Amazon EFS

These Security Hub CSPM controls evaluate the Amazon Elastic File System (Amazon EFS) service and resources. The controls might not be available in all AWS Regions. For more information, see Availability of controls by Region.

[EFS.1] Elastic File System should be configured to encrypt file data at-rest using AWS KMS

Related requirements: CIS AWS Foundations Benchmark v5.0.0/2.3.1, CIS AWS Foundations Benchmark v3.0.0/2.4.1, NIST.800-53.r5 CA-9(1), NIST.800-53.r5 CM-3(6), NIST.800-53.r5 SC-13, NIST.800-53.r5 SC-28, NIST.800-53.r5 SC-28(1), NIST.800-53.r5 SC-7(10), NIST.800-53.r5 SI-7(6), CRI Profile v2.2/PR.DS-01.01, CRI Profile v2.2/PR.PS-01.06

Category: Protect > Data Protection > Encryption of data-at-rest

Severity: Medium

Resource type: `AWS::EFS::FileSystem`

AWS Config rule: efs-encrypted-check

Schedule type: Periodic

Parameters: None

This control checks whether Amazon Elastic File System is configured to encrypt the file data using AWS KMS. The check fails in the following cases.

- `Encrypted` is set to `false` in the `DescribeFileSystems` response.
- The `KmsKeyId` key in the `DescribeFileSystems` response does not match the `KmsKeyId` parameter for `efs-encrypted-check`.

Note that this control does not use the `KmsKeyId` parameter for `efs-encrypted-check`. It only checks the value of `Encrypted`.

For an added layer of security for your sensitive data in Amazon EFS, you should create encrypted file systems. Amazon EFS supports encryption for file systems at-rest. You can enable encryption of data at rest when you create an Amazon EFS file system. To learn more about Amazon EFS encryption, see Data encryption in Amazon EFS in the *Amazon Elastic File System User Guide*.

Remediation

For details on how to encrypt a new Amazon EFS file system, see Encrypting data at rest in the *Amazon Elastic File System User Guide*.

[EFS.2] Amazon EFS volumes should be in backup plans

Related requirements: NIST.800-53.r5 CP-10, NIST.800-53.r5 CP-6, NIST.800-53.r5 CP-6(1), NIST.800-53.r5 CP-6(2), NIST.800-53.r5 CP-9, NIST.800-53.r5 SC-5(2), NIST.800-53.r5 SI-12, NIST.800-53.r5 SI-13(5), CRI Profile v2.2/PR.DS-11.01

Category: Recover > Resilience > Backup

Severity: Medium

Resource type: `AWS::EFS::FileSystem`

AWS Config rule: efs-in-backup-plan

Schedule type: Periodic

Parameters: None

This control checks whether Amazon Elastic File System (Amazon EFS) file systems are added to the backup plans in AWS Backup. The control fails if Amazon EFS file systems are not included in the backup plans.

Including EFS file systems in the backup plans helps you to protect your data from deletion and data loss.

Remediation

To enable automatic backups for an existing Amazon EFS file system, see Getting started 4: Create Amazon EFS automatic backups in the *AWS Backup Developer Guide*.

[EFS.3] EFS access points should enforce a root directory

Related requirements: NIST.800-53.r5 AC-6(10), CRI Profile v2.2/PR.DS-01.01, CRI Profile v2.2/PR.IR-01.05, CRI Profile v2.2/PR.PS-01.01, CRI Profile v2.2/PR.PS-01.02, CRI Profile v2.2/PR.PS-01.03

Category: Protect > Secure access management

Severity: Medium

Resource type: `AWS::EFS::AccessPoint`

AWS Config rule: efs-access-point-enforce-root-directory

Schedule type: Change triggered

Parameters: None

This control checks if Amazon EFS access points are configured to enforce a root directory. The control fails if the value of `Path` is set to `/` (the default root directory of the file system).

When you enforce a root directory, the NFS client using the access point uses the root directory configured on the access point instead of the file system's root directory. Enforcing a root directory for an access point helps restrict data access by ensuring that users of the access point can only reach files of the specified subdirectory.

Remediation

For instructions on how to enforce a root directory for an Amazon EFS access point, see Enforcing a root directory with an access point in the *Amazon Elastic File System User Guide*.

[EFS.4] EFS access points should enforce a user identity

Related requirements: NIST.800-53.r5 AC-6(2), PCI DSS v4.0.1/7.3.1, CRI Profile v2.2/PR.AA-01.01, CRI Profile v2.2/PR.AA-01.02, CRI Profile v2.2/PR.AA-03.02, CRI Profile v2.2/PR.AA-05.01, CRI Profile v2.2/PR.DS-01.01, CRI Profile v2.2/PR.DS-10.01

Category: Protect > Secure access management

Severity: Medium

Resource type: `AWS::EFS::AccessPoint`

AWS Config rule: efs-access-point-enforce-user-identity

Schedule type: Change triggered

Parameters: None

This control checks whether Amazon EFS access points are configured to enforce a user identity. This control fails if a POSIX user identity is not defined while creating the EFS access point.

Amazon EFS access points are application-specific entry points into an EFS file system that make it easier to manage application access to shared datasets. Access points can enforce a user identity, including the user's POSIX groups, for all file system requests that are made through the access point. Access points can also enforce a different root directory for the file system so that clients can only access data in the specified directory or its subdirectories.

Remediation

To enforce a user identity for an Amazon EFS access point, see Enforcing a user identity using an access point in the *Amazon Elastic File System User Guide*.

[EFS.5] EFS access points should be tagged

Category: Identify > Inventory > Tagging

Severity: Low

Resource type: `AWS::EFS::AccessPoint`

AWS Configrule: `tagged-efs-accesspoint` (custom Security Hub CSPM rule)

Schedule type: Change triggered

Parameters:

Parameter	Description	Type	Allowed custom values	Security Hub CSPM default value
`requiredTagKeys`	List of non-system tag keys that the evaluated resource must contain. Tag keys are case sensitive.	StringList (maximum of 6 items)	1–6 tag keys that meet AWS requirements.	No default value

This control checks whether an Amazon EFS access point has tags with the specific keys defined in the parameter `requiredTagKeys`. The control fails if the access point doesn't have any tag keys or if it doesn't have all the keys specified in the parameter `requiredTagKeys`. If the parameter `requiredTagKeys` isn't provided, the control only checks for the existence of a tag key and fails if the access point isn't tagged with any key. System tags, which are automatically applied and begin with `aws:`, are ignored.

A tag is a label that you assign to an AWS resource, and it consists of a key and an optional value. You can create tags to categorize resources by purpose, owner, environment, or other criteria. Tags can help you identify, organize, search for, and filter resources. Tagging also helps you track accountable resource owners for actions and notifications. When you use tagging, you can implement attribute-based access control (ABAC) as an authorization strategy, which defines permissions based on tags. You can attach tags to IAM entities (users or roles) and to AWS resources. You can create a single ABAC policy or a separate set of policies for your IAM principals. You can design these ABAC policies to allow operations when the principal's tag matches the resource tag. For more information, see What is ABAC for AWS? in the *IAM User Guide*.

> **Note**
>
> Don't add personally identifiable information (PII) or other confidential or sensitive information in tags. Tags are accessible to many AWS services, including AWS Billing. For more tagging best practices, see Tagging your AWS resources in the *AWS General Reference*.

Remediation

To add tags to an EFS access point, see Tagging Amazon EFS resources in the *Amazon Elastic File System User Guide*.

[EFS.6] EFS mount targets should not be associated with subnets that assign public IP addresses on launch

Related requirements: NIST.800-53.r5 SC-7, NIST.800-171.r2 3.1.20, PCI DSS v4.0.1/1.4.4, CRI Profile v2.2/PR.AA-03.02, CRI Profile v2.2/PR.IR-01.01, CRI Profile v2.2/PR.PS-01.01

Category: Protect > Network security > Resources not publicly accessible

Severity: Medium

Resource type: `AWS::EFS::FileSystem`

AWS Config rule: efs-mount-target-public-accessible

Schedule type: Periodic

Parameters: None

This control checks whether an Amazon EFS mount target is associated with subnets that assign public IP addresses on launch. The control fails if the mount target is associated with subnets that assign public IP addresses on launch.

Subnets have attributes that determine whether network interfaces created in the subnet automatically receive public IP addresses. For IPv4, the `MapPublicIpOnLaunch` attribute is set to `TRUE` for default subnets and `FALSE` for nondefault subnets (with an exception for nondefault subnets created through the EC2 launch instance wizard, where it's set to `TRUE`). For IPv6, the `AssignIpv6AddressOnCreation` attribute is set to `FALSE` for all subnets by default.

While Amazon EFS mount targets cannot be assigned public IPv4 addresses, placing them in subnets configured to assign public IP addresses on launch indicates that co-located instances launched in such subnets that may mount the EFS file system could automatically receive public IP addresses, which could risk the file system data becoming accessible from publicly-addressed hosts.

Mount targets in subnets with auto-assign public IPv6 addresses enabled can receive globally-routable IPv6 addresses.

> **Note**
>
> On Aug 3, 2026, Security Hub CSPM removed this control from the AWS Foundational Security Best Practices (FSBP) standard. This control will be available in the NIST SP 800-53 Rev. 5 standard, the NIST SP 800-171 Revision 2 standard, and the PCI DSS v4.0.1 standard.

Remediation

To associate an existing mount target with a different subnet, you must create a new mount target in a subnet that does not assign public IP addresses on launch and then remove the old mount target. For information about managing mount targets, see Creating and managing mount targets and security groups in the *Amazon Elastic File System User Guide*.

[EFS.7] EFS file systems should have automatic backups enabled

Related requirements: CRI Profile v2.2/PR.DS-11.01

Category: Recover > Resilience > Backups enabled

Severity: Medium

Resource type: `AWS::EFS::FileSystem`

AWS Config rule: efs-automatic-backups-enabled

Schedule type: Change triggered

Parameters: None

This control checks whether an Amazon EFS file system has automatic backups enabled. This control fails if the EFS file system doesn't have automatic backups enabled.

A data backup is a copy of your system, configuration, or application data that's stored separately from the original. Enabling regular backups helps you safeguard valuable data against unforeseen events like system failures, cyberattacks, or accidental deletions. Having a robust backup strategy also facilitates quicker recovery, business continuity, and peace of mind in the face of potential data loss.

Remediation

For information about using AWS Backup for EFS file systems, see Backing up EFS file systems in the *Amazon Elastic File System User Guide*.

[EFS.8] EFS file systems should be encrypted at rest

Related requirements: CIS AWS Foundations Benchmark v5.0.0/2.3.1, CRI Profile v2.2/PR.DS-01.01, CRI Profile v2.2/PR.PS-01.06, CRI Profile v2.2/PR.PS-01.07

Category: Protect > Data Protection > Encryption of data-at-rest

Severity: Medium

Resource type: `AWS::EFS::FileSystem`

AWS Config rule: efs-filesystem-ct-encrypted

Schedule type: Change triggered

Parameters: None

This control checks whether an Amazon EFS file system encrypts data with AWS Key Management Service (AWS KMS). The control fails if a file system isn't encrypted.

Data at rest refers to data that's stored in persistent, non-volatile storage for any duration. Encrypting data at rest helps you protect its confidentiality, which reduces the risk that an unauthorized user can access it.

Remediation

To enable encryption at rest for a new EFS file system, see Encrypting data at rest in the *Amazon Elastic File System User Guide*.

Security Hub CSPM controls for Amazon EKS

These Security Hub CSPM controls evaluate the Amazon Elastic Kubernetes Service (Amazon EKS) service and resources. The controls might not be available in all AWS Regions. For more information, see Availability of controls by Region.

[EKS.1] EKS cluster endpoints should not be publicly accessible

Related requirements: NIST.800-53.r5 AC-21, NIST.800-53.r5 AC-3, NIST.800-53.r5 AC-3(7), NIST.800-53.r5 AC-4, NIST.800-53.r5 AC-4(21), NIST.800-53.r5 AC-6, NIST.800-53.r5 SC-7, NIST.800-53.r5 SC-7(11), NIST.800-53.r5 SC-7(16), NIST.800-53.r5 SC-7(20), NIST.800-53.r5 SC-7(21), NIST.800-53.r5 SC-7(3), NIST.800-53.r5 SC-7(4), NIST.800-53.r5 SC-7(9), PCI DSS v4.0.1/1.4.4, CRI Profile v2.2/PR.AA-03.02, CRI Profile v2.2/PR.IR-01.01, CRI Profile v2.2/PR.IR-01.05

Category: Protect > Secure network configuration > Resources not publicly accessible

Severity: High

Resource type: `AWS::EKS::Cluster`

AWS Config rule: eks-endpoint-no-public-access

Schedule type: Periodic

Parameters: None

This control checks whether an Amazon EKS cluster endpoint is publicly accessible. The control fails if an EKS cluster has an endpoint that is publicly accessible.

When you create a new cluster, Amazon EKS creates an endpoint for the managed Kubernetes API server that you use to communicate with your cluster. By default, this API server endpoint is publicly available to the internet. Access to the API server is secured using a combination of AWS Identity and Access Management (IAM) and native Kubernetes Role Based Access Control (RBAC). By removing public access to the endpoint, you can avoid unintentional exposure and access to your cluster.

Remediation

To modify endpoint access for an existing EKS cluster, see Modifying cluster endpoint access in the Amazon EKS User Guide. You can set up endpoint access for a new EKS cluster when creating it. For instructions on creating a new Amazon EKS cluster, see Creating an Amazon EKS cluster in the Amazon EKS User Guide.

[EKS.2] EKS clusters should run on a supported Kubernetes version

Related requirements: NIST.800-53.r5 CA-9(1), NIST.800-53.r5 CM-2, NIST.800-53.r5 SI-2, NIST.800-53.r5 SI-2(2), NIST.800-53.r5 SI-2(4), NIST.800-53.r5 SI-2(5), PCI DSS v4.0.1/12.3.4, CRI Profile v2.2/PR.PS-02.03

Category: Identify > Vulnerability, patch, and version management

Severity: High

Resource type: `AWS::EKS::Cluster`

AWS Config rule: eks-cluster-supported-version

Schedule type: Change triggered

Parameters:

- `oldestVersionSupported`: `1.34` (not customizable)

This control checks whether an Amazon Elastic Kubernetes Service (Amazon EKS) cluster is running on a standard support Kubernetes version. The control fails if the Amazon EKS cluster is running on an unsupported or extended support version.

If your application doesn't require a specific version of Kubernetes, we recommend that you use the latest available Kubernetes version that's supported by EKS for your clusters. For more information, see Amazon EKS Kubernetes release calendar and Understand the Kubernetes version lifecycle on Amazon EKS in the Amazon EKS User Guide.

Remediation

To update an EKS cluster, see Update an existing cluster to a new Kubernetes version in the Amazon EKS User Guide.

[EKS.6] EKS clusters should be tagged

Category: Identify > Inventory > Tagging

Severity: Low

Resource type: `AWS::EKS::Cluster`

AWS Config rule: `tagged-eks-cluster` (custom Security Hub CSPM rule)

Schedule type: Change triggered

Parameters:

Parameter	Description	Type	Allowed custom values	Security Hub CSPM default value
`requiredTagKeys`	List of non-system tag keys that the evaluated resource	StringList (maximum of 6 items)	1–6 tag keys that meet AWS	No default value

Parameter	Description	Type	Allowed custom values	Security Hub CSPM default value
	must contain. Tag keys are case sensitive.		requirements.	

This control checks whether an Amazon EKS cluster has tags with the specific keys defined in the parameter `requiredTagKeys`. The control fails if the cluster doesn't have any tag keys or if it doesn't have all the keys specified in the parameter `requiredTagKeys`. If the parameter `requiredTagKeys` isn't provided, the control only checks for the existence of a tag key and fails if the cluster isn't tagged with any key. System tags, which are automatically applied and begin with `aws:`, are ignored.

A tag is a label that you assign to an AWS resource, and it consists of a key and an optional value. You can create tags to categorize resources by purpose, owner, environment, or other criteria. Tags can help you identify, organize, search for, and filter resources. Tagging also helps you track accountable resource owners for actions and notifications. When you use tagging, you can implement attribute-based access control (ABAC) as an authorization strategy, which defines permissions based on tags. You can attach tags to IAM entities (users or roles) and to AWS resources. You can create a single ABAC policy or a separate set of policies for your IAM principals. You can design these ABAC policies to allow operations when the principal's tag matches the resource tag. For more information, see What is ABAC for AWS? in the *IAM User Guide*.

> **Note**
>
> Don't add personally identifiable information (PII) or other confidential or sensitive information in tags. Tags are accessible to many AWS services, including AWS Billing. For more tagging best practices, see Tagging your AWS resources in the *AWS General Reference*.

Remediation

To add tags to an EKS cluster, see Tagging your Amazon EKS resources in the Amazon EKS User Guide.

[EKS.7] EKS identity provider configurations should be tagged

Category: Identify > Inventory > Tagging

Severity: Low

Resource type: `AWS::EKS::IdentityProviderConfig`

AWS Config rule: `tagged-eks-identityproviderconfig` (custom Security Hub CSPM rule)

Schedule type: Change triggered

Parameters:

Parameter	Description	Type	Allowed custom values	Security Hub CSPM default value
`requiredTagKeys`	List of non-system tag keys that the evaluated resource must contain. Tag keys are case sensitive.	StringList (maximum of 6 items)	1–6 tag keys that meet AWS requirements.	No default value

This control checks whether an Amazon EKS identity provider configuration has tags with the specific keys defined in the parameter `requiredTagKeys`. The control fails if the configuration doesn't have any tag keys or if it doesn't have all the keys specified in the parameter `requiredTagKeys`. If the parameter `requiredTagKeys` isn't provided, the control only checks for the existence of a tag key and fails if the configuration isn't tagged with any key. System tags, which are automatically applied and begin with `aws:`, are ignored.

A tag is a label that you assign to an AWS resource, and it consists of a key and an optional value. You can create tags to categorize resources by purpose, owner, environment, or other criteria. Tags can help you identify, organize, search for, and filter resources. Tagging also helps you track accountable resource owners for actions and notifications. When you use tagging, you can implement attribute-based access control (ABAC) as an authorization strategy, which defines permissions based on tags. You can attach tags to IAM entities (users or roles) and to AWS resources. You can create a single ABAC policy or a separate set of policies for your IAM principals.

You can design these ABAC policies to allow operations when the principal's tag matches the resource tag. For more information, see What is ABAC for AWS? in the *IAM User Guide*.

> **Note**
>
> Don't add personally identifiable information (PII) or other confidential or sensitive information in tags. Tags are accessible to many AWS services, including AWS Billing. For more tagging best practices, see Tagging your AWS resources in the *AWS General Reference*.

Remediation

To add tags to an EKS identity provider configurations, see Tagging your Amazon EKS resources in the Amazon EKS User Guide.

[EKS.8] EKS clusters should have audit logging enabled

Related requirements: NIST.800-53.r5 AC-2(12), NIST.800-53.r5 AC-2(4), NIST.800-53.r5 AC-4(26), NIST.800-53.r5 AC-6(9), NIST.800-53.r5 AU-10, NIST.800-53.r5 AU-12, NIST.800-53.r5 AU-2, NIST.800-53.r5 AU-3, NIST.800-53.r5 AU-6(3), NIST.800-53.r5 AU-6(4), NIST.800-53.r5 AU-9(7), NIST.800-53.r5 CA-7, NIST.800-53.r5 SC-7(9), NIST.800-53.r5 SI-3(8), NIST.800-53.r5 SI-4, NIST.800-53.r5 SI-4(20), NIST.800-53.r5 SI-7(8), PCI DSS v4.0.1/10.2.1, CRI Profile v2.2/DE.AE-02.01, CRI Profile v2.2/DE.AE-03.01, CRI Profile v2.2/DE.AE-03.02, CRI Profile v2.2/DE.CM-03.01, CRI Profile v2.2/PR.PS-04.02, CRI Profile v2.2/PR.PS-04.03

Category: Identify > Logging

Severity: Medium

Resource type: `AWS::EKS::Cluster`

AWS Config rule: eks-cluster-log-enabled

Schedule type: Change triggered

Parameters:

- `logTypes: audit` (not customizable)

This control checks whether an Amazon EKS cluster has audit logging enabled. The control fails if audit logging isn't enabled for the cluster.

> **Note**
>
> This control doesn't check whether Amazon EKS audit logging is enabled through Amazon Security Lake for the AWS account.

EKS control plane logging provides audit and diagnostic logs directly from the EKS control plane to Amazon CloudWatch Logs in your account. You can select the log types you need, and logs are sent as log streams to a group for each EKS cluster in CloudWatch. Logging provides visibility into the access and performance of EKS clusters. By sending EKS control plane logs for your EKS clusters to CloudWatch Logs, you can record operations for audit and diagnostic purposes in a central location.

Remediation

To enable audit logs for your EKS cluster, see Enabling and disabling control plane logs in the Amazon EKS User Guide.

[EKS.9] EKS node groups should run on a supported Kubernetes version

Category: Identify > Vulnerability, patch, and version management

Severity: High

Resource type: `AWS::EKS::Nodegroup`

AWS Config rule: eks-nodegroup-supported-version-check

Schedule type: Change triggered

Parameters:

- `oldestVersionSupported`: `1.34` (not customizable)

This control checks whether an Amazon EKS node group runs on a standard support Kubernetes version. The control fails if the Amazon EKS node group runs on an unsupported or extended support version.

Only Kubernetes versions in standard support receive the full set of security patches, bug fixes, and security features. Versions in extended support receive patches for critical and important vulnerabilities, but they don't receive patches for lower-severity vulnerabilities, non-security

bug fixes, or security features that are introduced in newer Kubernetes versions. Amazon EKS doesn't automatically upgrade node groups, so node-level patches apply only after you update your node groups to use the latest Amazon EKS optimized AMIs. Versions that are past the end of extended support no longer receive security patches, bug fixes, or compatibility updates from AWS. Unsupported versions may contain known vulnerabilities that have been addressed in newer releases, and they may experience compatibility issues with updated AWS services, container images, and third-party tools in the Kubernetes ecosystem. If your application doesn't require a specific version of Kubernetes, we recommend that you use the latest available Kubernetes version that's supported by Amazon EKS for your node groups. For more information, see Amazon EKS Kubernetes release calendar and Understand each phase of node updates in the Amazon EKS User Guide.

Remediation

To update an EKS node group, see Update a managed node group for your cluster in the Amazon EKS User Guide.

Security Hub CSPM controls for ElastiCache

These AWS Security Hub CSPM controls evaluate the Amazon ElastiCache service and resources. The controls might not be available in all AWS Regions. For more information, see Availability of controls by Region.

[ElastiCache.1] ElastiCache (Redis OSS) clusters should have automatic backups enabled

Related requirements: NIST.800-53.r5 CP-10, NIST.800-53.r5 CP-6, NIST.800-53.r5 CP-6(1), NIST.800-53.r5 CP-6(2), NIST.800-53.r5 CP-9, NIST.800-53.r5 SC-5(2), NIST.800-53.r5 SI-12, NIST.800-53.r5 SI-13(5), CRI Profile v2.2/PR.DS-11.01

Category: Recover > Resilience > Backups enabled

Severity: High

Resource type: `AWS::ElastiCache::CacheCluster`, `AWS:ElastiCache:ReplicationGroup`

AWS Config rule: elasticache-redis-cluster-automatic-backup-check

Schedule type: Periodic

Parameters:

Parameter	Description	Type	Allowed custom values	Security Hub CSPM default value
`snapshotRetentionPeriod`	Minimum snapshot retention period in days	Integer	1 to 35	1

This control evaluates whether an Amazon ElastiCache (Redis OSS) cluster has automatic backups enabled. The control fails if the `SnapshotRetentionLimit` for the Redis OSS cluster is less than the specified time period. Unless you provide a custom parameter value for the snapshot retention period, Security Hub CSPM uses a default value of 1 day.

ElastiCache (Redis OSS) clusters can back up their data. You can use the backup to restore a cluster or seed a new cluster. The backup consists of the cluster's metadata, along with all the data in the cluster. All backups are written to Amazon S3, which provides durable storage. You can restore your data by creating a new ElastiCache cluster and populating it with data from a backup. You can manage backups using the AWS Management Console, the AWS CLI, and the ElastiCache API.

> **Note**
>
> This control also evaluates ElastiCache (Redis OSS and Valkey) replication groups.

Remediation

For information about scheduling automatic backups for an ElastiCache cluster, see Scheduling automatic backups in the *Amazon ElastiCache User Guide*.

[ElastiCache.2] ElastiCache clusters should have automatic minor version upgrades enabled

Related requirements: NIST.800-53.r5 SI-2, NIST.800-53.r5 SI-2(2), NIST.800-53.r5 SI-2(4), NIST.800-53.r5 SI-2(5), PCI DSS v4.0.1/6.3.3, CRI Profile v2.2/ID.RA-01.03, CRI Profile v2.2/PR.PS-02.01

Category: Identify > Vulnerability, patch, and version management

Severity: High

Resource type: `AWS::ElastiCache::CacheCluster`

AWS Config rule: elasticache-auto-minor-version-upgrade-check

Schedule type: Periodic

Parameters: None

This control evaluates whether Amazon ElastiCache automatically applies minor version upgrades to a cache cluster. The control fails if the cache cluster doesn't have minor version upgrades automatically applied.

> **Note**
>
> This control doesn't apply to ElastiCache Memcached clusters.

Automatic minor version upgrade is a feature that you can enable in Amazon ElastiCache to automatically upgrade your cache clusters when a new minor cache engine version is available. These upgrades might include security patches and bug fixes. Staying up-to-date with patch installation is an important step in securing systems.

Remediation

To automatically apply minor version upgrades to an existing ElastiCache cache cluster, see Version management for ElastiCache in the *Amazon ElastiCache User Guide*.

[ElastiCache.3] ElastiCache replication groups should have automatic failover enabled

Related requirements: NIST.800-53.r5 CP-10, NIST.800-53.r5 SC-36, NIST.800-53.r5 SC-5(2), NIST.800-53.r5 SI-13(5), CRI Profile v2.2/PR.IR-03.01, CRI Profile v2.2/PR.IR-04.02, CRI Profile v2.2/RC.RP-01.01

Category: Recover > Resilience > High availability

Severity: Medium

Resource type: `AWS::ElastiCache::ReplicationGroup`

AWS Config rule: elasticache-repl-grp-auto-failover-enabled

Schedule type: Periodic

Parameters: None

This control checks whether an ElastiCache replication groups has automatic failover enabled. The control fails if automatic failover isn't enabled for a replication group.

When automatic failover is enabled for a replication group, the role of primary node will automatically fail over to one of the read replicas. This failover and replica promotion ensure that you can resume writing to the new primary after promotion is complete, which reduces overall downtime in case of failure.

Remediation

To enable automatic failover for an existing ElastiCache replication group,, see Modifying an ElastiCache cluster in the *Amazon ElastiCache User Guide*. If you use the ElastiCache console, set **Auto failover** to enabled.

[ElastiCache.4] ElastiCache replication groups should be encrypted at rest

Related requirements: NIST.800-53.r5 CA-9(1), NIST.800-53.r5 CM-3(6), NIST.800-53.r5 SC-13, NIST.800-53.r5 SC-28, NIST.800-53.r5 SC-28(1), NIST.800-53.r5 SC-7(10), NIST.800-53.r5 SI-7(6), CRI Profile v2.2/PR.DS-01.01, CRI Profile v2.2/PR.PS-01.06

Category: Protect > Data Protection > Encryption of data-at-rest

Severity: Medium

Resource type: `AWS::ElastiCache::ReplicationGroup`

AWS Config rule: elasticache-repl-grp-encrypted-at-rest

Schedule type: Periodic

Parameters: None

This control checks whether an ElastiCache replication group is encrypted at rest. The control fails if the replication group isn't encrypted at rest.

Encrypting data at rest reduces the risk that an unauthenticated user gets access to data that is stored on disk. ElastiCache (Redis OSS) replication groups should be encrypted at rest for an added layer of security.

Remediation

To configure at-rest encryption on an ElastiCache replication group, see Enabling at-rest encryption in the *Amazon ElastiCache User Guide*.

[ElastiCache.5] ElastiCache replication groups should be encrypted in transit

Related requirements: NIST.800-53.r5 AC-17(2), NIST.800-53.r5 AC-4, NIST.800-53.r5 IA-5(1), NIST.800-53.r5 SC-12(3), NIST.800-53.r5 SC-13, NIST.800-53.r5 SC-23, NIST.800-53.r5 SC-23(3), NIST.800-53.r5 SC-7(4), NIST.800-53.r5 SC-8, NIST.800-53.r5 SC-8(1), NIST.800-53.r5 SC-8(2), NIST.800-53.r5 SI-7(6), PCI DSS v4.0.1/4.2.1, CRI Profile v2.2/PR.DS-02.01, CRI Profile v2.2/PR.PS-01.06

Category: Protect > Data Protection > Encryption of data-in-transit

Severity: Medium

Resource type: `AWS::ElastiCache::ReplicationGroup`

AWS Config rule: elasticache-repl-grp-encrypted-in-transit

Schedule type: Periodic

Parameters: None

This control checks whether an ElastiCache replication group is encrypted in transit. The control fails if the replication group isn't encrypted in transit.

Encrypting data in transit reduces the risk that an unauthorized user can eavesdrop on network traffic. Enabling encryption in transit on an ElastiCache replication group encrypts your data whenever it's moving from one place to another, such as between nodes in your cluster or between your cluster and your application.

Remediation

To configure in-transit encryption on an ElastiCache replication group, see Enabling in-transit encryption in the *Amazon ElastiCache User Guide*.

[ElastiCache.6] ElastiCache (Redis OSS) replication groups of earlier versions should have Redis OSS AUTH enabled

Related requirements: NIST.800-53.r5 AC-2(1), NIST.800-53.r5 AC-3, NIST.800-53.r5 AC-3(15), NIST.800-53.r5 AC-3(7), NIST.800-53.r5 AC-6, PCI DSS v4.0.1/8.3.1, CRI Profile v2.2/PR.AA-03.01

Category: Protect > Secure access management

Severity: Medium

Resource type: `AWS::ElastiCache::ReplicationGroup`

AWS Config rule: elasticache-repl-grp-redis-auth-enabled

Schedule type: Periodic

Parameters: None

This control checks whether an ElastiCache (Redis OSS) replication group has Redis OSS AUTH enabled. The control fails if the Redis OSS version of the replication group nodes is below 6.0 and `AuthToken` isn't in use.

When you use Redis authentication tokens, or passwords, Redis requires a password before allowing clients to run commands, which improves data security. For Redis 6.0 and later versions, we recommend using Role-Based Access Control (RBAC). Since RBAC is not supported for Redis versions earlier than 6.0, this control only evaluates versions which can't use the RBAC feature.

Remediation

To use Redis AUTH on an ElastiCache (Redis OSS) replication group, see Modifying the AUTH token on an existing ElastiCache (Redis OSS) cluster in the *Amazon ElastiCache User Guide*.

[ElastiCache.7] ElastiCache clusters should not use the default subnet group

Related requirements: NIST.800-53.r5 AC-4, NIST.800-53.r5 AC-4(21), NIST.800-53.r5 SC-7, NIST.800-53.r5 SC-7(11), NIST.800-53.r5 SC-7(16), NIST.800-53.r5 SC-7(21), NIST.800-53.r5 SC-7(4), NIST.800-53.r5 SC-7(5), CRI Profile v2.2/PR.IR-01.01, CRI Profile v2.2/PR.PS-01.01

Category: Protect > Secure network configuration

Severity: High

Resource type: `AWS::ElastiCache::CacheCluster`

AWS Config rule: elasticache-subnet-group-check

Schedule type: Periodic

Parameters: None

This control checks whether an ElastiCache cluster is configured with a custom subnet group. The control fails if `CacheSubnetGroupName` for an ElastiCache cluster has the value `default`.

When launching an ElastiCache cluster, a default subnet group is created if one doesn't exist already. The default group uses subnets from the default Virtual Private Cloud (VPC). We

recommend using custom subnet groups that are more restrictive of the subnets that the cluster resides in, and the networking that the cluster inherits from the subnets.

Remediation

To create a new subnet group for an ElastiCache cluster, see Creating a subnet group in the *Amazon ElastiCache User Guide*.

Security Hub CSPM controls for Elastic Beanstalk

These AWS Security Hub CSPM controls evaluate the AWS Elastic Beanstalk service and resources.

These controls may not be available in all AWS Regions. For more information, see Availability of controls by Region.

[ElasticBeanstalk.1] Elastic Beanstalk environments should have enhanced health reporting enabled

Related requirements: NIST.800-53.r5 CA-7,NIST.800-53.r5 SI-2, CRI Profile v2.2/GV.RM-09.02, CRI Profile v2.2/PR.IR-03.01

Category: Detect > Detection services > Application monitoring

Severity: Low

Resource type: `AWS::ElasticBeanstalk::Environment`

AWS Config rule: `beanstalk-enhanced-health-reporting-enabled`

Schedule type: Change triggered

Parameters: None

This control checks whether enhanced health reporting is enabled for your AWS Elastic Beanstalk environments.

Elastic Beanstalk enhanced health reporting enables a more rapid response to changes in the health of the underlying infrastructure. These changes could result in a lack of availability of the application.

Elastic Beanstalk enhanced health reporting provides a status descriptor to gauge the severity of the identified issues and identify possible causes to investigate. The Elastic Beanstalk health agent, included in supported Amazon Machine Images (AMIs), evaluates logs and metrics of environment EC2 instances.

For additional information, see Enhanced health reporting and monitoring in the *AWS Elastic Beanstalk Developer Guide*.

Remediation

For instructions on how to enable enhanced health reporting, see Enabling enhanced health reporting using the Elastic Beanstalk console in the *AWS Elastic Beanstalk Developer Guide*.

[ElasticBeanstalk.2] Elastic Beanstalk managed platform updates should be enabled

Related requirements: NIST.800-53.r5 SI-2,NIST.800-53.r5 SI-2(2),NIST.800-53.r5 SI-2(4),NIST.800-53.r5 SI-2(5), PCI DSS v4.0.1/6.3.3, CRI Profile v2.2/PR.PS-02.01

Category: Identify > Vulnerability, patch, and version management

Severity: High

Resource type: `AWS::ElasticBeanstalk::Environment`

AWS Config rule: `elastic-beanstalk-managed-updates-enabled`

Schedule type: Change triggered

Parameters:

Parameter	Description	Type	Allowed custom values	Security Hub CSPM default value
`UpdateLevel`	Version update level	Enum	`minor`, `patch`	No default value

This control checks whether managed platform updates are enabled for an Elastic Beanstalk environment. The control fails if no managed platform updates are enabled. By default, the control passes if any type of platform update is enabled. Optionally, you can provide a custom parameter value to require a specific update level.

Enabling managed platform updates ensures that the latest available platform fixes, updates, and features for the environment are installed. Keeping up to date with patch installation is an important step in securing systems.

Remediation

To enable managed platform updates, see To configure managed platform updates under Managed platform updates in the *AWS Elastic Beanstalk Developer Guide*.

[ElasticBeanstalk.3] Elastic Beanstalk should stream logs to CloudWatch

Related requirements: PCI DSS v4.0.1/10.4.2, CRI Profile v2.2/DE.AE-03.01, CRI Profile v2.2/PR.PS-04.02, CRI Profile v2.2/PR.PS-04.03, CRI Profile v2.2/RS.MA-02.01

Category: Identify > Logging

Severity: High

Resource type: `AWS::ElasticBeanstalk::Environment`

AWS Config rule: `elastic-beanstalk-logs-to-cloudwatch`

Schedule type: Change triggered

Parameters:

Parameter	Description	Type	Allowed custom values	Security Hub CSPM default value
`RetentionInDays`	Number of days to keep log events before expiration	Enum	1, 3, 5, 7, 14, 30, 60, 90, 120, 150, 180, 365 , 400, 545, 731, 1827, 3653	No default value

This control checks whether an Elastic Beanstalk environment is configured to send logs to CloudWatch Logs. The control fails if an Elastic Beanstalk environment isn't configured to send logs to CloudWatch Logs. Optionally, you can provide a custom value for the `RetentionInDays` parameter if you want the control to pass only if logs are retained for the specified number of days before expiration.

CloudWatch helps you collect and monitor various metrics for your applications and infrastructure resources. You can also use CloudWatch to configure alarm actions based on specific metrics. We recommend integrating Elastic Beanstalk with CloudWatch to get increased visibility into your Elastic Beanstalk environment. Elastic Beanstalk logs include the eb-activity.log, access logs from the environment nginx or Apache proxy server, and logs that are specific to an environment.

Remediation

To integrate Elastic Beanstalk with CloudWatch Logs, see Streaming instance logs to CloudWatch Logs in the *AWS Elastic Beanstalk Developer Guide*.

Security Hub CSPM controls for Elastic Load Balancing

These AWS Security Hub CSPM controls evaluate the Elastic Load Balancing service and resources. The controls might not be available in all AWS Regions. For more information, see Availability of controls by Region.

[ELB.1] Application Load Balancer should be configured to redirect all HTTP requests to HTTPS

Related requirements: PCI DSS v3.2.1/2.3,PCI DSS v3.2.1/4.1, NIST.800-53.r5 AC-17(2), NIST.800-53.r5 AC-4, NIST.800-53.r5 IA-5(1), NIST.800-53.r5 SC-12(3), NIST.800-53.r5 SC-13, NIST.800-53.r5 SC-23, NIST.800-53.r5 SC-23(3), NIST.800-53.r5 SC-7(4), NIST.800-53.r5 SC-8, NIST.800-53.r5 SC-8(1), NIST.800-53.r5 SC-8(2), NIST.800-53.r5 SI-7(6), CRI Profile v2.2/PR.DS-02.01, CRI Profile v2.2/PR.PS-01.06

Category: Detect > Detection services

Severity: Medium

Resource type: `AWS::ElasticLoadBalancingV2::LoadBalancer`

AWS Config rule: alb-http-to-https-redirection-check

Schedule type: Periodic

Parameters: None

This control checks whether HTTP to HTTPS redirection is configured on all HTTP listeners of Application Load Balancers. The control fails if any of the HTTP listeners of Application Load Balancers do not have HTTP to HTTPS redirection configured.

Before you start to use your Application Load Balancer, you must add one or more listeners. A listener is a process that uses the configured protocol and port to check for connection requests. Listeners support both the HTTP and HTTPS protocols. You can use an HTTPS listener to offload the work of encryption and decryption to your load balancer. To enforce encryption in transit, you should use redirect actions with Application Load Balancers to redirect client HTTP requests to an HTTPS request on port 443.

To learn more, see Listeners for your Application Load Balancers in *User Guide for Application Load Balancers*.

Remediation

To redirect HTTP requests to HTTPS, you must add an Application Load Balancer listener rule or edit an existing rule.

For instructions on adding a new rule, see Add a rule in the *User Guide for Application Load Balancers*. For **Protocol : Port**, choose **HTTP**, and then enter **80**. For **Add action, Redirect to**, choose **HTTPS**, and then enter **443**.

For instructions on editing an existing rule, see Edit a rule in the *User Guide for Application Load Balancers*. For **Protocol : Port**, choose **HTTP**, and then enter **80**. For **Add action, Redirect to**, choose **HTTPS**, and then enter **443**.

[ELB.2] Classic Load Balancers with SSL/HTTPS listeners should use a certificate provided by AWS Certificate Manager

Related requirements: NIST.800-53.r5 AC-17(2), NIST.800-53.r5 AC-4, NIST.800-53.r5 IA-5(1), NIST.800-53.r5 SC-12(3), NIST.800-53.r5 SC-13, NIST.800-53.r5 SC-23, NIST.800-53.r5 SC-23(5), NIST.800-53.r5 SC-7(4), NIST.800-53.r5 SC-8, NIST.800-53.r5 SC-8(1), NIST.800-53.r5 SC-8(2), NIST.800-53.r5 SI-7(6), NIST.800-171.r2 3.13.8, CRI Profile v2.2/PR.DS-02.01, CRI Profile v2.2/PR.PS-01.06, CRI Profile v2.2/PR.PS-01.07

Category: Protect > Data Protection > Encryption of data-in-transit

Severity: Medium

Resource type: `AWS::ElasticLoadBalancing::LoadBalancer`

AWS Config rule: elb-acm-certificate-required

Schedule type: Change triggered

Parameters: None

This control checks whether the Classic Load Balancer uses HTTPS/SSL certificates provided by AWS Certificate Manager (ACM). The control fails if the Classic Load Balancer configured with HTTPS/SSL listener does not use a certificate provided by ACM.

To create a certificate, you can use either ACM or a tool that supports the SSL and TLS protocols, such as OpenSSL. Security Hub CSPM recommends that you use ACM to create or import certificates for your load balancer.

ACM integrates with Classic Load Balancers so that you can deploy the certificate on your load balancer. You also should automatically renew these certificates.

Remediation

For information about how to associate an ACM SSL/TLS certificate with a Classic Load Balancer, see the AWS Knowledge Center article How can I associate an ACM SSL/TLS certificate with a Classic, Application, or Network Load Balancer?

[ELB.3] Classic Load Balancer listeners should be configured with HTTPS or TLS termination

Related requirements: NIST.800-53.r5 AC-17(2), NIST.800-53.r5 AC-4, NIST.800-53.r5 IA-5(1), NIST.800-53.r5 SC-12(3), NIST.800-53.r5 SC-13, NIST.800-53.r5 SC-23, NIST.800-53.r5 SC-23(3), NIST.800-53.r5 SC-7(4), NIST.800-53.r5 SC-8, NIST.800-53.r5 SC-8(1), NIST.800-53.r5 SC-8(2), NIST.800-53.r5 SI-7(6), NIST.800-171.r2 3.13.8, NIST.800-171.r2 3.13.15, PCI DSS v4.0.1/4.2.1, CRI Profile v2.2/PR.DS-02.01, CRI Profile v2.2/PR.PS-01.06

Category: Protect > Data Protection > Encryption of data-in-transit

Severity: Medium

Resource type: `AWS::ElasticLoadBalancing::LoadBalancer`

AWS Config rule: elb-tls-https-listeners-only

Schedule type: Change triggered

Parameters: None

This control checks whether your Classic Load Balancer listeners are configured with HTTPS or TLS protocol for front-end (client to load balancer) connections. The control is applicable if a Classic Load Balancer has listeners. If your Classic Load Balancer does not have a listener configured, then the control does not report any findings.

The control passes if the Classic Load Balancer listeners are configured with TLS or HTTPS for front-end connections.

The control fails if the listener is not configured with TLS or HTTPS for front-end connections.

Before you start to use a load balancer, you must add one or more listeners. A listener is a process that uses the configured protocol and port to check for connection requests. Listeners can support both HTTP and HTTPS/TLS protocols. You should always use an HTTPS or TLS listener, so that the load balancer does the work of encryption and decryption in transit.

Remediation

To remediate this issue, update your listeners to use the TLS or HTTPS protocol.

To change all noncompliant listeners to TLS/HTTPS listeners

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, under **Load Balancing**, choose **Load Balancers**.
3. Select your Classic Load Balancer.
4. On the **Listeners** tab, choose **Edit**.
5. For all listeners where **Load Balancer Protocol** is not set to HTTPS or SSL, change the setting to HTTPS or SSL.
6. For all modified listeners, on the **Certificates** tab, choose **Change default**.
7. For **ACM and IAM certificates**, select a certificate.
8. Choose **Save as default**.
9. After you update all of the listeners, choose **Save**.

[ELB.4] Application Load Balancer should be configured to drop invalid http headers

Related requirements: NIST.800-53.r5 SC-7(4), NIST.800-53.r5 SC-8(2), PCI DSS v4.0.1/6.2.4, CRI Profile v2.2/DE.CM-01.03, CRI Profile v2.2/PR.IR-01.02, CRI Profile v2.2/PR.IR-01.03, CRI Profile v2.2/PR.PS-01.01, CRI Profile v2.2/PR.PS-01.03

Category: Protect > Network Security

Severity: Medium

Resource type: `AWS::ElasticLoadBalancingV2::LoadBalancer`

AWS Config rule: alb-http-drop-invalid-header-enabled

Schedule type: Change triggered

Parameters: None

This control evaluates whether an Application Load Balancer is configured to drop invalid HTTP headers. The control fails if the value of `routing.http.drop_invalid_header_fields.enabled` is set to `false`.

By default, Application Load Balancers are not configured to drop invalid HTTP header values. Removing these header values prevents HTTP desync attacks.

> **Note**
>
> We recommend disabling this control if ELB.12 is enabled in your account. For more information, see [ELB.12] Application Load Balancer should be configured with defensive or strictest desync mitigation mode.

Remediation

To remediate this issue, configure your load balancer to drop invalid header fields.

To configure the load balancer to drop invalid header fields

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Load balancers**.
3. Choose an Application Load Balancer.
4. From **Actions**, choose **Edit attributes**.
5. Under **Drop Invalid Header Fields**, choose **Enable**.
6. Choose **Save**.

[ELB.5] Application and Classic Load Balancers logging should be enabled

Related requirements: NIST.800-53.r5 AC-4(26), NIST.800-53.r5 AU-10, NIST.800-53.r5 AU-12, NIST.800-53.r5 AU-2, NIST.800-53.r5 AU-3, NIST.800-53.r5 AU-6(3), NIST.800-53.r5 AU-6(4), NIST.800-53.r5 CA-7, NIST.800-53.r5 SC-7(9), NIST.800-53.r5 SI-7(8), CRI Profile v2.2/DE.CM-03.01, CRI Profile v2.2/PR.PS-04.02, CRI Profile v2.2/PR.PS-04.03

Category: Identify > Logging

Severity: Medium

Resource type: `AWS::ElasticLoadBalancing::LoadBalancer`, `AWS::ElasticLoadBalancingV2::LoadBalancer`

AWS Config rule: elb-logging-enabled

Schedule type: Change triggered

Parameters: None

This control checks whether the Application Load Balancer and the Classic Load Balancerhave logging enabled. The control fails if `access_logs.s3.enabled` is `false`.

Elastic Load Balancing provides access logs that capture detailed information about requests sent to your load balancer. Each log contains information such as the time the request was received, the client's IP address, latencies, request paths, and server responses. You can use these access logs to analyze traffic patterns and to troubleshoot issues.

To learn more, see Access logs for your Classic Load Balancer in *User Guide for Classic Load Balancers*.

Remediation

To enable access logs, see Step 3: Configure access logs in the *User Guide for Application Load Balancers*.

[ELB.6] Application, Gateway, and Network Load Balancers should have deletion protection enabled

Related requirements: NIST.800-53.r5 CA-9(1), NIST.800-53.r5 CM-2, NIST.800-53.r5 CM-2(2), NIST.800-53.r5 CM-3, NIST.800-53.r5 SC-5(2), CRI Profile v2.2/DE.CM-09.03, CRI Profile v2.2/PR.IR-03.01

Category: Recover > Resilience > High availability

Severity: Medium

Resource type: `AWS::ElasticLoadBalancingV2::LoadBalancer`

AWS Config rule: elb-deletion-protection-enabled

Schedule type: Change triggered

Parameters: None

This control checks whether an Application, Gateway, or Network Load Balancer has deletion protection enabled. The control fails if deletion protection is disabled.

Enable deletion protection to protect your Application, Gateway, or Network Load Balancer from deletion.

Remediation

To prevent your load balancer from being deleted accidentally, you can enable deletion protection. By default, deletion protection is disabled for your load balancer.

If you enable deletion protection for your load balancer, you must disable delete protection before you can delete the load balancer.

To enable deletion protection for an Application Load Balancer, see Deletion protection in the *User Guide for Application Load Balancers*. To enable deletion protection for a Gateway Load Balancer, see Deletion protection in the *User Guide for Gateway Load Balancers*. To enable deletion protection for a Network Load Balancer, see Deletion protection in the *User Guide for Network Load Balancers*.

[ELB.7] Classic Load Balancers should have connection draining enabled

Related requirements: NIST.800-53.r5 CA-9(1), NIST.800-53.r5 CM-2, CRI Profile v2.2/PR.IR-03.01

Category: Recover > Resilience

Severity: Low

Resource type: `AWS::ElasticLoadBalancing::LoadBalancer`

AWS Config rule: `elb-connection-draining-enabled` (custom Security Hub CSPM rule)

Schedule type: Change triggered

Parameters: None

This control checks whether Classic Load Balancers have connection draining enabled.

Enabling connection draining on Classic Load Balancers ensures that the load balancer stops sending requests to instances that are de-registering or unhealthy. It keeps the existing

connections open. This is particularly useful for instances in Auto Scaling groups, to ensure that connections aren't severed abruptly.

Remediation

To enable connection draining on Classic Load Balancers, see Configure connection draining for your Classic Load Balancer in *User Guide for Classic Load Balancers*.

[ELB.8] Classic Load Balancers with SSL listeners should use a predefined security policy that has strong AWS Configuration

Related requirements: NIST.800-53.r5 AC-17(2), NIST.800-53.r5 AC-4, NIST.800-53.r5 IA-5(1), NIST.800-53.r5 SC-12(3), NIST.800-53.r5 SC-13, NIST.800-53.r5 SC-23, NIST.800-53.r5 SC-23(3), NIST.800-53.r5 SC-7(4), NIST.800-53.r5 SC-8, NIST.800-53.r5 SC-8(1), NIST.800-53.r5 SC-8(2), NIST.800-53.r5 SI-7(6), NIST.800-171.r2 3.13.8, NIST.800-171.r2 3.13.15, PCI DSS v4.0.1/4.2.1, CRI Profile v2.2/PR.DS-02.01, CRI Profile v2.2/PR.PS-01.06

Category: Protect > Data Protection > Encryption of data-in-transit

Severity: Medium

Resource type: `AWS::ElasticLoadBalancing::LoadBalancer`

AWS Config rule: elb-predefined-security-policy-ssl-check

Schedule type: Change triggered

Parameters:

- `predefinedPolicyName`: `ELBSecurityPolicy-TLS-1-2-2017-01` (not customizable)

This control checks whether your Classic Load Balancer HTTPS/SSL listeners use the predefined policy `ELBSecurityPolicy-TLS-1-2-2017-01`. The control fails if the Classic Load Balancer HTTPS/SSL listeners do not use `ELBSecurityPolicy-TLS-1-2-2017-01`.

A security policy is a combination of SSL protocols, ciphers, and the Server Order Preference option. Predefined policies control the ciphers, protocols, and preference orders to support during SSL negotiations between a client and load balancer.

Using `ELBSecurityPolicy-TLS-1-2-2017-01` can help you to meet compliance and security standards that require you to disable specific versions of SSL and TLS. For more information, see Predefined SSL security policies for Classic Load Balancers in *User Guide for Classic Load Balancers*.

Remediation

For information on how to use the predefined security policy `ELBSecurityPolicy-TLS-1-2-2017-01` with a Classic Load Balancer, see Configure security settings in *User Guide for Classic Load Balancers*.

[ELB.9] Classic Load Balancers should have cross-zone load balancing enabled

Related requirements: NIST.800-53.r5 CP-10, NIST.800-53.r5 CP-6(2), NIST.800-53.r5 SC-36, NIST.800-53.r5 SC-5(2), NIST.800-53.r5 SI-13(5), CRI Profile v2.2/PR.IR-01.03, CRI Profile v2.2/PR.IR-03.01, CRI Profile v2.2/PR.IR-04.02

Category: Recover > Resilience > High availability

Severity: Medium

Resource type: `AWS::ElasticLoadBalancing::LoadBalancer`

AWS Config rule: elb-cross-zone-load-balancing-enabled

Schedule type: Change triggered

Parameters: None

This control checks if cross-zone load balancing is enabled for the Classic Load Balancers (CLBs). The control fails if cross-zone load balancing is not enabled for a CLB.

A load balancer node distributes traffic only across the registered targets in its Availability Zone. When cross-zone load balancing is disabled, each load balancer node distributes traffic only across the registered targets in its Availability Zone. If the number of registered targets is not same across the Availability Zones, traffic wont be distributed evenly and the instances in one zone may end up over utilized compared to the instances in another zone. With cross-zone load balancing enabled, each load balancer node for your Classic Load Balancer distributes requests evenly across the registered instances in all enabled Availability Zones. For details see Cross-zone load balancing in the Elastic Load Balancing User Guide.

Remediation

To enable cross-zone load balancing in a Classic Load Balancer, see Enable cross-zone load balancing in the *User Guide for Classic Load Balancers*.

[ELB.10] Classic Load Balancer should span multiple Availability Zones

Related requirements: NIST.800-53.r5 CP-10, NIST.800-53.r5 CP-6(2), NIST.800-53.r5 SC-36, NIST.800-53.r5 SC-5(2), NIST.800-53.r5 SI-13(5), CRI Profile v2.2/PR.IR-01.03, CRI Profile v2.2/PR.IR-03.01, CRI Profile v2.2/PR.IR-04.02

Category: Recover > Resilience > High availability

Severity: Medium

Resource type: `AWS::ElasticLoadBalancing::LoadBalancer`

AWS Config rule: clb-multiple-az

Schedule type: Change triggered

Parameters:

Parameter	Description	Type	Allowed custom values	Security Hub CSPM default value
`minAvailabilityZones`	Minimum number of Availability Zones	Enum	`2, 3, 4, 5, 6`	`2`

This control checks whether a Classic Load Balancer has been configured to span at least the specified number of Availability Zones (AZs). The control fails if the Classic Load Balancer does not span at least the specified number of AZs. Unless you provide a custom parameter value for the minimum number of AZs, Security Hub CSPM uses a default value of two AZs.

A Classic Load Balancer can be set up to distribute incoming requests across Amazon EC2 instances in a single Availability Zone or multiple Availability Zones. A Classic Load Balancer that does not span multiple Availability Zones is unable to redirect traffic to targets in another Availability Zone if the sole configured Availability Zone becomes unavailable.

Remediation

To add Availability Zones to a Classic Load Balancer, see Add or remove subnets for your Classic Load Balancer in the *User Guide for Classic Load Balancers*.

[ELB.12] Application Load Balancer should be configured with defensive or strictest desync mitigation mode

Related requirements: NIST.800-53.r5 AC-4(21), NIST.800-53.r5 CA-9(1), NIST.800-53.r5 CM-2, PCI DSS v4.0.1/6.2.4, CRI Profile v2.2/GV.OC-04.03, CRI Profile v2.2/PR.IR-01.02, CRI Profile v2.2/PR.IR-01.03, CRI Profile v2.2/PR.IR-03.01, CRI Profile v2.2/PR.IR-04.02

Category: Protect > Data Protection > Data integrity

Severity: Medium

Resource type: `AWS::ElasticLoadBalancingV2::LoadBalancer`

AWS Config rule: alb-desync-mode-check

Schedule type: Change triggered

Parameters:

- `desyncMode`: `defensive, strictest` (not customizable)

This control checks whether an Application Load Balancer is configured with defensive or strictest desync mitigation mode. The control fails if an Application Load Balancer is not configured with defensive or strictest desync mitigation mode.

HTTP Desync issues can lead to request smuggling and make applications vulnerable to request queue or cache poisoning. In turn, these vulnerabilities can lead to credential stuffing or execution of unauthorized commands. Application Load Balancers configured with defensive or strictest desync mitigation mode protect your application from security issues that may be caused by HTTP Desync.

Remediation

To update desync mitigation mode of an Application Load Balancer, see Desync mitigation mode in the *User Guide for Application Load Balancers*.

[ELB.13] Application, Network and Gateway Load Balancers should span multiple Availability Zones

Related requirements: NIST.800-53.r5 CP-10, NIST.800-53.r5 CP-6(2), NIST.800-53.r5 SC-36, NIST.800-53.r5 SC-5(2), NIST.800-53.r5 SI-13(5), CRI Profile v2.2/PR.IR-01.03, CRI Profile v2.2/PR.IR-03.01, CRI Profile v2.2/PR.IR-04.02

Category: Recover > Resilience > High availability

Severity: Medium

Resource type: `AWS::ElasticLoadBalancingV2::LoadBalancer`

AWS Config rule: elbv2-multiple-az

Schedule type: Change triggered

Parameters:

Parameter	Description	Type	Allowed custom values	Security Hub CSPM default value
`minAvailabilityZones`	Minimum number of Availability Zones	Enum	`2, 3, 4, 5, 6`	`2`

This control checks whether an Elastic Load Balancer V2 (Application, Network, or Gateway Load Balancer) has registered instances from at least the specified number of Availability Zones (AZs). The control fails if an Elastic Load Balancer V2 doesn't have instances registered in at least the specified number of AZs. Unless you provide a custom parameter value for the minimum number of AZs, Security Hub CSPM uses a default value of two AZs.

Elastic Load Balancing automatically distributes your incoming traffic across multiple targets, such as EC2 instances, containers, and IP addresses, in one or more Availability Zones. Elastic Load Balancing scales your load balancer as your incoming traffic changes over time. It is recommended to configure at least two availability zones to ensure availability of services, as the Elastic Load Balancer will be able to direct traffic to another availability zone if one becomes unavailable. Having multiple availability zones configured will help eliminate having a single point of failure for the application.

Remediation

To add an Availability Zone to an Application Load Balancer, see Availability Zones for your Application Load Balancer in the *User Guide for Application Load Balancers*. To add an Availability Zone to an Network Load Balancer, see Network Load Balancers in the *User Guide for Network Load*

Balancers. To add an Availability Zone to a Gateway Load Balancer, see Create a Gateway Load Balancer in the *User Guide for Gateway Load Balancers*.

[ELB.14] Classic Load Balancer should be configured with defensive or strictest desync mitigation mode

Related requirements: NIST.800-53.r5 AC-4(21), NIST.800-53.r5 CA-9(1), NIST.800-53.r5 CM-2, PCI DSS v4.0.1/6.2.4, CRI Profile v2.2/GV.OC-04.03, CRI Profile v2.2/PR.IR-01.02, CRI Profile v2.2/PR.IR-01.03, CRI Profile v2.2/PR.IR-03.01, CRI Profile v2.2/PR.IR-04.02

Category: Protect > Data Protection > Data integrity

Severity: Medium

Resource type: `AWS::ElasticLoadBalancing::LoadBalancer`

AWS Config rule: clb-desync-mode-check

Schedule type: Change triggered

Parameters:

- `desyncMode`: `defensive, strictest` (not customizable)

This control checks whether a Classic Load Balancer is configured with defensive or strictest desync mitigation mode. The control fails if the Classic Load Balancer isn't configured with defensive or strictest desync mitigation mode.

HTTP Desync issues can lead to request smuggling and make applications vulnerable to request queue or cache poisoning. In turn, these vulnerabilities can lead to credential hijacking or execution of unauthorized commands. Classic Load Balancers configured with defensive or strictest desync mitigation mode protect your application from security issues that may be caused by HTTP Desync.

Remediation

To update desync mitigation mode on a Classic Load Balancer, see Modify desync mitigation mode in the *User Guide for Classic Load Balancers*.

[ELB.16] Application Load Balancers should be associated with an AWS WAF web ACL

Related requirements: NIST.800-53.r5 AC-4(21), CRI Profile v2.2/DE.CM-01.03, CRI Profile v2.2/PR.IR-01.01, CRI Profile v2.2/PR.IR-01.03

Category: Protect > Protective services

Severity: Medium

Resource type: `AWS::ElasticLoadBalancingV2::LoadBalancer`

AWS Config rule: alb-waf-enabled

Schedule type: Change triggered

Parameters: None

This control checks whether an Application Load Balancer is associated with an AWS WAF Classic or AWS WAF web access control list (web ACL). The control fails if the `Enabled` field for the AWS WAF configuration is set to `false`.

AWS WAF is a web application firewall that helps protect web applications and APIs from attacks. With AWS WAF, you can configure a web ACL, which is a set of rules that allow, block, or count web requests based on customizable web security rules and conditions that you define. We recommend associating your Application Load Balancer with an AWS WAF web ACL to help protect it from malicious attacks.

Remediation

To associate an Application Load Balancer with a web ACL, see Associating or disassociating a web ACL with an AWS resource in the *AWS WAF Developer Guide*.

[ELB.17] Application and Network Load Balancers with listeners should use recommended security policies

Related requirements: NIST.800-53.r5 AC-17(2), NIST.800-53.r5 AC-4, NIST.800-53.r5 IA-5(1), NIST.800-53.r5 SC-12(3), NIST.800-53.r5 SC-13, NIST.800-53.r5 SC-23, NIST.800-53.r5 SC-23(3), NIST.800-53.r5 SC-7(4), NIST.800-53.r5 SC-8, NIST.800-53.r5 SC-8(1), NIST.800-53.r5 SC-8(2), NIST.800-53.r5 SI-7(6), CRI Profile v2.2/PR.DS-02.01, CRI Profile v2.2/PR.PS-01.06

Category: Protect > Data Protection > Encryption of data-in-transit

Severity: Medium

Resource type: `AWS::ElasticLoadBalancingV2::Listener`

AWS Config rule: elbv2-predefined-security-policy-ssl-check

Schedule type: Change triggered

Parameters: `sslPolicies`: `ELBSecurityPolicy-TLS13-1-3-2021-06, ELBSecurityPolicy-TLS13-1-3-FIPS-2023-04, ELBSecurityPolicy-TLS13-1-2-Res-PQ-2025-09, ELBSecurityPolicy-TLS13-1-3-PQ-2025-09, ELBSecurityPolicy-TLS13-1-2-Res-FIPS-PQ-2025-09, ELBSecurityPolicy-TLS13-1-3-FIPS-PQ-2025-09, ELBSecurityPolicy-TLS13-1-2-RFC9151-FIPS-2023-07, ELBSecurityPolicy-TLS13-1-2-RFC9151-INTEROP1-FIPS-2023-07, ELBSecurityPolicy-TLS13-1-2-RFC9151-INTEROP2-FIPS-2023-07, ELBSecurityPolicy-TLS13-1-3-RFC9151-FIPS-2023-07, ELBSecurityPolicy-TLS13-1-2-FIPS-PQ-2025-09, ELBSecurityPolicy-TLS13-1-2-PQ-2025-09` (not customizable)

This control checks whether the HTTPS listener for an Application Load Balancer or the TLS listener for a Network Load Balancer is configured to encrypt data in transit by using a recommended security policy. The control fails if the HTTPS or TLS listener for a load balancer isn't configured to use a recommended security policy.

Elastic Load Balancing uses an SSL negotiation configuration, known as a *security policy*, to negotiate connections between a client and a load balancer. The security policy specifies a combination of protocols and ciphers. The protocol establishes a secure connection between a client and a server. A cipher is an encryption algorithm that uses encryption keys to create a coded message. During the connection negotiation process, the client and the load balancer present a list of ciphers and protocols that they each support, in order of preference. Using a recommended security policy for a load balancer can help you meet compliance and security standards.

Remediation

For information about recommended security policies and how to update listeners, see the following sections of the *Elastic Load Balancing User Guides*: Security policies for Application Load Balancers, Security policies for Network Load Balancers, Update an HTTPS listener for your Application Load Balancer, and Update a listener for your Network Load Balancer.

[ELB.18] Application and Network Load Balancer listeners should use secure protocols to encrypt data in transit

Related requirements: CRI Profile v2.2/PR.DS-02.01, CRI Profile v2.2/PR.PS-01.06

Category: Protect > Data Protection > Encryption of data-in-transit

Severity: Medium

Resource type: `AWS::ElasticLoadBalancingV2::Listener`

AWS Config rule: elbv2-listener-encryption-in-transit

Schedule type: Change triggered

Parameters: None

This control checks whether the listener for an Application Load Balancer or Network Load Balancer is configured to use a secure protocol for encryption of data in transit. The control fails if an Application Load Balancer listener isn't configured to use the HTTPS protocol, or a Network Load Balancer listener isn't configured to use the TLS protocol.

To encrypt data that's transmitted between a client and a load balancer, Elastic Load Balancer listeners should be configured to use industry-standard security protocols: HTTPS for Application Load Balancers, or TLS for Network Load Balancers. Otherwise, data that's transmitted between a client and a load balancer is vulnerable to interception, tampering, and unauthorized access. Use of HTTPS or TLS by a listener aligns with security best practices and helps ensure the confidentiality and integrity of data during transmission. This is particularly important for applications that handle sensitive information, or must comply with security standards that require encryption of data in transit.

Remediation

For information about configuring security protocols for listeners, see the following sections of the *Elastic Load Balancing User Guides*: Create an HTTPS listener for your Application Load Balancer and Create a listener for your Network Load Balancer.

[ELB.21] Application and Network Load Balancer target groups should use encrypted health check protocols

Related requirements: CRI Profile v2.2/PR.DS-02.01, CRI Profile v2.2/PR.PS-01.06

Category: Protect > Data Protection > Encryption of data-in-transit

Severity: Medium

Resource type: `AWS::ElasticLoadBalancingV2::TargetGroup`

AWS Config rule: elbv2-targetgroup-healthcheck-protocol-encrypted

Schedule type: Change triggered

Parameters: None

This control checks whether the target group for application and network load balancer health checks use an encrypted transport protocol. The control fails if the health check protocol does not use HTTPS. This control is not applicable to Lambda target types.

Load Balancers send health check requests to registered targets to determine their status and route traffic accordingly. The health check protocol specified in the target group configuration determines how these checks are performed. When health check protocols use unencrypted communication such as HTTP, the requests and responses can be intercepted or manipulated during transmission. This allows attackers to gain insights into infrastructure configuration, tamper with health check results, or conduct man-in-the-middle attacks that affect routing decisions. Using HTTPS for health checks provides encrypted communication between the load balancer and its targets, protecting the integrity and confidentiality of health status information.

Remediation

To configure encrypted health checks for your Application Load Balancer target group, see Update the health check settings of an Application Load Balancer target group in the *Elastic Load Balancing User Guide*. To configure encrypted health checks for your Network Load Balancer target group, see Update the health check settings of an Network Load Balancer target group in the *Elastic Load Balancing User Guide*.

[ELB.22] ELB target groups should use encrypted transport protocols

Related requirements: CRI Profile v2.2/PR.DS-02.01, CRI Profile v2.2/PR.PS-01.06

Category: Protect > Data Protection > Encryption of data-in-transit

Severity: Medium

Resource type: `AWS::ElasticLoadBalancingV2::TargetGroup`

AWS Config rule: elbv2-targetgroup-protocol-encrypted

Schedule type: Change triggered

Parameters: None

This control checks whether an Elastic Load Balancing target group uses an encrypted transport protocol. This control does not apply to target groups with a target type of Lambda or ALB, or

target groups using the GENEVE protocol. The control fails if the target group does not use HTTPS, TLS, or QUIC protocol.

Encrypting data in transit protects it from interception by unauthorized users. Target groups that use unencrypted protocols (HTTP, TCP, UDP) transmit data without encryption, making it vulnerable to eavesdropping. Using encrypted protocols (HTTPS, TLS, QUIC) ensures that data transmitted between load balancers and targets is protected.

Remediation

To use an encrypted protocol, you must create a new target group with HTTPS, TLS, or QUIC protocol. Target group protocol cannot be modified after creation. To create Application Load Balancer target group, see Create a target group for your Application Load Balancer in the *Elastic Load Balancing User Guide*. To create Network Load Balancer target group, see Create a target group for your Network Load Balancer in the *Elastic Load Balancing User Guide*.

Security Hub CSPM for Elasticsearch

These AWS Security Hub CSPM controls evaluate the Elasticsearch service and resources.

These controls may not be available in all AWS Regions. For more information, see Availability of controls by Region.

[ES.1] Elasticsearch domains should have encryption at-rest enabled

Related requirements: PCI DSS v3.2.1/3.4, NIST.800-53.r5 CA-9(1), NIST.800-53.r5 CM-3(6), NIST.800-53.r5 SC-13, NIST.800-53.r5 SC-28, NIST.800-53.r5 SC-28(1), NIST.800-53.r5 SC-7(10), NIST.800-53.r5 SI-7(6), CRI Profile v2.2/PR.DS-01.01, CRI Profile v2.2/PR.PS-01.06

Category: Protect > Data Protection > Encryption of data-at-rest

Severity: Medium

Resource type: `AWS::Elasticsearch::Domain`

AWS Config rule: `elasticsearch-encrypted-at-rest`

Schedule type: Periodic

Parameters: None

This control checks whether Elasticsearch domains have encryption at rest configuration enabled. The check fails if encryption at rest is not enabled.

For an added layer of security for your sensitive data in OpenSearch, you should configure your OpenSearch to be encrypted at rest. Elasticsearch domains offer encryption of data at rest. The feature uses AWS KMS to store and manage your encryption keys. To perform the encryption, it uses the Advanced Encryption Standard algorithm with 256-bit keys (AES-256).

To learn more about OpenSearch encryption at rest, see Encryption of data at rest for Amazon OpenSearch Service in the *Amazon OpenSearch Service Developer Guide*.

Certain instance types, such as `t.small` and `t.medium`, don't support encryption of data at rest. For details, see Supported instance types in the *Amazon OpenSearch Service Developer Guide*.

Remediation

To enable encryption at rest for new and existing Elasticsearch domains, see Enabling encryption of data at rest in the *Amazon OpenSearch Service Developer Guide*.

[ES.2] Elasticsearch domains should not be publicly accessible

Related requirements: PCI DSS v3.2.1/1.2.1,PCI DSS v3.2.1/1.3.1,PCI DSS v3.2.1/1.3.2,PCI DSS v3.2.1/1.3.4,PCI DSS v3.2.1/1.3.6, NIST.800-53.r5 AC-21, NIST.800-53.r5 AC-3, NIST.800-53.r5 AC-3(7), NIST.800-53.r5 AC-4, NIST.800-53.r5 AC-4(21), NIST.800-53.r5 AC-6, NIST.800-53.r5 SC-7, NIST.800-53.r5 SC-7(11), NIST.800-53.r5 SC-7(16), NIST.800-53.r5 SC-7(20), NIST.800-53.r5 SC-7(21), NIST.800-53.r5 SC-7(3), NIST.800-53.r5 SC-7(4), NIST.800-53.r5 SC-7(9), PCI DSS v4.0.1/1.4.4, CRI Profile v2.2/PR.IR-01.01

Category: Protect > Secure network configuration > Resources within VPC

Severity: Critical

Resource type: `AWS::Elasticsearch::Domain`

AWS Config rule: `elasticsearch-in-vpc-only`

Schedule type: Periodic

Parameters: None

This control checks whether Elasticsearch domains are in a VPC. It does not evaluate the VPC subnet routing configuration to determine public access. You should ensure that Elasticsearch domains are not attached to public subnets. See Resource-based policies in the *Amazon OpenSearch Service Developer Guide*. You should also ensure that your VPC is configured according

to the recommended best practices. See Security best practices for your VPC in the *Amazon VPC User Guide*.

Elasticsearch domains deployed within a VPC can communicate with VPC resources over the private AWS network, without the need to traverse the public internet. This configuration increases the security posture by limiting access to the data in transit. VPCs provide a number of network controls to secure access to Elasticsearch domains, including network ACL and security groups. Security Hub CSPM recommends that you migrate public Elasticsearch domains to VPCs to take advantage of these controls.

Remediation

If you create a domain with a public endpoint, you cannot later place it within a VPC. Instead, you must create a new domain and migrate your data. The reverse is also true. If you create a domain within a VPC, it cannot have a public endpoint. Instead, you must either create another domain or disable this control.

See Launching your Amazon OpenSearch Service domains within a VPC in the *Amazon OpenSearch Service Developer Guide*.

[ES.3] Elasticsearch domains should encrypt data sent between nodes

Related requirements: NIST.800-53.r5 AC-4, NIST.800-53.r5 SC-13, NIST.800-53.r5 SC-23, NIST.800-53.r5 SC-23(3), NIST.800-53.r5 SC-7(4), NIST.800-53.r5 SC-8, NIST.800-53.r5 SC-8(1), NIST.800-53.r5 SC-8(2), PCI DSS v4.0.1/4.2.1, CRI Profile v2.2/PR.DS-02.01, CRI Profile v2.2/PR.IR-01.05, CRI Profile v2.2/PR.PS-01.06

Category: Protect > Data Protection > Encryption of data-in-transit

Severity: Medium

Resource type: `AWS::Elasticsearch::Domain`

AWS Config rule: `elasticsearch-node-to-node-encryption-check`

Schedule type: Change triggered

Parameters: None

This control checks whether an Elasticsearch domain has node-to-node encryption enabled. The control fails if the Elasticsearch domain doesn't have node-to-node encryption enabled. The

control also produces failed findings if an Elasticsearch version doesn't support node-to-node encryption checks.

HTTPS (TLS) can be used to help prevent potential attackers from eavesdropping on or manipulating network traffic using person-in-the-middle or similar attacks. Only encrypted connections over HTTPS (TLS) should be allowed. Enabling node-to-node encryption for Elasticsearch domains ensures that intra-cluster communications are encrypted in transit.

There can be a performance penalty associated with this configuration. You should be aware of and test the performance trade-off before enabling this option.

Remediation

For information about enabling node-to-node encryption on new and existing domains, see Enabling node-to-node encryption in the *Amazon OpenSearch Service Developer Guide*.

[ES.4] Elasticsearch domain error logging to CloudWatch Logs should be enabled

Related requirements: NIST.800-53.r5 AC-2(4), NIST.800-53.r5 AC-4(26), NIST.800-53.r5 AC-6(9), NIST.800-53.r5 AU-10, NIST.800-53.r5 AU-12, NIST.800-53.r5 AU-2, NIST.800-53.r5 AU-3, NIST.800-53.r5 AU-6(3), NIST.800-53.r5 AU-6(4), NIST.800-53.r5 CA-7, NIST.800-53.r5 SC-7(9), NIST.800-53.r5 SI-3(8), NIST.800-53.r5 SI-4(20), NIST.800-53.r5 SI-7(8), CRI Profile v2.2/DE.AE-03.02, CRI Profile v2.2/PR.PS-04.02, CRI Profile v2.2/PR.PS-04.03

Category: Identify - Logging

Severity: Medium

Resource type: `AWS::Elasticsearch::Domain`

AWS Config rule: `elasticsearch-logs-to-cloudwatch`

Schedule type: Change triggered

Parameters:

- `logtype = 'error'` (not customizable)

This control checks whether Elasticsearch domains are configured to send error logs to CloudWatch Logs.

You should enable error logs for Elasticsearch domains and send those logs to CloudWatch Logs for retention and response. Domain error logs can assist with security and access audits, and can help to diagnose availability issues.

Remediation

For information on how to enable log publishing, see Enabling log publishing (console) in the *Amazon OpenSearch Service Developer Guide*.

[ES.5] Elasticsearch domains should have audit logging enabled

Related requirements: NIST.800-53.r5 AC-2(4), NIST.800-53.r5 AC-4(26), NIST.800-53.r5 AC-6(9), NIST.800-53.r5 AU-10, NIST.800-53.r5 AU-12, NIST.800-53.r5 AU-2, NIST.800-53.r5 AU-3, NIST.800-53.r5 AU-6(3), NIST.800-53.r5 AU-6(4), NIST.800-53.r5 CA-7, NIST.800-53.r5 SC-7(9), NIST.800-53.r5 SI-3(8), NIST.800-53.r5 SI-4(20), NIST.800-53.r5 SI-7(8), PCI DSS v4.0.1/10.4.2, CRI Profile v2.2/DE.AE-03.02, CRI Profile v2.2/PR.PS-04.02, CRI Profile v2.2/PR.PS-04.03

Category: Identify > Logging

Severity: Medium

Resource type: `AWS::Elasticsearch::Domain`

AWS Config rule: `elasticsearch-audit-logging-enabled` (custom Security Hub CSPM rule)

Schedule type: Change triggered

Parameters:

- `cloudWatchLogsLogGroupArnList` (not customizable). Security Hub CSPM does not populate this parameter. Comma-separated list of CloudWatch Logs log groups that should be configured for audit logs.

  This rule is `NON_COMPLIANT` if the CloudWatch Logs log group of the Elasticsearch domain is not specified in this parameter list.

This control checks whether Elasticsearch domains have audit logging enabled. This control fails if an Elasticsearch domain does not have audit logging enabled.

Audit logs are highly customizable. They allow you to track user activity on your Elasticsearch clusters, including authentication successes and failures, requests to OpenSearch, index changes, and incoming search queries.

Remediation

For detailed instructions on enabling audit logs, see Enabling audit logs in the *Amazon OpenSearch Service Developer Guide*.

[ES.6] Elasticsearch domains should have at least three data nodes

Related requirements: NIST.800-53.r5 CP-10, NIST.800-53.r5 CP-6(2), NIST.800-53.r5 SC-36, NIST.800-53.r5 SC-5(2), NIST.800-53.r5 SI-13(5), CRI Profile v2.2/PR.IR-03.01, CRI Profile v2.2/PR.IR-04.02

Category: Recover > Resilience > High availability

Severity: Medium

Resource type: `AWS::Elasticsearch::Domain`

AWS Config rule: `elasticsearch-data-node-fault-tolerance` (custom Security Hub CSPM rule)

Schedule type: Change triggered

Parameters: None

This control checks whether Elasticsearch domains are configured with at least three data nodes and `zoneAwarenessEnabled` is `true`.

An Elasticsearch domain requires at least three data nodes for high availability and fault-tolerance. Deploying an Elasticsearch domain with at least three data nodes ensures cluster operations if a node fails.

Remediation

To modify the number of data nodes in an Elasticsearch domain

1. Open the Amazon OpenSearch Service console at https://console.aws.amazon.com/aos/.
2. Under **Domains**, choose the name of the domain you want to edit.
3. Choose **Edit domain**.
4. Under **Data nodes**, set **Number of nodes** to a number greater than or equal to 3.

   For three Availability Zone deployments, set to a multiple of three to ensure equal distribution across Availability Zones.

5. Choose **Submit**.

[ES.7] Elasticsearch domains should be configured with at least three dedicated master nodes

Related requirements: NIST.800-53.r5 CP-10, NIST.800-53.r5 CP-6(2), NIST.800-53.r5 SC-36, NIST.800-53.r5 SC-5(2), NIST.800-53.r5 SI-13(5), CRI Profile v2.2/PR.IR-03.01, CRI Profile v2.2/PR.IR-04.02

Category: Recover > Resilience > High availability

Severity: Medium

Resource type: `AWS::Elasticsearch::Domain`

AWS Configrule: `elasticsearch-primary-node-fault-tolerance` (custom Security Hub CSPM rule)

Schedule type: Change triggered

Parameters: None

This control checks whether Elasticsearch domains are configured with at least three dedicated primary nodes. This control fails if the domain does not use dedicated primary nodes. This control passes if Elasticsearch domains have five dedicated primary nodes. However, using more than three primary nodes might be unnecessary to mitigate the availability risk, and will result in additional cost.

An Elasticsearch domain requires at least three dedicated primary nodes for high availability and fault-tolerance. Dedicated primary node resources can be strained during data node blue/green deployments because there are additional nodes to manage. Deploying an Elasticsearch domain with at least three dedicated primary nodes ensures sufficient primary node resource capacity and cluster operations if a node fails.

Remediation

To modify the number of dedicated primary nodes in an OpenSearch domain

1. Open the Amazon OpenSearch Service console at https://console.aws.amazon.com/aos/.
2. Under **Domains**, choose the name of the domain you want to edit.
3. Choose **Edit domain**.

4. Under **Dedicated master nodes**, set **Instance type** to the desired instance type.
5. Set **Number of master nodes** equal to three or greater.
6. Choose **Submit**.

[ES.8] Connections to Elasticsearch domains should be encrypted using the latest TLS security policy

Related requirements: NIST.800-53.r5 AC-17(2), NIST.800-53.r5 AC-4, NIST.800-53.r5 IA-5(1), NIST.800-53.r5 SC-12(3), NIST.800-53.r5 SC-13, NIST.800-53.r5 SC-23, NIST.800-53.r5 SC-23(3), NIST.800-53.r5 SC-7(4), NIST.800-53.r5 SC-8, NIST.800-53.r5 SC-8(1), NIST.800-53.r5 SC-8(2), NIST.800-53.r5 SI-7(6), PCI DSS v4.0.1/4.2.1, CRI Profile v2.2/PR.DS-02.01, CRI Profile v2.2/PR.IR-01.05, CRI Profile v2.2/PR.PS-01.06

Category: Protect > Data Protection > Encryption of data-in-transit

Severity: Medium

Resource type: `AWS::Elasticsearch::Domain`

AWS Config rule: `elasticsearch-https-required` (custom Security Hub CSPM rule)

Schedule type: Change triggered

Parameters: None

This controls checks whether an Elasticsearch domain endpoint is configured to use the latest TLS security policy. The control fails if the Elasticsearch domain endpoint isn't configured to use the latest supported policy or if HTTPs isn't enabled. The current latest supported TLS security policy is `Policy-Min-TLS-1-2-PFS-2023-10`.

HTTPS (TLS) can be used to help prevent potential attackers from using person-in-the-middle or similar attacks to eavesdrop on or manipulate network traffic. Only encrypted connections over HTTPS (TLS) should be allowed. Encrypting data in transit can affect performance. You should test your application with this feature to understand the performance profile and the impact of TLS. TLS 1.2 provides several security enhancements over previous versions of TLS.

Remediation

To enable TLS encryption, use the UpdateDomainConfig API operation to configure the DomainEndpointOptions object. This sets the `TLSSecurityPolicy`.

[ES.9] Elasticsearch domains should be tagged

Category: Identify > Inventory > Tagging

Severity: Low

Resource type: `AWS::Elasticsearch::Domain`

AWS Config rule: `tagged-elasticsearch-domain` (custom Security Hub CSPM rule)

Schedule type: Change triggered

Parameters:

Parameter	Description	Type	Allowed custom values	Security Hub CSPM default value
`requiredTagKeys`	List of non-system tag keys that the evaluated resource must contain. Tag keys are case sensitive.	StringList (maximum of 6 items)	1–6 tag keys that meet AWS requirements.	`No default value`

This control checks whether an Elasticsearch domain has tags with the specific keys defined in the parameter `requiredTagKeys`. The control fails if the domain doesn't have any tag keys or if it doesn't have all the keys specified in the parameter `requiredTagKeys`. If the parameter `requiredTagKeys` isn't provided, the control only checks for the existence of a tag key and fails if the domain isn't tagged with any key. System tags, which are automatically applied and begin with `aws:`, are ignored.

A tag is a label that you assign to an AWS resource, and it consists of a key and an optional value. You can create tags to categorize resources by purpose, owner, environment, or other criteria. Tags can help you identify, organize, search for, and filter resources. Tagging also helps you track accountable resource owners for actions and notifications. When you use tagging, you can implement attribute-based access control (ABAC) as an authorization strategy, which defines permissions based on tags. You can attach tags to IAM entities (users or roles) and to AWS resources. You can create a single ABAC policy or a separate set of policies for your IAM principals.

You can design these ABAC policies to allow operations when the principal's tag matches the resource tag. For more information, see What is ABAC for AWS? in the *IAM User Guide*.

> **Note**
>
> Don't add personally identifiable information (PII) or other confidential or sensitive information in tags. Tags are accessible to many AWS services, including AWS Billing. For more tagging best practices, see Tagging your AWS resources in the *AWS General Reference*.

Remediation

To add tags to an Elasticsearch domain, see Working with tags in the *Amazon OpenSearch Service Developer Guide*.

Security Hub CSPM controls for Amazon EMR

These AWS Security Hub CSPM controls evaluate the Amazon EMR (previously called Amazon Elastic MapReduce) service and resources. The controls might not be available in all AWS Regions. For more information, see Availability of controls by Region.

[EMR.1] Amazon EMR cluster primary nodes should not have public IP addresses

Related requirements: PCI DSS v3.2.1/1.2.1,PCI DSS v3.2.1/1.3.1,PCI DSS v3.2.1/1.3.2,PCI DSS v3.2.1/1.3.4,PCI DSS v3.2.1/1.3.6, PCI DSS v4.0.1/1.4.4, NIST.800-53.r5 AC-21, NIST.800-53.r5 AC-3, NIST.800-53.r5 AC-3(7), NIST.800-53.r5 AC-4, NIST.800-53.r5 AC-4(21), NIST.800-53.r5 AC-6, NIST.800-53.r5 SC-7, NIST.800-53.r5 SC-7(11), NIST.800-53.r5 SC-7(16), NIST.800-53.r5 SC-7(20), NIST.800-53.r5 SC-7(21), NIST.800-53.r5 SC-7(3), NIST.800-53.r5 SC-7(4), NIST.800-53.r5 SC-7(9), CRI Profile v2.2/DE.CM-01.03, CRI Profile v2.2/PR.AA-03.02, CRI Profile v2.2/PR.IR-01.01, CRI Profile v2.2/PR.PS-01.01

Category: Protect > Secure network configuration

Severity: High

Resource type: `AWS::EMR::Cluster`

AWS Config rule: emr-master-no-public-ip

Schedule type: Periodic

Parameters: None

This control checks whether master nodes on Amazon EMR clusters have public IP addresses. The control fails if public IP addresses are associated with any of the master node instances.

Public IP addresses are designated in the `PublicIp` field of the `NetworkInterfaces` configuration for the instance. This control only checks Amazon EMR clusters that are in a `RUNNING` or `WAITING` state.

Remediation

During launch, you can control whether your instance in a default or nondefault subnet is assigned a public IPv4 address. By default, default subnets have this attribute set to `true`. Nondefault subnets have the IPv4 public addressing attribute set to `false`, unless it was created by the Amazon EC2 launch instance wizard. In that case, the attribute is set to `true`.

After launch, you can't manually disassociate a public IPv4 address from your instance.

To remediate a failed finding, you must launch a new cluster in a VPC with a private subnet that has the IPv4 public addressing attribute set to `false`. For instructions, see Launch clusters into a VPC in the *Amazon EMR Management Guide*.

[EMR.2] Amazon EMR block public access setting should be enabled

Related requirements: PCI DSS v4.0.1/1.4.4, NIST.800-53.r5 AC-21, NIST.800-53.r5 AC-3, NIST.800-53.r5 AC-3(7), NIST.800-53.r5 AC-4, NIST.800-53.r5 AC-4(21), NIST.800-53.r5 AC-6, NIST.800-53.r5 SC-7, NIST.800-53.r5 SC-7(11), NIST.800-53.r5 SC-7(16), NIST.800-53.r5 SC-7(20), NIST.800-53.r5 SC-7(21), NIST.800-53.r5 SC-7(3), NIST.800-53.r5 SC-7(4), NIST.800-53.r5 SC-7(9), CRI Profile v2.2/PR.IR-01.01, CRI Profile v2.2/PR.IR-01.02, CRI Profile v2.2/PR.PS-01.02

Category: Protect > Secure access management > Resource not publicly accessible

Severity: Critical

Resource type: `AWS::::Account`

AWS Config rule: emr-block-public-access

Schedule type: Periodic

Parameters: None

This control checks whether your account is configured with Amazon EMR block public access. The control fails if the block public access setting isn't enabled or if any port other than port 22 is allowed.

Amazon EMR block public access prevents you from launching a cluster in a public subnet if the cluster has a security configuration that allows inbound traffic from public IP addresses on a port. When a user from your AWS account launches a cluster, Amazon EMR checks the port rules in the security group for the cluster and compares them with your inbound traffic rules. If the security group has an inbound rule that opens ports to the public IP addresses IPv4 0.0.0.0/0 or IPv6 ::/0, and those ports aren't specified as exceptions for your account, Amazon EMR doesn't let the user create the cluster.

> **Note**
>
> Block public access is enabled by default. To increase account protection, we recommend that you keep it enabled.

Remediation

To configure block public access for Amazon EMR, see Using Amazon EMR block public access in the *Amazon EMR Management Guide*.

[EMR.3] Amazon EMR security configurations should be encrypted at rest

Related requirements: NIST.800-53.r5 CA-9(1), NIST.800-53.r5 CP-9(8), NIST.800-53.r5 SI-12, CRI Profile v2.2/PR.DS-01.01, CRI Profile v2.2/PR.PS-01.06

Category: Protect > Data Protection > Encryption of data-at-rest

Severity: Medium

Resource type: `AWS::EMR::SecurityConfiguration`

AWS Config rule: emr-security-configuration-encryption-rest

Schedule type: Change triggered

Parameters: None

This control checks whether an Amazon EMR security configuration has encryption at rest enabled. The control fails if the security configuration doesn't enable encryption at rest.

Data at rest refers to data that's stored in persistent, non-volatile storage for any duration. Encrypting data at rest helps you protect its confidentiality, which reduces the risk that an unauthorized user can access it.

Remediation

To enable encryption at rest in an Amazon EMR security configuration, see Configure data encryption in the *Amazon EMR Management Guide*.

[EMR.4] Amazon EMR security configurations should be encrypted in transit

Related requirements: NIST.800-53.r5 AC-4, NIST.800-53.r5 SC-7(4), NIST.800-53.r5 SC-8, NIST.800-53.r5 SC-8(1), NIST.800-53.r5 SC-8(2), NIST.800-53.r5 SC-13, NIST.800-53.r5 SC-23, NIST.800-53.r5 SC-23(3), CRI Profile v2.2/PR.DS-02.01, CRI Profile v2.2/PR.PS-01.06

Category: Protect > Data Protection > Encryption of data-in-transit

Severity: Medium

Resource type: `AWS::EMR::SecurityConfiguration`

AWS Config rule: emr-security-configuration-encryption-transit

Schedule type: Change triggered

Parameters: None

This control checks whether an Amazon EMR security configuration has encryption in transit enabled. The control fails if the security configuration doesn't enable encryption in transit.

Data in transit refers to data that moves from one location to another, such as between nodes in your cluster or between your cluster and your application. Data may move across the internet or within a private network. Encrypting data in transit reduces the risk that an unauthorized user can eavesdrop on network traffic.

Remediation

To enable encryption in transit in an Amazon EMR security configuration, see Configure data encryption in the *Amazon EMR Management Guide*.

Security Hub CSPM controls for EventBridge

These AWS Security Hub CSPM controls evaluate the Amazon EventBridge service and resources.

These controls may not be available in all AWS Regions. For more information, see Availability of controls by Region.

[EventBridge.2] EventBridge event buses should be tagged

Category: Identify > Inventory > Tagging

Severity: Low

Resource type: `AWS::Events::EventBus`

AWS Config rule:`tagged-events-eventbus` (custom Security Hub CSPM rule)

Schedule type: Change triggered

Parameters:

Parameter	Description	Type	Allowed custom values	Security Hub CSPM default value
`requiredTagKeys`	List of non-system tag keys that the evaluated resource must contain. Tag keys are case sensitive.	StringList (maximum of 6 items)	1–6 tag keys that meet AWS requirements.	No default value

This control checks whether an Amazon EventBridge event bus has tags with the specific keys defined in the parameter `requiredTagKeys`. The control fails if the event bus doesn't have any tag keys or if it doesn't have all the keys specified in the parameter `requiredTagKeys`. If the parameter `requiredTagKeys` isn't provided, the control only checks for the existence of a tag key and fails if the event bus isn't tagged with any key. System tags, which are automatically applied and begin with `aws:`, are ignored.

A tag is a label that you assign to an AWS resource, and it consists of a key and an optional value. You can create tags to categorize resources by purpose, owner, environment, or other criteria. Tags can help you identify, organize, search for, and filter resources. Tagging also helps you track accountable resource owners for actions and notifications. When you use tagging, you can implement attribute-based access control (ABAC) as an authorization strategy, which defines permissions based on tags. You can attach tags to IAM entities (users or roles) and to AWS

resources. You can create a single ABAC policy or a separate set of policies for your IAM principals. You can design these ABAC policies to allow operations when the principal's tag matches the resource tag. For more information, see What is ABAC for AWS? in the *IAM User Guide*.

> **Note**
>
> Don't add personally identifiable information (PII) or other confidential or sensitive information in tags. Tags are accessible to many AWS services, including AWS Billing. For more tagging best practices, see Tagging your AWS resources in the *AWS General Reference*.

Remediation

To add tags to an EventBridge event bus, see Amazon EventBridge tags in the *Amazon EventBridge User Guide*.

[EventBridge.3] EventBridge custom event buses should have a resource-based policy attached

Related requirements: NIST.800-53.r5 AC-2, NIST.800-53.r5 AC-2(1), NIST.800-53.r5 AC-3, NIST.800-53.r5 AC-3(15), NIST.800-53.r5 AC-3(7), NIST.800-53.r5 AC-5, NIST.800-53.r5 AC-6, NIST.800-53.r5 AC-6(3), PCI DSS v4.0.1/10.3.1, CRI Profile v2.2/PR.AA-05.01

Category: Protect > Secure access management > Resource not publicly accessible

Severity: Low

Resource type: `AWS::Events::EventBus`

AWS Config rule: custom-eventbus-policy-attached

Schedule type: Change triggered

Parameters: None

This control checks if an Amazon EventBridge custom event bus has a resource-based policy attached. This control fails if the custom event bus doesn't have a resource-based policy.

By default, an EventBridge custom event bus doesn't have a resource-based policy attached. This allows principals in the account to access the event bus. By attaching a resource-based policy to the event bus, you can limit access to the event bus to specified accounts, as well as intentionally grant access to entities in another account.

Remediation

To attach a resource-based policy to an EventBridge custom event bus, see Using resource-based policies for Amazon EventBridge in the *Amazon EventBridge User Guide*.

[EventBridge.4] EventBridge global endpoints should have event replication enabled

Related requirements: NIST.800-53.r5 CP-10, NIST.800-53.r5 CP-6(2), NIST.800-53.r5 SC-36, NIST.800-53.r5 SC-5(2), NIST.800-53.r5 SI-13(5), CRI Profile v2.2/PR.IR-01.03, CRI Profile v2.2/PR.IR-03.01

Category: Recover > Resilience > High availability

Severity: Medium

Resource type: `AWS::Events::Endpoint`

AWS Config rule: `global-endpoint-event-replication-enabled`

Schedule type: Change triggered

Parameters: None

This control checks if event replication is enabled for an Amazon EventBridge global endpoint. The control fails if event replication isn't enabled for a global endpoint.

Global endpoints help make your application Regional-fault tolerant. To start, you assign an Amazon Route 53 health check to the endpoint. When failover is initiated, the health check reports an "unhealthy" state. Within minutes of failover initiation, all custom events are routed to an event bus in the secondary Region and are processed by that event bus. When you use global endpoints, you can enable event replication. Event replication sends all custom events to the event buses in the primary and secondary Regions using managed rules. We recommend enabling event replication when setting up global endpoints. Event replication helps you verify that your global endpoints are configured correctly. Event replication is required to automatically recover from a failover event. If you don’t have event replication enabled, you’ll have to manually reset the Route 53 health check to "healthy" before events are rerouted back to the primary Region.

> **Note**
>
> If you're using custom event buses, you'll need a custom even bus in each Region with the same name and in the same account for failover to work properly. Enabling event

replication can increase your monthly cost. For information about pricing, see Amazon EventBridge pricing.

Remediation

To enable event replication for EventBridge global endpoints, see Create a global endpoint in the *Amazon EventBridge User Guide*. For **Event replication**, select **Event replication enabled**.

Security Hub CSPM controls for Amazon Fraud Detector

These Security Hub CSPM controls evaluate the Amazon Fraud Detector service and resources.

These controls may not be available in all AWS Regions. For more information, see Availability of controls by Region.

[FraudDetector.1] Amazon Fraud Detector entity types should be tagged

Category: Identify > Inventory > Tagging

Severity: Low

Resource type: `AWS::FraudDetector::EntityType`

AWS Config rule: `frauddetector-entity-type-tagged`

Schedule type: Change triggered

Parameters:

Parameter	Description	Type	Allowed custom values	Security Hub CSPM default value
`requiredKeyTags`	List of non-system tag keys that the evaluated resource must contain. Tag keys are case sensitive.	StringList (maximum of 6 items)	1–6 tag keys that meet AWS requirements.	No default value

This control checks whether an Amazon Fraud Detector entity type has tags with the specific keys defined in the parameter `requiredKeyTags`. The control fails if the entity type doesn't have any tag keys or if it doesn't have all the keys specified in the parameter `requiredKeyTags`. If the parameter `requiredKeyTags` isn't provided, the control only checks for the existence of a tag key and fails if the entity type isn't tagged with any key. System tags, which are automatically applied and begin with `aws:`, are ignored.

A tag is a label that you assign to an AWS resource, and it consists of a key and an optional value. You can create tags to categorize resources by purpose, owner, environment, or other criteria. Tags can help you identify, organize, search for, and filter resources. Tagging also helps you track accountable resource owners for actions and notifications. When you use tagging, you can implement attribute-based access control (ABAC) as an authorization strategy, which defines permissions based on tags. You can attach tags to IAM entities (users or roles) and to AWS resources. You can create a single ABAC policy or a separate set of policies for your IAM principals. You can design these ABAC policies to allow operations when the principal's tag matches the resource tag. For more information, see Define permissions based on attributes with ABAC authorization in the *IAM User Guide*.

> **Note**
>
> Don't add personally identifiable information (PII) or other confidential or sensitive information in tags. Tags are accessible to many AWS services, including AWS Billing. For more tagging best practices, see Best practices and strategies in the *Tagging AWS Resources and Tag Editor User Guide*.

Remediation

To add tags to an Amazon Fraud Detector entity type (console)

1. Open the Amazon Fraud Detector console at https://console.aws.amazon.com/frauddetector.
2. In the navigation pane, choose **Entities**.
3. Select an entity type from the list.
4. In the **entity type tags** section, choose **Manage tags**.
5. Choose **Add new tag**. Enter the key and value for the tag. Repeat for additional key-value pairs.
6. When you are finished adding tags, choose **Save**.

[FraudDetector.2] Amazon Fraud Detector labels should be tagged

Category: Identify > Inventory > Tagging

Severity: Low

Resource type: `AWS::FraudDetector::Label`

AWS Config rule: `frauddetector-label-tagged`

Schedule type: Change triggered

Parameters:

Parameter	Description	Type	Allowed custom values	Security Hub CSPM default value
`requiredKeyTags`	List of non-system tag keys that the evaluated resource must contain. Tag keys are case sensitive.	StringList (maximum of 6 items)	1–6 tag keys that meet AWS requirements.	No default value

This control checks whether an Amazon Fraud Detector label has tags with the specific keys defined in the parameter `requiredKeyTags`. The control fails if the label doesn't have any tag keys or if it doesn't have all the keys specified in the parameter `requiredKeyTags`. If the parameter `requiredKeyTags` isn't provided, the control only checks for the existence of a tag key and fails if the label isn't tagged with any key. System tags, which are automatically applied and begin with `aws:`, are ignored.

A tag is a label that you assign to an AWS resource, and it consists of a key and an optional value. You can create tags to categorize resources by purpose, owner, environment, or other criteria. Tags can help you identify, organize, search for, and filter resources. Tagging also helps you track accountable resource owners for actions and notifications. When you use tagging, you can implement attribute-based access control (ABAC) as an authorization strategy, which defines permissions based on tags. You can attach tags to IAM entities (users or roles) and to

AWS resources. You can create a single ABAC policy or a separate set of policies for your IAM principals. You can design these ABAC policies to allow operations when the principal's tag matches the resource tag. For more information, see Define permissions based on attributes with ABAC authorization in the *IAM User Guide*.

> **Note**
>
> Don't add personally identifiable information (PII) or other confidential or sensitive information in tags. Tags are accessible to many AWS services, including AWS Billing. For more tagging best practices, see Best practices and strategies in the *Tagging AWS Resources and Tag Editor User Guide*.

Remediation

To add tags to an Amazon Fraud Detector label (console)

1. Open the Amazon Fraud Detector console at https://console.aws.amazon.com/frauddetector.
2. In the navigation pane, choose **Labels**.
3. Select a label from the list.
4. In the **labels tags** section, choose **Manage tags**.
5. Choose **Add new tag**. Enter the key and value for the tag. Repeat for additional key-value pairs.
6. When you are finished adding tags, choose **Save**.

[FraudDetector.3] Amazon Fraud Detector outcomes should be tagged

Category: Identify > Inventory > Tagging

Severity: Low

Resource type: `AWS::FraudDetector::Outcome`

AWS Config rule: `frauddetector-outcome-tagged`

Schedule type: Change triggered

Parameters:

Parameter	Description	Type	Allowed custom values	Security Hub CSPM default value
`requiredKeyTags`	List of non-system tag keys that the evaluated resource must contain. Tag keys are case sensitive.	StringList (maximum of 6 items)	1–6 tag keys that meet AWS requirements.	No default value

This control checks whether an Amazon Fraud Detector outcome has tags with the specific keys defined in the parameter `requiredKeyTags`. The control fails if the outcome doesn't have any tag keys or if it doesn't have all the keys specified in the parameter `requiredKeyTags`. If the parameter `requiredKeyTags` isn't provided, the control only checks for the existence of a tag key and fails if the outcome isn't tagged with any key. System tags, which are automatically applied and begin with `aws:`, are ignored.

A tag is a label that you assign to an AWS resource, and it consists of a key and an optional value. You can create tags to categorize resources by purpose, owner, environment, or other criteria. Tags can help you identify, organize, search for, and filter resources. Tagging also helps you track accountable resource owners for actions and notifications. When you use tagging, you can implement attribute-based access control (ABAC) as an authorization strategy, which defines permissions based on tags. You can attach tags to IAM entities (users or roles) and to AWS resources. You can create a single ABAC policy or a separate set of policies for your IAM principals. You can design these ABAC policies to allow operations when the principal's tag matches the resource tag. For more information, see Define permissions based on attributes with ABAC authorization in the *IAM User Guide*.

Note

Don't add personally identifiable information (PII) or other confidential or sensitive information in tags. Tags are accessible to many AWS services, including AWS Billing. For more tagging best practices, see Best practices and strategies in the *Tagging AWS Resources and Tag Editor User Guide*.

Remediation

To add tags to an Amazon Fraud Detector outcome (console)

1. Open the Amazon Fraud Detector console at https://console.aws.amazon.com/frauddetector.
2. In the navigation pane, choose **Outcomes**.
3. Select an outcome from the list.
4. In the **outcomes tags** section, choose **Manage tags**.
5. Choose **Add new tag**. Enter the key and value for the tag. Repeat for additional key-value pairs.
6. When you are finished adding tags, choose **Save**.

[FraudDetector.4] Amazon Fraud Detector variables should be tagged

Category: Identify > Inventory > Tagging

Severity: Low

Resource type: `AWS::FraudDetector::Variable`

AWS Config rule: `frauddetector-variable-tagged`

Schedule type: Change triggered

Parameters:

Parameter	Description	Type	Allowed custom values	Security Hub CSPM default value
`requiredKeyTags`	List of non-system tag keys that the evaluated resource must contain. Tag keys are case sensitive.	StringList (maximum of 6 items)	1–6 tag keys that meet AWS requirements.	No default value

This control checks whether an Amazon Fraud Detector variable has tags with the specific keys defined in the parameter `requiredKeyTags`. The control fails if the variable doesn't have any tag keys or if it doesn't have all the keys specified in the parameter `requiredKeyTags`. If the parameter `requiredKeyTags` isn't provided, the control only checks for the existence of a tag key and fails if the variable isn't tagged with any key. System tags, which are automatically applied and begin with `aws:`, are ignored.

A tag is a label that you assign to an AWS resource, and it consists of a key and an optional value. You can create tags to categorize resources by purpose, owner, environment, or other criteria. Tags can help you identify, organize, search for, and filter resources. Tagging also helps you track accountable resource owners for actions and notifications. When you use tagging, you can implement attribute-based access control (ABAC) as an authorization strategy, which defines permissions based on tags. You can attach tags to IAM entities (users or roles) and to AWS resources. You can create a single ABAC policy or a separate set of policies for your IAM principals. You can design these ABAC policies to allow operations when the principal's tag matches the resource tag. For more information, see Define permissions based on attributes with ABAC authorization in the *IAM User Guide*.

> **Note**
>
> Don't add personally identifiable information (PII) or other confidential or sensitive information in tags. Tags are accessible to many AWS services, including AWS Billing. For more tagging best practices, see Best practices and strategies in the *Tagging AWS Resources and Tag Editor User Guide*.

Remediation

To add tags to an Amazon Fraud Detector variable (console)

1. Open the Amazon Fraud Detector console at https://console.aws.amazon.com/frauddetector.
2. In the navigation pane, choose **Variables**.
3. Select a variable from the list.
4. In the **variables tags** section, choose **Manage tags**.
5. Choose **Add new tag**. Enter the key and value for the tag. Repeat for additional key-value pairs.
6. When you are finished adding tags, choose **Save**.

Security Hub CSPM controls for Amazon FSx

These AWS Security Hub CSPM controls evaluate the Amazon FSx service and resources. The controls might not be available in all AWS Regions. For more information, see Availability of controls by Region.

[FSx.1] FSx for OpenZFS file systems should be configured to copy tags to backups and volumes

Related requirements: NIST.800-53.r5 CA-9(1), NIST.800-53.r5 CM-2, NIST.800-53.r5 CM-2(2), CRI Profile v2.2/ID.AM-02.01, CRI Profile v2.2/ID.AM-07.01

Category: Identify > Inventory > Tagging

Severity: Low

Resource type: `AWS::FSx::FileSystem`

AWS Config rule: fsx-openzfs-copy-tags-enabled

Schedule type: Periodic

Parameters: None

This control checks whether an Amazon FSx for OpenZFS file system is configured to copy tags to backups and volumes. The control fails if the OpenZFS file system isn't configured to copy tags to backups and volumes.

Identification and inventory of your IT assets is an important aspect of governance and security. Tags help you categorize your AWS resources in different ways, for example, by purpose, owner, or environment. This is useful when you have many resources of the same type because you can quickly identify a specific resource based on the tags that you assigned to it.

Remediation

For information about configuring an FSx for OpenZFS file system to copy tags to backups and volumes, see Updating a file system in the *Amazon FSx for OpenZFS User Guide*.

[FSx.2] FSx for Lustre file systems should be configured to copy tags to backups

Related requirements: NIST.800-53.r5 CP-9, NIST.800-53.r5 CM-8, CRI Profile v2.2/ID.AM-02.01

Category: Identify > Inventory > Tagging

Severity: Low

Resource type: `AWS::FSx::FileSystem`

AWS Config rule: fsx-lustre-copy-tags-to-backups

Schedule type: Periodic

Parameters: None

This control checks whether an Amazon FSx for Lustre file system is configured to copy tags to backups and volumes. The control fails if the Lustre file system isn't configured to copy tags to backups and volumes.

Identification and inventory of your IT assets is an important aspect of governance and security. Tags help you categorize your AWS resources in different ways, for example, by purpose, owner, or environment. This is useful when you have many resources of the same type because you can quickly identify a specific resource based on the tags that you assigned to it.

Remediation

For information about configuring an FSx for Lustre file system to copy tags to backups, see Copying backups within the same AWS account in the *Amazon FSx for Lustre User Guide*.

[FSx.3] FSx for OpenZFS file systems should be configured for Multi-AZ deployment

Related requirements: CRI Profile v2.2/PR.IR-03.01, CRI Profile v2.2/PR.IR-04.02

Category: Recover > Resilience > High availability

Severity: Medium

Resource type: `AWS::FSx::FileSystem`

AWS Config rule: fsx-openzfs-deployment-type-check

Schedule type: Periodic

Parameters: `deploymentTypes: MULTI_AZ_1` (not customizable)

This control checks whether an Amazon FSx for OpenZFS file system is configured to use the multiple Availability Zones (Multi-AZ) deployment type. The control fails if the file system isn't configured to use the Multi-AZ deployment type.

Amazon FSx for OpenZFS supports several deployment types for file systems: *Multi-AZ (HA)*, *Single-AZ (HA)*, and *Single-AZ (non-HA)*. The deployment types offer different levels of availability and durability. Multi-AZ (HA) file systems are composed of a high-availability (HA) pair of file servers that are spread across two Availability Zones (AZs). We recommend using the Multi-AZ (HA) deployment type for most production workloads due to the high availability and durability model that it provides.

Remediation

You can configure an Amazon FSx for OpenZFS file system to use the Multi-AZ deployment type when you create the file system. You can't change the deployment type for an existing FSx for OpenZFS file system.

For information about deployment types and options for FSx for OpenZFS file systems, see Availability and durability for Amazon FSx for OpenZFS and Managing file system resources in the *Amazon FSx for OpenZFS User Guide*.

[FSx.4] FSx for NetApp ONTAP file systems should be configured for Multi-AZ deployment

Category: Recover > Resilience > High availability

Severity: Medium

Resource type: `AWS::FSx::FileSystem`

AWS Config rule: fsx-ontap-deployment-type-check

Schedule type: Periodic

Parameters:

Parameter	Description	Type	Allowed custom values	Security Hub CSPM default value
`deploymentTypes`	A list of deployment types to include in the evaluation. The control generates a `FAILED` finding if a file	Enum	`MULTI_AZ_1` , `MULTI_AZ_2`	`MULTI_AZ_1` , `MULTI_AZ_2`

Parameter	Description	Type	Allowed custom values	Security Hub CSPM default value
	system isn't configured to use a deployment type specified in the list.			

This control checks whether an Amazon FSx for NetApp ONTAP file system is configured to use a multiple Availability Zones (Multi-AZ) deployment type. The control fails if the file system isn't configured to use a Multi-AZ deployment type. You can optionally specify a list of deployment types to include in the evaluation.

Amazon FSx for NetApp ONTAP supports several deployment types for file systems: *Single-AZ 1*, *Single-AZ 2*, *Multi-AZ 1*, and *Multi-AZ 2*. The deployment types offer different levels of availability and durability. We recommend using a Multi-AZ deployment type for most production workloads due to the high availability and durability model that Multi-AZ deployment types provide. Multi-AZ file systems support all the availability and durability features of Single-AZ file systems. In addition, they're designed to provide continuous availability to data even when an Availability Zone (AZ) is unavailable.

Remediation

You can't change the deployment type for an existing Amazon FSx for NetApp ONTAP file system. However, you can back up the data, and then restore it on a new file system that uses a Multi-AZ deployment type.

For information about deployment types and options for FSx for ONTAP file systems, see Availability, durability, and deployment options and Managing file systems in the *FSx for ONTAP User Guide*.

[FSx.5] FSx for Windows File Server file systems should be configured for Multi-AZ deployment

Related requirements: CRI Profile v2.2/GV.OC-04.03, CRI Profile v2.2/GV.RM-09.02, CRI Profile v2.2/PR.IR-03.01, CRI Profile v2.2/PR.IR-04.02

Category: Recover > Resilience > High availability

Severity: Medium

Resource type: `AWS::FSx::FileSystem`

AWS Config rule: fsx-windows-deployment-type-check

Schedule type: Periodic

Parameters: `deploymentTypes: MULTI_AZ_1` (not customizable)

This control checks whether an Amazon FSx for Windows File Server file system is configured to use the multiple Availability Zones (Multi-AZ) deployment type. The control fails if the file system isn't configured to use the Multi-AZ deployment type.

Amazon FSx for Windows File Server supports two deployment types for file systems: *Single-AZ* and *Multi-AZ*. The deployment types offer different levels of availability and durability. Single-AZ file systems are composed of a single Windows file server instance and a set of storage volumes within a single Availability Zone (AZ). Multi-AZ file systems are composed of a high-availability cluster of Windows file servers spread across two Availability Zones. We recommend using the Multi-AZ deployment type for most production workloads due to the high availability and durability model that it provides.

Remediation

You can configure an Amazon FSx for Windows File Server file system to use the Multi-AZ deployment type when you create the file system. You can't change the deployment type for an existing FSx for Windows File Server file system.

For information about deployment types and options for FSx for Windows File Server file systems, see Availability and durability: Single-AZ and Multi-AZ file systems and Getting started with Amazon FSx for Windows File Server in the *Amazon FSx for Windows File Server User Guide*.

Security Hub CSPM controls for Global Accelerator

These AWS Security Hub CSPM controls evaluate the AWS Global Accelerator service and resources.

These controls may not be available in all AWS Regions. For more information, see Availability of controls by Region.

[GlobalAccelerator.1] Global Accelerator accelerators should be tagged

Category: Identify > Inventory > Tagging

Severity: Low

Resource type: `AWS::GlobalAccelerator::Accelerator`

AWS Config rule: `tagged-globalaccelerator-accelerator` (custom Security Hub CSPM rule)

Schedule type: Change triggered

Parameters:
